

7 **Draft Standard for**  
8 **Local and Metropolitan Area Networks—**  
9 **Bridges and Bridged Networks**

10 Prepared by the  
11 **IEEE 802.1 Working Group**

12 Sponsor  
13 **LAN/MAN Standards Committee**  
14 **of the**  
15 **IEEE Computer Society**

16 This and the following cover pages are not part of the draft. They provide revision and other information for  
17 IEEE 802.1 Working Group members and will be updated as convenient. New participants: Please read these  
18 cover pages, they contain information that should help you contribute effectively to this standards  
19 development project. The [Introduction to the current draft](#) should be useful to all readers.

20 The text proper of this draft begins with the [Title page](#).

### Important Notice

This document is an unapproved draft of a proposed IEEE Standard. IEEE hereby grants the named IEEE SA Working Group or Standards Committee Chair permission to distribute this document to participants in the receiving IEEE SA Working Group or Standards Committee, for purposes of review for IEEE standardization activities. No further use, reproduction, or distribution of this document is permitted without the express written permission of IEEE Standards Association (IEEE SA). Prior to any review or use of this draft standard, in part or in whole, by another standards development organization, permission must first be obtained from IEEE SA ([stds-copyright@ieee.org](mailto:stds-copyright@ieee.org)). This page is included as the cover of this draft, and shall not be modified or deleted.

IEEE Standards Association  
445 Hoes Lane  
Piscataway, NJ 08854, USA

## 1 Introduction to the current draft<sup>1</sup>

2 This document is a revision in progress of IEEE Std 802.1Q-2022, incorporating published amendments, draft  
3 amendments (if, and as, noted on the Title page), the agreed or proposed resolution of [Maintenance items](#)  
4 (see below), and additional [Technical corrections](#) and [Editorial corrections](#) to the description of existing  
5 functionality.

6 **In particular the current draft (D2.1) reflects ongoing detailed work on the PICS. Old PICS**  
7 **material has been removed. The material included is believed near complete for the**  
8 **subjects covered, but much remains to be done.**

9 These cover pages also include an introduction to [Participation in 802.1 standards development](#), a summary  
10 of the [PAR \(Project Authorization Request\)](#), and a general discussion of [Draft development](#).

## 11 Maintenance items

12 This draft includes the following proposed or agreed resolutions of maintenance items that were not  
13 addressed by rolled-up amendments.

- 14 — Maintenance item [0312](#). See below under [YANG modules](#).
- 15 NOTE—The ieee802-types.yang module also contains a typedef for MAC addresses (typedef mac-address) that  
seems to have the same issue. Needs to be discussed in YANGsters if that also needs to be updated.
- 17 — Maintenance item [0366](#). See also  
18 [.../docs2024/yangsters-kauer-maintenance-request-0366-0624-v01.pdf](#) and below under [YANG](#)  
19 [modules](#).

## 20 Technical corrections

21 This draft does not include any technical corrections beyond those addressed by the rolled-up amendments.

## 22 Editorial corrections

23 Pre-publication staff editing of amendments addressed a number of inconsistencies in terminology,  
24 capitalisation, etc. That editing was necessarily restricted to the text of each published amendment, though  
25 the choice between alternatives was largely determined by predominant use and general rules in the  
26 standard as a whole. This draft carries that resolution into the remaining text of the clauses touched by each  
27 amendment or the rest of the standard. In some cases the cost benefit of comprehensive change favours  
28 devoting time to more significant issues:

29 This draft also includes the following corrections that do not appear in the amendments:

- 30 — Tables in Clause 12 after Table 12-38 were mis-numbered.
- 31 — Clause 50 included “This is a” or “This is a variable” as a repetitive introduction to items in list of  
32 variables. Where this can be trivially accomplished, the unnecessary text has been  
33 removed/replaced.
- 34 — Figure 25-4 included some unwanted parentheses, and has been updated to remove these.

---

<sup>1</sup>The whole or parts of the introduction, possibly updated, to past drafts may be retained at the Editor’s discretion, with the most recent introduction first. The introduction to each draft may solicit input on specific subjects.

## 1 Keywords

2 The following Keywords have been added or removed to the Keywords in the frontmatter of the standard  
3 (following the Title Page proper which lists the base standard for this revision plus incorporated amendments),  
4 following the abstract. The starting point for the Keyword list was IEEE Std 802.1Q-2022, and the list omits  
5 some keywords found in amendments prior to that revision and additional Keywords to be found in the  
6 subsequent amendments incorporated in this revision. A complete list of past and present keywords would be  
7 extensive, and thus possibly undesirable.

8 — D1.6 added “MIB” and “YANG”.

## 9 MIB modules

10 The MIB modules specified by this standard are attached to the draft pdf as plain text (UTF-8) .mib files.

## 11 YANG modules

12 The MIB modules specified by this standard are attached to the draft pdf as plain text (UTF-8) .mib files.

13 As noted above, the following YANG modules in this draft have been updated as a result of maintenance  
14 activity not addressed by the included amendments:

- 15 — ieee802-dot1q-tsn-types@2024-03-21 ([48.6.3](#))
- 16 — ieee802-dot1q-sched@2024-10-22 ([48.6.17](#))
- 17 — ieee802-dot1q-psfp@2024-10-22 ([48.6.21](#))

18 A Revision statement has been added to each of these modules indicating that they are “TO BE Published ..”  
19 as part of the Revision, together with an indication of the change. The “TO BE ” is to be removed and the  
20 revision date updated at pre-publication time [the revision statements in published standard reflects only the  
21 historical derivation of each published (i.e. standardized) module version from its published predecessors.  
22 The description of the change from the prior published version should be retained. Note that these updated  
23 modules are not ‘the standard’ at this time.

## 24 Sources

25 This draft has been prepared from a set of Framemaker files with conditional text that supports the production  
26 of an amendment draft and a preliminary rollup of that amendment draft into the text of the base standard,  
27 IEEE Std 802.1Q-2022 as amended by prior amendments as of the close of their successful SA ballots.

28 For a description of the use of conditional text and other FrameMaker and IEEE Std 802.1Q Style  
29 considerations applicable to this draft see the EDITOR-PLEASE-READ-ME file in the FrameMaker books  
30 used to generate this draft.

## 1 Notes on PICS Revision (and potentially of Conformance clause changes)

### 2 0.1 TSN end-station capabilities

3 In the 2022:5.2 Conformant components and equipment list, an EVB station and a TSN CNC station are  
4 called out, but there is no generic station mentioned, despite the mention of ‘end station’ in 5.2 (PICS  
5 summary) and the existing Annex B. Introduce at least a ‘TSN station’.

6 2022:5.18 covers end station requirements for MMRP, MVRP, and MSRP.

7 Separate end-station classification runs the risk of ignoring the fact that a router port is an end station so far  
8 as bridge operation/architecture is concerned, so an end station can relay frames to and from the bridge  
9 network and propagate configuration information for that purpose. *Current recommendation detail needs*  
10 *checking.*

11 2022:5.19 covers VLAN-aware end station requirements for CFM. There is no statement to the effect that  
12 VLAN-unaware end stations can (or cannot) participate in CFM. ‘cannot’ seems likely, in which case we are  
13 left with ‘end-stations requirement for CFM’ and a definite statement that this standard makes no provision  
14 for CFM participation by VLAN-unaware end stations. It should be made clear that it is participation by the  
15 end station in CFM operations that is at issue. CFM could still be used in a network with end stations that  
16 do not participate in CFM, and on network paths to, and for traffic destined to, those end stations.  
17 Rephrase as End-station requirements for participation in CFM. Add a CFM-STA category.

18 2022:5.20 covers FQTSS end station requirement. FQTSS acronym needs expansion at this point.

19 2022:5.21 covers end station requirements for congestion notification (QCN)

20 2022:5.24 covers EVB stations, but these are in fact relays, and not end stations, so need not concern us for  
21 end station discussions.

22 2022:5.25 covers end station requirements for scheduled traffic. it references 2022:8.6.8.4 and 8.6.9. 8.6.8.4  
23 covers the use of transmission gates (elsewhere referenced as stream gates), and nothing else, so it would be  
24 much clearer if the PICS specifically identified support for transmission gates. 8.6.9 includes gate controls  
25 (including state machines) and nothing else. The 2022 text currently includes the statement “In an  
26 implementation that does not support enhancements for scheduled traffic, all gates are assumed to be  
27 permanently in the *open* state.” which would be clearer if it was worded as: “In an implementation that does  
28 not support transmission gates, all gates are assumed to be permanently in the *open* state.” and then deleted as  
29 clearly redundant.

30 2022:5.26 Frame preemption largely depends on 6.7.1, 6.7.2, so is best covered under IF which can reference  
31 the 8.6.8 text for that purpose. There is no difference between bridge and end station requirements for frame  
32 preemption which calls into question the need for 5.26 (check rest of 5 for other preemption references).

33 2022:5.27 PSFP references: 8.6.5.2.1, which has no differences between bridges and end stations, 8.6.6  
34 which does not state any differences but the astute reader might surmise that it is queuing for transmission  
35 relative to other frames transmitted by the end station so references to the ‘Forwarding Process’ should be  
36 interpreted in that light. Note that 8.6.10 is also referenced. *I need to figure out the difference between PSFP*  
37 *and scheduled traffic.*

38 2022:5.28 is based on an Informative Annex and has no business being in the Conformance clause. The  
39 requirements for supporting the CQF technique described in the Informative Annex could be stated in that  
40 Annex, and probably are already (*Check*).

<sup>1</sup> **0.2 MAC-specific bridging methods**

<sup>2</sup> 2022:5.22 is historic and does not belong here at all.

<sup>3</sup>

## 1 Participation in 802.1 standards development

2 All participants in IEEE 802.1 activities should be aware of the Working Group Policies and Procedures, and  
3 their obligations under the IEEE Patent Policy, the IEEE Standards Association (SA) Copyright Policy, and the  
4 IEEE SA Participation Policy. For information on these policies see [1.ieee802.org/rules/](http://1.ieee802.org/rules/) and the slides  
5 presented at the beginning of each of our Working Group and Task Group meeting.

6 The IEEE SA [PAR \(Project Authorization Request\)](#) is summarized in these cover pages and a link provided to  
7 the full text. As part of the IEEE 802® process, the PAR of each project is reviewed regularly to ensure its  
8 continued validity. A vote of “Approve” on this draft is also an affirmation that the PAR and CSD is still valid.

9 Comments on this draft are encouraged. NOTE: All issues related to IEEE standards presentation style,  
10 formatting, spelling, etc. are routinely handled between the 802.1 Editor and the IEEE Staff Editors prior to  
11 publication, after balloting and the process of achieving agreement on the technical content of the standard is  
12 complete. Readers are urged to devote their valuable time and energy only to comments that materially affect  
13 either the technical content of the document or the clarity of that technical content. Comments should not  
14 simply state what is wrong, but also what might be done to fix the problem.

15 Full participation in the work of IEEE 802.1 requires attendance at IEEE 802 meetings. Information on 802.1  
16 activities, working papers, and email distribution lists etc. can be found on the 802.1 Website:

17 <http://ieee802.org/1/>

18 Use of the email distribution list is not presently restricted to 802.1 members, and the working group has a  
19 policy of considering comments from all who are interested and willing to contribute to the development of the  
20 draft. Individuals not attending meetings have helped to identify sources of misunderstanding and ambiguity  
21 in past projects. The email lists exist primarily to allow the members of the working group to develop  
22 standards, and are not a general forum. All contributors to the work of 802.1 should familiarize themselves  
23 with the IEEE patent policy and anyone using the email distribution list will be assumed to have done so.  
24 Information can be found at <http://standards.ieee.org/db/patents/>

25 Comments on this draft may be sent to the 802.1 email exploder, to the Editors, or to the Chairs of the 802.1  
26 Working Group and Time-Sensitive Networking (TSN) Task Group.

27 Mick Seaman  
28 Editor, IEEE Std 802.1Q  
29 Email: [mickseaman@gmail.com](mailto:mickseaman@gmail.com)

30 Janos Farkas  
31 Chair, 802.1 TSN Task Group  
32  
33 Email: [Janos.Farkas@ericsson.com](mailto:Janos.Farkas@ericsson.com)

Glenn Parsons  
Chair, 802.1 Working Group  
+1 514-379-9037  
Email: [glenn.parsons@ericsson.com](mailto:glenn.parsons@ericsson.com)

34 NOTE: Comments whose distribution is restricted in any way cannot be considered, and may not be  
35 acknowledged.

36 **All participants in IEEE standards development have responsibilities under the IEEE patent policy and**  
37 **should familiarize themselves with that policy, see**  
38 <http://standards.ieee.org/about/sasb/patcom/materials.html>

39 As part of our IEEE 802 process, the text of the PAR and CSD (Criteria for Standards Development, formerly  
40 referred to as the 5 Criteria or 5C's) is reviewed on a regular basis in order to ensure their continued validity.  
41 A vote of “Approve” on this draft is also an affirmation by the balloter that the PAR is still valid.

## 1 PAR (Project Authorization Request)

2 The PAR for the Revision of IEEE Std 802.1Q-2022 was approved by IEEE NesCom, June 5th, 2023:

3 <https://development.standards.ieee.org/myproject-web/public/view.html#pardetail/10606>

4 This is a maintenance PAR so did not require an IEEE 802 CSD (Criteria for Standards Development).

5 The Scope and Purpose remains unchanged from that for IEEE Std 802.1Q-2022.

6 The Need for the Project is as follows:

7 “This revision project is needed in order to incorporate approved amendments and corrigenda, to incorporate  
8 technical and editorial corrections to existing functionality, and to ensure that consistency is maintained in the  
9 consolidated text.”

## 10 Draft development

11 During the early stages of draft development, 802.1 editors have a responsibility to attempt to craft technically  
12 coherent drafts from the resolutions of ballot comments and from the other discussions that take place in the  
13 working group meetings. Preparation of drafts often exposes inconsistencies in editor's instructions or  
14 exposes the need to make choices between approaches that were not fully apparent in the meeting. Choices  
15 and requests by the editors' for contributions on specific issues will be found in the editors' [Introduction to the](#)  
16 [current draft](#) and at appropriate points in the draft.

17 Any text with a Cyan background (as in this sentence) is temporary, with conditional tag 'Editor comment',  
18 inserted by the Editors to solicit comment, suggest a future change, or act simply as an aide memoire. Text  
19 can also be highlighted to draw it to the readers' attention, using conditional tag 'Editor highlight'. In both  
20 these cases conditional tagging helps location, and eventual removal, of text or highlighting and can control  
21 whether or not it is displayed.

22 The ballot comments received on each draft, and the editors' proposed and final disposition of comments on  
23 working group drafts, are part of the audit trail of the development of the standard and are available, along  
24 with all the revisions of the draft on the 802.1 website (for address see above).

25 During the early stages of draft development the proposed text can be moved around a great deal, and even  
26 minor rearrangement can lead to a lot of 'change', not all of which is noteworthy from the point of the reviewer,  
27 so the use of automatic change bars is not very effective. In early drafts change bars may be omitted or  
28 applied manually, with a view to drawing the readers attention to the most significant areas of change.  
29 Readers interested in viewing every change are encouraged to use Adobe Acrobat to compare the document  
30 with their selected prior draft. Note that the FrameMaker change bar feature is useless when it comes to  
31 indicating changes to Figures.

32 This draft has been prepared from a set of Framemaker files with conditional text that supports the production  
33 of an amendment draft and a preliminary roll up of that amendment draft into the text of the base standard, i.e.  
34 IEEE Std 802.1Q as of the last Revision as amended by prior amendments (usually as of the close of their  
35 successful SA ballots) as noted on the Title Page and the first Cover Page. The editor may make preliminary  
36 roll ups available to check consistency with the base standard and cross-references to text that does not  
37 appear in this amendment. Roll ups may also be recorded as part of the approved P802.1Q Revision project.

38 For a description of the use of conditional text and other FrameMaker and IEEE Std 802.1Q Style  
39 considerations applicable to this draft see the EDITOR-PLEASE-READ-ME file in the FrameMaker books  
40 used to generate these drafts.

41 There are generally multiple amendments under development at any time, and while they will add or amend  
42 different clauses in the base standard, there are some clauses (notably Clauses 12, 48, and the PICS  
43 Annexes that all are likely to change). They will need to be fully integrated before or during SA Ballot, and  
44 complete that ballot in serial order to avoid future problems.

45 Records of participants in the development of the standard are added after SA Ballot, as part of  
46 pre-publication editing by IEEE Staff.

(Revision of IEEE Std 802.1Q™-2022 as amended by IEEE Std 802.1Qcz™-2023,  
IEEE Std 802.1Qcw™-2023, IEEE Std 802.1Qcj™-2023, IEEE Std 802.1Qdj™-2024,  
IEEE Std 802.1Qdx™-2024, and IEEE Std 802.1Qdy™-2025)

# Draft Standard for Local and Metropolitan Area Networks— Bridges and Bridged Networks

1

2 **Abstract:** This standard specifies how the Media Access Control (MAC) Service is supported by  
3 Bridged Networks, the principles of operation of those networks, and the operation of MAC Bridges  
4 and VLAN Bridges, including management, protocols, and algorithms.

5 **Keywords:** Bridged Network, IEEE 802.1Q™, LAN, local area network, MAC Bridge, metropolitan  
6 area network, MIB, MSTP, Multiple Spanning Tree Protocol, PBN, Provider Bridged Network, Rapid  
7 Spanning Tree Protocol, RSTP, Shortest Path Bridging Protocol, SPB Protocol, Time-Sensitive  
8 Networking, TSN, Virtual Bridged Network, virtual LAN, VLAN Bridge, YANG.

## 1 Important Notices and Disclaimers Concerning IEEE Standards 2 Documents

3 IEEE Standards documents are made available for use subject to important notices and legal disclaimers.  
4 These notices and disclaimers, or a reference to this page (<https://standards.ieee.org/ipr/disclaimers.html>),  
5 appear in all IEEE standards and may be found under the heading “Important Notices and Disclaimers  
6 Concerning IEEE Standards Documents.”

### 7 Notice and Disclaimer of Liability Concerning the Use of IEEE Standards 8 Documents

9 IEEE Standards documents are developed within IEEE Societies and subcommittees of IEEE Standards  
10 Association (IEEE SA) Board of Governors. IEEE develops its standards through an accredited consensus  
11 development process, which brings together volunteers representing varied viewpoints and interests to  
12 achieve the final product. IEEE Standards are documents developed by volunteers with scientific, academic,  
13 and industry-based expertise in technical working groups. Volunteers involved in technical working groups  
14 are not necessarily members of IEEE or IEEE SA and participate without compensation from IEEE. While  
15 IEEE administers the process and establishes rules to promote fairness in the consensus development  
16 process, IEEE does not independently evaluate, test, or verify the accuracy of any of the information or the  
17 soundness of any judgments contained in its standards.

18 IEEE makes no warranties or representations concerning its standards, and expressly disclaims all  
19 warranties, express or implied, concerning all standards, including but not limited to the warranties of  
20 merchantability, fitness for a particular purpose and non-infringement. IEEE Standards documents do not  
21 guarantee safety, security, health, or environmental protection, or compliance with law, or guarantee against  
22 interference with or from other devices or networks. In addition, IEEE does not warrant or represent that the  
23 use of the material contained in its standards is free from patent infringement. IEEE standards documents are  
24 supplied “AS IS” and “WITH ALL FAULTS.”

25 Use of an IEEE standard is wholly voluntary. The existence of an IEEE Standard does not imply that there  
26 are no other ways to produce, test, measure, purchase, market, or provide other goods and services related to  
27 the scope of the IEEE standard. Furthermore, the viewpoint expressed at the time a standard is approved and  
28 issued is subject to change brought about through developments in the state of the art and comments  
29 received from users of the standard.

30 In publishing and making its standards available, IEEE is not suggesting or rendering professional or other  
31 services for, or on behalf of, any person or entity, nor is IEEE undertaking to perform any duty owed by any  
32 other person or entity to another. Any person utilizing any IEEE Standards document should rely upon their  
33 own independent judgment in the exercise of reasonable care in any given circumstances or, as appropriate,  
34 seek the advice of a competent professional in determining the appropriateness of a given IEEE standard.

35 IN NO EVENT SHALL IEEE BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL,  
36 EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO: THE  
37 NEED TO PROCURE SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR  
38 BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY,  
39 WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR  
40 OTHERWISE) ARISING IN ANY WAY OUT OF THE PUBLICATION, USE OF, OR RELIANCE UPON  
41 ANY STANDARD, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE AND  
42 REGARDLESS OF WHETHER SUCH DAMAGE WAS FORESEEABLE.

### 43 Translations

44 The IEEE consensus balloting process involves the review of documents in English only. In the event that an  
45 IEEE standard is translated, only the English language version published by IEEE is the approved IEEE  
46 standard.

## 1 Use by artificial intelligence systems

2 In no event shall material in any IEEE Standards documents be used for the purpose of creating, training,  
3 enhancing, developing, maintaining, or contributing to any artificial intelligence systems without the  
4 express, written consent of the IEEE SA in advance. “Artificial intelligence” refers to any software,  
5 application, or other system that uses artificial intelligence, machine learning, or similar technologies, to  
6 analyze, train, process, or generate content. Requests for consent can be submitted using the [Contact Us](#)  
7 form.<sup>1</sup>

## 8 Official statements

9 A statement, written or oral, that is not processed in accordance with the IEEE SA Standards Board  
10 Operations Manual is not, and shall not be considered or inferred to be, the official position of IEEE or any  
11 of its committees and shall not be considered to be or be relied upon as, a formal position of IEEE or IEEE  
12 SA. At lectures, symposia, seminars, or educational courses, an individual presenting information on IEEE  
13 standards shall make it clear that the presenter’s views should be considered the personal views of that  
14 individual rather than the formal position of IEEE, IEEE SA, the Standards Committee, or the Working  
15 Group. Statements made by volunteers may not represent the formal position of their employer(s) or  
16 affiliation(s). News releases about IEEE standards issued by entities other than IEEE SA should be  
17 considered the view of the entity issuing the release rather than the formal position of IEEE or IEEE SA.

## 18 Comments on standards

19 Comments for revision of IEEE Standards documents are welcome from any interested party, regardless of  
20 membership affiliation with IEEE or IEEE SA. However, **IEEE does not provide interpretations,**  
21 **consulting information, or advice pertaining to IEEE Standards documents.**

22 Suggestions for changes in documents should be in the form of a proposed change of text, together with  
23 appropriate supporting comments. Since IEEE standards represent a consensus of concerned interests, it is  
24 important that any responses to comments and questions also receive the concurrence of a balance of interests.  
25 For this reason, IEEE and the members of its Societies and subcommittees of the IEEE SA Board of  
26 Governors are not able to provide an instant response to comments or questions except in those cases where  
27 the matter has previously been addressed. For the same reason, IEEE does not respond to interpretation  
28 requests. Any person who would like to participate in evaluating comments or revisions to an IEEE standard is  
29 welcome to join the relevant IEEE SA working group. You can indicate interest in a working group using the  
30 Interests tab in the Manage Profile & Interests area of the [IEEE SA myProject system](#).<sup>2</sup> An IEEE Account is  
31 needed to access the application.

32 Comments on standards should be submitted using the [Contact Us](#) form.<sup>1</sup>

## 33 Laws and regulations

34 Users of IEEE Standards documents should consult all applicable laws and regulations. Compliance with the  
35 provisions of any IEEE Standards document does not constitute compliance to any applicable regulatory  
36 requirements. Implementers of the standard are responsible for observing or referring to the applicable  
37 regulatory requirements. IEEE does not, by the publication of its standards, intend to urge action that is not  
38 in compliance with applicable laws, and these documents may not be construed as doing so.

## 39 Data privacy

40 Users of IEEE Standards documents should evaluate the standards for considerations of data privacy and  
41 data ownership in the context of assessing and using the standards in compliance with applicable laws and  
42 regulations.

<sup>1</sup> Available at: <https://standards.ieee.org/content/ieee-standards/en/about/contact/>.

<sup>2</sup> Available at: <https://development.standards.ieee.org/myproject-web/public/view.html#landing>.

## 1 Copyrights

2 IEEE draft and approved standards are copyrighted by IEEE under U.S. and international copyright laws.  
3 They are made available by IEEE and are adopted for a wide variety of both public and private uses. These  
4 include both use, by reference, in laws and regulations, and use in private self-regulation, standardization,  
5 and the promotion of engineering practices and methods. By making these documents available for use and  
6 adoption by public authorities and private users, neither IEEE nor its licensors waive any rights in copyright  
7 to the documents.

## 8 Photocopies

9 Subject to payment of the appropriate licensing fees, IEEE will grant users a limited, non-exclusive license  
10 to photocopy portions of any individual standard for company or organizational internal use or individual,  
11 non-commercial use only. To arrange for payment of licensing fees, please contact Copyright Clearance  
12 Center, Customer Service, 222 Rosewood Drive, Danvers, MA 01923 USA; +1 978 750 8400;  
13 <https://www.copyright.com/>. Permission to photocopy portions of any individual standard for educational  
14 classroom use can also be obtained through the Copyright Clearance Center.

## 15 Updating of IEEE Standards documents

16 Users of IEEE Standards documents should be aware that these documents may be superseded at any time  
17 by the issuance of new editions or may be amended from time to time through the issuance of amendments,  
18 corrigenda, or errata. An official IEEE document at any point in time consists of the current edition of the  
19 document together with any amendments, corrigenda, or errata then in effect.

20 Every IEEE standard is subjected to review at least every 10 years. When a document is more than 10 years  
21 old and has not undergone a revision process, it is reasonable to conclude that its contents, although still of  
22 some value, do not wholly reflect the present state of the art. Users are cautioned to check to determine that  
23 they have the latest edition of any IEEE standard.

24 In order to determine whether a given document is the current edition and whether it has been amended  
25 through the issuance of amendments, corrigenda, or errata, visit [IEEE Xplore](#) or [contact IEEE](#).<sup>3</sup> For more  
26 information about the IEEE SA or IEEE's standards development process, visit the IEEE SA Website.

## 27 Errata

28 Errata, if any, for all IEEE standards can be accessed on the [IEEE SA Website](#).<sup>4</sup> Search for standard number  
29 and year of approval to access the web page of the published standard. Errata links are located under the  
30 Additional Resources Details section. Errata are also available in [IEEE Xplore](#). Users are encouraged to  
31 periodically check for errata.

## 32 Patents

33 IEEE Standards are developed in compliance with the [IEEE SA Patent Policy](#).<sup>5</sup>

34 Attention is called to the possibility that implementation of this standard may require use of subject matter  
35 covered by patent rights. By publication of this standard, no position is taken by the IEEE with respect to the  
36 existence or validity of any patent rights in connection therewith. If a patent holder or patent applicant has  
37 filed a statement of assurance via an Accepted Letter of Assurance, then the statement is listed on the  
38 IEEE SA Website at <https://standards.ieee.org/about/sasb/patcom/patents.html>. Letters of Assurance may  
39 indicate whether the Submitter is willing or unwilling to grant licenses under patent rights without  
40 compensation or under reasonable rates, with reasonable terms and conditions that are demonstrably free of  
41 any unfair discrimination to applicants desiring to obtain such licenses.

<sup>3</sup> Available at: <https://ieeexplore.ieee.org/browse/standards/collection/ieee>.

<sup>4</sup> Available at: <https://standards.ieee.org/standard/index.html>.

<sup>5</sup> Available at: <https://standards.ieee.org/about/sasb/patcom/materials.html>.

1 Essential Patent Claims may exist for which a Letter of Assurance has not been received. The IEEE is not  
2 responsible for identifying Essential Patent Claims for which a license may be required, for conducting  
3 inquiries into the legal validity or scope of Patents Claims, or determining whether any licensing terms or  
4 conditions provided in connection with submission of a Letter of Assurance, if any, or in any licensing  
5 agreements are reasonable or non-discriminatory. Users of this standard are expressly advised that  
6 determination of the validity of any patent rights, and the risk of infringement of such rights, is entirely their  
7 own responsibility. Further information may be obtained from the IEEE Standards Association.

## 8 **IMPORTANT NOTICE**

9 IEEE Standards do not guarantee or ensure safety, security, health, or environmental protection, or ensure  
10 against interference with or from other devices or networks. Technologies, application of technologies, and  
11 recommended procedures in various industries evolve over time. The IEEE standards development process  
12 allows participants to review developments in industries, technologies, and practices, and to determine what,  
13 if any, updates should be made to the IEEE standard. During this evolution, the technologies and  
14 recommendations in IEEE standards may be implemented in ways not foreseen during the standards  
15 development. IEEE Standards development activities consider research and information presented to the  
16 standards development group in developing any safety recommendations. Other information about safety  
17 practices, changes in technology or technology implementation, or impact by peripheral systems also may  
18 be pertinent to safety considerations during implementation of the standard. Implementers and users of IEEE  
19 Standards documents are responsible for determining and complying with all appropriate safety, security,  
20 environmental, health, data privacy, and interference protection practices and all applicable laws and  
21 regulations.

## 1 Participants

2 <<The following lists will be updated in the usual way prior to publication>>

3 At the time this standard was submitted to the IEEE-SA Standards Board for approval, the IEEE 802.1  
4 Working Group had the following membership:

5 **Glenn Parsons**, *Chair*  
6 **Jessy V. Rouyer**, *Vice Chair*  
7 **Mick Seaman**, *Editor, Chair, Security Task Group*  
8 **János Farkas**, *Chair, Time-Sensitive Networking Task Group*  
9 **David McCall**, *Vice Chair, Time-Sensitive Networking Task Group*  
10 **Mark Hantel**, *Chair, Maintenance Task Group*  
11

<<TBA>>

<sup>1</sup> The following members of the individual balloting committee voted on this standard. Balloters may have  
<sup>2</sup> voted for approval, disapproval, or abstention.

<<TBA>>

<sup>3</sup> When the IEEE-SA Standards Board approved this standard on XX Month 20xx, it had the following  
<sup>4</sup> membership:

<sup>5</sup> <<TBA>>

## 1 Historical participants

2 Since the initial publication, many IEEE standards have added functionality or provided updates to material  
3 included in this standard. The following is a historical list of participants who have dedicated their valuable  
4 time, energy, and knowledge to the creation of this material:

| IEEE 802.1Q Standard  | Date approved by IEEE | Officers at the time of Working Group Ballot                                                                                                                                                                                                                                                                    |

## 1 Introduction

This introduction is not part of IEEE Std 802.1Q™-20XX, IEEE Standard for Local and metropolitan area networks—Bridges and Bridged Networks.

2 IEEE Std 802.1Q™-20XX incorporated the text of the following amendments into IEEE Std 802.1Q™.

3 IEEE Std 802.1Qdy™-2025: YANG for Multiple Spanning Trees addresses requirements arising from  
4 industrial automation networks, specifying YANG for bridge and bridge component MSTP configuration  
5 and status reporting.

6 IEEE Std 802.1Qdx™-2024: YANG Data Models for the Credit-Based Shaper addressed the need to  
7 manage the credit-based shaper algorithm via a YANG model compatible with modern management  
8 systems.

9 IEEE Std 802.1Qdj™-2024: Configuration Enhancements for Time-Sensitive Networks described the  
10 relationships and division of responsibilities between Centralized User Configuration (CUC) components,  
11 that can be used to configure end stations' use of Time-Sensitive Networking (TSN) capabilities, and a  
12 Centralized Network Configuration (CNC) component that can be used to configure network resources  
13 within an administrative Configuration Domain. This standard also included a YANG model and modules  
14 that can be used by a network configuration protocol, such as NETCONF, to provide communication  
15 between the CNC and a CUC.

16 IEEE Std 802.1Qcj™-2023: Automatic Attachment to Provider Backbone Bridging (PBB) Services  
17 specified protocols, procedures and management objects for auto attachment of network devices to Provider  
18 Backbone service instances using Type, Length, Value (TLVs) within the Link Layer Discovery Protocol  
19 (LLDP).

20 IEEE Std 802.1Qcw™-2023: YANG Data Models for Scheduled Traffic, Frame Preemption, and Per-Stream  
21 Filtering and Policing support configuration and status reporting for bridges and bridge components with the  
22 capabilities of scheduled traffic, frame preemption, and per-stream filtering and policing.

23 IEEE Std 802.1Qcz™-2023: Congestion Isolation specified protocols, procedures and managed objects that  
24 support the isolation of congesting data flows within data center environments. Congestion isolation capable  
25 systems identify flows creating congestion, adjust transmission selection for packets of those flows, and  
26 signal to neighbors. This mechanism reduces head-of-line blocking for non-congesting flows sharing a  
27 traffic class in lossless networks. Congestion Isolation is intended to be used with higher layer protocols that  
28 utilize end-to-end congestion control in order to reduce packet loss and latency.

29 IEEE Std 802.1Q™-2022 incorporated the text of the following amendments into IEEE Std 802.1Q™-2018.

|                            |                                                             |
|----------------------------|-------------------------------------------------------------|
| 30 IEEE Std 802.1Qcc™-2018 | Stream Reservation Protocol (SRP) Enhancements and          |
| 31                         | Performance Improvements                                    |
| 32 IEEE Std 802.1Qcp™-2018 | YANG Data Model                                             |
| 33 IEEE Std 802.1Qcy™-2019 | Virtual Station Interface (VSI) Discovery and Configuration |
| 34                         | Protocol (VDP) Extension to Support Network Virtualization  |
| 35                         | Overlays Over Layer 3 (NVO3)                                |
| 36 IEEE Std 802.1Qcx™-2020 | YANG Data Model for Connectivity Fault Management           |
| 37 IEEE Std 802.1Qcr™-2020 | Asynchronous Traffic Shaping                                |

1 The 2018 revision of this standard incorporated the text of the following amendments into IEEE Std  
2 802.1Q-2014.

|                                          |                                                     |
|------------------------------------------|-----------------------------------------------------|
| 3 IEEE Std 802.1Qcd <sup>TM</sup> -2015  | Application Virtual Local Area Network (VLAN) Type, |
| 4                                        | Length, Value (TLV)                                 |
| 5 IEEE Std 802.1Qca <sup>TM</sup> -2015  | Path Control and Reservation                        |
| 6 IEEE Std 802.1Q-2014 Cor 1-2015        | Technical and editorial corrections                 |
| 7 IEEE Std 802.1Qbv <sup>TM</sup> -2015  | Enhancements for scheduled traffic                  |
| 8 IEEE Std 802.1Qbu <sup>TM</sup> -2016  | Frame preemption                                    |
| 9 IEEE Std 802.1Qbz <sup>TM</sup> -2016  | Enhancements to Bridging of IEEE 802.11 Media       |
| 10 IEEE Std 802.1Qci <sup>TM</sup> -2017 | Per-Stream Filtering and Policing                   |
| 11 IEEE Std 802.1Qch <sup>TM</sup> -2017 | Cyclic Queuing and Forwarding                       |

12 The 2014 revision of this standard incorporated the text of the following amendments into IEEE Std  
13 802.1Q-2011.

|                                          |                                                       |
|------------------------------------------|-------------------------------------------------------|

| 28 IEEE Std 802.1ag <sup>TM</sup> -2007  | Connectivity Fault Management                     |
| 29 IEEE Std 802.1ah <sup>TM</sup> -2008  | Provider Backbone Bridges                         |
| 30 IEEE Std 802-1Q-2005/Cor-1-2008       | Corrections to the Multiple Registration Protocol |
| 31 IEEE Std 802.1ap <sup>TM</sup> -2008  | Management Information Base (MIB) Definitions for |
| 32                                       | VLAN Bridges                                      |
| 33 IEEE Std 802.1Qaw <sup>TM</sup> -2009 | Management of Data Driven and Data Dependent      |
| 34                                       | Connectivity Faults                               |
| 35 IEEE Std 802.1Qay <sup>TM</sup> -2009 | Provider Backbone Bridge Traffic Engineering      |
| 36 IEEE Std 802.1aj <sup>TM</sup> -2009  | Two-Port Media Access Control (MAC) Relay         |
| 37 IEEE Std 802.1Qav <sup>TM</sup> -2009 | Forwarding and Queuing Enhancements for           |
| 38                                       | Time-Sensitive Streams                            |
| 39 IEEE Std 802.1Qau <sup>TM</sup> -2010 | Congestion Notification                           |
| 40 IEEE Std 802.1Qat <sup>TM</sup> -2010 | Stream Reservation Protocol                       |

41 Clause 13 of IEEE Std 802.1Q-2011 was also revised to include an updated specification of the Rapid  
42 Spanning Tree Algorithm and Protocol (RSTP), superseding references to IEEE Std 802.1D<sup>TM</sup>-2004 [B14].<sup>6</sup>

<sup>6</sup>The numbers in brackets correspond to those of the bibliography in Annex X.

1 The 2005 revision of this standard incorporated the text of the following amendments into  
2 IEEE Std 802.1Q-1998.

|                                       |                                          |
|---------------------------------------|------------------------------------------|
| 3 IEEE Std 802.1u <sup>TM</sup> -2001 | Technical and Editorial Corrections      |
| 4 IEEE Std 802.1v <sup>TM</sup> -2001 | VLAN Classification by Protocol and Port |
| 5 IEEE Std 802.1s <sup>TM</sup> -2002 | Multiple Spanning Trees                  |

6 This standard was first published as IEEE Std 802.1Q-1998, making use of the concepts and mechanisms of  
7 LAN Bridging that were introduced by IEEE Std 802.1D and defining additional mechanisms to allow the  
8 implementation of Virtual Bridged Networks.

9 For an introduction to this standard that details each of the provisions introduced by amendments and  
10 revisions throughout its development, refer to 1.3.

11 This standard contains state-of-the-art material. The area covered by this standard is undergoing evolution.  
12 Revisions are anticipated within the next few years to clarify existing material, to correct possible errors, and  
13 to incorporate new related material. Information on the current revision state of this and other IEEE 802  
14 standards may be obtained from

| 49 | Annex A (normative) | PICS proforma—Bridge implementations .....                                                   | 2050 |
| 50 | A.1                 | Introduction.....                                                                            | 2050 |

|    |         |                                                                |      |
|----|---------|----------------------------------------------------------------|------|
| 1  | A.2     | Abbreviations and special symbols.....                         | 2050 |
| 2  | A.2.1   | Status symbols .....                                           | 2050 |
| 3  | A.2.2   | General abbreviations .....                                    | 2050 |
| 4  | A.3     | Instructions for completing the PICS proforma.....             | 2051 |
| 5  | A.3.1   | General structure of the PICS proforma .....                   | 2051 |
| 6  | A.3.2   | Additional information .....                                   | 2051 |
| 7  | A.3.3   | Exception information .....                                    | 2051 |
| 8  | A.3.4   | Conditional status .....                                       | 2052 |
| 9  | A.4     | PICS proforma for IEEE Std 802.1Q—Bridge implementations ..... | 2053 |
| 10 | A.4.1   | Implementation identification .....                            | 2053 |
| 11 | A.4.2   | Protocol summary, IEEE Std 802.1Q .....                        | 2053 |
| 12 | A.5     | MAC Bridge conformance.....                                    | 2063 |
| 13 | A.5.1   | MAC Bridge conformance .....                                   | 2063 |
| 14 | A.5.2   | MAC Bridge component conformance .....                         | 2063 |
| 15 | A.5.3   | Bridge component conformance .....                             | 2064 |
| 16 | A.5.4   | ISS support of Bridge Port interface stacks .....              | 2067 |
| 17 | A.5.5   | Media access control methods .....                             | 2068 |
| 18 | A.6     | Customer VLAN Bridge conformance .....                         | 2069 |
| 19 | A.6.1   | C-VLAN Bridge conformance .....                                | 2069 |
| 20 | A.6.2   | C-VLAN component conformance .....                             | 2070 |
| 21 | A.6.3   | VLAN Bridge component conformance .....                        | 2070 |
| 22 | A.6.4   | Support of the EISS .....                                      | 2071 |
| 23 | A.6.5   | Port-and-Protocol VLAN classification conformance .....        | 2072 |
| 24 | A.7     | RST and MSTP conformance .....                                 | 2073 |
| 25 | A.7.1   | Rapid Spanning Tree Protocol (RSTP) .....                      | 2073 |
| 26 | A.7.2   | Multiple Spanning Tree Protocol (MSTP) .....                   | 2074 |
| 27 | A.7.3   | BPDU encoding .....                                            | 2075 |
| 28 | A.8     | MMRP, MVRP, and MRP conformance .....                          | 2076 |
| 29 | A.8.1   | Multiple MAC Registration Protocol (MMRP) .....                | 2076 |
| 30 | A.8.2   | Multiple VLAN Registration Protocol (MVRP) .....               | 2077 |
| 31 | A.8.3   | Multiple Registration Protocol (MRP) .....                     | 2078 |
| 32 | A.9     | Provider Bridge conformance .....                              | 2079 |
| 33 | A.9.1   | S-VLAN Bridge conformance .....                                | 2079 |
| 34 | A.9.2   | S-VLAN component conformance .....                             | 2079 |
| 35 | A.9.3   | Provider Edge Bridge (PEB) conformance .....                   | 2080 |
| 36 | A.9.4   | Remote Customer Service Interface (RCSI) conformance .....     | 2080 |
| 37 | A.10    | Connectivity Fault Management (CFM) conformance.....           | 2081 |
| 38 | A.10.1  | CFM—System and component support .....                         | 2081 |
| 39 | A.10.2  | CFM—Maintenance Domains and Maintenance Associations .....     | 2082 |
| 40 | A.10.3  | CFM—Down MEPs .....                                            | 2082 |
| 41 | A.10.4  | CFM—Up MEPs .....                                              | 2082 |
| 42 | A.10.5  | CFM—PEB Customer Edge and Access Port Down MEPs .....          | 2083 |
| 43 | A.10.6  | CFM—Common (Up and Down) MEP functionality .....               | 2083 |
| 44 | A.10.7  | CFM—MIPs .....                                                 | 2084 |
| 45 | A.10.8  | CFM—Common MEP and MIP functionality .....                     | 2084 |
| 46 | A.10.9  | CFM—End station exceptions .....                               | 2084 |
| 47 | A.10.10 | CFM PDU format transmission and validation .....               | 2085 |
| 48 | A.10.11 | CFM—Backbone Edge Bridge (BEB) functionality .....             | 2087 |
| 49 | A.10.12 | CFM—PBB Traffic Engineering functionality .....                | 2087 |

|    |         |                                                                        |      |
|----|---------|------------------------------------------------------------------------|------|
| 1  | A.11    | Provider Backbone Bridge conformance .....                             | 2088 |
| 2  | A.11.1  | Backbone Core Bridge (BCB) conformance .....                           | 2088 |
| 3  | A.11.2  | Backbone Edge Bridge (BEB) conformance .....                           | 2088 |
| 4  | A.11.3  | BEB I-component conformance .....                                      | 2089 |
| 5  | A.11.4  | BEB T-component conformance .....                                      | 2089 |
| 6  | A.11.5  | BEB Virtual Instance Port (VIP) conformance .....                      | 2089 |
| 7  | A.11.6  | B-component conformance .....                                          | 2090 |
| 8  | A.11.7  | PBB-TE S-VLAN component conformance .....                              | 2090 |
| 9  | A.11.8  | PBB-TE B-component conformance for PBB-TE .....                        | 2091 |
| 10 | A.12    | PBBN Auto Attach conformance .....                                     | 2092 |
| 11 | A.12.1  | Auto Attach Bridge (AAB) I-component conformance .....                 | 2092 |
| 12 | A.12.2  | Auto Attach Device (AAD) conformance .....                             | 2092 |
| 13 | A.12.3  | Auto Attach (common elements) conformance .....                        | 2092 |
| 14 | A.13    | Shortest Path Bridging (SPB) conformance .....                         | 2093 |
| 15 | A.13.1  | Shortest Path Bridging (SPB) conformance .....                         | 2093 |
| 16 | A.14    | Path Control and Reservation (PCR) conformance .....                   | 2094 |
| 17 | A.14.1  | Path Control and Reservation (PCR) conformance .....                   | 2094 |
| 18 | A.15    | TPMR conformance.....                                                  | 2096 |
| 19 | A.15.1  | TPMR conformance .....                                                 | 2096 |
| 20 | A.15.2  | TPMR component conformance .....                                       | 2096 |
| 21 | A.15.3  | MAC Status Protocol (MSP) .....                                        | 2097 |
| 22 | A.16    | Time and loss-sensitive stream transmission.....                       | 2098 |
| 23 | A.16.1  | Forwarding and queuing for time-sensitive streams (FQTSS) .....        | 2098 |
| 24 | A.16.2  | Stream Reservation Protocol (SRP) .....                                | 2099 |
| 25 | A.16.3  | 802.11 Designated MSRP Mode (DMN) conformance .....                    | 2100 |
| 26 | A.16.4  | MoCA Designated MSRP Mode (DMN) conformance .....                      | 2100 |
| 27 | A.16.5  | Scheduled traffic .....                                                | 2101 |
| 28 | A.16.6  | Asynchronous Traffic Shaping .....                                     | 2101 |
| 29 | A.17    | TSN Centralized Network Configuration (CNC) station .....              | 2102 |
| 30 | A.17.1  | TSN Centralized Network Configuration (CNC) station .....              | 2102 |
| 31 | A.18    | Congestion notification.....                                           | 2103 |
| 32 | A.18.1  | Congestion notification system conformance .....                       | 2103 |
| 33 | Annex C | (normative) Designated MSRP Node (DMN) Implementations .....           | 2104 |
| 34 | C.1     | DMNs on CSNs .....                                                     | 2104 |
| 35 | C.1.1   | CSN characteristics .....                                              | 2104 |
| 36 | C.1.2   | DMN handling on CSN .....                                              | 2105 |
| 37 | C.1.3   | MSRPDU handling on a CSN .....                                         | 2106 |
| 38 | C.1.4   | CSN bandwidth fluctuations .....                                       | 2107 |
| 39 | C.2     | DMN on MoCA .....                                                      | 2107 |
| 40 | C.2.1   | DMN Selection on MoCA Network .....                                    | 2107 |
| 41 | C.2.2   | MoCA network bandwidth management .....                                | 2111 |
| 42 | C.3     | DMNs on IEEE 802.11 media .....                                        | 2112 |
| 43 | C.3.1   | MSRP handling .....                                                    | 2113 |
| 44 | C.3.2   | BSS DMN selection .....                                                | 2116 |
| 45 | C.3.3   | BSS network bandwidth management .....                                 | 2117 |
| 46 | Annex D | (normative) IEEE 802.1 Organizationally Specific TLVs .....            | 2120 |
| 47 | D.1     | Requirements of the IEEE 802.1 Organizationally Specific TLV sets..... | 2120 |

|    |         |                                                                             |      |
|----|---------|-----------------------------------------------------------------------------|------|
| 1  | D.2     | Organizationally Specific TLV definitions.....                              | 2121 |
| 2  | D.2.1   | Port VLAN ID TLV .....                                                      | 2121 |
| 3  | D.2.2   | Port And Protocol VLAN ID TLV .....                                         | 2122 |
| 4  | D.2.3   | VLAN Name TLV .....                                                         | 2123 |
| 5  | D.2.4   | Protocol Identity TLV .....                                                 | 2123 |
| 6  | D.2.5   | VID Usage Digest TLV .....                                                  | 2124 |
| 7  | D.2.6   | Management VID TLV .....                                                    | 2124 |
| 8  | D.2.7   | Congestion Notification TLV .....                                           | 2125 |
| 9  | D.2.8   | ETS Configuration TLV .....                                                 | 2126 |
| 10 | D.2.9   | ETS Recommendation TLV .....                                                | 2128 |
| 11 | D.2.10  | Priority-based Flow Control Configuration TLV .....                         | 2129 |
| 12 | D.2.11  | Application Priority TLV .....                                              | 2130 |
| 13 | D.2.12  | EVB TLV .....                                                               | 2131 |
| 14 | D.2.13  | CDCP TLV .....                                                              | 2136 |
| 15 | D.2.14  | Application VLAN TLV .....                                                  | 2137 |
| 16 | D.2.15  | Congestion Isolation TLV .....                                              | 2139 |
| 17 | D.2.16  | Topology Recognition TLV .....                                              | 2140 |
| 18 | D.2.17  | PBBN Auto Attach System TLV .....                                           | 2142 |
| 19 | D.2.18  | PBBN Auto Attach Assignment TLV .....                                       | 2144 |
| 20 | D.3     | IEEE 802.1 Organizationally Specific TLV management.....                    | 2146 |
| 21 | D.3.1   | IEEE 802.1 Organizationally Specific TLV selection management .....         | 2146 |
| 22 | D.3.2   | IEEE 802.1 managed objects—TLV variables .....                              | 2146 |
| 23 | D.4     | PICS proforma for IEEE 802.1 Organizationally Specific TLV extensions ..... | 2148 |
| 24 | D.4.1   | Implementation identification .....                                         | 2148 |
| 25 | D.4.2   | Protocol summary, IEEE Std 802.1Q .....                                     | 2148 |
| 26 | D.4.3   | Major capabilities and options .....                                        | 2149 |
| 27 | D.5     | IEEE 802.1/LLDP extension MIB.....                                          | 2151 |
| 28 | D.5.1   | Internet Standard Management Framework .....                                | 2151 |
| 29 | D.5.2   | Structure of the IEEE 802.1/LLDP extension MIB .....                        | 2151 |
| 30 | D.5.3   | Relationship to other MIBs .....                                            | 2160 |
| 31 | D.5.4   | Security considerations for IEEE 802.1 LLDP extension MIB module .....      | 2160 |
| 32 | D.5.5   | IEEE 802.1 LLDP extension MIB module—version 2 .....                        | 2163 |
| 33 | D.5.6   | EVB extensions to the IEEE 802.1 LLDP extension MIB module .....            | 2235 |
| 34 | D.6     | IEEE 802.1/LLDP extension YANG.....                                         | 2246 |
| 35 | D.6.1   | YANG framework .....                                                        | 2246 |
| 36 | D.6.2   | IEEE 802.1 Organizationally Specific TLV YANG data models .....             | 2246 |
| 37 | D.6.3   | Structure of the IEEE 802.1/LLDP extension YANG models .....                | 2252 |
| 38 | D.6.4   | Security considerations .....                                               | 2252 |
| 39 | D.6.5   | Definition of the IEEE 802.1/LLDP extension YANG modules .....              | 2255 |
| 40 | D.6.6   | IEEE 802.1/LLDP extension YANG modules .....                                | 2259 |
| 41 | Annex E | (normative) Notational conventions used in state diagrams.....              | 2288 |
| 42 | Annex F | (informative) Shared and Independent VLAN Learning (SVL and IVL) .....      | 2290 |
| 43 | F.1     | Requirements for Shared and Independent Learning .....                      | 2290 |
| 44 | F.1.1   | Connecting independent VLANs .....                                          | 2291 |
| 45 | F.1.2   | Duplicate MAC addresses .....                                               | 2292 |
| 46 | F.1.3   | Asymmetric VLANs and Rooted-Multipoint connectivity .....                   | 2293 |
| 47 | F.1.4   | Shared learning and Shortest Path Bridging VID (SPBV) mode .....            | 2296 |
| 48 | F.1.5   | Generic constraints on SVL and IVL use .....                                | 2298 |
| 49 | Annex G | (informative) MAC method-dependent aspects of VLAN support.....             | 2299 |
| 50 | G.1     | Example tagged IEEE 802.3 EtherType-encoded frame format .....              | 2299 |

|    |         |                                                                                            |      |
|----|---------|--------------------------------------------------------------------------------------------|------|
| 1  | G.2     | Padding and frame size considerations .....                                                | 2299 |
| 2  | G.2.1   | Treatment of PAD fields in IEEE 802.3 frames .....                                         | 2299 |
| 3  | G.2.2   | Maximum PDU size .....                                                                     | 2300 |
| 4  | G.2.3   | Minimum PDU size .....                                                                     | 2300 |
| 5  | G.3     | Tag insertion and removal for LLC media .....                                              | 2301 |
| 6  | G.4     | IEEE 802.11 and PMPN media .....                                                           | 2301 |
| 7  | G.4.1   | IEEE 802.11 Portal convergence .....                                                       | 2301 |
| 8  | G.4.2   | Point-to-Multipoint Network convergence: multiple connections .....                        | 2301 |
| 9  | G.4.3   | Point-to-Multipoint Network convergence: single connection .....                           | 2302 |
| 10 | Annex H | (informative) Interoperability considerations.....                                         | 2303 |
| 11 | H.1     | Requirements for interoperability .....                                                    | 2303 |
| 12 | H.1.1   | Static filtering requirements .....                                                        | 2303 |
| 13 | H.1.2   | Configuration requirements for VLAN-tagging .....                                          | 2303 |
| 14 | H.2     | Homogeneous VLAN-aware networks.....                                                       | 2304 |
| 15 | H.2.1   | Consistency of static VLAN filtering .....                                                 | 2304 |
| 16 | H.2.2   | Consistent view of the “untagged VLAN(s)” on a given LAN .....                             | 2305 |
| 17 | H.3     | Heterogeneous networks: Intermixing MAC Bridges (M) and VLAN Bridges (V) .....             | 2306 |
| 18 | H.3.1   | Example: Adding a VLAN Bridge to provide filtering to a MAC Bridged Network                |      |
| 19 |         | 2306                                                                                       |      |
| 20 | H.3.2   | Example: Adding a MAC Bridge to a (previously) Homogeneous VLAN Bridged                    |      |
| 21 |         | Network .....                                                                              | 2307 |
| 22 | H.4     | Intermixing Port-based classification and Port-and-Protocol-based classification or future |      |
| 23 |         | enhancements in VLAN Bridges .....                                                         | 2307 |
| 24 | H.4.1   | Example: Intermixing Protocol-based ingress rules .....                                    | 2308 |
| 25 | H.4.2   | Differing views of untagged traffic on a given LAN .....                                   | 2308 |
| 26 | Annex I | (informative) Priority and drop precedence.....                                            | 2309 |
| 27 | I.1     | Traffic types.....                                                                         | 2309 |
| 28 | I.2     | Managing latency and throughput .....                                                      | 2310 |
| 29 | I.3     | Traffic type to traffic class mapping.....                                                 | 2310 |
| 30 | I.4     | Traffic types and priority values.....                                                     | 2312 |
| 31 | I.5     | Supporting the credit-based shaper algorithm .....                                         | 2313 |
| 32 | I.6     | Supporting drop precedence .....                                                           | 2314 |
| 33 | I.7     | Priority Code Point allocation.....                                                        | 2314 |
| 34 | I.8     | Interoperability.....                                                                      | 2315 |
| 35 | Annex J | (informative) CFM protocol design and use.....                                             | 2317 |
| 36 | J.1     | Origin of CFM .....                                                                        | 2317 |
| 37 | J.2     | Deployment of CFM .....                                                                    | 2317 |
| 38 | J.3     | MD Level allocation alternative .....                                                      | 2318 |
| 39 | J.4     | Relationship of IEEE Std 802.1Q CFM to other standards .....                               | 2318 |
| 40 | J.5     | Interpreting Linktrace results.....                                                        | 2319 |
| 41 | J.6     | MP addressing: Individual and Shared MP addresses .....                                    | 2320 |
| 42 | J.6.1   | Individual MP address model .....                                                          | 2321 |
| 43 | J.6.2   | Shared MP address model and the CFM Port .....                                             | 2321 |
| 44 | Annex K | (informative) TPMR use cases.....                                                          | 2324 |
| 45 | K.1     | Use case 1—TPMR as User to Network Interface (UNI) demarcation device .....                | 2324 |
| 46 | K.2     | Use case 2—TPMRs with aggregated links .....                                               | 2325 |
| 47 | K.3     | Use case 3—Multiple TPMRs .....                                                            | 2325 |
| 48 | K.4     | Special cases .....                                                                        | 2326 |

|    |         |                                                                              |      |
|----|---------|------------------------------------------------------------------------------|------|
| 1  | Annex L | (informative) Operation of the credit-based shaper algorithm .....           | 2329 |
| 2  | L.1     | Overview of credit-based shaper operation .....                              | 2329 |
| 3  | L.2     | “Class measurement intervals” in Bridges.....                                | 2334 |
| 4  | L.3     | Determining worst-case latency contribution and buffering requirements ..... | 2335 |
| 5  | L.3.1   | Interference delay .....                                                     | 2336 |
| 6  | L.3.2   | Maximum interference delay and maximum buffer requirement .....              | 2344 |
| 7  | L.4     | Operation of credit-based shaper in Coordinated Shared Network (CSN).....    | 2345 |
| 8  | Annex M | (normative) Support for PFC in link layers without MAC Control .....         | 2346 |
| 9  | M.1     | Overview.....                                                                | 2346 |
| 10 | M.2     | PFC PDU format.....                                                          | 2346 |
| 11 | Annex N | (informative) Buffer requirements for PFC .....                              | 2347 |
| 12 | N.1     | Overview.....                                                                | 2347 |
| 13 | N.2     | Delay model.....                                                             | 2347 |
| 14 | N.3     | Interface Delay.....                                                         | 2350 |
| 15 | N.4     | Cable Delay.....                                                             | 2350 |
| 16 | N.5     | Higher Layer Delay .....                                                     | 2350 |
| 17 | N.6     | Computation example .....                                                    | 2351 |
| 18 | Annex O | (informative) Preserving the integrity of FCS fields in MAC Bridges .....    | 2352 |
| 19 | O.1     | Background.....                                                              | 2352 |
| 20 | O.2     | Basic mathematical ideas behind CRC and FCS .....                            | 2353 |
| 21 | O.3     | Detection Lossless Circuit approach.....                                     | 2354 |
| 22 | O.4     | Algorithmic modification of an FCS .....                                     | 2355 |
| 23 | O.4.1   | Data changed, length unchanged .....                                         | 2355 |
| 24 | O.4.2   | Length changed, original data unchanged .....                                | 2356 |
| 25 | O.4.3   | Preservation of detectability .....                                          | 2357 |
| 26 | O.5     | Conclusions.....                                                             | 2358 |
| 27 | Annex P | (informative) Frame duplication and misordering .....                        | 2359 |
| 28 | P.1     | Background.....                                                              | 2359 |
| 29 | P.2     | Frame duplication .....                                                      | 2359 |
| 30 | P.3     | Frame misordering .....                                                      | 2360 |
| 31 | P.4     | Other considerations .....                                                   | 2361 |
| 32 | Annex Q | (informative) Traffic scheduling .....                                       | 2362 |
| 33 | Q.1     | Motivation.....                                                              | 2362 |
| 34 | Q.2     | Using gate operations to create protected windows.....                       | 2363 |
| 35 | Q.3     | Availability of PTP .....                                                    | 2364 |
| 36 | Q.4     | Scheduled traffic and end stations .....                                     | 2364 |
| 37 | Q.5     | CycleTimeExtension variables .....                                           | 2364 |
| 38 | Annex R | (informative) Preemption and IEEE 802.1AE MAC Security .....                 | 2365 |
| 39 | Annex S | (informative) Preemption and scheduled traffic .....                         | 2367 |
| 40 | S.1     | Scheduling used in isolation .....                                           | 2367 |
| 41 | S.2     | Preemption used in isolation.....                                            | 2367 |
| 42 | S.3     | Scheduling and preemption used in combination, no HOLD/RELEASE .....         | 2368 |
| 43 | S.4     | Scheduling and preemption used in combination with HOLD/RELEASE .....        | 2368 |

|    |                       |                                                                    |      |
|----|-----------------------|--------------------------------------------------------------------|------|
| 1  | S.5                   | Bandwidth allocation and express traffic.....                      | 2368 |
| 2  | Annex T (informative) | Cyclic queuing and forwarding .....                                | 2370 |
| 3  | T.1                   | Overview of CQF.....                                               | 2370 |
| 4  | T.2                   | An approach to CQF implementation.....                             | 2371 |
| 5  | T.3                   | Use of Per-Stream Filtering and Policing for CQF.....              | 2372 |
| 6  | T.3.1                 | Stream filter configuration .....                                  | 2372 |
| 7  | T.3.2                 | Stream gate configuration .....                                    | 2372 |
| 8  | T.4                   | Use of traffic scheduling for CQF .....                            | 2373 |
| 9  | T.5                   | Timing considerations.....                                         | 2374 |
| 10 | T.5.1                 | Choice of T .....                                                  | 2374 |
| 11 | T.5.2                 | Cycle interleaving .....                                           | 2375 |
| 12 | T.5.3                 | Cycle alignment between adjacent Ports .....                       | 2377 |
| 13 | Annex U (informative) | TSN configuration examples .....                                   | 2378 |
| 14 | U.1                   | Examples for time-aware talker.....                                | 2378 |

## 2 IEEE Standard for 3 Local and Metropolitan Area Networks—

# 4 Bridges and Bridged Networks

## 5 1. Overview

6 IEEE 802® Local Area Networks (LANs, 3.119)<sup>6</sup> of all types can be connected together with Media Access  
7 Control (MAC) Bridges (3.159) or Virtual Local Area Network (VLAN) Bridges (3.306), collectively  
8 known as Bridges (3.28). This standard defines the operation of Bridges and Bridged Networks. VLANs  
9 facilitate the administration of logical groups of stations. Stations in the same VLAN communicate as if they  
10 were on the same LAN, while traffic between VLANs is restricted. Management of VLAN Bridges and  
11 stations allows stations to be added to, removed from, or moved between VLANs.

12 This standard further extends the specification of VLAN Bridges to enable a service provider organization to  
13 use a common infrastructure of Bridges and LANs to offer the equivalent of separate LANs, ~~Bridged~~, or  
14 ~~Virtual~~ Bridged Networks to independent customer organizations.

15 The above update was missed when 1Q title changed from original 1998 and 2005 "Virtual Bridged Area networks". Note  
however that this second paragraph of 1. and the one following duplicate information in 1.3, so there is an argument for  
removing both of them. We don't want to end up with the whole of 1.3 transferred back into this introductory text. On the  
other hand I am not aiming for perfection here, only ease of future maintenance and clarity for the new reader.

19 a

20 This standard specifies protocols and protocol entities within the architecture of Bridges that provide  
21 capabilities for detecting, verifying, and isolating connectivity failures in Bridged Networks. These  
22 capabilities can be used in networks operated by multiple independent organizations, each with restricted  
23 management access to each other's equipment.

### 24 1.1 Scope

25 This standard specifies Bridges that interconnect individual LANs, each supporting the IEEE 802 MAC  
26 Service using a different or identical media access control method, to provide Bridged Networks and  
27 VLANs.

### 28 1.2 Purpose

29 Bridges, as specified by this standard, allow the compatible interconnection of information technology  
30 equipment attached to separate individual LANs.

---

<sup>6</sup> IEEE and IEEE 802 are registered trademarks in the U.S. Patent & Trademark Office, owned by The Institute of Electrical and Electronics Engineers, Incorporated.

## 1.3 Introduction

For the purpose of compatible interconnection of information technology equipment using the IEEE 802 MAC Service supported by interconnected IEEE 802 standard LANs using different or identical media access control methods, this standard specifies the operation of VLAN-unaware MAC Bridges and VLAN Bridges and requirements to be satisfied by equipment claiming conformance<sup>7</sup> to this standard. It further specifies requirements for configuration and management of Bridges and Bridged Networks, and defines supporting SMIPv2 (IETF STD 58)<sup>8</sup> Management Information Based (MIB) modules, YANG configuration and operational state models,<sup>9</sup> and TLVs for use with IEEE Std 802.1AB.<sup>10</sup>

Management, MIBs, and YANG were referenced (or not) in a haphazard way in 1.3 by the various 802.1Q amendments. The inserted text above should cover all those statements and remove the need for repetitious verbiage. As a consequence some feature specific references to MIB and YANG have been removed from the remainder of 1.3.

The very long list in 1.3 that follows this brief introduction was impossible to manage. Any addition or removal would renumber many referenced items. Now broken up into logical groups, 1..3.1 ... to aid understanding, but mainly to make maintenance a practical proposition.

### 1.3.1 Bridge and Bridged Network architecture and operation<sup>11</sup>

~~This standard:~~~~To this end, it:~~

- a) Positions the support of the MAC Service ~~VLANs~~ within an architectural description of the MAC Sublayer.
  - b) Specifies VLANs, supporting of multiple instances of the MAC Service over a common Bridged Network of LANs interconnected by Bridges.
  - c) Defines the principles of operation of ~~the~~ MAC Bridges and VLAN Bridges in terms of the support and preservation of the MAC Service, and the maintenance of quality of service (QoS).
  - d) Specifies an Enhanced Internal Sublayer Service (EISS) provided to the Media Access-Independent functions that provide frame relay in a VLAN Bridge.<sup>12</sup>
  - e) Establishes the principles and a model of Virtual Bridged Network operation.
  - f) Identifies the functions to be performed by Bridges, and provides an architectural model of the operation of a Bridge in terms of processes and entities that provide those functions.
  - g) Specifies reserved multicast address that are filtered by MAC Bridges and VLAN Bridges to facilitate discovery of, and communication with, their nearest neighbours.
  - h) Specifies a frame format that allows a VLAN Identifier (VID) and priority information to be carried by VLAN-tagged user data frames.
  - i) Specifies the rules that govern the addition or removal of VLAN tags to and from user data frames.
- ~~There is no 1.3 mention of frame classification into a VLAN, as introduced in 802.1v and now covered in 6.9 and 6.12.~~
- j) ~~Establishes the requirements for VLAN Bridge Management in a Virtual Bridged Network, identifying managed objects and defining management operations.~~
  - k) ~~Defines SMIPv2 (IETF STD 58)<sup>7</sup> Management Information Based (MIB) modules for the management of VLAN Bridge capabilities including spanning tree protocols and Provider Bridges.~~

<sup>7</sup> Clause 5.

<sup>8</sup> Information on references can be found in Clause 2.

<sup>9</sup> Clauses 17 and 48. Modules include their revision history. Augmented by each amendment.

<sup>10</sup> Annex D.

<sup>11</sup> Clauses 6, 7, 8, 9, and 11. Note that earlier revisions of this standard relied on provisions of IEEE Std 802.1D (now withdrawn) now incorporated in this standard, so clause order does not strictly reflect logical and descriptive dependency. Clauses 6 and 8 in particular also integrate provisions that support later amendments. The informative Annexes provide supporting information.

<sup>12</sup> The Internal Sublayer Service (ISS), which augments the specification of the MAC Service with elements necessary for MAC Bridge relay between LANs and supports the EISS in VLAN Bridges, is specified in IEEE Std 802.1AC.

- 1 l) ~~Define YANG configuration and operational state models (Clause 48) in support of Two-Port MAC~~  
2 ~~Relays, Customer VLAN Bridges, and Provider Bridges, including Connectivity Fault Management~~  
3 ~~(CFM) for those Bridges.~~

4 j), k), l) removed as part of moving generalized management statements to the first paragraph of 1.3. Note that at this point  
in the introduction there has been no hint as to what a Two-Port MAC Relay might be, nor any indication of the particular  
nature of any of the other items mentioned in l).

### 7 1.3.2 Automatic configuration of Bridge Network and VLAN topology<sup>13</sup>

8 This standard:

- 9 a) Establishes the requirements for automatic configuration of Bridged Network and VLAN topology.  
10 b) Defines the operation of ~~the Multiple Spanning Tree Algorithm and Protocol (MSTP)~~ interoperable  
11 algorithms and protocols that provide simple and full connectivity throughout a Bridged Network  
12 comprising arbitrary interconnected Bridges and consistently assign frames for any given VLAN to  
13 a spanning tree active topology.  
14 c) ~~Describes the protocols and procedures necessary to support interoperation between Multiple~~  
15 ~~Spanning Tree (MST) and Single Spanning Tree (SST) Bridges in the same Virtual Bridged~~  
16 ~~Networks.~~  
17 d) ~~Specifies the requirements to be satisfied by equipment claiming conformance to this standard.~~

18 RSTP, MSTP, and SPB are defined. The deleted text assumes a detailed knowledge of the standard, not appropriate for an  
introduction.

20 This standard specifies protocols, procedures, and managed objects to support the Multiple Registration  
21 Protocol (MRP). MRP allows participants in an MRP Application to declare and register attributes with  
22 ~~other neighbouring~~ participants in a Bridged Network, the set of Four applications are defined—one to  
23 register VIDs [Multiple VLAN Registration Protocol (MVRP)], one to register MAC addresses [Multiple  
24 MAC Registration Protocol (MMRP)], one to register Streams and configure associated network resources  
25 [Multiple Stream Registration Protocol (MSRP)], ~~and one that provides the ability to flush learned MAC~~  
26 ~~Address Entries held in the Filtering Database (FDB) of an I-component on a per-I-SID basis [Multiple~~  
27 ~~I-SID Registration Protocol (MIRP)].~~ MVRP will furthermore provide for the rapid healing of network  
28 failures without interrupting services to unaffected VLANs. To this end, it specifies the following:

- 29 e) MRP and the operation of MRP entities.<sup>14</sup>  
30 f) The generic frame formats used in MRP exchanges.  
31 g) The MMRP application of MRP, and the frame formats that it uses.  
32 h) The MVRP application of MRP, and the frame formats that it uses.

33 MIRP reference moved to the Provider Backbone Networks clause below. In the present clause there is no reason why the  
reader should know about ISIDs.

<sup>13</sup> Clause 7 provides an overview of the physical network topology, active topology, and VLAN topology. Clauses 13 and 14 specify the Rapid Spanning Tree Algorithm and Protocol (RSTP) and the Multiple Spanning Tree Algorithm and Protocol (MSTP) and their interoperability with Shortest Path Bridging (SPB). Clause 8.9 describes the consistent allocation of VIDs to spanning trees, shortest path trees, or Ethernet Switched Paths. Clauses 10 and 11 specify MRP, MMRP, and MVRP.

<sup>14</sup> MRP (Clause 10), added by IEEE Std 802.1ak-2007, replaced the Generic Attribute Registration Protocol (GARP), defined in IEEE Std 802.1D™-2004 [B14], that was used to support GVRP and GMRP in earlier revisions of IEEE Std 802.1Q. Similarly, GVRP and GMRP were replaced by MVRP (11.2) and MMRP (10.9–10.12), respectively.

### 1.3.3 Provider Bridges and Provider Bridged Networks<sup>15</sup>

To enable a service provider to use a Virtual Bridged Network to provide separate instances of the IEEE 802 MAC Service, MAC Internal Sublayer Service (ISS), and EISS to multiple independent customers, in a manner that does not require cooperation among the customers and that requires a minimum of cooperation between the customers and the provider of the MAC Service, this standard further specifies the operation of Provider Bridges. To this end, it:

- a) Differentiates Customer VLANs (C-VLANs) that are under the administrative control of a single customer of a service provider, from the Service VLANs (S-VLANs) that are used by a service provider to support different customers.
- b) Specifies VLAN tag formats for both C-VLANs and S-VLANs, allowing each to be distinguished and separately applied and administered by customers and by a service provider.
- c) Specifies the functionality of a generic VLAN Bridge component within a system and the specific requirements of derived C-VLAN and S-VLAN components.
- d) Specifies a C-VLAN Bridge as comprising a single C-VLAN component, and a Provider Bridge as encompassing Bridges that comprise a single S-VLAN component and no C-VLAN components (S-VLAN Bridge) or a single S-VLAN component and one or more C-VLAN components (Provider Edge Bridge).
- e) Specifies parameters and mappings that allow the EISS to support traffic classes that comprise distinct aggregate flows supporting different QoS characteristics and provide independent guarantees to different customers, through support of priority and drop precedence marking.
- f) Specifies the incorporation of flow metering, transmission queue management, and transmission selection algorithms within the forwarding process of a Bridge.
- g) Positions the support of S-VLANs within the architectural description of the MAC Sublayer and specifies their relationship to media access method-dependent functions and to the media-independent functions used by customers to administer their networks, including the support of C-VLANs.
- h) Allocates the reserved multicast addresses to media access method-dependent, provider network, and customer network functions, specifying the filtering to be applied in each type of VLAN Bridge component.
- i) Defines the principles of network operation in terms of the support and preservation of the MAC Service, and the maintenance of QoS for each service instance, including the segregation of data belonging to different organizations.
- j) Specifies customer interfaces to a Provider Bridged Network (PBN) in terms of the operation and configuration of the VLAN Bridge components of Provider Bridges, including interfaces that
  - 1) Provide access to a single service instance through a Bridge Port.
  - 2) Allow a customer to select among and identify service instances by Customer VLAN Identifier (C-VID).
  - 3) Allow a customer to select among and identify service instances by Service VLAN Identifier (S-VID).
  - 4) Support customer signaling of priority information on a frame by frame basis.
  - 5) Multiplex service instances over LANs that provide access to a provider network.
  - 6) Support fault tolerance through redundant provision of access LANs and equipment.
- k) ~~Describes the functions to be performed within the PBN in order to support and maintain the connectivity provided to customer service instances.~~
- l) ~~Establishes the requirements for Bridge Management in the PBN, identifying the managed objects and defining the management operations.~~

There is no management specification that addresses PBNs specifically, beyond management of the aspects of individual Bridges. The deleted list items above were probably 'aspirational'.

<sup>15</sup> Clauses 15 and 16. PBN capabilities were added by IEEE Std 802.1ad-2005.

- 1 m) Specifies performance requirements, and recommends default values and applicable ranges for the  
2 operational parameters of a Provider Bridge.

3 The following paragraph and list item were previously (i. e., in 802.1Q-2022) positioned after bf), between a description of  
MIRP for PBBNs and the description of PFC. I have not shown the move as a change remove and change add, but simply  
moved the text.

6 This standard allows an S-tagged service interface connecting two independently administered PBNs to be  
7 used to handle traffic (identified by a single S-VID) for a given customer attached to one PBN as if the  
8 customer were directly attached to the other PBN using a Port-based or C-tagged service interface. To this  
9 end, it:

- 10 n) Specifies the use of a Port-mapping S-VLAN component to associate selected S-VIDs registered on  
11 an external port with distinct internal ports, each of which supports a separate service interface.<sup>16</sup>

#### 12 1.3.4 Connectivity Fault Management<sup>17</sup>

13 This standard specifies protocols, procedures, and managed objects to support Connectivity Fault  
14 Management (CFM). These allow discovery and verification of the path, through Bridges and LANs, taken  
15 for frames addressed to and from specified network users, and support detection and isolation of a  
16 connectivity fault to a specific Bridge or LAN. To this end, it:

- 17 a) Defines Maintenance Domains, Maintenance Associations (MAs), their constituent Maintenance  
18 Points (MPs), and the managed objects required to create and administer them.  
19 b) Describes the protocols and procedures used by MPs to detect and diagnose connectivity faults  
20 within a Maintenance Domain.

~~21 This standard specifies CFM protocols, procedures, and managed objects that provide confirmation of  
22 successful transmission of frames conveying specified data. This capability supports diagnosis of faults  
23 sensitive to, or caused by, particular data patterns, and their isolation to part of the transmission path.  
24 Connectivity verification can be carried out from any single point with bridged connectivity to MPs on the  
25 path, can isolate failures to communicate in a specific direction, and can be carried out while service is being  
26 provided to other users of the data path. To this end, it:~~

- ~~27 c) Defines the extensions to CFM capabilities defined by Clause 18 through Clause 22 to facilitate  
28 diagnosis and isolation of faults sensitive to, or caused by, particular data patterns in frames  
29 transmitted by a service user.  
30 d) Describes the protocols and procedures for data-driven and data-dependent connectivity fault  
31 management (DDCFM).~~

#### 32 1.3.5 Provider Backbone Bridges and Provider Backbone Bridged Networks<sup>18</sup>

33 To allow scaling of Provider Networks to at least 2<sup>24</sup> S-VLANs, this standard further specifies the operation  
34 of Provider Backbone Bridges (PBBs) by means of an architecture and Bridge protocols compatible and  
35 interoperable with PBN protocols and equipment, allowing interconnection of multiple PBNs. To this end,  
36 it:

- 37 a) Introduces BEBs that, by exchanging backbone frames that encapsulate the addresses, VLAN tags,  
38 and data of customer frames, support the virtual, media-independent equivalent of a number of  
39 independent instances of the service provided by media-dependent frame transmission procedures.  
40 b) Extends the parameters of the ISS and EISS to include a connection identifier, capable of  
41 referencing the backbone addresses and other parameters, used to convey customer frames from one  
42 BEB to all, or one of, the other BEBs supporting a particular backbone service instance.

<sup>16</sup> Remote Customer Service Interface (RCSI) capability added to 16.2 by IEEE Std 802.1Qbc-2011.

<sup>17</sup> Clauses 18, 19, 20, 21, 22. CFM capabilities were added by IEEE Std 802.1ag-2007.

<sup>18</sup> Clauses 25 and 26. Provider Backbone Bridge capabilities were added by IEEE Std 802.1ah-2008.

- c) Specifies the format of the Backbone Service Instance tag (I-TAG) that encapsulates the customer addresses, and introduces a Backbone Service Instance Identifier (I-SID) that allows each BEB to support a number of backbone service instances and permits the unambiguous identification of up to  $2^{24}$  backbone service instances within a single [Provider Backbone Bridged Network \(PBBN\)](#).
- d) Provides a model of BEB operation in terms of VLAN Bridge components that allows the use of Provider Bridges as Backbone Core Bridges (BCBs), with PBBN traffic carried as frames containing I-TAGs on particular Backbone VLANs (B-VLANs) potentially coexisting with PBN traffic carried as frames without I-TAGs on other B-VLANs.
- e) Specifies the interfaces that a PBBN can provide to transport service frames. These comprise a Port-based service interface that assigns all received untagged and priority-tagged frames to a single S-VLAN transported over a single backbone service instance, an S-tagged service interface capable of mapping individual S-VLANs to different backbone service instances, and an I-tagged service interface capable of mapping frames from one set of backbone service instances to another.
- f) Describes the use of redundant Bridges and access LANs to protect backbone service access against failure of any of those systems or components.
- g) Specifies the management of BEBs in terms of the model of operation [item c) above], making use of defined management objects for the individual VLAN Bridge components, and adding managed objects to facilitate service creation.
- h) Describes the use of CFM to detect and isolate faults in the connectivity provided to individual S-VLANs across the PBBN, in the connectivity provided to the group of S-VLANs supported by a single backbone service instance (identified by an I-SID), and in the connectivity provided to individual B-VLANs within the backbone itself.
- i) Specifies extensions to MSTP to allow network administrators to protect against loops through peered PBBNs without requiring coupling of spanning trees that operate independently for each PBBN.

### 1.3.6 [Provider Backbone Bridged Network traffic engineered paths](#)<sup>19</sup>

This standard specifies protocols, procedures, and managed objects to allow support of provisioning systems that explicitly select traffic engineered paths within Provider Backbone Bridged Networks (PBBNs) by allowing a network operator to disable unknown destination address forwarding, source address learning and spanning tree protocols for administratively selected VIDs, while allowing other network control protocols to dynamically determine active topologies for other services. These interoperable capabilities are supported by management of individual Bridges by Simple Network Management Protocol (SNMP) using an SMIV2 MIB, by extensions to the other control protocols specified in this standard, by the use of CFM with the addresses and VIDs that specify traffic engineered connections, and by 1:1 path protection switching capable of load sharing. To this end, it:

- a) Enables construction of active topologies by an external agent that is responsible for setting up Ethernet Switched Paths (ESPs) by splitting the B-VID space between distributed spanning tree protocols and provisioned control.
- b) Supports discard of frames with unknown destination addresses for B-VIDs under provisioned control.
- c) Supports the operation of Continuity Check, Loopback, and Linktrace protocols on provisioned traffic engineered paths.
- d) Supports 1:1 protection switching capable of load sharing for Traffic Engineering service instances (TESIs).
- e) Supports protection of a group of TESIS that traverses a sequence of LANs and intervening Bridges using a method that does not require the modification of data or control frames.

<sup>19</sup> Provider Backbone Traffic Engineering (PBB-TE) capabilities were addressed by IEEE Std 802.1Qay-2009, with substantive additions to the PBBN and CFM Clauses (25, 26, and 18, 19, 20, 21, 22). IEEE Std 802.1Qbf-2011 added infrastructure segment protection.

- 1 f) ~~This standard specifies protocols, procedures, and managed objects to support~~ Supports topology  
2 change signaling to alter the binding (held in an I-Component) of Customer addresses to backbone  
3 addresses on a per-I-SID basis. ~~This is accomplished by extending the use of MRP. To this end, it~~  
4 ~~specifies the~~ specifying the MIRP application of MRP ~~and the frame formats that it uses.~~<sup>20</sup>  
5 NOTE—MIRP can only trigger the flushing of learned MAC address information; it does not propagate the  
6 registration of I-SIDs. ~~The name Multiple I-SID Registration Protocol is chosen because MIRP is a Multiple~~  
7 ~~Registration Protocol (MRP) application and can be extended to perform I-SID registrations.~~  
8 g) ~~Provides required extension to SNMP management by SMIPv2 MIB modules.~~

9 This standard does not specify operation of ESPs through multiple Provider Backbone Bridge Traffic  
10 Engineering (PBB-TE) Regions. All the Backbone Edge Bridges (BEBs) specified for use in a PBB-TE  
11 Region are combined I type and B type Backbone Edge Bridges (IB-BEBs).

### 12 1.3.7 Auto Attach for PBBNs<sup>21</sup>

13 This standard specifies the protocols, procedures, and management objects for auto attachment of network  
14 devices to backbone service instances (BSIs) by adding an Auto Attach Protocol (AAP) over the Link Layer  
15 Discovery Protocol (LLDP). The AAP simplifies the deployment and administration of PBBNs ~~networks~~ by  
16 automatically coupling end stations or Bridges to BSIs.

17 To this end, it:

- 18 a) Introduces the concepts of Auto Attach Protocol (AAP), Auto Attach System (AAS) on devices  
19 supporting Auto Attach<sup>22</sup>; non-PBB-based Auto Attach Devices (AADs) and PBB-based Auto  
20 Attach BEBs (AABs).  
21 b) Describes the process of discovery and advertising of capabilities for AADs and AABs supporting  
22 the AAP acting as an AAS.  
23 c) Describes the bindings between Backbone Service Instance Identifiers (I-SIDs) and VLAN  
24 Identifiers.  
25 d) Specifies IEEE 802.1 Organizationally Specific LLDP TLVs for discovery and capabilities  
26 advertising, and attachment of C-VLANs to Backbone Service Instances.  
27 e) ~~Specifies SNMP MIB support for PBBN Auto Attach.~~  
28 f) ~~Specifies YANG extensions to the LLDP YANG modules for the PBBN Auto Attach LLDP TLVs.~~  
29 g) ~~Specifies SNMP MIB extensions to the LLDP EVB extension MIB module for the PBBN Auto~~  
30 ~~Attach LLDP TLVs.~~  
31 **Removed as per comment near the beginning of this clause (1.3).**

<sup>20</sup> Clause 39, added by IEEE Std 802.1Qbe-2011.

<sup>21</sup> Clause 50 and supporting management and LLDP capabilities were added by IEEE Std 802.1Qcj-2023.

<sup>22</sup> The term “Auto Attach” is used interchangeably with “PBBN Auto Attach” where it is clear from the context that “PBBN Auto Attach” is discussed.

### 1.3.8 Shortest Path Bridging<sup>23</sup>

This standard specifies Shortest Path Bridging (SPB) of unicast and multicast frames, specifying protocols to calculate multiple active topologies that can share learned station information, and support of a VLAN by multiple, per-topology, Shortest Path VLAN Identifiers (SPVIDs). To this end, it:

- a) Describes the use of shortest paths to increase throughput and minimize transit delay, while introducing a negligible rate of frame misordering.
- b) Requires that active topologies calculated by spanning tree protocols and Shortest Path Tree (SPT) protocols be stable, predictable, and reproducible to maintain the characteristics of the MAC Service provided.
- c) Requires, except in the case of SPB using Equal Cost Multiple Paths (ECMP), active topologies that are reverse path congruent and unicast-multicast congruent to permit learning of station location from the source addresses of all frames and simplify the detection and management of faults.

~~NOTE 4 — ECMP operation does not provide (nor does this standard attempt to define for ECMP VLANs) reverse path congruence and unicast-multicast congruence as these concepts cease to have utility in an ECMP context.~~

NOTE above provides a snippet that is far too detailed for this Introduction. Clause 44 (ECMP) provides more easily understood detail.

- d) Specifies the calculation of symmetric sets of SPTs, each rooted at a Bridge within an SPT Region comprising Bridges operating compatible protocols and configurations.
- e) Specifies the use of Bridge Protocol Data Units (BPDUs) to identify and bound SPT Regions and to ensure loop-free interoperability with regions using the Rapid Spanning Tree Algorithm and Protocol (RSTP) and MSTP.
- f) Specifies both Shortest Path Bridging VID (SPBV) and Shortest Path Bridging MAC (SPBM) modes:
  - 1) for SPBV, identifying each SPT by SPVID and locating end stations by source MAC address learning.
  - 2) for SPBM, identifying each SPT by VID and source MAC address and distributing end station location information explicitly.
- g) Supports management selection of the Common Spanning Tree (CST), a Multiple Spanning Tree Instance (MSTI), or SPB for support of any given VLAN within an SPT Region.
- h) Specifies a protocol that automatically assigns SPVIDs for each VLAN supported by SPBV.
- i) Supports load sharing by Equal Cost Trees (ECTs) through the calculation of multiple SPT Sets, with each shortest path VLAN being assigned to one SPT Set.
- j) Specifies Intermediate System to Intermediate System Protocol for Shortest Path Bridging (ISIS-SPB): the use of and extensions to the Intermediate System to Intermediate System (IS-IS) Protocol to calculate SPTs for both SPBV and SPBM.
- k) Describes the addressing of ISIS-SPB entities and specifies the group MAC addresses they use.
- l) Specifies the use of loop prevention (for SPBV and for multicast frames for SPBM) and loop mitigation (for unicast frames for SPBM).
- m) Specifies an Agreement Protocol that prevents loops, specifying the necessary state information and computation as part of ISIS-SPB and communicating agreement information for the CIST and (as a compact Digest) for SPTs in each BPDU.
- n) Specifies load spreading by distributing unicast traffic over the set of available equal cost paths and assigning multicast traffic flows to a variety of trees.
- o) Specifies a flow filtering tag (F-TAG) containing a flow hash used in unicast ECMP traffic distribution and a TTL (time-to-live) field used to mitigate the effects of traffic loops resulting from transient conditions or control software errors or faults.

<sup>23</sup> Clauses 27 and 28, added by IEEE Std 802.1aq-2012. Clause 44, ECMP support added by IEEE Std 802.1Qbp-2014.

### 1 **1.3.9 IS-IS based explicit path control, bandwidth reservation, and redundancy**<sup>24</sup>

2 This standard ~~also~~ specifies ~~further~~ protocol extensions, procedures, and managed objects to IS-IS for  
3 providing capabilities beyond Shortest Path Bridging (SPB) for Bridged Networks. These extensions  
4 involve explicit path control, bandwidth reservation, and redundancy (protection, restoration) for data flows.  
5 Thus, this standard specifies bridging on explicit paths for unicast and multicast frames, specifying protocols  
6 to determine multiple active topologies. To this end, it:

- 7 a) Describes the use of explicit trees, e.g., to improve resiliency and decrease the probability of  
8 congestion.
- 9 b) Requires that active topologies calculated by one or multiple entities external to the routing protocol  
10 are such that the characteristics of the MAC Service are provided.
- 11 c) Supports management selection of explicit trees for support of any given VLAN within an SPT  
12 Region.
- 13 d) Specifies Intermediate System to Intermediate System Path Control and Reservation (ISIS-PCR):  
14 the use of and extensions to the Intermediate System to Intermediate System (IS-IS) protocol to  
15 establish explicit trees.
- 16 e) Specifies the use of ISIS-PCR for recording bandwidth assignments.
- 17 f) Specifies redundancy for ISIS-SPB and ISIS-PCR.

### 18 **1.3.10 Two-Port MAC Relays (TPMRs)**<sup>25</sup>

19 This standard specifies the function of a Two-Port MAC Relay (TPMR), along with protocols and  
20 procedures that support its operation. A TPMR is a type of Bridge that has only two externally accessible  
21 Bridge Ports, and supports a subset of the functionality of a MAC Bridge. A TPMR is transparent to all  
22 frame-based media-independent protocols, except those explicitly addressed to it and those that are destined  
23 for reserved MAC addresses that the relay function of the TPMR is defined not to forward. It is remotely  
24 manageable through at least one of its external MACs, and signals a failure of either MAC's LAN through  
25 the other MAC. A TPMR should only be attached to point-to-point LANs. ~~The conformance requirements  
26 for a TPMR are stated in 5.13 and 5.15.~~

### 27 **1.3.11 Time and loss-sensitive stream transmission**<sup>26</sup>

28 To enable the end-to-end management of resource reservation for QoS guaranteed streams, this standard  
29 further specifies protocols, procedures, and managed objects, usable by existing higher layer mechanisms,  
30 that allow network resources to be reserved for specific traffic streams traversing a Bridged Network. To this  
31 end, it:

- 32 a) Specifies the use of Dynamic Reservation Entries (8.8.7) in the FDB to control the forwarding of  
33 frames associated with a particular Stream.
- 34 b) Specifies a Stream Reservation Protocol (SRP). SRP facilitates the registration, deregistration, and  
35 maintenance of stream reservation information in relevant Bridges to establish end-to-end stream  
36 paths.

37 This standard allows Bridges to provide performance guarantees for time-sensitive (i.e., bounded latency  
38 and latency variation) loss-sensitive real-time audio/video (AV) data stream transmission (AV traffic). It  
39 specifies priority regeneration and controlled bandwidth queue draining algorithms. VLAN tag encoded  
40 priority values are allocated, in aggregate, to segregate frames among queues that support AV traffic and  
41 queues that support non-AV traffic, allowing simultaneous support of both AV traffic and other bridged  
42 traffic over and between wired and wireless Local Area Networks (LANs). To this end, it:

<sup>24</sup> Clause 45, added by IEEE Std 802.1Qca-2015.

<sup>25</sup> Capabilities added by IEEE Std\_802.1aj-2009, including Clause 23, MAC status propagation (MSP).

<sup>26</sup> Clause 34 added by IEEE Std 802.1Qav-2009, Clause 35 added by IEEE Std 802.1Qat-2010, updated by IEEE Std 802.1Qcc-2018.

c) Defines status parameters that allow the boundaries of an ~~an Stream Reservation Protocol (SRP—see Clause 35)~~ domain ~~(35.1.4)~~ to be identified and maintained.

d) Specifies how the priority information in frames received at SRP domain boundary ports is regenerated.

~~NOTE 1—The priorities in frames transmitted from outside an SRP domain to a Bridge inside an SRP domain are remapped in order to ensure that traffic that is not associated with a reservation does not disrupt traffic that is associated with a reservation. Hence, traffic entering an SRP domain that uses Priority Code Point values associated with reserved traffic classes will be remapped to Priority Code Point values that are not associated with reserved traffic classes.<sup>27</sup>~~

~~NOTE above, and below, far too much detail for this Introduction.~~

e) Specifies how priority information is used to determine the traffic classes to be used for time-sensitive streams.

f) Defines a credit-based shaper algorithm to shape traffic in accordance with stream reservations.

~~NOTE 2—The credit-based shaper algorithm operates on the outbound queues; the mechanisms specified for the support of time-sensitive AV traffic do not involve any form of ingress metering or policing.~~

This standard also specifies:

g) ~~Defines~~ Enhancements for scheduled traffic to allow transmissions scheduled relative to a known timescale.<sup>28</sup>

h) ~~Defines~~ Frame preemption to interrupt transmission of preemptable frames by express frames.<sup>29</sup>

~~This standard specifies protocols, procedures, and managed objects that:~~

i) ~~Allow for the~~ Protocols, procedures, and managed objects for filtering and policing of individual traffic streams.<sup>30</sup>

j) ~~Allow for~~ Asynchronous Traffic Shaping (ATS) over full-duplex links with constant bit data rates.<sup>31</sup>

### **1.3.12 Network configuration for time-sensitive applications<sup>32</sup>**

This standard specifies ~~enhancements to~~ protocols, procedures, and managed objects for the configuration of network resources for time-sensitive applications that require timely, high probability, delivery of frames without end station retransmission. To this end, it:

a) Describes three approaches to network configuration: fully distributed, centralized network/distributed user, and fully centralized.

~~b) Specifies managed objects for forwarding and queuing enhancements for time-sensitive streams (FQTSS).~~

c) Describes Centralized User Configuration (CUC) and Centralized Network Configuration (CNC) entities.

~~d) Specifies managed objects for configuration of Bridges by a CNC.~~

~~e) Specifies YANG configuration and operational state models (Clause 48) in support of Scheduled Traffic, Frame Preemption, Per-Stream Filtering and Policing, and CUC configuration.~~

~~Deleted list items are all covered, for the purposes of this Introduction, by the first sentence under this heading "managed objects ... configuration of network resources ... time-sensitive ..." and by the text in the paragraph following the 1.3 heading. In general there is obviously a tension between the desire of each amendment project to describe in detail what that project has set out to do (and in most cases has done), and the fact that the purpose of an amendment project is to modify the text of the complete standard, within which the subject of the~~

<sup>27</sup> Notes in text, tables, and figures, are given for information only and do not contain requirements needed to implement the standard.

<sup>28</sup> Added by IEEE Std 802.1Qbv-2015.

<sup>29</sup> Added by IEEE Std 802.1Qbu-2016.

<sup>30</sup> Additions to 8.6 by IEEE Std 802.1Qci-2017, with subsequent amendment.

<sup>31</sup> Added by IEEE Std 802.1Qcr-2020, which included revisions to flow classification and metering(8.6.5), transmission selection (8.6.5), and ATS support in end stations (Clause 47).

<sup>32</sup> Clause 46, added by IEEE Std 802.1Qcc-2018, revised by IEEE Std 802.1Qdj-2024.

amendment may have already been addressed (less technical refinement). We might make more use of the 'Introduction' that precedes the 'Contents' in amendments for effectively recording the Scope of the Amendment. Temporary text of that nature has also been preserved for amendment rolled up into the current 802.1Q Revision in the 'Introduction' for this Revision.

### 1.3.13 Congestion notification<sup>33</sup>

This standard specifies protocols, procedures, and managed objects to support congestion notification. These allow a Virtual Bridged Network or a portion thereof, with a limited bandwidth-delay product, to transfer long-lived data flows with a significantly reduced chance of frame loss compared to a network without congestion notification. To this end, it:

- a) Defines a means for VLAN Bridges that support congestion notification to form Congestion Managed Domains within a Virtual Bridged Network.
- b) Defines a means for detecting congested queues in end stations and VLAN Bridges, for signaling such congestion to the end stations sourcing the frames causing the congestion, and for those end stations to control the rate of transmission of those frames.

### 1.3.14 Congestion Isolation<sup>34</sup>

This standard specifies protocols, procedures, and managed objects that support the isolation of congesting data flows within data center environments. This is achieved by enabling systems to ~~individually~~ identify ~~individual~~ flows creating congestion, isolate those flows to the congesting queue, and signal to neighbors. This mechanism reduces head-of-line blocking for non-congesting flows sharing the same traffic class. Congestion Isolation is used with higher layer protocols that utilize end-to-end congestion control in order to reduce packet loss and latency. To this end, it:

- a) Defines a means for VLAN-aware Bridges that support congestion isolation to identify flows that are creating congestion.
- b) Defines a means for adjusting transmission selection for frames of congesting flows.
- c) Provides a means for discovering peer VLAN-aware Bridges and stations that support congestion isolation.
- d) Defines a means for signaling congestion isolation to supporting peer Bridges and stations.
- e) Defines a means for recognizing a system's level and port orientation within the topology relative to the edge.

### 1.3.15 Priority-based Flow Control<sup>35</sup>

This standard specifies protocols, procedures, and managed objects to support Priority-based Flow Control (PFC). These allow a Virtual Bridged Network, or a portion thereof, to enable flow control per traffic class on IEEE 802 point-to-point full-duplex links. To this end, it:

- a) Defines a means for a system to ~~inhibit~~ pause transmission of data frames ~~on~~ of certain priorities from the remote system on the link.

### 1.3.16 Enhanced Transmission Selection<sup>36</sup>

This standard specifies protocols, procedures, and managed objects for enhancement of transmission selection to support allocation of bandwidth among traffic classes. When the offered load in a traffic class does not use its allocated bandwidth, Enhanced Transmission Selection (ETS) will allow other traffic classes

<sup>33</sup> Clauses 30, 31, 32, and 33, added by IEEE Std\_802.1Qau-2010.

<sup>34</sup> Clause 49, added by IEEE Std 802.1Qcz-2023.

<sup>35</sup> Clause 36, added by IEEE Std 802.1Qbb-2011.

<sup>36</sup> Clause 37 (ETS) and Clause 38 (DCBX) added by IEEE Std 802.1Qaz-2011.

to use the available bandwidth. Bandwidth is used by traffic classes subject to ETS when there are no frames to be transmitted for traffic classes subject to strict priority or credit-based shaper algorithms. It defines the Data Center Bridging eXchange protocol (DCBX), which controls the application of ETS and PFC.

#### 1.3.17 Edge Virtual Bridging (EVB)<sup>37</sup>

This standard specifies protocols, procedures, and managed objects that:

- a) Provide for the discovery, configuration, and control of a pair of direct-attached Port-mapping S-VLAN components to extend the operation of a Customer Bridge to remote ports and enable coexistence of multiple services on station-resident ports (e.g., embedded bridging).
- b) Provide for discovery, configuration, and operation of reflective relay (8.6.1) for a Bridge Port.
- c) Provide for discovery of, and coordinated configuration of, edge relays (ERs) and other devices that utilize the reflective relay service.
- d) ~~Provide for dynamic profile-driven port configuration.~~
- e) Provide for Network Virtualization Overlays over Layer 3 (NVO3)-related port configuration.<sup>38</sup>

By all means be 'dynamic', and 'profile-driven' sounds good as well, but the word 'dynamic' does not appear anywhere in the EVB and related Clauses (40-43), and the above is the only instance of 'profile-driven' in the whole of the standard. So as a reader I am at a loss to understand for what I should be thankful.

#### Miscellaneous, without a home—for removal if none can be found

- a) ~~Provides for the use of IEEE 802.11™ media as links internal to, as well as links providing access to, a Bridged Network or Virtual Bridged Network.~~

I can find no text anywhere in 802.1Q which addresses the above, previously item ch) in 802.1Q-2022 specifically. It was introduced by IEEE Std 802.1Qbz-2016 'Enhancements to Bridging of IEEE 802.11 Media' which made useful clarifications in the general area of protocol identification and stacked tag handling, which are applicable to 802.11 and other media with a predominantly LLC encoding history, but did not differentiate as to the use of types of 802.11 link.

<sup>37</sup> Clauses 40, 41, 42, and 43, added by IEEE Std 802.1Qbg-2012.

<sup>38</sup> Clauses 40 and 41 revised by IEEE Std 802.1Qcy-2019.

### 3. Definitions

For the purposes of this document, the following terms and definitions apply. The *IEEE Standards Dictionary Online* should be consulted for terms not defined in this clause.<sup>18</sup>

This standard makes use of the following terms defined in IEEE Std 802:

- end station
- station

The following terms are specific to this standard:

**3.1 Active Segment:** The Infrastructure Segment, either the Working Segment or the Protection Segment, that is currently carrying traffic of Traffic Engineering service instances (TESIs) associated with the Infrastructure Protection Group (IPG).

**3.2 Active Service Access Point [SAP] (Active SAP):** The SAP, bounding a Maintenance Point (MP), that is on the side of the MP toward the monitored Maintenance Association (MA).

**3.3 Adjacency:** A neighbor in Intermediate System to Intermediate System (IS-IS) Protocol. From section 3.6 of ISO/IEC 10589:2002.

**3.4 Agreement Protocol:** A protocol that uses control plane synchronization between adjacent Bridges to guarantee loop prevention, so enabling rapid transition to forwarding after network topology changes.

NOTE—See 13.16 and 13.17.

**3.5 Almost Directed Acyclic Graph (ADAG):** A directed graph that can be transformed into a Directed Acyclic Graph (DAG) by removing all arcs incoming to the ADAG Root.

**3.6 audio/video (AV) traffic:** Traffic associated with audio and/or video applications that is sensitive to transmission latency and latency variation, and, for some applications, packet loss.

**3.7 Auto Attach BEB (AAB) Bridge component:** A Backbone Edge Bridge having at least one I-component that uses the AAP to respond to requests from AADs to couple LANs or VLANs to backbone service instances within a PBBN.

**3.8 Auto Attach Device (AAD):** An end station, MAC Bridge, C-VLAN Bridge, or S-VLAN Bridge that uses the AAP to request attachment to a backbone service instance within a PBBN.

**3.9 Auto Attach Protocol (AAP):** A protocol operating over LLDP used by an Auto Attach System (AAS) which provides auto attachment to a PBBN.

**3.10 Auto Attach System (AAS):** An Auto Attach Device (AAD) or Auto Attach BEB (AAB).

**3.11 B-component (B-Comp):** A Service Virtual Local Area Network (S-VLAN) component with one or more Customer Backbone Ports (CBPs).

**3.12 B-DEI field:** A field of a Backbone Virtual Local Area Network (B-VLAN) tag (B-TAG) that identifies the drop eligibility of the frame.

**3.13 B-PCP field:** A field of a Backbone Virtual Local Area Network (B-VLAN) tag (B-TAG) that indicates the B-VLAN priority of the frame.

<sup>18</sup> *IEEE Standards Dictionary Online* is available at <https://dictionary.ieee.org>.

1 **3.14 Backbone Core Bridge (BCB):** A Service Virtual Local Area Network (S-VLAN) Bridge used within  
2 the core of a Provider Backbone Bridged Network (PBBN).

3 **3.15 Backbone Edge Bridge (BEB):** A system that encapsulates customer frames for transmission across a  
4 Provider Backbone Bridged Network (PBBN).

5 **3.16 Backbone Media Access Control (B-MAC) address:** An individual Media Access Control (MAC)  
6 address associated with a Provider Instance Port (PIP) and used in creating the MAC header of I-tagged  
7 frames transmitted across a Provider Backbone Bridged Network (PBBN).

8 **3.17 Backbone Media Access Control (B-MAC) Frame:** A local area network (LAN) frame addressed  
9 with B-MAC addresses.

10 **3.18 backbone service instance:** An instance of the Media Access Control (MAC) Service in a Provider  
11 Backbone Bridged Network (PBBN), provided between two or more Virtual Instance Ports (VIPs) in  
12 Backbone Edge Bridges (BEBs).

13 **3.19 Backbone Service Instance tag (I-TAG):** A tag with an EtherType value allocated for “IEEE 802.1Q  
14 Backbone Service Instance Tag EtherType.”

15 **3.20 Backbone Virtual Local Area Network (B-VLAN):** A Virtual Local Area Network (VLAN)  
16 identified by a B-VLAN Identifier (B-VID).

17 **3.21 Backbone Virtual Local Area Network [B -VLAN] Identifier (B-VID):** A Virtual Local Area  
18 Network (VLAN) Identifier (VID) conveyed in a B-VLAN tag (B-TAG).

19 **3.22 Backbone Virtual Local Area Network [B -VLAN] tag (B-TAG):** An Service Virtual Local Area  
20 Network (S-VLAN) tag (S-TAG) used in conjunction with Backbone Media Access Control (B-MAC)  
21 addresses.

22 **3.23 Backbone Virtual Local Area Network (B-VLAN) tagged frames:** Frames that contain a B-VLAN  
23 tag (B-TAG) immediately following the Source MAC Address field.

24 **3.24 base time:** A time from which future cycles of gate close and open events are calculated.

25 **3.25 Base Virtual Local Area Network [VLAN] Identifier [VID] (Base VID):** The identifier of a VLAN  
26 in management operations in both Shortest Path Bridging VID (SPBV) mode and Shortest Path Bridging  
27 Media Access Control (MAC) (SPBM) mode.

28 **3.26 bit time:** The duration of one bit as transferred to and from the Media Access Control (MAC).

29 **3.27 Boundary Port:** A Bridge Port attaching a Multiple Spanning Tree (MST) Bridge to a Local Area  
30 Network (LAN) that is not in the same region.

31 **3.28 Bridge:** A system that includes Media Access Control (MAC) Bridge or Virtual Local Area Network  
32 (VLAN) Bridge component functionality.

33 **3.29 Bridge Local Computation Engine (BLCE):** A computation engine in a Bridge that performs path  
34 and routing computations. The BLCE implements, e.g., Shortest Path First (SPF), Constrained Shortest Path  
35 First (CSPF), or the Maximally Redundant Trees Algorithm (IETF RFC 7811).

1 **3.30 Bridge Port:** A Service Access Point (SAP) that provides the Enhanced Internal Sublayer Service  
2 (EISS) to the Media Access Control (MAC) Relay Entity of a Virtual Local Area Network (VLAN) Bridge  
3 component, or that provides the Internal Sublayer Service (ISS) to the MAC Relay Entity of a MAC Bridge,  
4 and the interface stack that supports that SAP.

5 NOTE—See 6.1, 8.5, and IEEE Std 802.1AC.

6 **3.31 Bridged Network:** A concatenation of individual IEEE 802 Local Area Networks (LANs)  
7 interconnected by Bridges.

8 **3.32 Centralized Network Configuration (CNC):** A centralized component that configures network  
9 resources on behalf of TSN applications (users).

10 **3.33 Centralized User Configuration (CUC):** A centralized entity that discovers end stations, retrieves end  
11 station capabilities and user requirements, and configures TSN features in end stations.

12 **3.34 C-tagged service interface:** The interface provided by a Provider Edge Bridge (PEB) to allow the  
13 attached customer to select between and identify service instances using the C-VID associated with  
14 transmitted and received frames.

15 **3.35 candidate Protection Segment:** In the case of M:1 Infrastructure Protection Switching (IPS), an  
16 Infrastructure Segment that can assume the role of Protection Segment.

17 **3.36 Common and Internal Spanning Tree (CIST):** The single spanning tree calculated by the Rapid  
18 Spanning Tree Algorithm and Protocol (RSTP) and the logical continuation of that connectivity through  
19 Multiple Spanning Tree (MST) Bridges and Regions, calculated by the Multiple Spanning Tree Algorithm  
20 and Protocol (MSTP) to ensure that all Local Area Networks (LANs) in the Bridged Network are simply and  
21 fully connected.

22 **3.37 Common Spanning Tree (CST):** The single spanning tree calculated by the Rapid Spanning Tree  
23 Algorithm and Protocol (RSTP) and Multiple Spanning Tree Algorithm and Protocol (MSTP) to connect  
24 Multiple Spanning Tree (MST) Regions.

25 **3.38 Configuration Domain:** A set of stations that are under a common configuration and management  
26 scheme, and a single administration.

27 **3.39 congestion-aware system:** A Bridge component or end station that is capable of detecting congestion  
28 and sending congestion notifications.

29 **3.40 Congestion Controlled Flow (CCF):** A sequence of frames with the same priority, that the  
30 transmitting end station treats as belonging to a single flow, using a single Reaction Point (RP) to control the  
31 transmission rate of all those frames.

32 **3.41 congesting flow:** A sequence of frames the end-to-end congestion controlled higher layer protocol  
33 treats as belonging to a single flow that is experiencing congestion within a congestion isolation aware  
34 system.

35 **3.42 congestion isolation aware system:** A Bridge component conforming to the congestion isolation  
36 provisions of this standard.

37 **3.43 Congestion Isolation Message (CIM):** A message transmitted by a congestion isolation aware system,  
38 conveying congesting flow information used by the upstream peer congestion isolation aware system.

1 **3.44 Congestion Isolation Point (CIP):** A Virtual Local Area Network (VLAN) Bridge or end station Port  
2 function that monitors a set of queues for congesting flows, isolates congesting flows to a congesting queue,  
3 and can generate Congestion Isolation Messages.

4 **3.45 Congestion Notification Domain (CND):** A connected subset of the end stations and Virtual Local  
5 Area Network (VLAN) Bridges in a Virtual Bridged Network that are compatibly configured to support a  
6 Congestion Notification Priority Value (CNPV).

7 **3.46 Congestion Notification Message (CNM):** A message transmitted by a Congestion Point (CP) to a  
8 Reaction Point (RP), in response to a frame received from that RP, conveying congestion information used  
9 by the RP to reduce its transmission rate.

10 **3.47 Congestion Notification Priority Value (CNPV):** A value of the priority parameter that a  
11 congestion-aware system uses to support congestion notification.

12 **3.48 Congestion Notification Tag (CN-TAG):** A tag that conveys a Flow Identifier (ID), that a Reaction  
13 Point (RP) can add to transmitted Congestion Controlled Flow (CCF) frames, and that a Congestion Point  
14 (CP) includes in a Congestion Notification Message (CNM).

15 **3.49 Congestion Point (CP):** A Virtual Local Area Network (VLAN) Bridge or end station Port function  
16 that monitors a single queue serving one or more Congestion Notification Priority Values (CNPVs),  
17 can generate Congestion Notification Messages (CNMs), and can remove Congestion Notification Tags  
18 (CN-TAGs).

19 NOTE—See 31.1.1.1.

20 **3.50 congruent:** (A) An adjective to describe two or more paths that coincide at all points when  
21 superimposed. (B) An adjective to describe a set of trees specifying paths that coincide at all points when  
22 superimposed, for all Virtual Local Area Networks (VLANs). *See also:* **reverse path congruent, unicast**  
23 **multicast congruent, downstream congruent, and symmetric.**

24 **3.51 Connectivity Fault Management (CFM):** Management capabilities for detecting, verifying, and  
25 isolating connectivity failures in Virtual Bridged Networks.

26 **3.52 constrained routing (CR):** Shortest path routing on a topology pruned to only contain the links  
27 meeting a given constraint.

28 **3.53 Constrained Shortest Path First (CSPF):** The phrase for the Dijkstra Shortest Path First Algorithm  
29 when it is run after pruning the links not meeting a given constraint.

30 **3.54 constrained tree:** A tree meeting a certain constraint, e.g., providing a minimal available bandwidth.

31 **3.55 Continuity Check Message (CCM):** A multicast Connectivity Fault Management (CFM) protocol  
32 data unit (PDU) transmitted periodically by a Maintenance Association (MA) Endpoint (MEP) in order to  
33 ensure continuity over the MA to which the transmitting MEP belongs.

34 **3.56 current Protection Segment:** In the case of M:1 Infrastructure Protection Switching (IPS), the  
35 candidate Protection Segment that is currently assuming the role of Protection Segment.

36 **3.57 customer:** The purchaser of a service instance from a service provider.

37 NOTE—Certain terms in this standard, including customer and service provider, reflect common business relationships  
38 that exist among the users of equipment implemented in conformance with this standard. The use of these terms does not  
39 imply or impose any requirement on such business relationships. A customer is often a business.

1 **3.58 Customer Backbone Port (CBP):** A Backbone Edge Bridge (BEB) Port that can receive and transmit  
2 I-tagged frames for multiple customers and can assign Backbone Virtual Local Area Network (B-VLAN)  
3 Identifiers (B-VIDs) and translate Backbone Service Instance Identifier (I-SID) on the basis of the received  
4 I-SID.

5 **3.59 Customer Bridge:** A Media Access Control (MAC) Bridge or a Customer Virtual Local Area Network  
6 (C-VLAN) Bridge.

7 **3.60 Customer Bridged Network (CBN):** A network of Customer Bridges.

8 **3.61 Customer Edge Port (CEP):** A Customer Virtual Local Area Network (C-VLAN) component Port on  
9 a Provider Edge Bridge (PEB) that is connected to customer-owned equipment and receives and transmits  
10 frames for a single customer.

11 **3.62 customer equipment:** The physical embodiment of one or more customer systems.

12 **3.63 Customer Media Access Control (C-MAC) address:** A Media Access Control (MAC) address within  
13 a Customer Bridged Network (CBN) or Provider Bridged Network (PBN). C-MAC addresses are carried  
14 within an Backbone Service Instance tag (I-TAG) in a Provider Backbone Bridged Network (PBBN).

15 **3.64 Customer Network Port (CNP):** A Service Virtual Local Area Network (S-VLAN) component Port  
16 on a Provider Bridge or within a Provider Edge Bridge (PEB) that receives and transmits frames for a single  
17 customer.

18 **3.65 customer system:** A system attached to a Provider Bridged Network (PBN) but not intended by the  
19 service provider to be under the control of the service provider.

20 **3.66 Customer Virtual Local Area Network (C-VLAN):** A Virtual Local Area Network (VLAN)  
21 identified by a C-VLAN Identifier (C-VID).

22 **3.67 Customer Virtual Local Area Network (C-VLAN) Bridge:** A system comprising a single C-VLAN  
23 component.

24 **3.68 Customer Virtual Local Area Network (C-VLAN) component:** A Virtual Local Area Network  
25 (VLAN) Bridge component with each Port supported by an instance of the Enhanced Internal Sublayer  
26 Service (EISS) that can recognize, insert, and remove C-VLAN tags (C-TAGs).

27 **3.69 Customer Virtual Local Area Network [C-VLAN] Identifier (C-VID):** A Virtual Local Area  
28 Network (VLAN) Identifier (VID) conveyed in a C-VLAN tag (C-TAG).

29 **3.70 Customer Virtual Local Area Network [C-VLAN] tag (C-TAG):** A Virtual Local Area Network  
30 (VLAN) tag with a Tag Protocol Identification value allocated for “802.1Q Tag Protocol EtherType.”

31 **3.71 cut-bridge:** A Bridge whose removal partitions the network.

32 **3.72 cut-link:** A link whose removal partitions the network.

33 **3.73 Data Center Bridging (DCB):** A set of protocols and capabilities for use in a data center environment.

34 **3.74 data-driven and data-dependent connectivity fault management (DDCFM):** Connectivity Fault  
35 Management (CFM) capabilities that facilitate detecting and isolating data-driven and data-dependent faults  
36 (DDFs) in Virtual Bridged Networks.

1 **3.75 data-driven and data-dependent fault (DDF):** A fault that is sensitive to, or caused by, particular data  
2 patterns in frames transmitted by a service user.

3 **3.76 Decapsulator Responder (DR):** An entity for decapsulating Send Frame Messages (SFM) and  
4 sending the decapsulated frames toward destinations specified by their own destination\_address field.

5 **3.77 Designated Multiple Stream Registration Protocol [MSRP] Node (DMN):** A single station on a  
6 shared medium (e.g., IEEE 802.11 or a Coordinated Shared Network (CSN)) that controls MSRP access for  
7 all other stations on that shared medium.

8 **3.78 Directed Acyclic Graph (DAG):** A directed graph containing no directed cycle.

9 **3.79 Domain Service Access Point (DoSAP):** A member of a set of Service Access Points (SAPs) at which  
10 a Maintenance Domain is capable of offering connectivity to systems outside the Maintenance Domain.  
11 Each DoSAP provides access to an instance either of the Enhanced Internal Sublayer Service (EISS) or of  
12 the Internal Sublayer Service (ISS).

13 **3.80 Down Maintenance Association [MA] Endpoint [MEP] (Down MEP):** A MEP residing in a Bridge  
14 that receives Connectivity Fault Management (CFM) protocol data units (PDUs) from, and transmits them  
15 toward, the direction of the Local Area Network (LAN).

16 **3.81 Down Maintenance Point [MP] (Down MP):** A Maintenance Association (MA) Endpoint (MEP) or a  
17 Maintenance Domain Intermediate Point (MIP) Half Function (MHF) residing in a Bridge that receives  
18 Connectivity Fault Management (CFM) protocol data units (PDUs) from, and transmits them toward, the  
19 direction of the Local Area Network (LAN).

20 **3.82 downlink relay port (DRP):** A port of an edge relay (ER) that is capable of supporting at least one  
21 Virtual Station Interface (VSI). For NVO3 a port of a tNVE that is capable of supporting at least one NVO3  
22 Tenant Station Interface (TSI) (see IETF RFC 8394).

23 **3.83 downstream congruent:** A phrase to describe the path for a given frame relayed by a first Bridge when  
24 that path passes through a second Bridge and is thereafter the same as the path for any other frame (assigned  
25 to the same Virtual Local Area Network (VLAN) and destined to the same station) relayed by the second  
26 Bridge.

27 **3.84 Edge Control Protocol (ECP):** A protocol that provides reliable delivery of control service data units  
28 (SDUs).

29 **3.85 edge relay (ER):** A Bridge supporting the transfer of frames between one or more downlink relay ports  
30 (DRPs) and one uplink relay port (URP).

31 **3.86 Edge Virtual Bridging (EVB):** The set of functions supporting Virtual Station Interfaces (VSIs) in  
32 Bridges and attached end stations.

33 **3.87 Edge Virtual Bridging (EVB) Bridge:** A Customer Virtual Local Area Network (C-VLAN) Bridge  
34 that supports the Virtual Station Interface (VSI) Discovery and Configuration Protocol (VDP).

35 **3.88 Edge Virtual Bridging (EVB) station:** An end station containing one or more edge relays (ERs).

36 **3.89 Enhanced Internal Sublayer Service [EISS] Service Access Point [SAP] (EISS-SAP):** An instance  
37 of the EISS.

38 NOTE—See 6.8.

1 **3.90 Equal Cost Multiple Paths (ECMP):** The use of multiple possible next hop choices for frames within  
2 a single service in Shortest Path Bridging Media Access Control (MAC) (SPBM) mode networks.

3 **3.91 Equal Cost Multiple Paths [ECMP] path Maintenance Association [MA] (ECMP path MA):** An  
4 MA that monitors a set, which can be complete, of equal connectivity paths between two specific endpoints  
5 as constructed by ECMP.

6 **3.92 Equal Cost Tree (ECT):** One of the shortest path trees from the root Bridge selected from alternatives  
7 with the same path costs.

8 **3.93 Equal Cost Tree (ECT) Algorithm:** A Shortest Path Tree (SPT) algorithm yielding a consistent result  
9 for a given root Bridge when run by all Bridges within an SPT Region.

10 **3.94 Ethernet:** A term that is used to refer either to the IEEE 802.3 media access method or to the  
11 IEEE 802.3 frame format.

12 NOTE—In many places, “Ethernet” is also used as part of a reserved term with its own specific meaning.

13 **3.95 Ethernet Switched Path (ESP):** A provisioned traffic engineered unidirectional connectivity path  
14 among two or more Customer Backbone Ports (CBPs) that extends over a Provider Backbone Bridged  
15 Network (PBBN). The path is identified by a 3-tuple <ESP-DA, ESP-SA, ESP-VID>, where ESP-DA and  
16 ESP-SA are Media Access Control (MAC) addresses and ESP-VID is a Virtual Local Area Network  
17 (VLAN) Identifier (VID) allocated to Traffic Engineering Multiple Spanning Tree Instance Identifier  
18 (TE-MSTID).

19 NOTE—The use of “Ethernet” in this definition does not imply that an ESP is limited to use in conjunction with  
20 IEEE Std 802.3™.

21 **3.96 Ethernet Switched Path [ESP] Virtual Local Area Network [VLAN] Identifier [VID] (ESP-VID):**  
22 A VLAN Identifier (VID) associated with a special (Traffic Engineering) value of the Multiple Spanning  
23 Tree Instance Identifier (MSTID) in the Multiple Spanning Tree (MST) Configuration Table, the  
24 TE-MSTID, indicating that the VID is under the control of an external agent responsible for setting up ESPs  
25 and that learning is disabled and forwarding is enabled.

26 **3.97 Expedited traffic:** Traffic that requires preferential treatment as a consequence of jitter, latency, or  
27 throughput constraints or as a consequence of management policy.

28 **3.98 Explicit Tree (ET):** An explicitly defined tree, which is specified by its Edge Bridges and the paths  
29 among the Edge Bridges. If only the Edge Bridges are specified but the paths are not, then it is a loose  
30 explicit tree. If the paths are also specified, then it is a strict explicit tree.

31 **3.99 Explicit Tree Database (ETDB):** A database storing explicit trees.

32 **3.100 Fault Alarm:** An out-of-band signal, which can be a Simple Network Management Protocol (SNMP)  
33 Notification, that notifies a system administrator of a connectivity failure.

34 **3.101 flow filtering tag (F-TAG):** A tag with a Tag Protocol Identification value allocated for “IEEE  
35 802.1Q Flow Filtering Tag EtherType.”

36 **3.102 flow hash:** An arbitrary value that serves to distinguish flows that may be subject to different  
37 treatment in a bridged network, for example, flows subject to independent treatment by Equal Cost Multiple  
38 Paths (ECMP).

39 **3.103 Flow Identifier [ID] (Flow ID):** An ID assigned by a congestion-aware end station, unique within the  
40 scope of one or more of the source Media Access Control (MAC) addresses used by that system to transmit  
41 Congestion Controlled Flow (CCF) frames.

1 **3.104 forced switch (FS):** An administrative command to force the backbone service instances assigned to a  
2 Traffic Engineering (TE) protection group to be carried by this group's protection entity.

3 **3.105 forward path test (FPT):** A test to determine whether a data frame that matches the specified filter  
4 condition can reach a specific location within a network.

5 **3.106 Frame:** A unit of data transmission on an IEEE 802 Local Area Network (LAN) that conveys a Media  
6 Access Control (MAC) Protocol Data Unit (MPDU).

7 **3.107 Frame relay:** Forwarding of frames between the Ports of a Bridge.

8 **3.108 gate-close event:** An event that occurs when the transmission gate associated with a queue transitions  
9 from the Open state to the Closed state, disconnecting the transmission selection function of the forwarding  
10 process from the queue and preventing it from selecting frames from that queue.

11 **3.109 gate-open event:** An event that occurs when the transmission gate associated with a queue transitions  
12 from the Closed state to the Open state, connecting the transmission selection function of the forwarding  
13 process to a queue and allowing it to select frames from that queue.

14 **3.110 gating cycle:** The period of time over which the sequence of operations in a gate control list repeats.

15 **3.111 Generalized Almost Directed Acyclic Graph (GADAG):** A directed graph that has only Almost  
16 Directed Acyclic Graphs (ADAGs) as all of its topology blocks.

17 **3.112 Group:** An association of

- 18 a) A group Media Access Control (MAC) address
- 19 b) A set of properties that define membership characteristics
- 20 c) A set of properties that define the forwarding/filtering behavior of a Bridge with respect to frames  
21 destined for members of that group MAC address  
22 with a set of end stations that all wish to receive information destined for that group MAC address.  
23 NOTE—An example of the information that Group members might wish to receive is a multicast video data  
24 stream.

25 **3.113 GroupID:** A service instance identifier used in Virtual Station Interface (VSI) Discovery and  
26 Configuration Protocol (VDP).

27 **3.114 I-component (I-Comp):** A Service Virtual Local Area Network (S-VLAN) component with one or  
28 more Provider Instance Ports (PIPs).

29 **3.115 I-DEI field:** A field of the Backbone Service Instance tag (I-TAG) that indicates the drop eligibility of  
30 a frame in a backbone service instance.

31 **3.116 I-PCP field:** A field of the Backbone Service Instance tag (I-TAG) that indicates the priority of a  
32 frame in a backbone service instance.

33 **3.117 I-SID field:** A field of the Backbone Service Instance tag (I-TAG) that identifies the backbone service  
34 instance of a frame.

35 **3.118 I-tagged frame:** A frame that contains a Backbone Service Instance tag (I-TAG) immediately  
36 following the Source MAC Address field.

1 **3.119 IEEE 802 Local Area Network [LAN] (IEEE 802 LAN):** LAN technologies that provide a Media  
2 Access Control (MAC) Service equivalent to the MAC Service defined in IEEE Std 802.1AC. IEEE 802  
3 LANs include IEEE 802.3 (Ethernet) and IEEE 802.11 (Wireless) LANs.

4 NOTE—The term “Local Area Network” and the abbreviation LAN are used exclusively to refer to an individual LAN  
5 specified by a MAC technology, without the inclusion of Bridges. This precise use of terminology within this  
6 specification allows a Bridged Network to be distinguished from an individual LAN that has been bridged to other LANs  
7 in the network (a bridged LAN). In more general usage, such precise terminology is not required, as it is an explicit goal  
8 of IEEE Std 802.1Q that Bridges are transparent to the users of the MAC Service.

9 **3.120 Independent Virtual Local Area Network [VLAN] Learning (IVL):** Configuration and operation  
10 of the Learning Process and the Filtering Database (FDB) such that, for a given set of VLAN Identifiers  
11 (VIDs), if a given individual Media Access Control (MAC) Address is learned in association with one VID,  
12 that learned information is not used in forwarding decisions taken for that address relative to any other VID  
13 in the given set.

14 NOTE—In a Bridge that supports only IVL operation, the “given set of VIDs” is the set of all VIDs.

15 **3.121 Independent Virtual Local Area Network [VLAN] Learning [IVL] Bridge (IVL Bridge):** A  
16 Bridge that supports only IVL.

17 **3.122 Infrastructure Protection Group (IPG):** In the case of 1:1 Infrastructure Protection Switching (IPS),  
18 a set comprising a Working Segment and a Protection Segment or, in the case of M:1 IPS, a set comprising a  
19 Working Segment and one or more Protection Segments.

20 **3.123 Infrastructure Protection Switching (IPS):** The switching of a selected group of Traffic  
21 Engineering service instances (TESIs) from a Working Segment to a Protection Segment or from a  
22 Protection Segment to a Working Segment due to failure of connectivity, restoration of connectivity, or  
23 administrative command.

24 **3.124 Infrastructure Segment:** A sequence of Provider Network Ports (PNPs) and the intervening Local  
25 Area Networks (LANs) and Bridge relay entities.

26 **3.125 Intermediate Service Access Point (ISAP):** A Service Access Point (SAP), interior to a Maintenance  
27 Domain, through which frames can pass in transit from Domain Service Access Point (DoSAP) to DoSAP.

28 **3.126 Intermediate System to Intermediate System (IS-IS) Path Control and Reservation (ISIS-PCR):**  
29 IS-IS with the Path Control and Reservation extensions specified by Clause 45 of IEEE Std 802.1Q-2022.

30 **3.127 Internal Spanning Tree (IST):** The connectivity provided by the Common and Internal Spanning  
31 Tree (CIST) within a Multiple Spanning Tree (MST) Region.

32 **3.128 Internal Sublayer Service (ISS) Service Access Point (ISS-SAP):** An instance of the ISS.

33 NOTE—See IEEE Std 802.1AC.

34 **3.129 latency:** The delay experienced by a frame in the course of its propagation between two points in a  
35 network, measured from the time that a known reference point in the frame passes the first point to the time  
36 that the reference point in the frame passes the second point.

37 NOTE—Latency is sometimes referred to as *frame delay*.

38 **3.130 Layer Management Interface (LMI):** An interface used for carrying management controls,  
39 counters, status parameters, or event indications that are not communicated to an entity’s peers.

40 NOTE—This is not one of the Service Access Points (SAPs) defined in this standard.

1 **3.131 Legacy region:** A set of Local Area Networks (LANs) connected such that there is physical  
2 connectivity between any pair of LANs using only Media Access Control (MAC) Bridges.

3 NOTE—If, in a Bridged Network containing both MAC Bridges and Virtual Local Area Network (VLAN) Bridges, all  
4 VLAN Bridges were to be removed, the result would be one or more Bridged Networks, each with its own distinct  
5 spanning tree. Each of those networks is a legacy region.

6 **3.132 Link status notification:** Notification of the status of a Local Area Network (LAN) by transmitting a  
7 frame conveying information about the MAC\_Operational parameter associated with the LAN.

8 **3.133 Linktrace Message (LTM):** A Connectivity Fault Management (CFM) protocol data unit (PDU)  
9 initiated by a Maintenance Association (MA) Endpoint (MEP) to trace a path to a target Media Access  
10 Control (MAC) address, forwarded from Maintenance Domain (MD) Intermediate Point (MIP) to MIP, up to  
11 the point at which the LTM reaches its target, a MEP, or can no longer be forwarded.

12 **3.134 Linktrace Output Multiplexer (LOM):** A Connectivity Fault Management (CFM) shim that enables  
13 the Linktrace Responder to forward Linktrace Messages (LTMs) out of a specific Bridge Port without  
14 passing the LTMs through the Frame filtering entity.

15 **3.135 Linktrace Reply (LTR):** A unicast Connectivity Fault Management (CFM) protocol data unit (PDU)  
16 sent by an Maintenance Point (MP) to a Maintenance Association (MA) Endpoint (MEP), in response to  
17 receiving a Linktrace Message (LTM) from that MEP.

18 **3.136 Listener:** The end station that is the destination, receiver, or consumer of a stream.

19 **3.137 Loop-Free Alternate (LFA):** A loop-free backup path for local repair after a failure event.

20 **3.138 Loopback Message (LBM):** A unicast Connectivity Fault Management (CFM) protocol data unit  
21 (PDU) transmitted by a Maintenance Association (MA) Endpoint (MEP), addressed to a specific  
22 Maintenance Point (MP), in the expectation of receiving a Loopback Reply (LBR).

23 **3.139 Loopback Reply (LBR):** A unicast Connectivity Fault Management (CFM) protocol data unit (PDU)  
24 transmitted by an Maintenance Point (MP) to a Maintenance Association (MA) Endpoint (MEP), in  
25 response to a Loopback Message (LBM) received from that MEP.

26 **3.140 Maintenance Association Identifier (MAID):** An identifier for a Maintenance Association (MA),  
27 unique over the domain that Connectivity Fault Management (CFM) is to protect against the accidental  
28 concatenation of service instances. The MAID has two parts: the Maintenance Domain Name and the Short  
29 MA Name.

30 **3.141 Maintenance Association (MA):** A set of MA Endpoints (MEPs), each configured with the same  
31 Maintenance Association Identifier (MAID) and Maintenance Domain (MD) Level, established to verify the  
32 integrity of a single service instance. Equivalently, an MA is the closure of the Maintenance Entities among  
33 a set of MEPs so configured.

34 **3.142 Maintenance Association [MA] Endpoint [MEP] Identifier [ID] (MEPID):** A small integer,  
35 unique over a given MA, identifying a specific MEP.

36 **3.143 Maintenance Association [MA] Endpoint (MEP):** An actively managed Connectivity Fault  
37 Management (CFM) entity, associated with a specific Domain Service Access Point (DoSAP) of a service  
38 instance, which can generate and receive CFM protocol data units (PDUs) and track any responses. It is an  
39 endpoint of a single MA and is an endpoint of a separate Maintenance Entity for each of the other MEPs in  
40 the same MA.

1 **3.144 Maintenance Association [MA] Endpoint [MEP] Continuity Check Message [CCM] Database**  
2 **(MEP CCM Database):** A database, maintained by every MEP, that maintains received information about  
3 other MEPs in the MA.

4 **3.145 Maintenance Domain:** The network or the part of the network for which faults in connectivity can be  
5 managed. The boundary of a Maintenance Domain is defined by a set of Domain Service Access Points  
6 (DoSAPs), each of which can become a point of connectivity to a service instance.

7 **3.146 Maintenance Domain Intermediate Point (MIP):** A Connectivity Fault Management (CFM) entity  
8 consisting of two MIP Half Functions (MHFs).

9 **3.147 Maintenance Domain Intermediate Point [MIP] Continuity Check Message [CCM] Database**  
10 **(MIP CCM Database):** A database, maintained optionally by a MIP or Maintenance Association (MA)  
11 Endpoint (MEP), that maintains received information about the MEPs in the Maintenance Domain.

12 **3.148 Maintenance Domain Intermediate Point [MIP] Half Function (MHF):** A Connectivity Fault  
13 Management (CFM) entity, associated with a single Maintenance Domain, and thus with a single  
14 Maintenance Domain Level (MD Level) and a set of Virtual Local Area Network (VLAN) Identifiers  
15 (VIDs), that can generate CFM protocol data units (PDUs), but only in response to received CFM PDUs.

16 **3.149 Maintenance Domain Level (MD Level):** A small integer in a field in a Connectivity Fault  
17 Management (CFM) protocol data unit (PDU) that is used, along with the Virtual Local Area Network  
18 (VLAN) Identifier (VID) in the VLAN tag, to identify to which Maintenance Domain among those  
19 associated with the CFM frame's VID, and thus to which Maintenance Association (MA), a CFM PDU  
20 belongs.

21 **3.150 Maintenance Domain Name:** The identifier, unique over the domain that Connectivity Fault  
22 Management (CFM) is to protect against accidental concatenation of service instances, of a particular  
23 Maintenance Domain.

24 **3.151 Maintenance Entity:** A point-to-point relationship between two Maintenance Association (MA)  
25 Endpoints (MEPs) within a single MA.

26 **3.152 Maintenance Point (MP):** One of either a Maintenance Association (MA) Endpoint (MEP) or a  
27 Maintenance Domain Intermediate Point (MIP).

28 **3.153 Maintenance Point (MP) Level Demultiplexer:** The component of an MP that separates  
29 Connectivity Fault Management (CFM) protocol data units (PDUs) at different Maintenance Domain Levels  
30 (MD Levels).

31 **3.154 Maintenance Point (MP) Multiplexer:** A component of an MP that merges frames from more than  
32 one input Service Access Point (SAP), sending them to a single output SAP.

33 **3.155 Maintenance Point (MP) OpCode Demultiplexer:** A component of an MP that identifies and  
34 separates Connectivity Fault Management (CFM) protocol data units (PDUs) with different values of the  
35 OpCode field.

36 **3.156 Maintenance Point (MP) Type Demultiplexer:** A component of an MP that identifies and separates  
37 Connectivity Fault Management (CFM) protocol data units (PDUs) based on the Length/Type field.

38 **3.157 manual switch:** An administrative command to move the backbone service instances assigned to a  
39 Traffic Engineering (TE) protection group to a specific TE service instance (TESI) associated with this TE  
40 protection group in absence of signal failures on both of the entities in the group.

1 **3.158 Maximally Redundant Trees (MRTs):** A pair of trees with a common MRT Root where the path  
2 from any leaf Bridge to the MRT Root along the first tree (MRT-Blue) and the path from the same leaf  
3 Bridge along the second tree (MRT-Red) share the minimum number of Bridges and the minimum number  
4 of links.

5 **3.159 Media Access Control (MAC) Bridge:** A Bridge that does not recognize Virtual Local Area Network  
6 (VLAN) tagged frames.

7 **3.160 Media Access Control (MAC) Bridge component:** The media access method-independent  
8 functionality supporting an instance of the Internal Sublayer Service (ISS) at each Bridge Port and the  
9 functionality that relays frames between Bridge Ports.

10 **3.161 Media Access Control (MAC) Bridged Network:** A concatenation of individual IEEE 802 Local  
11 Area Networks (LANs) interconnected by MAC Bridges.

12 **3.162 Media Access Control (MAC) status notification:** A layer management interaction with an  
13 underlying MAC Service to change the status of the MAC\_Operational parameter in a Bridge that is a peer  
14 user of that service.

15 **3.163 Media Access Control (MAC) status propagation:** The process of communicating a  
16 MAC\_Operational parameter value through one or more Two-Part MAC Relays (TPMRs), using link status  
17 notification, MAC status notification, or both.

18 **3.164 MRT-Blue:** One of the two Maximally Redundant Trees (MRTs), specifically, the increasing MRT  
19 where links in the Generalized Almost Directed Acyclic Graph (GADAG) are taken in the direction from a  
20 lower topologically ordered Bridge to a higher one.

21 **3.165 MRT-Red:** One of the two Maximally Redundant Trees (MRTs), specifically, the decreasing MRT  
22 where links in the Generalized Almost Directed Acyclic Graph (GADAG) are taken in the direction from a  
23 higher topologically ordered Bridge to a lower one.

24 **3.166 MRT Root:** The common root of the two Maximally Redundant Trees (MRTs), i.e., of MRT-Blue and  
25 MRT-Red.

26 **3.167 Multi-Topology (MT):** One of a set of independent topologies that the Intermediate System to  
27 Intermediate System (IS-IS) Protocol supports within an IS-IS domain.

28 **3.168 Multi-Topology Identifier (MTID):** The identifier of an Intermediate System to Intermediate System  
29 (IS-IS) Protocol Multi-Topology (MT).

30 **3.169 Multicast:**

- 31 a) A group Media Access Control (MAC) address (noun).
- 32 b) To transmit a frame using a group MAC address as the destination address (verb).
- 33 c) Containing a group MAC address as the destination address (adjective).

34 **3.170 Multiple Spanning Tree Instance (MSTI):** One of a number of spanning trees calculated by the  
35 Multiple Spanning Tree Algorithm and Protocol (MSTP) within a Multiple Spanning Tree (MST) Region.

36 **3.171 Multiple Spanning Tree (MST) Bridge:** A Bridge capable of supporting the Common Spanning Tree  
37 (CST), and one or more Multiple Spanning Tree Instances (MSTIs), and of selectively mapping frames  
38 classified in any given Virtual Local Area Network (VLAN) to the CST or a given MSTI.

1 **3.172 Multiple Spanning Tree [MST] Configuration Identifier (MCID):** A name for, revision level, and  
2 a summary of a given allocation of Virtual Local Area Networks (VLANs) to spanning trees.

3 NOTE—Each MST Bridge uses a single MST Configuration Table and Configuration Identifier.

4 **3.173 Multiple Spanning Tree (MST) Configuration Table:** A configurable table that allocates each and  
5 every possible Virtual Local Area Network (VLAN) Identifier (VID) to the Common Spanning Tree (CST)  
6 or a specific Multiple Spanning Tree Instance (MSTI).

7 **3.174 Multiple Spanning Tree (MST) Region:** One or more MST Bridges with the same MST  
8 Configuration Identifiers (MCIDs), interconnected by and including Local Area Networks (LANs) for  
9 which one of those Bridges is the Designated Bridge for the Common and Internal Spanning Tree (CIST)  
10 and that have no Bridges attached that cannot receive and transmit Rapid Spanning Tree (RST) Bridge  
11 Protocol Data Units (BPDUs).

12 **3.175 Multiple Stream Registration Protocol (MSRP):** A protocol designed to provide quality of service  
13 (QoS) for streams in bridged networks by reserving resources within each Bridge along the streams' paths.

14 **3.176 Network Virtualization Edge (NVE):** A term as defined in IETF RFC 7365.

15 **3.177 Network Virtualization Overlays over Layer 3 (NVO3):** A framework conforming to  
16 IETF RFC 7365.

17 **3.178 nNVE:** Network-side VNE as defined in IETF RFC 8394.

18 **3.179 Operations, Administration, and Maintenance (OAM):** A group of network management functions  
19 that provide network fault indication, performance information, and data and diagnosis functions.

20 NOTE—Examples are ATM OAM ITU-T I.610 (02/1999) [B51]<sup>19</sup> and IEEE 802.3™ Clause 57 OAM.

21 **3.180 operator:** (A) A provider of a single network of Provider Bridges or a single Layer 2 or Layer 3  
22 backbone network to the service provider. (B) An enumeration of a state machine event. (C) A symbol  
23 denoting a mathematical operation.

24 NOTE 1—(A) An operator can, in fact, be identical to, or a part of the same organization as, the service provider, but for  
25 the purposes of IEEE Std 802.1Q, the operator and service provider are presumed to be separate organizations.

26 NOTE 2—(A) Certain terms in this standard, including “customer,” “service provider,” and “operator,” reflect common  
27 business relationships that often exist among organizations and individuals that use equipment implemented in  
28 accordance with this standard. Terms such as “customer VID” or “operator MD Level” are no more than convenient  
29 labels for entities defined here; their use does not imply any requirement upon the business relationships among vendors  
30 or users of devices compliant with this standard.

31 **3.181 Owner:** A user of a system (and in particular, a Bridge) who has full access to the System Group of  
32 the SNMPv2-MIB (IETF RFC 3418).

33 **3.182 packet:** A protocol data unit, comprising data, addressing, and protocol identification information,  
34 sent by an instance of an identified class of protocol entities and transmitted in one or more frames (e.g., an  
35 IPv6 packet).

36 **3.183 Passive Service Access Point [SAP] (Passive SAP):** The SAP, bounding an Maintenance Point (MP),  
37 that is on the side of the MP away from the monitored Maintenance Association (MA).

38 **3.184 Path Computation Element (PCE):** An entity that is capable of computing a path through a network  
39 based on a representation of the network's topology (obtained by undefined means external to the PCE). A  
40 PCE is a higher layer entity in a Bridge or an end station.

<sup>19</sup> Numbers in brackets correspond to the numbers in the bibliography in Annex X.

1 **3.185 Path Control Agent (PCA):** The agent that is part of the Intermediate System to Intermediate System  
2 (IS-IS) Domain and thus can perform IS-IS operations on behalf of a Path Computation Element (PCE), e.g.,  
3 maintain Link State Database (LSDB) and send Link State protocol data units (PDUs) (LSPs).

4 **3.186 Paused state:** A state of a queue in which the transmission selection entity does not select frames  
5 from the queue.

6 **3.187 Point of Local Repair (PLR):** A Bridge that locally redirects the data traffic to a backup path, e.g., to  
7 a loop-free alternate path after a failure event.

8 **3.188 point-to-multipoint Ethernet Switched Path [ESP] (point-to-multipoint ESP):** An ESP among  
9 one root Customer Backbone Port (CBP) and n leaf CBPs.

10 **3.189 point-to-multipoint Traffic Engineering service instance [TESI] (point-to-multipoint TESI):** A  
11 TESI supported by a set of Ethernet Switched Paths (ESPs) that comprises one point-to-multipoint ESP from  
12 a root to n leaves plus a point-to-point ESP from each of the leaves to the root.

13 **3.190 point-to-point Ethernet Switched Path [ESP] (point-to-point ESP):** An ESP between two  
14 Customer Backbone Ports (CBPs). The ESP-DA and the ESP-SA in the ESP's 3-tuple identifier are the  
15 individual Media Access Control (MAC) addresses of the two CBPs.

16 **3.191 point-to-point Traffic Engineering service instance [TESI] (point-to-point TESI):** A TESI  
17 supported by two point-to-point Ethernet Switched Paths (ESPs) where the ESPs' endpoints have the same  
18 Customer Backbone Port (CBP) Media Access Control (MAC) addresses.

19 **3.192 policing:** A process of monitoring network traffic and deliberately dropping frames that are in excess  
20 of previously defined criteria.

21 **3.193 Port:** A Service Access Point (SAP) and the interface stack supporting that SAP.

22 **3.194 Port State:** One of a number of possible combinations of forwarding and learning variables, used by a  
23 spanning tree protocol or Shortest Path Tree (SPT) protocol for each tree for each Bridge Port, to enforce the  
24 active topology of that tree.

25 **3.195 Port-based service interface:** The interface provided by a Provider Bridge that associates all  
26 customer frames with a single service instance.

27 **3.196 Port-mapping Service Virtual Local Area Network [S-VLAN] component (Primary S-VLAN  
28 component):** An S-VLAN component with one externally accessible port and one or more additional ports,  
29 each connected to another Bridge component via an internal Local Area Network (LAN), and for which  
30 each registered S-VLAN Identifier's (S-VID's) member set includes the externally accessible port and  
31 exactly one other port.

32 NOTE—See 6.14.

33 **3.197 preemption:** The suspension of the transmission of a preemptable frame to allow one or more express  
34 frames to be transmitted before transmission of the preemptable frame is resumed.

35 **3.198 Primary Virtual Local Area Network [VLAN] Identifier [VID] (Primary VID):** The VID, among  
36 a list of VIDs associated with a service instance, on which all Connectivity Fault Management (CFM)  
37 protocol data units (PDUs) generated by Maintenance Points (MPs) except for forwarded Linktrace  
38 Messages (LTMs) are to be transmitted.

39 **3.199 Priority-tagged frame:** A tagged frame whose tag header carries priority information but carries no  
40 Virtual Local Area Network (VLAN) identification information.

1 **3.200 Protection Segment:** An Infrastructure Segment associated with an Infrastructure Protection Group  
2 (IPG) that can carry Traffic Engineering service instance (TESI) traffic when the Working Segment  
3 associated with that IPG has failed or when directed by administrative command.

4 **3.201 protocol group database:** Specifies a group of protocols by assigning a unique protocol group  
5 identifier to all protocols of the same group.

6 **3.202 protocol group identifier:** Designates a group of protocols that are associated together when  
7 assigning a Virtual Local Area Network (VLAN) Identifier (VID) to a frame.

8 **3.203 protocol template:** A tuple of values that specify a data-link encapsulation format and an  
9 identification of the protocol layer above the data-link layer.

10 **3.204 Provider Access Port (PAP):** A Port-mapping Service Virtual Local Area Network (S-VLAN)  
11 component port within a Provider Edge Bridge (PEB) that receives and transmits frames for a single  
12 customer [single S-VLAN Identifier (S-VID)].

13 **3.205 Provider Backbone Bridge (PBB):** A Backbone Core Bridge (BCB) or a Backbone Edge Bridge  
14 (BEB).

15 **3.206 Provider Backbone Bridge Traffic Engineering (PBB-TE) Region:** A contiguous set of combined  
16 I type and B type Backbone Edge Bridges (IB-BEBs) and Backbone Core Bridges (BCBs) that implement  
17 traffic engineering capabilities.

18 **3.207 Provider Backbone Bridged Network (PBBN):** A network using Backbone Edge Bridges (BEBs)  
19 and Backbone Core Bridges (BCBs) to interconnect Provider Bridged Networks (PBNs) and other networks.

20 **3.208 Provider Bridge:** A Provider Edge Bridge (PEB) or a Service Virtual Local Area Network (S-VLAN)  
21 Bridge.

22 **3.209 Provider Bridged Network (PBN):** A network using Provider Bridges to offer customer protocol  
23 transparent connectivity.

24 **3.210 Provider Edge Bridge (PEB):** A system comprising one or more Service Virtual Local Area Network  
25 (S-VLAN) components and one or more Customer Virtual Local Area Network (C-VLAN) components.

26 **3.211 Provider Edge Port (PEP):** A Customer Virtual Local Area Network (C-VLAN) component Port  
27 within a Provider Edge Bridge (PEB) that connects to a Customer Network Port (CNP) and receives and  
28 transmits frames for a single customer.

29 **3.212 Provider Instance Port (PIP):** The set of Virtual Instance Ports (VIPs) that are supported by a single  
30 instance of the Internal Sublayer Service (ISS).

31 **3.213 Provider Network Port (PNP):** A Service Virtual Local Area Network (S-VLAN) component Port  
32 on a Provider Bridge that can transmit and receive frames for multiple customers.

33 **3.214 Rapid Spanning Tree (RST) Bridge:** A Bridge that uses the Rapid Spanning Tree Algorithm and  
34 Protocol (RSTP) to calculate a single spanning tree and is only capable of forwarding frames on that tree.

35 **3.215 Reaction Point (RP):** An end station port function that controls the transmission rate of frames for  
36 one or more Congestion Controlled Flows (CCFs).

37 NOTE—See 31.2.2.2.

1 **3.216 redundant trees:** A pair of trees with a common root where the paths from any leaf Bridge to the root  
2 along the first tree and the second tree are disjoint.

3 **3.217 Reflected Frame Message (RFM):** A Connectivity Fault Management (CFM) protocol data unit  
4 (PDU) transmitted by a Reflection Responder (RR) in order to perform forward path test (FPT).

5 **3.218 Reflection Responder (RR):** An entity that encapsulates and reflects selected data frames to a target  
6 location and allows a copy of each reflected frame to continue to its destination without encapsulation.

7 **3.219 Reflective relay:** A mode of operation of the active topology enforcement function in which a  
8 received frame on a port that supports reflective operation can be forwarded on the same port on which it  
9 was received.

10 **3.220 Remote Customer Access Port (RCAP):** A Port-mapping Service Virtual Local Area Network  
11 (S-VLAN) component port on a Provider Edge Bridge (PEB) that is intended to be directly connected to  
12 another Provider Bridged Network (PBN) under a different administration, and receives and transmits  
13 frames for one or more customers.

14 **3.221 return path test (RPT):** A test to determine if a data frame can be sent without error from a specific  
15 location within a network to a station specified by the destination\_address field of the data frame.

16 **3.222 reverse path congruent:** A phrase to describe two paths where a unicast frame traverses exactly the  
17 same Bridges and Local Area Networks (LANs) along the path from the source to the destination, but in the  
18 reverse order as a frame transmitted from that destination to the source.

19 **3.223 rooted-multipoint:** A service instance in which each Service Access Point (SAP) is either a Root or a  
20 Leaf, and a Data.Request at a Leaf does not result in a Data.Indication at any other Leaf.

21 NOTE—See 6.2.1 and F.1.3.2.

22 **3.224 S-channel:** A point-to-point Service Virtual Local Area Network (S-VLAN) established between a  
23 Port-mapping S-VLAN component in an Edge Virtual Bridging (EVB) Bridge and a Port-mapping S-VLAN  
24 component in an EVB station.

25 **3.225 S-channel Access Port (CAP):** The Port that terminates an S-channel.

26 **3.226 S-channel Discovery and Configuration Protocol (CDCP):** A protocol that is used to configure  
27 Service Virtual Local Area Network (S-VLAN) components to create S-channels.

28 **3.227 S-tagged service interface:** The interface provided by a Provider Bridge to allow the attached  
29 customer to select between and identify service instances using the Service Virtual Local Area Network  
30 (S-VLAN) Identifier (S-VID) associated with transmitted and received frames.

31 **3.228 Segment Endpoint Bridge (SEB):** A Provider Backbone Bridge (PBB) at the endpoint of an  
32 Infrastructure Segment.

33 **3.229 Segment Endpoint Port (SEP):** A Provider Network Port (PNP) at the endpoint of an Infrastructure  
34 Segment.

35 **3.230 Segment Identifier (SEG-ID):** A pair of Segment Monitoring Path Identifiers (SMP-IDs) specifying  
36 the identity of an Infrastructure Segment.

37 **3.231 Segment Intermediate Bridge (SIB):** A Provider Backbone Bridge (PBB) having an intermediate  
38 position within an Infrastructure Segment.

1 **3.232 Segment Intermediate Port (SIP):** A Provider Network Port (PNP) having an intermediate position  
2 within an Infrastructure Segment.

3 **3.233 Segment Monitoring Path (SMP):** A unidirectional path carrying Connectivity Fault Management  
4 (CFM) traffic associated with the monitoring of an Infrastructure Segment.

5 **3.234 Segment Monitoring Path Identifier (SMP-ID):** A 3-tuple <SMP-DA, SMP-SA, SMP-VID> where  
6 the SMP-DA is the Media Access Control (MAC) address of the destination Provider Network Port (PNP)  
7 of the Segment Monitoring Path (SMP), the SMP-SA is the MAC address of the origin PNP of the SMP, and  
8 SMP-VID is a Virtual Local Area Network (VLAN) Identifier (VID) allocated to the Traffic Engineering  
9 Multiple Spanning Tree Instance Identifier (TE-MSTID) and associated with the SMP.

10 NOTE—See 8.9.

11 **3.235 Send Frame Message (SFM):** A Connectivity Fault Management (CFM) protocol data unit (PDU)  
12 destined to a Decapsulator Responder (DR) in order to perform return path test (RPT).

13 **3.236 Send Frame Message (SFM) Originator:** A function on a Bridge interface, an end station, or a test  
14 equipment to send SFM encapsulated data frames.

15 **3.237 Service Access Point (SAP):** The point at which a service is offered.

16 NOTE—In this standard, an instance of either the Internal Sublayer Service (ISS) (IEEE Std 802.1AC) or the Enhanced  
17 Internal Sublayer Service (EISS) (6.8). This term is used in place of the awkward “ISS Service Access Point” or “EISS  
18 Service Access Point,” where no loss of clarity is introduced.

19 **3.238 service frame:** A Local Area Network (LAN) frame exchanged between a provider and a customer.

20 **3.239 service instance:** A set of Service Access Points (SAPs) such that a Data.Request primitive presented  
21 to one SAP can result in a Data.Indication primitive occurring at one or more of the other SAPs in that set.

22 NOTE—In general, a service provider can use a number of technologies to support a service instance; within this  
23 standard, a service instance is supported by a single Service Virtual Local Area Network (S-VLAN).

24 **3.240 service provider:** An organization that contracts to provide one or more service instances to a  
25 customer.

26 **3.241 Service Virtual Local Area Network (S-VLAN):** A Virtual Local Area Network (VLAN) identified  
27 by an S-VLAN Identifier (S-VID).

28 **3.242 Service Virtual Local Area Network (S-VLAN) Bridge:** A system comprising a single S-VLAN  
29 component.

30 **3.243 Service Virtual Local Area Network (S-VLAN) component:** A Virtual Local Area Network  
31 (VLAN) Bridge component with each Port supported by an instance of the Enhanced Internal Sublayer  
32 Service (EISS) that can recognize, insert, and remove S-VLAN tags (S-TAGs).

33 **3.244 Service Virtual Local Area Network [S-VLAN] Identifier (S-VID):** A Virtual Local Area Network  
34 (VLAN) Identifier (VID) conveyed in an S-VLAN tag (S-TAG).

35 **3.245 Service Virtual Local Area Network [S-VLAN] tag (S-TAG):** A Virtual Local Area Network  
36 (VLAN) tag with a Tag Protocol Identification value allocated for “802.1Q Service Tag EtherType.”

37 **3.246 Shared Risk Link Group (SRLG):** A set of links that share a resource whose failure affects each  
38 link.

1 **3.247 Shared Virtual Local Area Network [VLAN] Learning (SVL):** Configuration and operation of the  
2 Learning Process and the Filtering Database (FDB) such that, for a given set of VLANs, if an individual  
3 Media Access Control (MAC) Address is learned in one VLAN, that learned information is used in  
4 forwarding decisions taken for that address relative to all other VLANs in the given set.

5 NOTE—In a Bridge that supports only SVL operation, the “given set of VLANs” is the set of all VLANs.

6 **3.248 Shared Virtual Local Area Network [VLAN] Learning [SVL] Bridge (SVL Bridge):** A type of  
7 Bridge that supports only SVL.

8 **3.249 Shared Virtual Local Area Network [VLAN] Learning [SVL]/Independent VLAN Learning**  
9 **[IVL] Bridge (SVL/IVL Bridge):** A type of Bridge that simultaneously supports both SVL and IVL.

10 **3.250 shim:** A protocol entity that uses the same service as it provides.

11 NOTE—Within this standard, shims make use of the Internal Sublayer Service (ISS) or the Enhanced Internal Sublayer  
12 Service (EISS).

13 **3.251 Short Maintenance Association [MA] Name (Short MA Name):** The part of the Maintenance  
14 Association Identifier (MAID) that is unique within the Maintenance Domain and is appended to the  
15 Maintenance Domain Name to form the MAID.

16 **3.252 Shortest Path Bridging (SPB):** The method of bridging using Shortest Path Trees (SPTs) for  
17 forwarding from each Bridge. SPB is used for references that are applicable to all modes of SPB: Shortest  
18 Path Bridging Media Access Control (MAC) (SPBM) mode and Shortest Path Bridging Virtual Local Area  
19 Network (VLAN) Identifier (VID) (SPBV) mode.

20 **3.253 Shortest Path Bridging (SPB) System Identifier:** A unique 6-byte value for each Intermediate  
21 System to Intermediate System Protocol for Shortest Path Bridging (ISIS-SPB) capable Bridge and is  
22 equivalent to the Intermediate System to Intermediate System (IS-IS) Protocol System Identifier (ID).

23 NOTE—See 8.13.8.

24 **3.254 Shortest Path Bridging Media Access Control [MAC] [SPBM] mode (SPBM mode):** The Shortest  
25 Path Bridging (SPB) method where all Shortest Path Trees (SPTs) are rooted at a Backbone Edge Bridge  
26 (BEB). In frames with a group destination address, the SPT is identified by a destination MAC address  
27 derived from the SPSrcID; in frames with an individual address, the SPT is identified by a MAC address  
28 of the source BEB. This method does not use learning.

29 **3.255 Shortest Path Bridging Media Access Control [MAC] [SPBM] mode Maintenance Association**  
30 **[MA] (SPBM MA):** An MA for monitoring and diagnosing connectivity associated with a Virtual Local  
31 Area Network (VLAN) Identifier (VID) assigned to the SPBM Multiple Spanning Tree Instance Identifier  
32 (MSTID). There are three types of SPBM MA—SPBM VID MAs, SPBM path MAs, and SPBM group  
33 MAs.

34 NOTE—See 27.18.1.

35 **3.256 Shortest Path Bridging Media Access Control [MAC] [SPBM] mode Virtual Local Area**  
36 **Network [VLAN] Identifier [VID] (SPBM VID):** A VID associated with the SPBM-MSTID value of the  
37 Multiple Spanning Tree Instance Identifier (MSTID) in the Multiple Spanning Tree (MST) Configuration  
38 Table.

39 **3.257 Shortest Path Bridging Virtual Local Area Network [VLAN] Identifier [VID] [SPBV] mode**  
40 **(SPBV mode):** The Shortest Path Bridging (SPB) method where Shortest Path VLAN Identifiers (SPVIDs)  
41 are used to identify the Shortest Path Trees (SPTs) for individual and group addresses. This method is  
42 learning capable.

1 **3.258 Shortest Path First (SPF):** Abbreviation for the Dijkstra Shortest Path First Algorithm that is used in  
2 link state protocols such as Intermediate System to Intermediate System (IS-IS) Protocol.

3 **3.259 Shortest Path Source Identifier (SPSourceID):** A 20-bit identifier of a Bridge that is unique within  
4 a Shortest Path Tree (SPT) Domain. SPSourceID is used to auto-create SPT Domain significant group  
5 Media Access Control (MAC) addresses utilizing the local address bit in Shortest Path Bridging MAC  
6 (SPBM) mode.

7 NOTE—See 27.10.

8 **3.260 Shortest Path Tree (SPT) Bridge:** A Virtual Local Area Network (VLAN) Bridge capable of  
9 operating Shortest Path Bridging (SPB) protocols.

10 **3.261 Shortest Path Tree (SPT) Domain:** A set of SPT Bridges that are interconnected by Local Area  
11 Networks (LANs) and have the same configured Intermediate System to Intermediate System (IS-IS)  
12 Protocol area address. An SPT Domain contains one or more SPT Regions, each comprising some or all of  
13 the Bridges in the Domain.

14 **3.262 Shortest Path Tree (SPT) Region:** A set of Local Area Networks (LANs) and SPT Bridges  
15 interconnected via Ports on those SPT Bridges, where each LAN's Common and Internal Spanning Tree  
16 (CIST) Designated Bridge is an SPT Bridge, and each Port is either the Designated Port on one of the LANs  
17 or else a non-Designated Port of an SPT Bridge that is connected to one of the LANs, whose Multiple  
18 Spanning Tree (MST) Configuration Identifier (MCID) matches exactly the MCID or the Auxiliary MCID  
19 of the Designated Bridge of that LAN.

20 NOTE—See 27.4.1.

21 **3.263 Shortest Path Tree (SPT) Set:** A set of SPTs determined by one Equal Cost Tree (ECT) Algorithm  
22 and capable of supporting one or more Virtual Local Area Networks (VLANs) within an SPT Region. The  
23 set is the union of all the SPTs from all sources to all other Bridges using that single ECT Algorithm. A  
24 single SPT Set is created for each ECT Algorithm. Active SPT Sets are identified by their {ECT Algorithm,  
25 FID} tuples.

26 NOTE—See 8.9.4 and 13.6.

27 **3.264 Shortest Path Virtual Local Area Network [VLAN] Identifier (SPVID):** The identifier of both the  
28 VLAN and the Shortest Path Tree (SPT) that is used for the transmission of a tagged frame in Shortest Path  
29 Bridging VLAN Identifier (VID) (SPBV) mode.

30 **3.265 Single Spanning Tree (SST) Bridge:** A Bridge capable of supporting only a single spanning tree.

31 **3.266 spanning tree:** A simply and fully connected active topology formed from the arbitrary physical  
32 topology of connected Bridged Network components by relaying frames through selected Bridge Ports and  
33 not through others. The protocol parameters and states used and exchanged to facilitate the calculation of  
34 that active topology and to control the Media Access Control (MAC) relay function.

35 **3.267 Station-facing Bridge Port (SBP):** A Bridge Port that supports the Edge Virtual Bridging (EVB)  
36 status parameters with an EVBMode parameter value of “EVB Bridge”. For NVO3 a port of an nNVE that  
37 supports VDP.

38 NOTE—See 40.4.

39 **3.268 Stream:** A unidirectional flow of data (e.g., audio and/or video) from a Talker to one or more  
40 Listeners.

1 **3.269 Stream Reservation Protocol (SRP) domain boundary port:** A Port of a station that is a member of  
2 an SRP domain for a given stream reservation (SR) class and that is connected via an individual Local Area  
3 Network (LAN) to a Port of a station that either is within a different SRP domain for that SR class or is not  
4 part of any SRP domain.

5 NOTE—The term *SRP domain* is defined in 35.1.4.

6 **3.270 Stream Reservation Protocol (SRP) domain core port:** A Port of a station that is a member of an  
7 SRP domain for a given stream reservation (SR) class and that is connected, via an individual Local Area  
8 Network (LAN) that is part of the active topology, to a Port of a station that is a member of the same SRP  
9 domain for that SR class.

10 **3.271 stream reservation (SR) class:** A traffic class whose bandwidth can be reserved for time-sensitive  
11 streams using the Stream Reservation Protocol (SRP). A priority value is associated with each SR class. SR  
12 classes are denoted by consecutive letters of the alphabet, starting with A and continuing for up to seven  
13 classes.

14 **3.272 StreamID:** A 64-bit field that uniquely identifies a stream.

15 **3.273 symmetric:** An adjective to describe paths, trees, or sets of trees. Symmetric algorithms are used to  
16 create a set of trees that are *reverse path congruent* with respect to sources and destinations. Symmetric  
17 algorithms are used to create a set of trees that are *unicast multicast congruent* with respect to a given  
18 source. *See also:* **reverse path congruent** and **unicast multicast congruent**.

19 **3.274 T-component:** A Two-Port Media Access Control (MAC) Relay (TPMR) component with one  
20 Provider Instance Port (PIP).

21 **3.275 Tag header:** A header that allows priority information, and optionally, Virtual Local Area Network  
22 (VLAN) identification information, to be associated with a frame.

23 **3.276 Tagged frame:** A frame that contains a tag header immediately following the Source MAC Address  
24 field of the frame.

25 **3.277 Talker:** The end station that is the source or producer of a stream.

26 **3.278 time-aware:** An adjective to describe use of time that is synchronized with other stations using a  
27 protocol (e.g., IEEE Std 802.1AS).

28 **3.279 time-sensitive stream:** A stream of data frames that are required to be delivered with a bounded  
29 latency.

30 **3.280 tNVE:** Terminal-side NVE as defined in IETF RFC 8394.

31 **3.281 topology block:** A maximally two-connected (induced) subgraph, a cut-link with the two Bridges at  
32 either end, or an isolated Bridge.

33 **3.282 traffic class:** A classification used to expedite transmission of frames generated by critical or  
34 time-sensitive services.

35 **3.283 Traffic Engineering Database (TED):** A database storing the traffic engineering information  
36 propagated by a link state protocol, e.g., Intermediate System to Intermediate System (IS-IS).

1 **3.284 Traffic Engineering service instance (TESI):** An instance of the Media Access Control (MAC)  
2 Service supported by a set of Ethernet Switched Paths (ESPs) and identified by Traffic Engineering service  
3 instance Identifier (TE-SID), forming a bidirectional service. A TESI is point-to-point or  
4 point-to-multipoint.

5 **3.285 Traffic Engineering service instance Identifier (TE-SID):** An identifier of the Traffic Engineering  
6 service instance (TESI) that corresponds to a series of 3-tuples <ESP-DA, ESP-SA, ESP-VID>, each one  
7 identifying one of the TESI's Ethernet Switched Paths (ESPs).

8 NOTE—The TE-SID is not used as a tag parameter.

9 **3.286 Traffic Engineering (TE):** The process that controls the placement of traffic demands in a network in  
10 order to optimize the resource utilization and to ensure that the quality of service (QoS) objectives for each  
11 defined class of service are met.

12 **3.287 Traffic Engineering (TE) protection group:** A group of two point-to-point Traffic Engineering  
13 service instances (TESIs) between a pair of Customer Backbone Ports (CBPs), which carries an assigned set  
14 of backbone service instances and continues to carry these backbone service instances if any one of the  
15 TESIs in the group is failed or disabled.

16 **3.288 traffic specification (TSpec):** A specification that characterizes the bandwidth that a stream can  
17 consume.

18 **3.289 transmission gate:** A gate that connects or disconnects the transmission selection function of the  
19 forwarding process from the queue, allowing or preventing it from selecting frames from that queue. The  
20 gate has two states, Open and Closed.

21 **3.290 TSN features:** The protocols and mechanisms that constitute the set of tools available for building a  
22 time-sensitive network.

23 **3.291 Two-connected:** A topology that has no cut-bridges. This is a topology that requires at least two  
24 Bridges to be removed before it is partitioned.

25 **3.292 Two-Port Media Access Control [MAC] Relay (TPMR):** A Bridge that has exactly two externally  
26 accessible Ports and supports a subset of the functionality of a MAC Bridge as specified in 5.15 of  
27 IEEE Std 802.1Q-2022.

28 **3.293 Two-Port Media Access Control [MAC] Relay (TPMR) component:** A MAC Bridge component  
29 with two Bridge Ports.

30 **3.294 unicast:**

- 31 a) An individual Media Access Control (MAC) address (noun).
- 32 b) To transmit a frame using an individual MAC address as the destination address (verb).
- 33 c) Containing an individual MAC address as the destination address (adjective).

34 **3.295 unicast multicast congruent:** A phrase to describe the path taken by a unicast frame to a given  
35 destination when that path is the same as the path taken by any multicast frame [assigned to the same Virtual  
36 Local Area Network (VLAN)] from that source to the same destination.

37 **3.296 Untagged frame:** A frame that does not contain a tag header immediately following the Source MAC  
38 Address field of the frame.

1 **3.297 Up Maintenance Association [MA] Endpoint [MEP] (Up MEP):** A MEP residing in a Bridge that  
2 transmits Connectivity Fault Management (CFM) protocol data units (PDUs) toward, and receives them  
3 from, the direction of the Media Access Control (MAC) Relay Entity.

4 **3.298 Up Maintenance Point [MP] (Up MP):** A Maintenance Association (MA) Endpoint (MEP) or a  
5 Maintenance Domain Intermediate Point (MIP) Half Function (MHF) residing in a Bridge that transmits  
6 Connectivity Fault Management (CFM) protocol data units (PDUs) toward, and receives them from, the  
7 direction of the Media Access Control (MAC) Relay Entity.

8 **3.299 Uplink Access Port (UAP):** A Port on a Port-mapping Service Virtual Local Area Network  
9 (S-VLAN) component that connects an Edge Virtual Bridging (EVB) Bridge with an EVB station.

10 **3.300 uplink relay port (URP):** A port of an edge relay (ER) that supports the Edge Virtual Bridging (EVB)  
11 status parameters with an EVBMode parameter value of “EVB station.”  
12 NOTE—See 40.4.

13 **3.301 Virtual Bridged Network:** A concatenation of individual IEEE 802 Local Area Networks (LANs)  
14 interconnected by Bridges, including Virtual Local Area Network (VLAN) Bridges.

15 **3.302 virtual edge bridge (VEB):** An edge relay (ER) that requires reflective relay service to be disabled on  
16 the Station-facing Bridge Port (SBP) of the attached Bridge.

17 **3.303 virtual edge port aggregator (VEPA):** An edge relay (ER) that always forwards frames through its  
18 uplink relay port (URP) and that can make use of reflective relay service provided by the Station-facing  
19 Bridge Port (SBP) of the attached Bridge.

20 **3.304 Virtual Instance Port (VIP):** A Bridge Port on an I-component or a T-component in a Backbone  
21 Edge Bridge (BEB) that provides access to a single backbone service instance.

22 **3.305 Virtual Local Area Network (VLAN):** The closure of a set of Media Access Control (MAC) Service  
23 Access Points (MSAPs) such that a data request in one MSAP in the set is expected to result in a data  
24 indication in another MSAP in the set.  
25 NOTE—See also 6.2.

26 **3.306 Virtual Local Area Network (VLAN) Bridge:** A system comprising a single VLAN Bridge  
27 component implemented in accordance with Clause 5 of IEEE Std 802.1Q-2022.

28 **3.307 Virtual Local Area Network (VLAN) Bridge component:** The media access method-independent  
29 functionality supporting an instance of the Enhanced Internal Sublayer Service (EISS) at each Bridge Port  
30 that can recognize, insert, and remove VLAN tags, and the functionality that relays frames between Bridge  
31 Ports.

32 **3.308 Virtual Local Area Network (VLAN) Bridged Network:** A Virtual Bridged Network.

33 **3.309 Virtual Local Area Network (VLAN) tagged frame:** A tagged frame whose tag header carries both  
34 VLAN identification and priority information.

35 **3.310 Virtual Network Instance (VNI):** A term as defined in IETF RFC 7365.

36 **3.311 Virtual Network Instance Identifier (VNI ID):** A 3-octet identifier for a VNI.

37 **3.312 virtual station:** An end station instantiated within an Edge Virtual Bridging (EVB) station.

1 **3.313 Virtual Station Interface (VSI):** An interface to a virtual station that is attached to a downlink relay  
2 port (DRP) of an edge relay (ER). For NVO3 a VSI is equivalent to an NVO3 Tenant Station Interface (TSI)  
3 (see IETF RFC 8394).

4 **3.314 Virtual Station Interface [VSI] Discovery and Configuration Protocol (VDP):** A protocol that  
5 supports the association of a VSI with a Bridge Port.

6 **3.315 Working Segment:** The Infrastructure Segment, among the Infrastructure Segments associated with  
7 an Infrastructure Protection Group (IPG), on which Traffic Engineering service instance (TESI) traffic is  
8 carried when no connectivity failure of that segment has been detected and no administrative command is  
9 active.

10

## 4. Abbreviations

The following abbreviations are used in this standard:

|        |                                                |
|--------|------------------------------------------------|
| AAB    | Auto Attach BEB                                |
| AAD    | Auto Attach Device                             |
| AAP    | Auto Attach Protocol                           |
| AAS    | Auto Attach System                             |
| ACK    | acknowledgment                                 |
| ADAG   | Almost Directed Acyclic Graph                  |
| AP     | Agreement Protocol                             |
| ATS    | Asynchronous Traffic Shaping                   |
| AV     | audio/video                                    |
| AVB    | audio/video bridging                           |
| B-BEB  | B type Backbone Edge Bridge                    |
| B-Comp | B-component                                    |
| B-DA   | Backbone Destination MAC address               |
| B-DEI  | B-VLAN Drop Eligible Indicator                 |
| B-MAC  | Backbone Media Access Control                  |
| B-PCP  | B-VLAN Priority Code Point                     |
| B-SA   | Backbone Source MAC address                    |
| B-TAG  | B-VLAN tag                                     |
| B-VID  | Backbone VLAN Identifier                       |
| B-VLAN | Backbone Virtual Local Area Network            |
| BCB    | Backbone Core Bridge                           |
| BEB    | Backbone Edge Bridge                           |
| BLCE   | Bridge Local Computation Engine                |
| BNF    | Backus-Naur Form                               |
| BPDU   | Bridge Protocol Data Unit                      |
| BSI    | backbone service instance                      |
| CBS    | committed burst size                           |
| C-DA   | Customer Destination MAC address               |
| C-MAC  | Customer Media Access Control                  |
| C-SA   | Customer Source MAC address                    |
| C-TAG  | C-VLAN tag                                     |
| C-VID  | Customer VLAN Identifier                       |
| C-VLAN | Customer Virtual Local Area Network            |
| CAP    | S-channel Access Port                          |
| CBN    | Customer Bridged Network                       |
| CBP    | Customer Backbone Port                         |
| CCF    | Congestion Controlled Flow                     |
| CCM    | Continuity Check Message                       |
| CCP    | Current Congestion Point                       |
| CDCP   | S-channel Discovery and Configuration Protocol |

| 99 | VTID     | VSI Type Identifier                                            |

1 YANG Yet Another Next Generation<sup>22</sup>

3

---

<sup>22</sup>YANG is best viewed as a name, not an acronym.

## 5. Conformance

This clause specifies the mandatory and optional capabilities provided by conformant implementations of this standard. An implementation can:

- a) Compose all or part of the functionality of a system.
- b) Provide, as specified by this standard, one or more instances of the MAC Service to other functional entities whose specification is outside the scope of this standard.
- c) Provide, as specified by this standard, one or more instances of the MAC Internal Sublayer Service (ISS) to other implementations or instances of the same implementation that conform to this standard.

Accordingly, and as detailed in 5.4, this clause specifies conformance requirements for common systems and for functional components within systems, possibly connected to other system components with interfaces that are not otherwise accessible.

### 5.1 Requirements terminology

For consistency with existing IEEE and IEEE 802.1™ standards, requirements placed upon conformant implementations of this standard are expressed using the following terminology:

- a) **Shall** is used for mandatory requirements.
- b) **May** is used to describe implementation or administrative choices (“may” means “is permitted to,” and hence, “may” and “may not” mean precisely the same thing).
- c) **Should** is used for recommended choices (the behaviors described by “should” and “should not” are both permissible but not equally desirable choices).

NOTE—The usage in 17.7 follows the IETF model.

The Protocol Implementation Conformance Statement (PICS) proformas (see Annex A for Bridges and Annex B for end station implementations) reflect the occurrences of the words “shall,” “may,” and “should” within the standard.

The standard avoids needless repetition and apparent duplication of its formal requirements by using **is**, **is not**, **are**, and **are not** for definitions and the logical consequences of conformant behavior. Behavior that is permitted but is neither always required nor directly controlled by an implementer or administrator, or whose conformance requirement is detailed elsewhere, is described by **can**. Behavior that never occurs in a conformant implementation or system of conformant implementations is described by **cannot**. The word **allow** is used as a replacement for the phrase “Support the ability for,” and the word **capability** means “can be configured to.”

### 5.2 Conformant components and equipment

This subclause specifies requirements and options for the following core components:

- a) VLAN Bridge component (5.4)
- b) MAC Bridge component (5.13)

for the following components that use that core functionality:

- c) Customer VLAN (C-VLAN) component (5.5)
- d) Service VLAN (S-VLAN) component (5.6)
- e) I-component (5.7)
- f) B-component (5.8)

- 1 g) TPMR component (5.15)
- 2 h) T-component (5.17)
- 3 i) Edge relay (ER) (5.24.1)

4 and for the following systems that include instances of the above components:

- 5 j) C-VLAN Bridge (5.9)
- 6 k) S-VLAN Bridge (5.10.1)
- 7 l) Provider Edge Bridge (5.10.2)
- 8 m) Backbone Edge Bridge (BEB) (5.12)
- 9 n) MAC Bridge (5.14)
- 10 o) TPMR (5.16)
- 11 p) Edge Virtual Bridging (EVB) Bridge (5.23)
- 12 q) EVB station (5.24)
- 13 r) TSN CNC station (5.29)
- 14 s) VDP-NVO3 (5.30)

15 NOTE—Both S-VLAN Bridges and Provider Edge Bridges are examples of Provider Bridges.

### 16 5.3 Protocol Implementation Conformance Statement (PICS)

17 A claim of conformance specifies implementation of a C-VLAN component, an S-VLAN component, an  
18 I-component, a B-component, a VLAN-unaware MAC Bridge component, or a specific system. A  
19 component or system can support multiple claims for a range of possible behaviors.

20 The supplier of an implementation that is claimed to conform to this standard shall provide the information  
21 necessary to identify both the supplier and the implementation, and shall complete a copy of the PICS  
22 proforma provided in Annex A for that specific Bridge component or system, or Annex B for an end station  
23 implementation, together with any further information and completed PICS(s) required to identify  
24 subcomponents.

25 NOTE 1—C-VLAN component and S-VLAN component PICS both require completion of a PICS for a VLAN Bridge  
26 component; the VLAN Bridge PICS requires a claim of conformance for a single C-VLAN component; the Provider  
27 Edge Bridge requires a claim of conformance for a single S-VLAN component and one or more claims for C-VLAN  
28 components.

29 NOTE 2—The claim of conformance that could be made to this standard for an implementation of a VLAN-aware  
30 Bridge is replaced by a claim of conformance to a VLAN Bridge. Although the current and subsequent amendment(s) or  
31 revision(s) of this standard have changed the presentation of the information, the technical requirements of conformance  
32 remain unchanged.

33 NOTE 3—I-component and B-component PICS both require completion of a PICS for an S-VLAN component.

### 34 5.4 VLAN Bridge component requirements

35 An implementation of a VLAN Bridge component shall:

- 36 a) Conform to the relevant standard for the MAC technology implemented at each Port in support of  
37 the MAC ISS, as specified in IEEE Std 802.1AC.
- 38 b) Support the MAC Enhanced Internal Sublayer Service (EISS) at each Port, as specified in 6.8 and  
39 6.9.
- 40 c) Implement an ISO/IEC 8802-2 conformant Logical Link Control (LLC) class with Type 1 operation  
41 as required by 8.2.
- 42 d) Relay and filter frames as described in 8.1 and specified in 8.5, 8.6, 8.7, and 8.8.
- 43 e) Maintain the information required to support Basic Filtering Services, as described in 6.16 and in 8.1  
44 and specified in 8.5, 8.7, and 8.8.

- 1 f) Conform to the provisions for addressing specified in 8.13.
- 2 g) Implement Rapid Spanning Tree Algorithm and Protocol (RSTP), as specified in Clause 13.
- 3 h) Encode transmitted BPDUs and validate received BPDUs as specified in Clause 14.
- 4 i) Specify the following parameters of the implementation:
  - 5 1) Filtering Database Size, the maximum number of entries
  - 6 2) Permanent Database Size, the maximum number of entries
- 7 j) Specify the following performance characteristics of the implementation:
  - 8 1) A Guaranteed Port Filtering Rate for each Bridge Port
  - 9 2) A Guaranteed Bridge Relaying Rate for the Bridge
  - 10 3) The related time intervals  $T_F$  and  $T_R$  for these parameters as specified in Clause 24
- 11 k) Operation of the Bridge within the specified parameters shall not violate any of the other
- 12 conformance provisions of this standard.
- 13 l) On each Port, support at least one of the permissible values for the Acceptable Frame Types
- 14 parameter, as defined in 6.9.
- 15 m) Support the following on each Port that supports untagged and priority-tagged frames:
  - 16 1) A Port VLAN Identifier (PVID) value (6.9)
  - 17 2) Configuration of at least one VID whose untagged set includes that Port (8.8.2)
  - 18 3) Configuration of the PVID value via management operations (12.10)
  - 19 4) Configuration of Static Filtering Entries via management operations (12.7)
- 20 n) Allow tag headers to be inserted, modified, and removed from relayed frames, as specified in 8.1
- 21 and Clause 9, as required by the value(s) of the Acceptable Frame Types parameter supported on
- 22 each Port, and by the ability of each Port to transmit VLAN-tagged and/or untagged frames.
- 23 o) Allow automatic configuration and management of VLAN topology using the Multiple VLAN
- 24 Registration Protocol (MVRP) (5.4.2, Clause 11) on all Ports.
- 25 p) Allow static and dynamic configuration information for at least one VID, by means of Static and
- 26 Dynamic VLAN Registration Entries in the FDB (8.8).
- 27 q) Support at least one Filtering Identifier (FID) (8.8.3, 8.8.8, 8.8.9, and IEEE Std 802.1AC).
- 28 r) Allow allocation of at least one VID to each FID that is supported (8.8.3, 8.8.8, 8.8.9, and
- 29 IEEE Std 802.1AC).
- 30 NOTE—Under some circumstances, the ability for VLAN Bridges to successfully interoperate depends on the
- 31 number of FIDs supported and on the number of VIDs that can be allocated to each FID. These circumstances
- 32 are discussed in Annex B, along with interoperability implications.

### 33 5.4.1 VLAN Bridge component options

34 An implementation of a VLAN Bridge component may:

- 35 a) Support MST operation (5.4.1.1).
- 36 b) Support Port-and-Protocol-based VLAN classification (5.4.1.2), including multiple VID values per
- 37 port, administrative control of the values of the multiple VIDs, and a Protocol Group Database.
- 38 c) Support CFM operation (5.4.1.4).
- 39 d) Support Shortest Path Bridging (SPB) operation (5.4.5).
- 40 e) Support congestion notification (5.4.3).
- 41 f) Support Priority-based Flow Control (PFC) (5.11).
- 42 g) Support Extended Filtering Services (6.16.5) and the operation of Multiple MAC Registration
- 43 Protocol (MMRP, 10.9) to support automatic configuration and management of MAC address
- 44 information on all Ports (5.4.1.3).
- 45 h) Allow the FDB to contain Static and Dynamic VLAN Registration Entries (8.8) for more than one
- 46 VID, up to a maximum of 4094 VIDs.

- 1 i) Allow translation of VIDs through support of the VID Translation Table or through support of both  
2 the VID Translation Table and Egress VID translation table on one or more Bridge Ports (6.9).
- 3 NOTE 1—The maximum number of VIDs that can be supported is 4094 rather than 4096, as the VID values 0  
4 and FFF are reserved, as indicated in Table 9-2. As conformance to this standard is only with regard to  
5 externally visible protocol behavior, this limit on the number of VIDs that can be supported does not imply any  
6 such limitation with regard to the internal architecture of a Bridge.
- 7 j) On each Port, support all of the permissible values for the Acceptable Frame Types parameter, as  
8 defined in 6.9, and support configuration of the parameter value via management.
- 9 k) Support enabling and disabling of Ingress Filtering (8.6.2).
- 10 l) Allow configuration of more than one VID whose untagged set includes that Port (8.8.2).
- 11 m) Support the management functionality defined in Clause 12.
- 12 n) Support the use of a remote management protocol. Bridges claiming to support remote management  
13 shall:
- 14 1) State which remote management protocol standard(s) or specification(s) are supported.
- 15 2) State which standard(s) or specification(s) for managed object definitions and encodings are  
16 supported for use by the remote management protocol.
- 17 o) Support multiple Traffic Classes for relaying and filtering frames through one or more outbound  
18 Ports, controlling the mapping of the priority of forwarded frames as specified in 6.9.4 and  
19 IEEE Std 802.1AC.
- 20 p) Support more than one FID (8.8).
- 21 q) Allow allocation of more than one VID to each supported FID (8.8, 8.8.8).
- 22 r) Allow configuration of fixed VID to FID allocations (8.8.8, 12.10.3).
- 23 s) Allow configuration of the Restricted\_MAC\_Address\_Registration parameter (10.12.2.3) for each  
24 Port of the Bridge.
- 25 t) Support the ability to configure the value of the Restricted\_VLAN\_Registration parameter  
26 (11.2.3.2.3) for each Port of the Bridge.
- 27 u) Support Forwarding and Queuing Enhancements for time-sensitive streams (FQTSS) (5.4.1.5).
- 28 v) Support SMIv2 MIB modules for the management of VLAN Bridge capabilities (Clause 17).
- 29 NOTE 2—In previous versions of this standard, the MIB modules were maintained by IETF (e.g., IETF RFC  
4363 for the Q-BRIDGE MIB). For this version of the standard, the relevant set of MIB modules required to  
manage a Bridge is contained in Clause 17.
- 32 w) Support YANG modules for the management of VLAN Bridge capabilities (Clause 48).
- 33 x) Support Multiple Stream Registration Protocol (MSRP) (Clause 35).
- 34 y) Support the operation of MVRP (5.4.2, 11.2) as a New-Only Participant.
- 35 z) Support the MVRP extension MIB module defined in 17.7.15.
- 36 aa) Support Enhanced Transmission Selection (ETS) (5.4.1.6).
- 37 ab) Support Data Center Bridging eXchange protocol (DCBX) (5.4.1.7).
- 38 ac) Support the enhancements for scheduled traffic as specified in 8.6.8.4.
- 39 ad) Support the management entities for scheduled traffic as specified in 12.29.
- 40 ae) Support frame preemption as specified in 6.7.1, 6.7.2, and 8.6.8.
- 41 af) Support Stream reservation remote management (5.4.1.11).
- 42 ag) Support for Congestion Isolation (CI) operation (5.4.7).

#### 1 5.4.1.1 Multiple Spanning Tree (MST) operation (optional)

2 A VLAN Bridge implementation in conformance to the provisions of this standard for an MST Bridge  
3 (5.4.1, 8.3, 8.4, 8.6.1, 8.9, 8.10, 11.2, 11.2.3.1, Clause 13, and Clause 14) shall:

- 4 a) Support MSTP as specified in Clause 13.
- 5 b) Support the Common and Internal Spanning Tree (CIST) plus a stated maximum number of  
6 Multiple Spanning Tree Instances (MSTIs), where that number is at least 2 (8.9) and at most 64  
7 (13.14).  
8 NOTE—In other words, a conformant MST Bridge supports a minimum of three spanning tree instances—the  
9 CIST and at least two additional MSTIs.
- 10 c) Support a stated maximum number of FIDs not less than the number of MSTIs (8.9).
- 11 d) Support the ability to associate each FID to a spanning tree (8.9.3).
- 12 e) Support the transmission and reception of MST Configuration Identifier (MCID) information  
13 (8.9.2).
- 14 f) Support a Port State for each Port for each spanning tree instance supported (8.4, 13.38).
- 15 g) Support operation of a spanning tree protocol for each spanning tree instance and Port (8.10,  
16 Clause 13).
- 17 h) Use the Bridge Group Address as specified in 8.13.3.
- 18 i) Support the default values for Bridge Forward Delay and Bridge Priority parameters specified in  
19 13.26.
- 20 j) Support the operation of MVRP in each supported spanning tree context (11.2.3.1.1, 11.2.3.1.2).
- 21 k) Support the Bridge management functions for the Bridge protocol entity for each supported  
22 spanning tree, independently (12.8).
- 23 l) Support, in particular, management of the Bridge priority parameters, and of the port priority and  
24 path cost parameters for every port, independently for each supported spanning tree (12.8.1.1,  
25 12.8.1.3, 13.27).
- 26 m) Support VLAN management functions for each supported spanning tree (12.10.1 and 12.11.1).
- 27 n) Support management of the MSTI configuration (12.12).

28 A VLAN Bridge implementation in conformance to the provisions of this standard for an MST Bridge  
29 (5.4.1, Clause 13) may:

- 30 o) Support a greater number of FIDs than spanning trees (8.8.8).
- 31 p) Support SMIv2 MIB modules for the management of VLAN Bridge capabilities (Clause 17).
- 32 q) Support YANG modules for the management of MSTP (48.6.26, 48.6.27, 48.6.28, 48.6.29).

#### 33 5.4.1.2 Port-and-Protocol-based VLAN classification (optional)

34 A VLAN Bridge component implementation in conformance to the provisions of this standard for  
35 Port-and-Protocol-based VLAN classification (5.4.1) shall:

- 36 a) Support one or more of the following Protocol Classifications and Protocol Template formats:  
37 Ethernet, RFC\_1042, SNAP\_8021H, SNAP\_Other, or LLC\_Other (6.12).

38 A VLAN Bridge component implementation in conformance to the provisions of this standard for  
39 Port-and-Protocol-based VLAN classification (5.4.1) may:

- 40 b) Support configuration of the contents of the Protocol Group Database.

### 1 5.4.1.3 Multiple MAC Registration Protocol (MMRP) operation (optional)

2 A Bridge implementation in conformance to the provisions of this standard for the support of MMRP shall:

- 3 a) Conform to the operation of the MRP Applicant, Registrar, LeaveAll, and Periodic Transmission  
4 state machines, as defined in 10.7.7, 10.7.8, 10.7.9, and 10.7.10, as required for one or the other of  
5 the following variants of the MRP Participant, as defined in 10.6 and 10.7:
  - 6 1) The Full Participant
  - 7 2) The Full Participant, point-to-point subset
- 8 b) Exchange Multiple Registration Protocol Data Units (MRPDUs) as required by those state  
9 machines, formatted in accordance with the generic protocol data unit (PDU) format described in  
10 10.8, and able to carry application-specific information as defined in 10.12, using the group MAC  
11 addresses reserved for use by MRP applications, as defined in Table 10-1.
- 12 c) Implement the MMRP Application component as defined in 10.12.
- 13 d) Propagate registration information in accordance with the operation of MAP for the Base Spanning  
14 Tree Context, as specified in 10.3.1.
- 15 e) Forward, filter, or discard MAC frames carrying any MRP Application address as the destination  
16 MAC address in accordance with the requirements of 8.13.6.

### 17 5.4.1.4 Connectivity Fault Management (CFM) (optional)

18 A VLAN Bridge component implementation that conforms to the provisions of this standard for CFM  
19 (Clause 18 through Clause 22) shall:

- 20 a) Support the creation of Maintenance Domains at eight Maintenance Domain Levels (MD Levels),  
21 with multiple nonoverlapping Maintenance Domains at each MD Level, using the managed objects  
22 specified in 12.14.
- 23 b) Support the creation of a Maintenance Association (MA) for each VID supported by the Bridge for  
24 each MD Level.
- 25 c) Support the creation of a single Maintenance Domain Intermediate Point (MIP) for each  
26 Maintenance Domain on each Port, all MIPs being at the same MD Level.
- 27 d) Support the creation of eight Up MA Endpoints (MEPs) for each VID on each Port, each MEP at a  
28 different MD Level.
- 29 e) Support the creation of eight Down MEPs for each VID on each Port, each MEP at a different MD  
30 Level.
- 31 f) Support the creation of eight Down MEPs attached to no VID on each Port, each MEP at a different  
32 MD Level.
- 33 g) Support the maintenance of a MEP CCM Database.
- 34 h) Provide control via all of the required managed objects specified in 12.14.
- 35 i) Conform to the state machines and procedures in Clause 20.
- 36 j) Transmit and receive required CFM PDUs in the formats specified in Clause 21.

37 A VLAN Bridge component implementation that conforms to the provisions of this standard for CFM may:

- 38 k) Support the creation of MIPs at different MD Levels on a single Port.
- 39 l) Support the creation of MIPs at MD Levels lower than or equal to MEPs on the same Port.
- 40 m) Support the maintenance of a MIP CCM Database in a MIP or MEP.
- 41 n) Support the CFM MIB module defined in 17.5 and/or the CFM YANG modules defined in  
42 Clause 48.
- 43 o) Support the creation of MAs that are associated with more than one VID (22.1.5).
- 44 p) Support the creation and operation of Reflection Responder (RR) and Reflected Frame Message  
45 (RFM) Receiver for the forward path test (FPT).
- 46 q) Support the creation and operation of Decapsulator Responder (DR) and Send Frame Message  
47 (SFM) Originator for the return path test (RPT).

### 1 5.4.1.5 Forwarding and Queuing Enhancements for time-sensitive streams 2 (FQTSS)—requirements

3 A VLAN Bridge component implementation that conforms to the provisions of this standard for FQTSS  
4 shall:

- 5 a) Support a minimum of two traffic classes on all Ports, of which:
  - 6 1) A minimum of one traffic class supports the strict priority algorithm for transmission selection  
7 (8.6.8.1), and
  - 8 2) One traffic class is a stream reservation (SR) class.
- 9 b) Support the operation of the credit-based shaper algorithm (8.6.8.2) on all Ports as the transmission  
10 selection algorithm used for the SR class.
- 11 c) Support SRP domain boundary port priority regeneration override as defined in 6.9.4, and the  
12 default priority regeneration override value defined in Table 6-5, for SR class “B.”
- 13 d) Support the tables and procedures for mapping priorities to traffic classes as defined in 34.5.

14 A VLAN Bridge component implementation that conforms to the provisions of this standard for FQTSS  
15 may:

- 16 e) Support the management entities defined in 12.20 by means of the SNMPv2 MIB module defined in  
17 17.7.12.
- 18 f) Support two or more SR classes (a maximum of seven), and support the operation of the  
19 credit-based shaper algorithm (8.6.8.2) on all Ports as the transmission selection algorithm used for  
20 those SR classes. The number of SR classes supported shall be stated in the PICS.
- 21 g) Support SRP domain boundary port priority regeneration override as defined in 6.9.4, and the  
22 default priority regeneration override value defined in Table 6-5, for SR class “A.” If more than two  
23 SR classes are supported, the default priority regeneration override values used for the additional SR  
24 classes shall be stated in the PICS.
- 25 h) Support the classMeasurementInterval attribute (12.20.1).
- 26 i) Support the SR Class to Priority Mapping Table (12.20.4).

### 27 5.4.1.6 ETS Bridge requirements

28 A device supporting ETS shall:

- 29 a) Support the ETS algorithm (8.6.8.3).
- 30 b) Support at least 3 traffic classes (37.3).  
31 NOTE—A minimum of 3 traffic classes allows a minimum configuration such that one traffic class contains  
32 priorities with PFC enabled, one traffic class contains priorities with PFC disabled, and one traffic class using  
33 strict priority.
- 34 c) Support bandwidth configuration with a granularity of 1% or finer (37.3).
- 35 d) Support bandwidth allocation with a precision of 10% (37.3).
- 36 e) Support a transmission selection policy such that if one of the traffic classes does not consume its  
37 allocated bandwidth, then any unused bandwidth is available to other traffic classes (37.3).
- 38 f) Support DCBX (Clause 38).

### 39 5.4.1.7 DCBX Bridge requirements

40 A device supporting DCBX shall:

- 41 a) Support Link Layer Discovery Protocol (LLDP) transmit and receive mode (IEEE Std 802.1AB).
- 42 b) Support the DCBX ETS Configuration Type, Length, Value (TLV) (D.2.8).
- 43 c) Support the ETS Recommendation TLV (D.2.9).

- 1 d) Support the Priority-based Flow Control Configuration TLV (D.2.10).
- 2 e) Support the Application Priority TLV (D.2.11).
- 3 f) Support the asymmetric and symmetric DCBX state machines (38.4).
- 4 g) Support the Application VLAN TLV (D.2.14).

#### 5 5.4.1.8 Per-Stream Filtering and Policing (PSFP) requirements

6 A VLAN Bridge component implementation that conforms to the provisions of this standard for PSFP shall:

- 7 a) Support PSFP as specified in 8.6.5.2.1 and 8.6.6 items d) and e).
- 8 b) Support the state machines for stream gate control as specified in 8.6.10.
- 9 c) Support the management entities for PSFP as specified in 12.31.

#### 10 5.4.1.9 Cyclic queuing and forwarding (CQF) requirements

11 A VLAN Bridge component implementation that conforms to the provisions of this standard for CQF (see  
12 Annex T) shall:

- 13 a) Support the enhancements for scheduled traffic as specified in 8.6.8.4.
- 14 b) Support the state machines for scheduled traffic as specified in 8.6.9.
- 15 c) Support the state machines for stream gate control as specified in 8.6.10.
- 16 d) Support the management entities for scheduled traffic as specified in 12.29.
- 17 e) Support the requirements for Per-Stream Filtering and Policing (PSFP) as stated in 5.4.1.8.
- 18 f) Support the management entities for PSFP as specified in 12.31.

#### 19 5.4.1.10 Asynchronous Traffic Shaping (ATS) requirements

20 A VLAN Bridge component implementation that conforms to the provisions of this standard for ATS shall:

- 21 a) Support per-stream classification and metering for ATS as specified in 8.6.5.2.2.
- 22 b) Support queuing with support for stream gates as specified in 8.6.6 items d) and e).
- 23 c) Support the ATS transmission selection algorithm as specified in 8.6.8.5.
- 24 d) Support the ATS scheduler state machines as specified in 8.6.11.
- 25 e) Support the management entities for ATS as specified in 12.31.

#### 26 5.4.1.11 Stream reservation remote management (optional)

27 A VLAN-aware Bridge component implementation that conforms to the provisions of this standard for  
28 Stream reservation remote management shall:

- 29 a) Support the management functionality defined in Clause 12.
- 30 b) Support the use of a remote management protocol. Bridges claiming to support remote management  
31 shall state the following:
  - 32 1) Which remote management protocol standard(s) or specification(s) are supported for the server  
33 implementation.
  - 34 2) Which standard(s) or specification(s) for managed object definitions and encodings are  
35 supported for use by the remote management protocol.
- 36 c) Support TE-MSTID (5.5.2).
- 37 d) Support the entities for Stream reservation remote management (12.32).
- 38 e) Support the adminIdleSlope attribute (12.20.1).

## 1 5.4.2 Multiple VLAN Registration Protocol (MVRP) requirements

2 A VLAN Bridge implementation in conformance to the provisions of this standard for the support of MVRP  
3 shall:

- 4 a) Conform to the operation of the MRP Applicant, Registrar, LeaveAll, and Periodic Transmission  
5 state machines, as defined in 10.7.7, 10.7.8, 10.7.9, and 10.7.10, as required for one or the other of  
6 the following variants of the MRP Participant, as defined in 10.6 and 10.7:
  - 7 1) The Full Participant
  - 8 2) The Full Participant, point-to-point subset
- 9 b) Exchange MRPDUs as required by those state machines, formatted in accordance with the generic  
10 PDU format described in 10.8, and able to carry application-specific information as defined in 11.2,  
11 using the group MAC addresses reserved for use by MVRP.
- 12 c) Implement the MVRP Application component as defined in 11.2.
- 13 d) Propagate registration information:
  - 14 1) In a Single Spanning Tree (SST) Bridge, in accordance with the operation of MAP for the Base  
15 Spanning Tree Context, as specified in 10.3 and 10.3.1; or
  - 16 2) In an MST Bridge, in accordance with the operation of MAP for MST contexts as specified in  
17 11.2.3.1.2 of this standard.
- 18 e) Forward, filter, or discard MAC frames carrying any MRP Application address as the destination  
19 MAC address in accordance with the requirements of 8.13.6.
- 20 f) If a VID Translation Table (6.9) is in use for a Bridge Port, translate VIDs in Multiple VLAN  
21 Registration Protocol Data Units (MRPDUs) as specified in 11.2.4.

## 22 5.4.3 VLAN Bridge requirements for congestion notification

23 A VLAN Bridge implementation that conforms to the provisions of this standard for congestion notification  
24 (Clause 30 through Clause 33) shall:

- 25 a) Support, on one or more Ports, the creation of at least one Congestion Point (CP) (32.1.1).
- 26 b) Support, at each CP, the generation of Congestion Notification Messages (CNMs) (32.7) and the  
27 removal of Congestion Notification tags (CN-TAGs) (32.1.1).
- 28 c) Support the ability to configure the variables controlling the operation of each CP (12.21.1, 12.21.2,  
29 12.21.3, 12.21.4).
- 30 d) Support the operation of each Port in each of the Congestion Notification Domain (CND) defense  
31 modes separately for each Congestion Notification Priority Value (CNPV) (32.1.1).
- 32 e) Support the LLDP capabilities required for conformance to IEEE Std 802.1AB.
- 33 f) Support the use of the Congestion Notification TLV in LLDP (32.1.1).

34 A Provider Instance Port (PIP, 6.10) that conforms to the provisions of this standard for congestion  
35 notification shall:

- 36 g) Support CNM translation (32.16).

37 A Provider Edge Port (PEP) (15.4) that conforms to the provisions of this standard for congestion  
38 notification shall:

- 39 h) Support CNM translation (32.16).

40 A VLAN Bridge implementation that conforms to the provisions of this standard for congestion notification  
41 may:

- 42 i) Support the creation of up to seven CPs on a Bridge Port (31.1.1).
- 43 j) Support the IEEE8021-CN-MIB (17.7.13).

#### 1 5.4.4 Multiple Stream Registration Protocol (MSRP) requirements

2 A VLAN Bridge implementation in conformance to the provisions of this standard for the support of MSRP  
3 shall:

- 4 a) Conform to the operation of the MRP Applicant, Registrar, and LeaveAll state machines, as defined  
5 in 10.7.7, 10.7.8, and 10.7.9, as required for one or more of the following variants of the MRP  
6 Participant, as defined in 10.6 and 10.7:
    - 7 1) The Full Participant
    - 8 2) The Full Participant, point-to-point subset
  - 9 b) Exchange MRPDUs as required by those state machines, formatted in accordance with the generic  
10 PDU format described in 10.8, and able to carry application-specific information as defined in  
11 Clause 35, using the “Individual LAN Scope group address, Nearest Bridge group address” as  
12 defined in Table 8-1, Table 8-2, and Table 8-3 (C-VLAN, S-VLAN, and TPMR component  
13 Reserved addresses, respectively).
  - 14 c) Implement the MSRP Application component as defined in Clause 35.
  - 15 d) Propagate registration information in accordance with the operation of MAP for the Base Spanning  
16 Tree Context, as specified in 10.3.1.
  - 17 e) Forward, filter, or discard MAC frames carrying any MRP Application address as the destination  
18 MAC address in accordance with the requirements of 8.13.6.
  - 19 f) Not redeclare its attributes unless responding to a LeaveAll event.
- 20 NOTE—In order to meet the requirement specified in 5.4.4(f), the Periodic Transmission state machine  
21 (10.7.10) is specifically excluded from MSRP. A Bridge is allowed to generate an MSRP LeaveAll event to  
22 force an immediate redeclaration of all MSRP attributes from its neighbor(s).

#### 23 5.4.5 Shortest Path Bridging (SPB) operation (optional)

24 A VLAN Bridge implementation that conforms to the provisions of this standard for SPB in Clause 27 shall:

- 25 a) Support SPB, in either VID mode (SPBV) or MAC mode (SPBM), as specified in Clause 27.
- 26 b) Support the IS-IS Link State Protocol with procedures to ensure Loop Prevention as specified in  
27 Clause 28 to provide Shortest Path Tree (SPT) computation for SPB.
- 28 c) Encode, decode, and validate SPT BPDUs for the Agreement Protocol (13.17) and support  
29 Agreement Protocol logic in Intermediate System to Intermediate System (IS-IS) Protocol as  
30 specified in Clause 28.
- 31 d) Support at least three FIDs.
- 32 e) Support the management functionality specified in Clause 12.

33 A VLAN Bridge implementation in conformance to the provisions of this standard for SPB in Clause 27  
34 may:

- 35 f) Support both SPB VID mode (SPBV) and SPB MAC mode (SPBM).
- 36 g) Support the SPB MIB module defined in 17.7.19.
- 37 h) Support both the VID Translation Table and Egress VID translation table (6.9) on SPBV Boundary  
38 Ports.
- 39 i) Support the CFM modifications for SPBM as specified in Clause 20 and summarized in 27.18.
- 40 j) Support Equal Cost Multiple Paths (ECMP) operation of SPBM (5.4.5.1).
- 41 k) Support ECMP operation of SPBM with flow filtering (5.4.5.2).

#### 1 5.4.5.1 SPBM ECMP operation (optional)

2 An SPBM-capable VLAN-aware bridge implementation that conforms to the provisions of this standard for  
3 ECMP in 44.1 shall:

- 4 a) Support SPBM ECMP as specified in 44.1.
- 5 b) Support the management functionality specified in Clause 12.

6 An SPBM-capable VLAN-aware bridge implementation that conforms to the provisions of this standard for  
7 ECMP may:

- 8 c) Support the IEEE8021-ECMP-MIB module objects `ieee8021EcmpEctStaticTable` and  
9 `ieee8021EcmpTopSrvTable` defined in 17.7.21.

#### 10 5.4.5.2 SPBM ECMP operation with flow filtering (optional)

11 An SPBM-capable VLAN-aware bridge implementation that conforms to the provisions of this standard for  
12 ECMP with flow filtering shall:

- 13 a) Support SPBM ECMP as specified in 44.1.
- 14 b) Support flow filtering as specified in 44.2, including inserting, modifying, and removing flow  
15 filtering tags (F-TAGs) from relayed frames as required by the applicable values in the Flow  
16 Filtering Control Table for each port.
- 17 c) Support the management functionality specified in Clause 12.

18 An SPBM-capable VLAN-aware bridge implementation that conforms to the provisions of this standard for  
19 ECMP with flow filtering may:

- 20 d) Support the CFM modifications for ECMP using flow filtering as specified in Clause 20 and  
21 summarized in 44.2.5.
- 22 e) Support the IEEE8021-ECMP-MIB module defined in 17.7.21.

#### 23 5.4.6 Path Control and Reservation (PCR) (optional)

24 A VLAN Bridge implementation that conforms to the provisions of this standard for PCR in Clause 45 shall:

- 25 a) Support the IS-IS link state protocol with the extensions for explicit path control (ISIS-PCR) as  
26 specified in 45.1.
- 27 b) Support the SPB Link Metric sub-TLV as specified in 28.12.7.
- 28 c) Support the SPB Base VLAN-Identifiers sub-TLV as specified in 28.12.4.
- 29 d) Support the SPB Instance sub-TLV as specified in 28.12.5.
- 30 e) Support the SPBV MAC address sub-TLV as specified in 28.12.9.
- 31 f) Support the SPBM Service Identifier and Unicast Address sub-TLV as specified in 28.12.10.
- 32 g) Support the ST ECT Algorithm as specified in 45.1.2 and the use of the ST ECT Algorithm as  
33 specified in 45.3.2.
- 34 h) Support the Topology sub-TLV, the Hop sub-TLV, and the corresponding ISIS-PCR operations for  
35 explicit trees as specified in 45.1.
- 36 i) Support the management functionality specified in 12.26.

37 A VLAN Bridge implementation that conforms to the provisions of this standard for PCR in Clause 45 may:

- 38 j) Support the LT ECT Algorithm as specified in 45.1.2.
- 39 k) Support the LTS ECT Algorithm as specified in 45.1.2.
- 40 l) Support the MRT ECT Algorithm as specified in 45.3.3.
- 41 m) Support the MRTG ECT Algorithm as specified in 45.3.4.

- 1 n) Support the Administrative Group sub-TLV and the corresponding ISIS-PCR operations as specified
- 2 in 45.1.11.
- 3 o) Support the Bandwidth Constraint sub-TLV and the corresponding ISIS-PCR operations as specified
- 4 in 45.1.12.
- 5 p) Support the Bandwidth Assignment sub-TLV and the corresponding ISIS-PCR operations as
- 6 specified in 45.2.1.
- 7 q) Support the Timestamp sub-TLV as specified in 45.2.2.
- 8 r) Support LFA for unicast data flows as specified in 45.3.1.
- 9 s) Support the PCR Management Information Base (MIB) objects defined in 17.7.19.

#### 10 **5.4.7 VLAN Bridge requirements for congestion isolation (optional)**

11 A VLAN-aware Bridge implementation that conforms to the provisions of this standard for congestion  
12 isolation in Clause 49 shall:

- 13 a) Support, on one or more Ports, the creation of at least one Congestion Isolation Point (49.3.1).
- 14 b) Support Explicit Congestion Notification (ECN) as defined by IETF RFC 3168 and associated
- 15 updates along with Active Queue Management (AQM) as described in 49.2.1.
- 16 c) Support per-stream classification and metering for CI as specified in 8.6.5.2.3.
- 17 d) Support, at each Congestion Isolation Point, the variables and procedures of the Congestion
- 18 Isolation Protocol (49.4).
- 19 e) Support the ability to configure the variables controlling the operation of Congestion Isolation
- 20 (12.33.1), the CI Peer Table (12.33.2), the CI Stream Table (12.33.3), and each CIP (12.33.4).
- 21 f) Conform to the required capabilities of IEEE Std 802.1AB.
- 22 g) Support the use of the Congestion Isolation TLV in LLDP (D.2.15).

23 A VLAN Bridge implementation that conforms to the provisions of this standard for congestion isolation  
24 may:

- 25 h) Support the monitoring of more than one queue on a Bridge Port (49.4.1.2.5).
- 26 i) Support transmission selection algorithms other than strict priority.
- 27 j) Support the de-isolation of congesting flows by means other than the empty status of a congesting
- 28 queue (49.2.6).
- 29 k) Support the Congestion Isolation YANG model (48.3.8).
- 30 l) Support Topology Recognition (49.5).

#### 31 **5.5 C-VLAN component conformance**

32 A C-VLAN component comprises a VLAN Bridge component with the EISS on all Ports supported by the  
33 use of a C-VLAN tag (C-TAG) (6.8, 9.5).

34 A conformant implementation of a C-VLAN component shall:

- 35 a) Comprise a single conformant VLAN Bridge component.
- 36 b) Recognize and use C-TAGs.
- 37 c) Filter the reserved MAC addresses specified in Table 8-1.
- 38 d) Use the Customer Bridge MVRP Address specified in Table 10-1.

39 A conformant implementation of a C-VLAN component shall not:

- 40 e) Use S-VLAN tags (S-TAGs) except in support of the functionality specified in 6.13.

### 1 5.5.1 C-VLAN component options

2 A conformant C-VLAN component may implement the options specified for a VLAN Bridge component  
3 whose use is not specifically prohibited by 5.4.1 and may:

- 4 a) Support encoding the drop\_eligible parameter in the PCP field of the tag header (6.9.3).
- 5 b) Allow support of the ISS as specified in 6.13 to facilitate priority selection on a Provider Bridged  
6 Network (PBN).
- 7 c) Implement RSTP, with the enhancements to support Customer Edge Ports (CEPs), as specified in  
8 13.41.
- 9 d) Support TE-MSTID (5.5.2).

### 10 5.5.2 TE-MSTID (optional)

11 A C-VLAN component implementation that conforms to the provisions of this standard for TE-MSTID  
12 shall:

- 13 a) Disable learning for a set of Customer VLAN Identifiers (C-VIDs) allocated to the Traffic  
14 Engineering Multiple Spanning Tree Instance Identifier (TE-MSTID) as specified in 8.4 and 8.9,  
15 with the exception that support for PBB-TE is not required; and
- 16 b) Discard frames with unregistered destination addresses for C-VIDs allocated to the TE-MSTID  
17 (8.8.1).

18 A C-VLAN component implementation that conforms to the provisions of this standard for TE-MSTID may

- 19 c) Allow control of all C-VIDs by an external agent, conforming to the Reserved VID values of  
20 Table 9-2.

### 21 5.6 S-VLAN component conformance

22 An S-VLAN component comprises a VLAN Bridge component with the EISS on all Ports supported by the  
23 use of an S-TAG (6.8, 9.5).

24 A conformant implementation of an S-VLAN component shall:

- 25 a) Comprise a single conformant VLAN Bridge component.
- 26 b) Recognize and use S-TAGs.
- 27 c) Support encoding the drop\_eligible parameter in the PCP field of the tag header (6.9.3).
- 28 d) Filter the reserved MAC addresses specified in Table 8-2.
- 29 e) Use the Provider Bridge MVRP Address specified in Table 8-1.
- 30 f) Allow the Acceptable Frame Types parameter (6.9) to be set to *Admit All Frames* for each Port.
- 31 g) Allow the Enable Ingress Filtering parameter (8.6.2) to be set for each Port.

32 A conformant implementation of an S-VLAN component shall not:

- 33 h) Recognize or use C-TAGs.
- 34 i) Allow support of the ISS as specified in 6.13 for any of its Ports.
- 35 j) Configure the Customer Bridge MVRP Addresses specified in Table 10-1 in the FDB (8.8) or  
36 Permanent Database (8.8.11).
- 37 k) Use the Customer Bridge MVRP Address specified in Table 10-1.

### 1 5.6.1 S-VLAN component options

2 A conformant S-VLAN component may implement any of the options specified for a VLAN Bridge  
3 component (5.4.1).

### 4 5.6.2 S-VLAN component requirements for Provider Backbone Bridge Traffic Engineering 5 (PBB-TE)

6 An S-VLAN component implementation that conforms to the provisions of this standard for PBB-TE  
7 (25.10) shall:

- 8 a) Disable learning for a set of Backbone VLAN Identifiers (B-VIDs) allocated to Traffic Engineering  
9 Multiple Spanning Tree Instance Identifier (TE-MSTID) as specified in 8.4 and in 8.9.
- 10 b) Discard frames with unregistered destination addresses for B-VIDs allocated to TE-MSTID (8.8.1).

11 An S-VLAN component implementation that conforms to the provisions of this standard for PBB-TE  
12 (25.10) may:

- 13 c) Allow control of all B-VIDs by an external agent, conforming to the Reserved VID values of  
14 Table 9-2.
- 15 d) Support MIP creation and the corresponding CFM extensions for Traffic Engineering service  
16 instances (TESIs) as specified in 26.9.
- 17 e) Support Infrastructure Protection Switching (IPS) as specified in 26.11.

### 18 5.6.3 S-VLAN component requirements for PBB-TE IPS

19 An S-VLAN component implementation that conforms to the provisions of this standard for PBB-TE IPS  
20 (26.11) shall:

- 21 a) Support 1:1 IPS as specified in 26.11.2.

22 An S-VLAN component implementation that conforms to the provisions of this standard for PBB-TE IPS  
23 (26.11) may:

- 24 b) Support M:1 IPS as specified in 26.11.5.

### 25 5.6.4 S-VLAN component requirements for ECMP with flow filtering

26 An S-VLAN component implementation that conforms to the provisions of this standard for ECMP with  
27 flow filtering shall:

- 28 a) Support F-TAG processing as specified in 44.2.2 on each Provider Network Port (PNP).

## 29 5.7 I-component conformance

30 An I-component comprises an S-VLAN component (5.6) with the EISS on each Customer Network Port  
31 (CNP) supported by the use of an S-TAG (6.9, 9.5), and the EISS for each Virtual Instance Port (VIP)  
32 configured on a PIP supported by the use of both an S-TAG (6.9, 9.5) and a Backbone Service Instance tag  
33 (I-TAG) (6.10, 9.5).

34 A conformant implementation of an I-component shall:

- 35 a) Comprise a single conformant S-VLAN component.
- 36 b) Recognize and use I-TAGs on one or more PIPs (6.10).
- 37 c) Support 1:1 mapping between Service VLAN Identifier (S-VID) values and Backbone Service  
38 Instance Identifier (I-SID) values.

- 1 d) Support the `connection_identifier` parameter on the EISS of each VIP (6.10) and in the FDB  
2 (8.8.12).
- 3 e) Support the termination of PBN spanning trees by inhibiting transmission of PBN BPDUs at a PIP.

#### 4 **5.7.1 I-component options**

5 A conformant I-component may implement any of the options specified for an S-VLAN component (5.6.1),  
6 and may:

- 7 a) Support many-to-one mapping from S-VID values to I-SID values.
- 8 b) Support a Common Spanning Tree (CST) among PBNs interconnected with one or more backbone  
9 service instances by permitting transmission of PBN BPDUs through VIPs at a PIP.
- 10 c) Filter frames received at PIPs that have the Backbone Source MAC address (B-SA) used by the PIP,  
11 to prevent such frames from circulating if backbone service instances in two or more attached  
12 PBBNs are configured in a loop.
- 13 d) Use back-to-back Backbone Service Instance Multiplex Entities (6.18) on a PIP to enable  
14 monitoring of backbone service instances with CFM.
- 15 e) Support the Multiple I-SID Registration Protocol (MIRP) defined in 39.1.1.
- 16 f) Support the MVRP Extension MIB module defined in 17.7.15.
- 17 g) Support the MIRP MIB module defined in 17.7.16.

#### 18 **5.8 B-component conformance**

19 A B-component comprises an S-VLAN component with the EISS on each PNP supported by the use of an  
20 S-TAG (6.9, 9.5), and the EISS on each Customer Backbone Port (CBP) supported by the use of both an  
21 S-TAG (6.9, 9.5) and an I-TAG (6.11, 9.5). A conformant implementation of a B-component shall:

- 22 a) Comprise a single conformant S-VLAN component.
- 23 b) Recognize and use I-TAGs on one or more CBPs (6.11).
- 24 c) Terminate PBBN spanning tree by inhibiting transmission of PBBN BPDUs at a CBP.

#### 25 **5.8.1 B-component options**

26 A conformant B-component may implement any of the options specified for an S-VLAN component (5.6.1),  
27 and may:

- 28 a) Translate I-SID values by supporting the Local-SID field in the Backbone Service Instance table in  
29 CBPs (6.11).
- 30 b) Assign B-VID values based on I-SID values by supporting the B-VID field in the Backbone Service  
31 Instance table in CBPs (6.11).
- 32 c) Use the Default Backbone Destination field in the Backbone Service Instance table in CBPs (6.11)  
33 as the destination MAC address for any frames received with the Backbone Service Instance Group  
34 address (26.4).
- 35 d) Use back-to-back Backbone Service Instance Multiplex Entities (6.18) on a CBP to enable  
36 monitoring of backbone service instances with CFM.
- 37 e) Support the MIRP defined in 39.1.2.
- 38 f) Support the MVRP Extension MIB module defined in 17.7.15.
- 39 g) Support the MIRP MIB module defined in 17.7.16.

## 1 5.8.2 B-component requirements for PBB-TE

2 A B-component implementation that conforms to the provisions of this standard for PBB-TE (25.10) shall:

- 3 a) Disable learning for a set of B-VIDs allocated to TE-MSTID as specified in 8.4 and in 8.9.
- 4 b) Discard frames with unregistered destination addresses for B-VIDs allocated to TE-MSTID (8.8.1).
- 5 c) Support the Default Backbone Destination field in the Backbone Service Instance tables on the
- 6 CBPs providing TESI as specified in 6.11.
- 7 d) Support the B-VID field in the Backbone Service Instance tables on the CBPs providing TESI as
- 8 specified in 6.11.
- 9 e) Support the creation of MEPs for the TESI on CBPs as specified in 26.9.
- 10 f) Support 1:1 protection switching as specified in 26.10.3.
- 11 g) Provide control via all of the PBB-TE required managed objects specified in Clause 12.

12 A B-component implementation that conforms to the provisions of this standard for PBB-TE (25.10) may:

- 13 h) Allow control of all B-VIDs by an external agent, conforming to the Reserved VID values of
- 14 Table 9-2.
- 15 i) Support MIP creation and the corresponding CFM extensions for TESI as specified in 26.9.
- 16 j) Support the Hold-Off timer used by the protection switching protocol as specified in 26.10.3.
- 17 k) Support sharing of TESI among TE protection groups in order to provide 1:1 protection switching
- 18 that is capable load sharing as specified in 12.14.1.2 and 25.10.2.
- 19 l) Support the Mismatch defect identification as specified in 26.11.
- 20 m) Support the PBB-TE MIB module defined in Clause 17.
- 21 n) Support IPS as specified in 26.11.

## 22 5.8.3 B-component requirements for PBB-TE IPS

23 A B-component implementation that conforms to the provisions of this standard for PBB-TE IPS (26.11)

24 shall:

- 25 a) Support 1:1 IPS as specified in 26.11.2.

26 A B-component implementation that conforms to the provisions of this standard for PBB-TE IPS (26.11)

27 may:

- 28 b) Support M:1 IPS as specified in 26.11.5.

## 29 5.8.4 B-component requirements for ECMP with flow filtering

30 A B-component implementation that conforms to the provisions of this standard for ECMP with flow

31 filtering shall:

- 32 a) Support F-TAG processing as specified in 44.2.2 on each CBP and PNP.

## 33 5.9 C-VLAN Bridge conformance

34 A C-VLAN Bridge shall comprise a single conformant C-VLAN component (5.5).

35 Each C-VLAN Bridge Port shall be capable of attaching directly to an IEEE 802 LAN.

### 36 5.9.1 C-VLAN Bridge options

37 A C-VLAN Bridge may implement any C-VLAN component option (5.5).

## 1 5.9.2 C-VLAN Bridge requirements for PBBN Auto Attach (optional)

2 A C-VLAN Bridge that conforms to the provisions for PBBN Auto Attach (Clause 50) shall:

- 3 a) Support Link Layer Discovery Protocol (LLDP) transmit and receive mode (IEEE Std 802.1AB™).
- 4 b) Support the PBBN Auto Attach System TLV (D.2.17).
- 5 c) Support the PBBN Auto Attach Assignment TLV (D.2.18).
- 6 d) Support the AAD state machine (50.6).
- 7 e) Support management entities for PBBN Auto Attach as specified in 12.34.

8 A C-VLAN Bridge that conforms to the provisions for PBBN Auto Attach may:

- 9 f) Support SNMP MIB extensions for AAP (17.7.26).
- 10 g) Support SNMP MIB extensions for AAP LLDP TLVs (D.5.6).
- 11 h) Support YANG for AAP LLDP TLVs (D.6.6.7).

## 12 5.10 Provider Bridge conformance

13 A Provider Bridge shall comprise one S-VLAN (5.6) component, zero or more C-VLAN components (5.5),  
14 and zero or more Port-mapping S-VLAN components (5.6).

15 NOTE—The one mandatory S-VLAN component in a Provider Bridge is generally referred to simply as the S-VLAN  
16 component; however, when this component needs to be distinguished from other components in a Provider Bridge  
17 (particularly Port-mapping S-VLAN components), it is sometimes referred to as the “primary S-VLAN component.”

18 Each Port shall be capable of being configured as one of, and may be capable of being configured as any of:

- 19 a) A Provider Network Port (PNP)
- 20 b) A Customer Network Port (CNP)
- 21 c) A Customer Edge Port (CEP)
- 22 d) A Remote Customer Access Port (RCAP)

23 as specified in Clause 15. Each Port configured as a PNP or CNP shall be capable of attaching the S-VLAN  
24 component of the Provider Bridge directly to an IEEE 802 LAN. Each Port configured as a CEP shall be  
25 capable of attaching a C-VLAN component within the Provider Bridge directly to an IEEE 802 LAN. Each  
26 Port configured as an RCAP shall be capable of attaching a Port-mapping S-VLAN component (15.6) within  
27 the Provider Bridge directly to an IEEE 802 LAN.

### 28 5.10.1 S-VLAN Bridge conformance

29 An S-VLAN Bridge shall comprise a single conformant S-VLAN component (5.6). An S-VLAN Bridge  
30 does not have any physical interfaces configured as a CEP or RCAP, nor does it include any C-VLAN  
31 components.

### 32 5.10.2 Provider Edge Bridge conformance

33 A Provider Edge Bridge is a conformant Provider Bridge with a primary S-VLAN component, the capability  
34 to include one or more C-VLAN components as specified in 15.4 and the capability to include zero or more  
35 Port-mapping S-VLAN components as specified in 15.6.

36 Each C-VLAN component shall comprise a single CEP and a single distinct PEP for each service instance  
37 that can be provided through that CEP. Each PEP shall be connected within the Provider Edge Bridge, as  
38 specified in 6.14, to a distinct CNP on the S-VLAN component. Each C-VLAN component shall implement  
39 RSTP, with the enhancements to support CEPs, as specified in 13.41.

1 Each Port-mapping S-VLAN component shall comprise a single RCAP and one or more Provider Access  
2 Ports (PAPs) each associated with one Remote Customer Service Interface (RCSI) provided through that  
3 RCAP. Each PAP shall be connected within the Provider Edge Bridge, as specified in 6.14, to a distinct CNP  
4 on the primary S-VLAN component or CEP on a C-VLAN component. A PNP shall also be provided,  
5 connected internally to a PNP on the primary S-VLAN component as specified in 15.6.

6 NOTE—The single CEP supported by a C-VLAN component and the single RCAP supported by a Port-mapping  
S-VLAN component can be supported by two or more independent instances of a MAC, aggregated as specified by Link  
Aggregation (IEEE Std 802.1AX).

### 9 5.10.3 S-VLAN Bridge requirements for PBBN Auto Attach (optional)

10 An S-VLAN Bridge that conforms to the provisions for PBBN Auto Attach (Clause 50) shall:

- 11 a) Support Link Layer Discovery Protocol (LLDP) transmit and receive mode (IEEE Std 802.1AB).
- 12 b) Support the PBBN Auto Attach System TLV (D.2.17).
- 13 c) Support the PBBN Auto Attach Assignment TLV (D.2.18).
- 14 d) Support the AAD state machine (50.6).
- 15 e) Support management entities for PBBN Auto Attach as specified in 12.34.

16 An S-VLAN Bridge that conforms to the provisions for PBBN Auto Attach may:

- 17 f) Support SNMP MIB extensions for AAP (17.7.26).
- 18 g) Support SNMP MIB extensions for AAP LLDP TLVs (D.5.6).
- 19 h) Support YANG for AAP LLDP TLVs (D.6.6.7).

## 20 5.11 System requirements for Priority-based Flow Control (PFC)

21 A system that conforms to the provisions of this standard for PFC (see Clause 36) shall:

- 22 a) Support, on one or more ports, enabling PFC on at least one priority (36.1.2).
- 23 b) Support, for each PFC Priority, processing PFC M\_CONTROL.requests (36.1.3.1).
- 24 c) Support, for each PFC Priority, processing PFC M\_CONTROL.indications (36.1.3.3).
- 25 d) Abide by the PFC delay constraints (36.1.3.3).
- 26 e) Provide PFC-aware system queue functions (36.2).
- 27 f) Enable use of PFC only in a domain controlled by DCBX (Clause 38).

28 A system that conforms to the provisions of this standard for PFC may:

- 29 g) Support enabling PFC on up to eight priorities per port.
- 30 h) Support the IEEE8021-PFC-MIB (17.7.17).

## 31 5.12 Backbone Edge Bridge (BEB) conformance

32 A BEB system shall comprise zero or more I-components and zero or one B-component and zero or more  
33 T-components, but at least one I-component or one B-component or one T-component, supporting externally  
34 accessible ports as specified in Clause 25. Each externally accessible port shall be designated as one of, and  
35 may be capable of being configured as any of the following:

- 36 a) A PNP
- 37 b) A PIP
- 38 c) A CBP
- 39 d) A CNP
- 40 e) A CEP
- 41 f) An RCAP

### 1 5.12.1 BEB requirements for PBB-TE

2 A BEB that conforms to the provisions of this standard for PBB-TE (25.10) shall comprise one  
3 B-component capable of providing TESIs (5.8.2) and one or more I-components (5.7) or T-components  
4 (5.17)1

### 5 5.12.2 Backbone Edge Bridge requirements for PBBN Auto Attach (optional)

6 An Auto Attach BEB (AAB) shall be a conformant Backbone Edge Bridge (BEB, 5.12) with at least one  
7 I-component (5.7) and shall have one or more C-VLAN components providing externally visible Customer  
8 Edge Ports (CEP) as specified in 50.2.

9 Each externally accessible AAB port that supports PBBN Auto Attach shall:

- 10 a) Support Link Layer Discovery Protocol (LLDP) transmit and receive mode (IEEE Std 802.1AB).
- 11 b) Support the PBBN Auto Attach System TLV (D.2.17).
- 12 c) Support the PBBN Auto Attach Assignment TLV (D.2.18).
- 13 d) Support the C-tagging service interface (50.2.2) and S-tagging service interface (50.2.1).
- 14 e) Support the AAB state machine (50.7).
- 15 f) Support the management entities for PBBN Auto Attach as specified in 12.34.

16 Each externally accessible AAB port that supports PBBN Auto Attach may:

- 17 g) Support the IEEE Std 802.1Q Organizationally Specific Management VID TLV (D.2.6)
- 18 h) Support SNMP MIB extensions for AAP (17.7.26).
- 19 i) Support SNMP MIB extensions for AAP LLDP TLVs (D.5.6).
- 20 j) Support YANG for AAP LLDP TLVs (D.6.6.7).

## 21 5.13 MAC Bridge component requirements

22 An implementation of a VLAN-unaware MAC Bridge component shall:

- 23 a) Conform to the relevant standard for the MAC technology implemented at each Port in support of  
24 the MAC ISS, as specified in IEEE Std 802.1AC.
- 25 b) Support the VLAN-unaware MAC Relay Entity by means of an ISS interface (not an EISS  
26 interface).
- 27 c) Implement an ISO/IEC 8802-2 conformant LLC class with Type 1 operation as required by 8.2.
- 28 d) Maintain the information required to support Basic Filtering Services, as described in  
29 IEEE Std 802.1AC and in 8.1 and specified in 8.5, 8.7, and 8.8.
- 30 e) Conform to the provisions for addressing specified in 8.13.
- 31 f) Implement RSTP, as specified in Clause 13.
- 32 g) Encode transmitted BPDUs and validate received BPDUs as specified in Clause 14.
- 33 h) Specify the following parameters of the implementation:
  - 34 1) Filtering Database Size, the maximum number of entries
  - 35 2) Permanent Database Size, the maximum number of entries
- 36 i) Specify the following performance characteristics of the implementation:
  - 37 1) A Guaranteed Port Filtering Rate for each Bridge Port
  - 38 2) A Guaranteed Bridge Relaying Rate for the Bridge
  - 39 3) The related time intervals  $T_F$  and  $T_R$  for these parameters as specified in Clause 24
- 40 j) Operation of the Bridge within the specified parameters shall not violate any of the other  
41 conformance provisions of this standard.

### 1 5.13.1 MAC Bridge component options

2 An implementation of a MAC Bridge component may:

- 3 a) Support Extended Filtering Services (6.16.5) and the operation of MMRP (10.9) to support  
4 automatic configuration and management of MAC address information on all Ports (5.4.1.3).
- 5 b) Support the management functionality defined in Clause 12.
- 6 c) Support the use of a remote management protocol. Bridges claiming to support remote management  
7 shall:
  - 8 1) State which remote management protocol standard(s) or specification(s) are supported.
  - 9 2) State which standard(s) or specification(s) for managed object definitions and encodings are  
10 supported for use by the remote management protocol.
- 11 d) Support multiple Traffic Classes for relaying and filtering frames through one or more outbound  
12 Ports, controlling the mapping of the priority of forwarded frames as specified in IEEE Std 802.1AC  
13 and 6.9.4.
- 14 e) Allow configuration of the Restricted\_MAC\_Address\_Registration parameter (10.12.2.3) for each  
15 Port of the Bridge.
- 16 f) Support the ISS with signaled priority on each Bridge Port (6.20).
- 17 g) Support SMIv2 MIB modules for the management of MAC Bridge capabilities (Clause 17).
- 18 h) Support YANG modules for the management of MAC Bridge capabilities (Clause 48);
- 19 i) Support CFM operation (5.4.1.4).
- 20 j) Support ETS (5.4.1.6).
- 21 k) Support PFC (5.11).
- 22 l) Support DCBX (5.4.1.7).
- 23 m) Support the enhancements for scheduled traffic as specified in 8.6.8.4.
- 24 n) Support the state machines for scheduled traffic as specified in 8.6.9.
- 25 o) Support frame preemption as specified in 6.7.1, 6.7.2, and 8.6.8.

#### 26 5.13.1.1 Per-Stream Filtering and Policing (PSFP) requirements

27 A MAC Bridge component implementation that conforms to the provisions of this standard for PSFP shall:

- 28 a) Support PSFP as specified in 8.6.5.2 and 8.6.6.
- 29 b) Support the state machines for stream gate control as specified in 8.6.10.
- 30 c) Support the management entities for PSFP as specified in 12.31.

#### 31 5.13.1.2 Cyclic queuing and forwarding requirements

32 A MAC Bridge component implementation that conforms to the provisions of this standard for CQF (see  
33 Annex T) shall:

- 34 a) Support the enhancements for scheduled traffic as specified in 8.6.8.4.
- 35 b) Support the state machines for scheduled traffic as specified in 8.6.9.
- 36 c) Support the state machines for stream gate control as specified in 8.6.10.
- 37 d) Support the management entities for scheduled traffic as specified in 12.29.
- 38 e) Support the requirements for PSFP as stated in 5.13.1.1.
- 39 f) Support the management entities for PSFP as specified in 12.31.

### 1 5.13.1.3 Asynchronous Traffic Shaping (ATS) requirements

2 A MAC Bridge component implementation that conforms to the provisions of this standard for ATS shall:

- 3 a) Support per-stream classification and metering for ATS as specified in 8.6.5.2.2.
- 4 b) Support queuing with support for stream gates as specified in 8.6.6 items d) and e).
- 5 c) Support the ATS transmission selection algorithm as specified in 8.6.8.5.
- 6 d) Support the ATS scheduler state machines as specified in 8.6.11.
- 7 e) Support the management entities for ATS as specified in 12.31.

### 8 5.14 MAC Bridge conformance

9 A MAC Bridge shall comprise a single conformant MAC Bridge component (5.13).

10 Each Bridge Port shall be capable of attaching directly to an IEEE 802 LAN.

#### 11 5.14.1 MAC Bridge options

12 A MAC Bridge may implement any MAC Bridge component option (5.13.1).

#### 13 5.14.2 MAC Bridge requirements for PBBN Auto Attach (optional)

14 A MAC Bridge that conforms to the provisions for PBBN Auto Attach (Clause 50) shall:

- 15 a) Support Link Layer Discovery Protocol (LLDP) transmit and receive mode (IEEE Std 802.1AB).
- 16 b) Support the PBBN Auto Attach System TLV (D.2.17).
- 17 c) Support the PBBN Auto Attach Assignment TLV (D.2.18).
- 18 d) Support the AAD state machine (50.6).
- 19 e) Support the management entities for PBBN Auto Attach as specified in 12.34.

20 A MAC Bridge that conforms to the provisions for PBBN Auto Attach may:

- 21 f) Support SNMP MIB extensions for AAP (17.7.26).
- 22 g) Support SNMP MIB extensions for AAP LLDP TLVs (D.5.6).
- 23 h) Support YANG for AAP LLDP TLVs (D.6.6.7).

### 24 5.15 TPMR component conformance

25 A TPMR component comprises a MAC Bridge component. A conformant implementation of a TPMR  
26 component shall:

- 27 a) Support exactly two Bridge Ports other than a Management Port.
- 28 b) Support the operation of the following functions of the Forwarding Process:
  - 29 1) Frame filtering (8.6.3)
  - 30 2) Queuing frames (8.6.6)
  - 31 3) Transmission selection (8.6.8)
- 32 c) Support the operation of the MAC Status Propagation Entity (MSPE), by means of the functions and  
33 protocol specified in Clause 23.
- 34 d) Support at least one traffic class on each Bridge Port.
- 35 e) Support the management functionality specified in 12.19.
- 36 f) Support only the following entries in the FDB:

- 1) Static Filtering Entries, permanently configured in the FDB and that cannot be modified by management, that specify filtering on both of the TPMR's Bridge Ports for the group MAC addresses defined in Table 8-3.
  - 2) A Static Filtering Entry, permanently configured in the FDB and that cannot be modified by management, that specifies forwarding or filtering on each of the TPMR's Bridge Ports for the MAC address associated with the management entity of the TPMR. The values that are configured into this filtering entry are determined by the implementer, and shall be stated in the PICS.
- g) Support a MIP on an MA that is not associated with any VLAN on each of the TPMR's Bridge Ports. The default MD level shall be zero.
- NOTE—As a TPMR is a non-VLAN-aware Bridge, these MPs are not associated with a particular VID (22.1.7). This default level 0 MIP allows detection and identification of the TPMR without configuration. Such a MIP can of course be disabled by management.

A conformant implementation of a TPMR component shall not:

- h) Implement RSTP defined in Clause 13.
- i) Encode transmitted BPDUs and validate received BPDUs (Clause 14).
- j) Support Extended Filtering Services for relaying and filtering frames (6.16.5).

#### 5.15.1 TPMR component options

An implementation of a TPMR component may:

- a) Support multiple traffic classes on each Bridge Port.
- b) Support the ISS with signaled priority on each Bridge Port (6.20).

#### 5.16 TPMR conformance

An implementation of a TPMR shall:

- a) Comprise a single conformant TPMR component (5.15).
- b) Support exactly two externally accessible Ports, each capable of attaching directly to an IEEE 802 LAN.
- c) Be capable of supporting a management entity using the TPMR Port Connectivity (8.5.2) on one of its externally accessible ports.
- d) Support remote management of the TPMR managed objects specified in 12.19.

##### 5.16.1 TPMR options

A TPMR may implement any TPMR component option (5.15.1).

An implementation of a TPMR may:

- a) Support a management entity using the Bridge Port Connectivity (8.5.1) on a Management Port (8.3) or the externally accessible ports.
- b) Support remote management using Simple Network Management Protocol (SNMP) over IEEE 802 Networks (IETF RFC 4789, 8.13.7).  
NOTE—While IETF RFC 4789 is specifically referenced, the standard does not preclude the support of other transports for SNMP.
- c) Support remote management using the TPMR MIB module defined in 17.7.11.
- d) Support remote management using the TPMR YANG modules defined in 48.3.2.

## 1 5.17 T-component conformance

2 A T-component comprises a TPMR component (5.15) with one PIP (6.11).

3 A conformant implementation of an T-component shall:

- 4 a) Comprise a single conformant TPMR component.
- 5 b) Recognize and use I-TAGs on one PIP (6.10).
- 6 c) Support a single VIP at the PIP.

### 7 5.17.1 T-component options

8 A conformant T-component may implement any of the options specified for a TPMR component (5.15.1).

## 9 5.18 End station requirements for MMRP, MVRP, and MSRP

10 This subclause defines the conformance requirements for end station implementations claiming  
11 conformance to MVRP, MMRP, and MSRP. Although this standard is principally concerned with defining  
12 the requirements for VLAN Bridges, the conformance requirements for end station implementations of  
13 MVRP, MMRP, and MSRP are included in order to give guidance to such implementations. The PICS  
14 proforma defined in Annex B is concerned with conformance claims with respect to end station  
15 implementations.

16 For the reasons stated in 10.6, it is recommended that end stations that do not require the ability to perform  
17 Source Pruning implement the Applicant-Only Participant, in preference to the Simple-Applicant  
18 Participant.

### 19 5.18.1 MMRP requirements and options

20 An end station for which conformance to MMRP is claimed shall:

- 21 a) Conform to the operation of the MRP Applicant, Registrar, LeaveAll, and Periodic Transmission  
22 state machines, as defined in 10.7.7, 10.7.8, 10.7.9, and 10.7.10, as required for one or more of the  
23 following variants of the MRP Participant, as defined in 10.6 and 10.7:
  - 24 1) The Full Participant
  - 25 2) The Full Participant, point-to-point subset
  - 26 3) The Applicant-Only Participant
  - 27 4) The Simple-Applicant Participant
- 28 b) Exchange MPDUs as required by the MRP state machine(s) implemented, formatted in accordance  
29 with the generic PDU format described in 10.8, and able to carry application-specific information as  
30 defined in 10.12.1, using the “Individual LAN Scope group address, Nearest Bridge group address”  
31 as defined in Table 8-1, Table 8-2, and Table 8-3 (C-VLAN and MAC Bridge, S-VLAN, and TPMR  
32 component Reserved addresses, respectively).

33 An end station for which conformance to the operation of the Applicant state machine (10.7.7) is claimed  
34 may:

- 35 c) Perform source pruning, as defined in 10.10.3 and 10.12.

36 It is recommended that only those end stations that require the ability to perform Source Pruning (10.10.3)  
37 conform to the operation of the Full Participant or the Full Participant, point-to-point subset.

38 NOTE—If an end station does not require the ability to perform Source Pruning, then there is no need for it to  
39 implement Registrar functionality.

## 1 5.18.2 MVRP requirements and options

2 An end station for which conformance to MVRP is claimed shall:

- 3 a) Conform to the operation of the MRP Applicant, Registrar, LeaveAll, and Periodic Transmission  
4 state machines, as defined in 10.7.7, 10.7.8, 10.7.9, and 10.7.10, as required for one or more of the  
5 following variants of the MRP Participant, as defined in 10.6 and 10.7:
  - 6 1) The Full Participant
  - 7 2) The Full Participant, point-to-point subset
  - 8 3) The Applicant-Only Participant
  - 9 4) The Simple-Applicant Participant
- 10 b) Exchange MPDUs as required by the MRP state machine(s) implemented, formatted in accordance  
11 with the generic PDU format described in 10.8, and able to carry application-specific information as  
12 defined in 11.2.3, using the MVRP Application address as defined in Table 10-1.

13 An end station for which conformance to MVRP is claimed may:

- 14 c) Perform source pruning, as defined in 10.10.3 and 11.2.1.1.

15 It is recommended that only those end stations that require the ability to perform Source Pruning (11.2.1.1)  
16 conform to the operation of the Full Participant or the Full Participant, point-to-point subset.

17 NOTE—If an end station does not require the ability to perform Source Pruning, then there is no need for it to  
18 implement Registrar functionality.

- 19 d) Support the operation of MVRP (5.4.2, 11.2) as a New-Only Participant.
- 20 e) Support the MVRP Extension MIB module defined in 17.7.15.

## 21 5.18.3 MSRP requirements and options

22 An end station for which conformance to MSRP is claimed shall:

- 23 a) Conform to the operation of the MRP Applicant, Registrar, and LeaveAll state machines, as defined  
24 in 10.7.7, 10.7.8, and 10.7.9, as required for one or more of the following variants of the MRP  
25 Participant, as defined in 10.6 and 10.7:
  - 26 1) The Full Participant
  - 27 2) The Full Participant, point-to-point subset
  - 28 3) The Applicant-Only Participant
  - 29 4) The Simple-Applicant Participant
- 30 b) Exchange MPDUs as required by the MRP state machine(s) implemented, formatted in accordance  
31 with the generic PDU format described in 10.8, and able to carry application-specific information as  
32 defined in 35.2.2, using the “Individual LAN Scope group address, Nearest Bridge group address”  
33 as defined in Table 8-1, Table 8-2, and Table 8-3 (C-VLAN, S-VLAN, and TPMR component  
34 Reserved addresses, respectively).
- 35 c) Not redeclare its attributes unless responding to a LeaveAll event.

36 An end station for which conformance to the operation of the Applicant state machine (10.7.7) is claimed  
37 may:

- 38 d) Perform Talker pruning, as defined in 35.2.1.4(b), 35.2.3.1, and 35.2.4.3.2.
- 39 e) Perform Listener pruning as described in 35.2.3.1.

40 NOTE—In order to meet the requirement specified in 5.18.3(c), the Periodic Transmission state machine (10.7.10) is  
41 specifically excluded from MSRP. An end station is allowed to generate an MSRP LeaveAll event to force an immediate  
42 redeclaration of all MSRP attributes from its neighbor(s).

## 1 5.19 VLAN-aware end station requirements for CFM

2 A VLAN-aware Station implementation that conforms to the provisions of this standard for CFM (Clause 18  
3 through Clause 22) shall:

- 4 a) Support the creation of Maintenance Domains at eight MD Levels, with multiple nonoverlapping  
5 Maintenance Domains at each MD Level, using the managed objects specified in 12.14.
- 6 b) Support the creation of an MA on each VID supported by the Station for each MD Level.
- 7 c) Support the creation of eight Down MEPs on each VID on each Port, each MEP at a different MD  
8 Level.
- 9 d) Support the creation of eight Down MEPs attached to no VID on each Port, each MEP at a different  
10 MD Level.
- 11 e) Support the maintenance of a MEP CCM Database.
- 12 f) Provide control via all of the required managed objects specified in 12.14.
- 13 g) Conform to the state machines and procedures in Clause 20.
- 14 h) Transmit and receive required CFM PDUs in the formats specified in Clause 21.

15 A VLAN-aware Station implementation that conforms to the provisions of this standard for CFM may:

- 16 i) Support the CFM MIB module defined in 17.5.
- 17 j) Support the CFM YANG modules defined in Clause 48.
- 18 k) Support the creation of MAs that are associated with more than one VID (22.1.5).

## 19 5.20 End station requirements—FQTSS

20 An end station implementation that conforms to the provisions of this standard for FQTSS shall:

- 21 a) Support a minimum of two traffic classes on all Ports, of which:
  - 22 1) A minimum of one traffic class supports the strict priority algorithm for transmission selection  
23 (8.6.8.1), and
  - 24 2) One traffic class is an SR class.
- 25 b) Support the operation of the credit-based shaper algorithm (8.6.8.2) as the transmission selection  
26 algorithm used for frames transmitted for each stream associated with the SR class.
- 27 c) Support the operation of the credit-based shaper algorithm (8.6.8.2) on all Ports as the transmission  
28 selection algorithm used for the SR class.
- 29 d) Use the default priority associated with SR class “B” as shown in Table 6-5 as the priority value  
30 carried in transmitted SR class “B” data frames.

31 An end station implementation that conforms to the provisions of this standard for FQTSS may:

- 32 e) Support two or more SR classes (a maximum of seven), and support the operation of the  
33 credit-based shaper algorithm (8.6.8.2) on all Ports as the transmission selection algorithm used for  
34 those SR classes. The number of SR classes supported shall be stated in the PICS.
- 35 f) Use the default priority associated with SR class “A” as shown in Table 6-5 as the priority value  
36 carried in transmitted SR class “A” data frames. If more than two SR classes are supported, the  
37 priority value carried in transmitted data frames for the additional SR classes shall be stated in the  
38 PICS.

## 1 5.21 End station requirements for congestion notification

2 A VLAN-aware end station implementation that conforms to the provisions of this standard for congestion  
3 notification (Clause 30 through Clause 33) shall:

- 4 a) Support the creation of at least one Reaction Point (RP) (31.2.2.2).
- 5 b) Support, if CPs are supported, the ability to configure the variables controlling the operation of each  
6 CP, if any (12.21.1, 12.21.2, 12.21.3, 12.21.4).
- 7 c) Support, at each supported CP, if any, the generation of CNMs (32.7).
- 8 d) Support the ability to configure the variables controlling the operation of each RP (12.21.1, 12.21.5,  
9 12.21.6).
- 10 e) Support the operation of its Port in at least the `cptDisabled` and `cptInterior` CND defense modes  
11 separately for each CNPV (32.1.1).
- 12 f) Conform to the required specifications of the LLDP of IEEE Std 802.1AB.
- 13 g) Support the use of the Congestion Notification TLV in LLDP (32.1.1).
- 14 h) Support, in each RP, the limiting of frames output in response to the reception of CNMs (31.2.2.2).
- 15 i) Support, if multiple RPs are supported, the ability to distinguish among CNMs pertaining to  
16 different RPs, and direct each such message to the correct RP (31.2.5).

17 A VLAN-aware end station implementation that conforms to the provisions of this standard for congestion  
18 notification (Clause 30 through Clause 33) may:

- 19 j) Support the creation of one or more CPs (31.1.1).
- 20 k) Support the creation of more than one RP (31.2.2.2).
- 21 l) Support more than one CNPV per RP (31.2.1).
- 22 m) Support the operation of its Port in both the `cptInterior` and `cptInteriorReady` CND defense modes  
23 separately for each CNPV (31.1.1).
- 24 n) Support the IEEE8021-MIRP-MIB (17.7.13).

## 25 5.22 MAC-specific bridging methods

26 MAC-specific bridging methods may exist. Use of a MAC-specific bridging method and the method  
27 specified in this standard on the same LAN shall:

- 28 a) Not prevent communication between stations in a network.
- 29 b) Preserve the MAC Service.
- 30 c) Preserve the characteristics of each bridging method within its own domain.
- 31 d) Provide for the ability of both bridging techniques to coexist simultaneously on a LAN without  
32 adverse interaction.

## 33 5.23 EVB Bridge requirements

34 An EVB Bridge shall comprise a single conformant C-VLAN component (5.5) and zero or one  
35 Port-mapping S-VLAN component (5.6) per externally accessible port.

36 Each externally accessible port shall be capable of being configured as one of, and may be capable of being  
37 configured as any of the following:

- 38 a) A C-VLAN Bridge Port
- 39 b) A Station-facing Bridge Port (SBP)

1 c) An Uplink Access Port (UAP)

2 as specified in Clause 40.

3 A conformant EVB Bridge implementation shall:

4 d) Support the functionality of a C-VLAN component (5.5).

5 e) Support at least one SBP on the C-VLAN component (Clause 40).

6 f) Support the EVB status parameters for EVBMode = EVB Bridge (40.4).

7 g) Support an LLDP nearest Customer Bridge database (Clause 40).

8 h) Support the EVB TLV on each SBP (D.2.12).

9 i) Support Edge Control Protocol (ECP) on each SBP (Clause 43).

10 j) Support the Bridge role of Virtual Station Interface (VSI) Discovery and Configuration Protocol  
11 (VDP) on each SBP (Clause 41).

12 A conformant EVB Bridge may support S-channels. A conformant EVB Bridge with S-channel support  
13 shall:

14 k) Support at least one Port-mapping S-VLAN component (22.6.4) and associated UAP, configured as  
15 specified in 40.2 a)–d).

16 l) Support S-channel Discovery and Configuration Protocol (CDCP), as specified in Clause 42,  
17 operating in Bridge mode.

18 m) Support the enhanced filtering utility criteria (8.7.2) and not support the default filtering utility  
19 criteria (8.7.1).

20 A conformant EVB Bridge implementation may:

21 n) Support configuration of reflective relay on each SBP of the C-VLAN component (8.6.1).

22 o) Support management for the EVB components (12.4–12.12, 12.26).

23 p) Support the MIB module defined in 17.7.20.

24 q) Support assignment of VIDs to GroupIDs (41.2.9).

25 r) Support the use of the M and S bits in VDP (41.2.3).

## 26 5.24 EVB station requirements

27 An EVB station shall comprise one or more conformant ERs (5.24.1) and zero or one Port-mapping  
28 S-VLAN component (5.6) per externally accessible port.

29 Each externally accessible port shall be capable of being configured as one of, and may be capable of being  
30 configured as any of the following:

31 a) An Uplink Access Port (UAP)

32 b) An uplink relay port (URP)

33 as specified in Clause 40.

34 Each downlink relay port (DRP) shall be capable of attaching to one or more VSIs.

35 Each URP shall be capable of attaching its ER to the LAN connecting to an EVB Bridge, or in the  
36 case where a Port-mapping S-VLAN component is present, to an internal LAN (6.14) connecting the URP  
37 to a S-channel Access Port (CAP).

38 A conformant EVB station implementation shall:

39 c) Support at least one ER (5.24.1, Clause 40).

40 d) Support the EVB status parameters for EVBMode = EVB station on each URP (40.4).

- 1 e) Support an LLDP nearest Customer Bridge database (Clause 40).
- 2 f) Support the EVB TLV on each URP of each ER (D.2.12).
- 3 g) Support ECP on each URP of each ER (Clause 43).
- 4 h) Support the station role of VDP for each URP of each ER (Clause 41).

5 In addition, a conformant EVB station implementation that supports a Port-mapping S-VLAN components  
6 shall:

- 7 i) Support a Port-mapping S-VLAN component (22.6.4) on each port configured as a UAP (40.2)  
8 configured as specified in 40.2 (a)–(d).
- 9 j) Support CDCP, as specified in Clause 42, operating in Station mode.
- 10 k) Support the enhanced filtering utility criteria (8.7.2) and not support the default filtering utility  
11 criteria (8.7.1).

12 A conformant EVB station implementation may:

- 13 l) Support multiple ERs (Clause 40).
- 14 m) Support management for the EVB components (12.4–12.12, 12.26).
- 15 n) Support the MIB module defined in 17.7.20.
- 16 o) Support assignment of VIDs to GroupIDs (41.2.9).
- 17 p) Support the use of the M and S bits in VDP (41.2.3).

#### 18 5.24.1 Edge relay (ER) requirements

19 A conformant implementation of an ER shall:

- 20 a) Conform to the relevant standard for the MAC technology implemented at each Port in support of  
21 the MAC ISS, as specified in IEEE Std 802.1AC and 6.14.
- 22 b) Support the MAC EISS at each Port, as specified in 6.8 and 6.9.
- 23 c) Recognize and use C-TAGs (6.9).
- 24 d) Relay and filter frames as described in 8.1 and specified in 8.5, 8.6, and 8.8.
- 25 e) Support the following on each DRP Port that supports untagged and priority-tagged frames:  
26 1) A PVID value (6.9)  
27 2) Configuration of at least one VID whose untagged set includes that Port (8.8.2)
- 28 f) Support setting the Acceptable Frame Types parameter (6.9) to *Admit Only VLAN-tagged Frames* on  
29 the URP.
- 30 g) Allow tag headers to be inserted, modified, and removed from relayed frames, as specified in 8.1  
31 and Clause 9, as required by the value(s) of the Acceptable Frame Types parameter supported on  
32 each Port, and by the ability of each Port to transmit VLAN-tagged and/or untagged frames.
- 33 h) Support at least one FID (IEEE Std 802.1AC, 8.8.3, 8.8.8, and 8.8.9).
- 34 i) Allow allocation of at least one VID to each FID that is supported (IEEE Std 802.1AC, 8.8.3, 8.8.8,  
35 and 8.8.9).
- 36 j) Support exactly one URP (Clause 40) supporting the parameters of 40.4 for EVBMode = EVB  
37 station.
- 38 k) Support one or more DRPs each supporting access to VSIs (Clause 40).
- 39 l) Filter the reserved MAC addresses specified in Table 8-1.
- 40 m) If more than one DRP is supported, support setting the Enable Ingress Filtering parameter (8.6.2) on  
41 each DRP and the URP.
- 42 n) Support the requirements of either a virtual edge bridge (VEB) ER (5.24.1.1) or a virtual edge port  
43 aggregator (VEPA) ER (5.24.1.2).

1 A conformant implementation of an ER may:

- 2 o) Support the following if the URP supports untagged and priority-tagged frames:
  - 3 1) A PVID value (6.9)
  - 4 2) Configuration of at least one VID whose untagged set includes that Port (8.8.2)
- 5 p) Comprise a single conformant C-VLAN component (5.4).
- 6 q) Support disabling of learning on each DRP (8.6.1).
- 7 r) Support the ability to discard frames received at each DRP if there is no entry in the FDB that
- 8 specifies forwarding on that Port for the frame's source MAC address and VLAN.
- 9 s) Support the operation of the learning process as described in 8.7.

#### 10 **5.24.1.1 VEB ER requirements**

11 In addition to the requirements stated in 5.24.1, a conformant VEB ER implementation shall:

- 12 a) Request that reflective relay service not be provided by setting adminReflectiveRelayRequest to
- 13 FALSE (40.4).

#### 14 **5.24.1.2 VEPA ER requirements**

15 In addition to the requirements stated in 5.24.1, a conformant VEPA ER implementation shall:

- 16 a) Disable learning on the URP (8.6.1).
- 17 b) Filter frames as specified in 8.6.3.1.

18 A conformant VEPA ER implementation may:

- 19 c) Filter frames received at each DRP that are destined for the URP until reflective relay is enabled
- 20 (40.4).

21 A conformant VEPA ER implementation should:

- 22 d) Request the provision of reflective relay service by setting adminReflectiveRelayRequest to TRUE
- 23 (40.4).

24 NOTE—This item is optional because there can be cases where an EVB station is configured to prohibit VSIs

25 from communicating with each other in VEPA mode.

### 26 **5.25 End station requirements—enhancements for scheduled traffic**

27 An end station implementation that conforms to the provisions of this standard for enhancements for

28 scheduled traffic shall:

- 29 a) Support the enhancements for scheduled traffic as specified in 8.6.8.4.
- 30 b) Support the state machines for scheduled traffic as specified in 8.6.9.

## 1 5.26 End station requirements—enhancements for frame preemption

2 An end station implementation that conforms to the provisions of this standard for frame preemption shall:

- 3 a) Support the provisions of 6.7.1, 6.7.2, and 8.6.8.

## 4 5.27 End station requirements—PSFP

5 An end-station implementation that conforms to the provisions of this standard for PSFP shall:

- 6 a) Support PSFP as specified in 8.6.5.2.1 and 8.6.6.  
7 b) Support the state machines for stream gate control as specified in 8.6.10.  
8 c) Support the management entities for PSFP as specified in 12.31.

## 9 5.28 End station requirements—Cyclic queuing and forwarding

10 An end station implementation that conforms to the provisions of this standard for CQF (see Annex T) shall:

- 11 a) Support the enhancements for scheduled traffic as specified in 8.6.8.4.  
12 b) Support the state machines for scheduled traffic as specified in .  
13 c) Support the state machines for stream gate control as specified in 8.6.10.  
14 d) Support the management entities for scheduled traffic as specified in 12.29.  
15 e) Support the requirements for PSFP as stated in 5.27.  
16 f) Support the management entities for PSFP as specified in 12.31.

## 17 5.29 TSN CNC station requirements

18 This subclause (5.29) defines the conformance requirements for a station that supports the Time-Sensitive  
19 Networking (TSN) Centralized Network Configuration (CNC) requirements (46.1.3). The TSN CNC station  
20 component is implemented within an end station or Bridge.

21 A TSN CNC station implementation that conforms to the provisions of this standard shall:

- 22 a) Support the use of a remote management protocol. The TSN CNC claiming to support remote  
23 management shall state the following:  
24 1) Which remote management protocol standard(s) or specification(s) are supported for the client  
25 implementation.  
26 2) Which standard(s) or specification(s) for managed object definitions and encodings are  
27 supported for use by the remote management protocol.  
28 b) Support the managed object definitions and encodings for Stream reservation remote management  
29 (12.32).  
30 c) Support the use of at least one protocol for User/network configuration information that complies  
31 with the requirements for protocol integration defined in 46.2. The TSN CNC shall state which  
32 User/network configuration information protocol standard(s) or specification(s) are supported.  
33 d) If SRP (Clause 35) is supported by the TSN CNC for the User/network configuration information,  
34 the TSN CNC shall support MRP External Control (12.32.4).

35 A TSN CNC station implementation that conforms to the provisions of this standard may:

- 36 e) Use the YANG modules identified in 46.3.

### 1 5.30 VDP-NVO3 requirements

2 In the Split-NVE scenario, the nNVE implements the bridge role VDP and tNVE implements the station role  
3 VDP. While the nNVE and tNVE share the VDP functionality of an EVB Bridge and an EVB Station, their  
4 conformance requirements are different. This clause lists the conformance requirements for nNVE and  
5 tNVE to operate VDP in the Split-NVE scenario.

#### 6 5.30.1 VDP-NVO3 nNVE requirements

7 A conformant VDP-NVO3 nNVE implementation shall:

- 8 a) Support the Bridge role of VDP on each SBP (Clause 41).
- 9 b) Support assignment of VIDs to GroupIDs (41.2.9).

10 A conformant VDP-NVO3 nNVE implementation may:

- 11 c) Support the functionality of a C-VLAN component (5.5).
- 12 d) Support at least one SBP on the C-VLAN component (Clause 40).
- 13 e) Support an LLDP nearest Customer Bridge database (Clause 40).
- 14 f) Support the EVB status parameters for EVBMode = NVO3 Mode (40.4.4) and NVERole = nNVE  
15 (40.5.1).
- 16 g) Support the EVB Bridge status parameters about IPv4 and IPv6 address capability (D.2.12.3).
- 17 h) Support the EVB TLV on each SBP (D.2.12).
- 18 i) Support ECP on each SBP (Clause 43).
- 19 j) Support the use of the M, S, and N bits in VDP (41.2.3).
- 20 k) Support the use of IP addresses in VDP filter info format (41.2.9).

#### 21 5.30.2 VDP-NVO3 tNVE requirements

22 A conformant VDP-NVO3 tNVE implementation shall:

- 23 a) Support the station role of VDP for each URP (Clause 41).
- 24 b) Support assignment of VIDs to GroupIDs (41.2.9).

25 A conformant VDP-NVO3 tNVE implementation may:

- 26 c) Support one ER (5.24.1, Clause 40).
- 27 d) Support an LLDP nearest Customer Bridge database (Clause 40).
- 28 e) Support the EVB status parameters for EVBMode = NVO3 Mode (40.4.4) and NVERole = tNVE  
29 (40.5.2).
- 30 f) Support the EVB station status parameters about IPv4 and IPv6 address capability (D.2.12.4).
- 31 g) Support the EVB TLV on each URP (D.2.12).
- 32 h) Support ECP on each URP (Clause 43).
- 33 i) Support the use of the M, S, and N bits in VDP (41.2.3).
- 34 j) Support the use of IP addresses in VDP filter info format (41.2.9)

### 35 5.31 End station requirements—ATS

36 An end station implementation that conforms to the provisions of this standard for ATS shall:

- 37 a) Support a minimum of two traffic classes, of which:
  - 38 1) One traffic class supports the strict priority transmission selection algorithm (8.6.8.1) and
  - 39 2) One traffic class supports the ATS transmission selection algorithm (8.6.8.5).
- 40 b) Support the ATS talker transmission behavior, as specified in 47.1.

### 1 5.32 End station requirements for congestion isolation

2 An end station implementation that conforms to the provisions of this standard for congestion isolation in  
3 Clause 49 shall

- 4 a) Support Explicit Congestion Notification (ECN) as defined by IETF RFC 3168 and associated  
5 updates along with Active Queue Management (AQM) as described in 49.2.1.
- 6 b) Support, at each Congestion Isolation Point, the variables and procedures of the Congestion  
7 Isolation Protocol (49.4).
- 8 c) Conform to the required capabilities of IEEE Std 802.1AB.
- 9 d) Support the use of the Congestion Isolation TLV in LLDP (D.2.15).

10 An end station implementation that conforms to the provisions of this standard for congestion isolation in  
11 Clause 49 may

- 12 e) Support transmission selection algorithms other than strict priority.
- 13 f) Support the de-isolation of congesting flows by means other than the empty status of a congesting  
14 queue (49.2.6).
- 15 g) Support the Congestion Isolation YANG model (48.3.8).
- 16 h) Support non-relay end station or server functionality of Topology Recognition (49.5).

### 17 5.33 End station requirements for PBBN Auto Attach (optional)

18 An end station that conforms to the provisions for PBBN Auto Attach (Clause 50) shall:

- 19 a) Support Link Layer Discovery Protocol (LLDP) transmit and receive mode (IEEE Std 802.1AB).
- 20 b) Support the PBBN Auto Attach System TLV (D.2.17).
- 21 c) Support the PBBN Auto Attach Assignment TLV (D.2.18).
- 22 d) Support the AAD state machine (50.6).
- 23 e) Support the management entities for PBBN Auto Attach as specified in 12.34.

24 An end station implementation that conforms to the provisions for PBBN Auto Attach may:

- 25 f) Support SNMP MIB extensions for AAP (17.7.26).
- 26 g) Support SNMP MIB extensions for AAP LLDP TLVs (D.5.6).
- 27 h) Support YANG for AAP LLDP TLVs (D.6.6.7).

28

## 6. Support of the MAC Service

[MAC Bridges and](#) VLAN Bridges interconnect the separate IEEE 802 LANs that compose a Virtual Bridged Network by relaying and filtering frames between the separate MACs of the bridged LANs.

The position of [a MAC Bridge’s VLAN-unaware MAC Relay Entity and of a](#) VLAN Bridge’s MAC Relay Entity (8.2) within the MAC Sublayer is shown in Figure 6-1.

NOTE—The notation IEEE Std 802.n in this figure indicates that the specifications for these functions can be found in the relevant standard for the media access method concerned; for example, n would be 3 (IEEE Std 802.3) in the case of Ethernet.

**Figure 6-1—Internal organization of the MAC sublayer**

The MAC Sublayer comprises:

- a) Media access method-specific functions<sup>23</sup> that realize transmission and reception of MAC Protocol Data Units (MPDUs).
- b) Media access method-dependent convergence functions that use item a) to provide a media access method-independent service.

<sup>23</sup> The media access method-specific functions that realize a MAC Service for use in end stations are specified for each IEEE 802 LAN media access control method or “MAC type” (e.g., IEEE 802.3, IEEE 802.11) by the relevant standard for that media access control method and are commonly referred to as “the MAC.” The media access method-dependent convergence functions are specified in IEEE Std 802.1AC.

- 1 c) Media access method-independent functions that use a media-independent service to provide the  
2 same or another media-independent service.

3 A MAC Bridge's MAC Relay Entity forwards frames between the instances of the media-independent ISS  
4 (IEEE Std 802.1AC).

5 A VLAN Bridge's MAC Relay Entity forwards frames between the instances of the media-independent  
6 EISS (6.8). The EISS is provided by the functions specified in 6.9 using the media-independent ISS  
7 (IEEE Std 802.1AC). The convergence functions that provide the ISS using the media-specific functions for  
8 each IEEE 802 LAN MAC type are specified in IEEE Std 802.1AC.

9 This clause:

- 10 a) Summarizes basic architectural concepts and terms used throughout this standard, introduces the  
11 primitives and parameters of the MAC Service, and defines VLANs in terms of the connectivity  
12 provided to service users (IEEE Std 802.1AC, 6.2, 6.3).  
13 b) Describes how Bridges preserve and maintain the quality of the MAC Service (6.4, 6.5).  
14 c) Specifies the MAC ISS and MAC status parameters, their support by specific media access methods  
15 (IEEE Std 802.1AC), and support for signaled priority (IEEE Std 802.1AC, 6.14, 6.15, 6.20).  
16 d) Specifies the EISS used by VLAN-aware stations, the encoding of VID and priority parameters in  
17 transmitted frames, and the classification of received frames that do not explicitly convey those  
18 parameters (6.8, 6.9, 6.12).  
19 e) Specifies how entities defined in terms of the ISS can support the EISS (6.17).

## 20 6.1 Basic architectural concepts and terms

21 The architectural concepts used in this and other IEEE 802.1 standards are based on the layered protocol  
22 model introduced by the OSI Reference Model (ISO/IEC 7498-1) and used in the MAC Service definition  
23 (IEEE Std 802.1AC), in IEEE Std 802, in other IEEE 802 standards, and elsewhere in networking.  
24 IEEE 802.1 standards in particular have developed terms and distinctions useful in describing the MAC  
25 Service and its support by protocol entities within the MAC Sublayer.<sup>24</sup> For further detailed discussion of  
26 these concepts and terms, see IEEE Std 802.1AC.

## 27 6.2 Provision of the MAC Service

28 The MAC Service provided in end stations attached to MAC Bridged Networks and Virtual Bridged  
29 Networks is the (unconfirmed) connectionless mode MAC Service defined in IEEE Std 802.1AC. The MAC  
30 Service is defined as an abstraction of the features common to a number of specific MAC Services; it  
31 describes the transfer of user data between source and destination end stations, via MA-UNITDATA request  
32 primitives and corresponding MA-UNITDATA indication primitives issued at MAC Service Access Points  
33 (MSAPs). Each MA-UNITDATA request and indication primitive has four parameters: Destination Address,  
34 Source Address, MAC Service data unit (MSDU), and Priority.

35 NOTE 1—The primitives of the MAC Service are closely aligned with those of the ISS (IEEE Std 802.1AC).

36 In a MAC Bridged Network, MAC Bridges provide a single instance of the MAC Service for the network as  
37 a whole—a single LAN, as defined in IEEE Std 802.1AC—by forwarding between the individual LANs that  
38 compose the network, though frames with specified group destination addresses are confined to individual  
39 LANs.

40 NOTE 2—MAC Bridges can be configured to completely partition a bridged network, though that is rarely intended.

<sup>24</sup> Drawing on prior network layer standards, including ISO/IEC 7498-1, wherever possible.

1 In a Virtual Bridged Network, VLANs are defined in terms of the connectivity associations  
2 (IEEE Std 802.1AC) supported by the network: if service requests made at two different MSAPs both result  
3 in service indications at any third MSAP, then the two MSAPs are transmitting on the same VLAN; and if  
4 the service requests made at any given MSAP can result in service indications at either (or both) of two  
5 MSAPs, then those two MSAPs are receiving on the same VLAN. When only two MSAPs are in  
6 bidirectional communication, they are using the same VLAN for both transmit and receive if a third station  
7 could be added in such a way that it would receive transmissions from both.

8 NOTE 3—This definition of a VLAN accommodates an unavoidable and sometimes useful consequence of  
9 configuration possibilities: use of a single MSAP can result in transmission on one VLAN and reception on another.

10 NOTE 4—Protocol VLAN classification can be used to classify frames transmitted from a single MSAP into separate  
11 VLANs. Where protocol classification is used, the preceding rules apply to frames of a single classification.

## 12 6.2.1 Point-to-point, multipoint-to-multipoint, and rooted-multipoint connectivity

13 The types of connectivity supported by associations of Bridge Ports in Virtual Bridged Networks are often  
14 classified into three categories: point-to-point, multipoint-to-multipoint, and rooted-multipoint.  
15 Point-to-point connectivity is an association of exactly two Bridge Ports such that an ingress frame (for a  
16 given VLAN) at one Bridge Port may result in an egress frame at the other Bridge Port.  
17 Multipoint-to-multipoint connectivity is an association of two or more Bridge Ports such that an ingress  
18 frame at one Bridge Port may result in an egress frame at any or all of the other Bridge Ports.  
19 Rooted-multipoint connectivity is an association of two or more Bridge Ports where each Bridge Port is  
20 designated as either a Root or a Leaf Port, and an ingress frame at a Root Port may result in an egress frame  
21 at any or all Leaf Ports and other Root Ports, while an ingress frame at a Leaf Port may result in an egress  
22 frame at any or all Root Ports but never results in an egress frame at another Leaf Port. Note that  
23 point-to-point connectivity is a special case of the more general multipoint-to-multipoint connectivity, and  
24 that both point-to-point connectivity and multipoint-to-multipoint connectivity are special cases of  
25 rooted-multipoint connectivity where all Bridge Ports are designated as Root Ports.

## 26 6.3 Support of the MAC Service

27 In a MAC Bridged Network at most one LAN can be supported on each of the individual LANs that, bridged  
28 together, compose the network. On the individual LANs of a Virtual Bridged Network, frames for different  
29 VLANs can be distinguished by the addition of a VLAN tag as the initial octets of a frame's MSDU.

30 When a VLAN-unaware end station is attached to an individual LAN, it will transmit and receive only  
31 untagged frames, and thus uses the VID(s) assigned by the Bridge Ports that classify those frames.

32 NOTE 1—Where there are only two stations attached to an individual LAN, each can assign received untagged frames  
33 to a different VID. However, such assignments can defeat the operation of network configuration protocols and can only  
34 be recommended at the edge of a network to facilitate initial classification of untagged frames transmitted by  
35 VLAN-unaware end stations. Otherwise, a change in a frame's VID can severely impact network operation by  
36 introducing frame forwarding loops. The same considerations apply to the use of protocol VLAN classification. The use  
37 of different VID assignments by Bridge Ports attached to the same LAN is usually a network configuration error.

38 NOTE 2—The LLC Entity in a VLAN-unaware end station can receive MAC Service indications that correspond to the  
39 receipt of VLAN-tagged frames but, being unable to recognize the tag's EtherType value, will discard the frame and not  
40 deliver it to any LLC User.

41 A VLAN-aware end station can use the EISS Multiplex Entity (6.17) to provide multiple SAPs, one per VID  
42 of interest, to separate MAC Clients.

43 The objective of Bridge operation is to maximize the availability of the MAC Service to end stations and to  
44 assist in the maintenance of the network. Bridges can be configured to provide redundant paths between end  
45 stations, enabling the network to continue providing service in the event of component failure (of Bridge or  
46 LAN). The paths supported between end stations are predictable and configurable. Group addressed  
47 (multicast and broadcast) frames for any given VLAN take the same path as frames addressed to an

1 individual end station (unicast), thus permitting the use of either individually addressed or group addressed  
2 frames to configure or diagnose paths for frames with either group or individual destination addresses. The  
3 paths taken for frames for any given VLAN between any two stations are symmetric, i.e., frames from  
4 station A (say) to station B traverse the same Bridges and LANs as those from B to A, only in the reverse  
5 order. This symmetry reduces the probability of one-way connectivity between stations and permits the use  
6 of station location learning to localize traffic (6.5.10).

7 The VLAN Identifier (VID) conveyed in the VLAN tag associates each frame with the following:

- 8 a) A VLAN
- 9 b) A loop-free active topology

## 10 **6.4 Preservation of the MAC Service**

11 The MAC Service offered by a network consisting of LANs interconnected by Bridges is similar to that  
12 offered by a single LAN (see 6.5).

- 13 a) Frames transmitted between end stations carry the MAC addresses of the peer-end stations in their  
14 destination and source address fields, not an address of a Bridge. The MAC Relay is not directly  
15 addressed by communicating end stations.
- 16 b) The MAC addresses of end stations are not restricted by the network's topology or configuration.
- 17 c) All MAC addresses need to be unique within a VLAN, and within any set of VLANs for which  
18 filtering information is shared by a Bridge.

## 19 **6.5 Quality of service (QoS) maintenance**

### 20 **6.5.1 Service availability**

21 Service availability is measured as that fraction of some total time during which the MAC Service is  
22 provided. The operation of a Bridge can increase or lower the service availability.

23 The service availability can be increased by automatic reconfiguration of the network in order to avoid the  
24 use of a failed component (e.g., repeater, cable, or connector) in the data path. The service availability can be  
25 lowered by failure of a Bridge, through denial of service by the Bridge, or through frame filtering by the  
26 Bridge. Changes in topology, caused by component failures, the addition or removal of components, or  
27 administrative changes, are detected and signaled by the following means:

- 28 a) Physical detection of component failure and signaling of that failure by the EISS (6.8 and 6.9).
- 29 b) Detection of component failure through the operation of a spanning tree algorithm and protocol.
- 30 c) Explicit signaling of reconfiguration events through the operation of a spanning tree algorithm and  
31 protocol.

32 NOTE 1—Each reference to spanning tree algorithms and protocols throughout Clause 6 includes any whose purpose is  
33 to verify that each transmitted frame gives rise to at most one service indication at any of the MSAPs for which frames  
34 for that LAN or VLAN are to be received. Such protocols include RSTP (13.4), MSTP (13.5), and SPB (Clause 27).

35 Automatic reconfiguration can be achieved rapidly on the detection of a physical topology change (see  
36 Clause 13), thus minimizing any service denial that is caused by the reconfiguration.

37 A Bridge may deny service and discard frames (6.5.2) in order to preserve other aspects of the MAC Service  
38 (6.5.3 and 6.5.4) when automatic reconfiguration takes place. Service may be denied to end stations that do  
39 not benefit from the reconfiguration; hence, the service availability is lowered for those end stations. Bridges  
40 may filter frames in order to localize traffic in the network. Should an end station move, it may then be

1 unable to receive frames from other end stations until the filtering information held by the Bridges is  
2 updated.

3 To minimize the effects of service denial caused by reconfiguration events, filtering information that has  
4 been dynamically learned can be modified when automatic reconfiguration takes place, or in preparation for  
5 future reconfiguration events (Clause 13 and 13.16). However, filtering information that is statically  
6 configured cannot be modified in this way.

7 A Bridge may deny service and discard frames in order to prevent access to the network by devices that are  
8 not authorized for such access.

9 To maximize the service availability, no loss of service or delay in service provision should be caused by  
10 Bridges, except as a consequence of a failure, removal, or insertion of a network component; or as a  
11 consequence of the movement of an end station; or as a consequence of an attempt to perform unauthorized  
12 access. These events are regarded as extraordinary. The operation of any additional protocol necessary to  
13 maintain the quality of the MAC Service is thus limited to the configuration of the network and is  
14 independent of individual instances of service provision.

15 NOTE 2—This is true only in circumstances where admission control mechanisms are not present, i.e., where the  
16 Bridges provide a “best effort” service.

17 NOTE 3—The operation of management on the Bridge can result in the Bridge being reset, either as a result of a specific  
18 Bridge reset operation or as a consequence of manipulating the Bridge’s configuration. From the point of view of service  
19 availability, resetting the Bridge is an extraordinary event that has a similar effect to physical removal of the Bridge from  
20 the network, followed by reinsertion of the Bridge into the network.

## 21 6.5.2 Frame loss

22 The MAC Service does not guarantee the delivery of Service Data Units (SDUs). Frames transmitted by a  
23 source station arrive, uncorrupted, at the destination station with high probability. The operation of a Bridge  
24 introduces minimal additional frame loss.

25 A frame transmitted by a source station can fail to reach its destination station as a result of:

- 26 a) Frame corruption during physical layer transmission or reception.
- 27 b) Frame discard by a Bridge because:
  - 28 1) It is unable to transmit the frame within some maximum period of time and, hence, must  
29 discard the frame to prevent the maximum frame lifetime (6.5.6) from being exceeded.
  - 30 2) It is unable to continue to store the frame due to exhaustion of internal buffering capacity as  
31 frames continue to arrive at a rate in excess of that at which they can be transmitted.
  - 32 3) The size of the SDU carried by the frame exceeds the maximum supported by the MAC  
33 procedures employed on the LAN to which the frame is to be relayed.
  - 34 4) Changes in the connected topology of the network necessitate frame discard for a limited  
35 period of time to maintain other aspects of QoS (13.16).
  - 36 5) The device attached to the Bridge is not authorized for access to the network.
  - 37 6) The configuration of Static Filtering Entries or Static VLAN Registration Entries in the FDB  
38 (8.8.1, 8.8.2) disallows the forwarding of frames with particular destination addresses or  
39 VLAN classifications on specific Ports.
  - 40 7) A flow metering algorithm (8.6.5) determines that discard is necessary.
  - 41 8) The Bridge supports enhancements for scheduled traffic (8.6.8.4) and the size of the service  
42 data unit exceeds the value of queueMaxSDU (8.6.8.4) for the traffic class queue on which the  
43 frame is to be queued.

44 NOTE—As Static Filtering Entries and Static VLAN Registration Entries are associated with particular Ports or  
45 combinations of Ports, there is a possibility that misconfiguration of such entries will lead to unintended frame discard  
46 during or following automatic reconfiguration of the network.

### 6.5.3 Frame misordering

The MAC Service (IEEE Std 802.1AC) permits a negligible rate of reordering of frames with a given priority for a given combination of destination address, source address, and flow hash, if present, transmitted on a given VLAN. MA\_UNITDATA.indication service primitives corresponding to MA\_UNITDATA.request primitives, with the same requested priority and for the same combination of VLAN classification, destination address, source address, and flow hash, if present, are received in the same order as the request primitives were processed.

NOTE 1—The operation of the Forwarding Process in Bridges (8.6) is such that the frame-ordering characteristics of the MAC Service are preserved.

Where Bridges in a network are capable of connecting the individual MACs in such a way that multiple paths between any source station–destination station pairs exist, the operation of a protocol is required to ensure that a single path is used for every sequence of frames whose order must be maintained.

NOTE 2—Where STP is in use (see Clause 8 of IEEE Std 802.1D, 1998 Edition [B13]), frame misordering cannot occur during normal operation. When a protocol that is capable of rapid reconfiguration after network component failure (such as RSTP, MSTP, or SPB) is used, there is an increased probability that frames that are in transit through the network will be misordered, because a Bridge can buffer frames awaiting transmission through its Ports. The probability of misordering occurring as a result of such an event is dependent on implementation choices and is associated with reconfiguration events. Some known LAN protocols, for example, LLC Type 2 (ISO/IEC 8802-2), are sensitive to frame misordering and duplication; in order to allow Bridges that support RSTP to be used in environments where sensitive protocols are in use, the forceVersion parameter (13.7.2) can be used to force a Bridge that supports RSTP to operate in an STP-compatible manner. A more detailed discussion of misordering in RSTP can be found in K.3 of IEEE Std 802.1D-2004 [B14].

### 6.5.4 Frame duplication

The MAC Service (IEEE Std 802.1AC) permits a negligible rate of duplication of frames. The operation of Bridges introduces a negligible rate of duplication of user data frames.

The potential for frame duplication in a bridged network arises through the possibility of the following:

- a) Repeated transmission, through a given Bridge Port, of a frame received on another Bridge Port
- b) Multiple paths between source and destination end stations
- c) A loop in a path between source and destination stations

A Bridge does not transmit any received frame more than once through any Port (8.6.7).

When Bridges in a network connect individual LANs in such a way that physical topology is capable of providing multiple paths between any source and destination, a protocol is required to ensure that the active topology comprises a single path. SST Bridges assign all frames to a single active topology, other Bridges assign frames to an active topology using the VID or VID and destination address. For frames assigned to Ethernet Switched Paths (ESPs) by PBB-TE, the protocol comprises the operation of an external agent that configures Static Filtering Entries in the FDB (see 25.10); for all other frames RSTP, MSTP, or Intermediate System to Intermediate System Protocol for Shortest Path Bridging (ISIS-SPB) is used to configure the controls used for active topology enforcement (8.6.1). Reception of duplicate copies of a single transmitted frame can be avoided by loop prevention (6.5.4.1) or loop mitigation (6.5.4.2).

NOTE—Where RSTP, MSTP, or SPB is used (see Clause 13), there is a probability that a reconfiguration event can cause frames that are in transit through the network to be duplicated, because a Bridge can buffer frames awaiting transmission through its Ports. As the probability of duplication occurring as a result of such an event is small, and the frequency of reconfiguration events is also small, the degradation of the properties of the MAC Service caused by this source of frame duplication is considered to be negligible. A more detailed discussion of frame duplication in RSTP can be found in K.2 of IEEE Std 802.1D-2004 [B14].

#### 1 6.5.4.1 Loop prevention

2 Each Bridge that participates in RSTP, MSTP, or ISIS-SPB calculates a spanning tree for each active  
3 topology, and prevents loops by exchanging information between neighboring Bridges to ensure either that  
4 their topology calculations are consistent and each frame is consistently allocated to the same active  
5 topology, or that frames are not relayed.

#### 6 6.5.4.2 Loop mitigation

7 Each Bridge that participates in SPBM may mitigate loops. The properties of loop mitigation are listed  
8 below. Allowing temporary loops to form for unicast traffic and using loop mitigation provides for faster  
9 response to topology changes. Loop mitigation is accomplished if a unicast frame can only be forwarded by  
10 the Bridges as follows:

- 11 a) From at most one reception Port to at most one transmission Port; and
- 12 b) To a different transmission Port from the reception Port;
- 13 and
- 14 c) Each Bridge does not relay, from any reception Port, a frame whose source address and VID are the  
15 same as that used by any entity within the Bridge; and
- 16 d) Each Bridge does not transmit, through any Port, a frame whose destination address and VID are the  
17 same as that used by any entity within the Bridge;
- 18 and
- 19 e) All LANs in the network provide only point-to-point connectivity.

20 Loop mitigation limits the effect of loops since any loop in the active topology cannot include either the  
21 source or destination of the frame, nor can the loop cause multiple copies of the initial frame to be delivered  
22 to the destination, or to or from any LAN in the network that is not part of the loop.

23 Loop mitigation does not require that neighboring Bridges assign a given frame to the same active topology;  
24 or even that the reception and transmission Ports for that frame have been derived from the same topology  
25 calculation within a given Bridge. While this standard specifies the calculation of paths that are reverse path  
26 congruent (Clause 3) to support bidirectional communication, that property has no bearing on loop  
27 mitigation. As a consequence, the Dynamic Filtering Entries that are used for active topology enforcement  
28 (8.6.1) and loop mitigation with SPBM (27.4.1) can be updated one at a time after ISIS-SPB has completed  
29 a link state calculation or during the course of that calculation.

#### 30 6.5.5 Transit delay

31 The MAC Service introduces a frame transit delay that is dependent on the particular media and MAC  
32 method employed. Frame transit delay is the elapsed time between an MA\_UNITDATA.request primitive  
33 and the corresponding MA\_UNITDATA.indication primitive. Elapsed time values are calculated only on  
34 SDUs that are successfully transferred.

35 Since the MAC Service is provided at an abstract interface within an end station, it is not possible to specify  
36 precisely the total frame transit delay. It is, however, possible to measure those components of delay  
37 associated with media access and with transmission and reception; and the transit delay introduced by an  
38 intermediate system, in this case a Bridge, can be measured.

39 The minimum additional transit delay introduced by a Bridge is the time taken to receive a frame plus that  
40 taken to access the media onto which the frame is to be relayed. Note that the frame is completely received  
41 before it is relayed as the Frame Check Sequence (FCS) is to be calculated and the frame discarded if in  
42 error.

## 6.5.6 Frame lifetime

The MAC Service ensures that an upper bound to the transit delay is experienced for a particular instance of communication. This maximum frame lifetime is necessary to ensure the correct operation of higher layer protocols. The additional transit delay introduced by a Bridge is discussed in 6.5.5.

To enforce the maximum frame lifetime, a Bridge may be required to discard frames. Since the information provided by the MAC Sublayer to a Bridge does not include the transit delay already experienced by any particular frame, Bridges discard frames to enforce a maximum delay in each Bridge.

The value of the maximum Bridge transit delay is based on both the maximum delays imposed by all Bridges in the network and the desired maximum frame lifetime. A recommended and an absolute maximum value are specified in Table 6-1.

**Table 6-1—Bridge transit delay**

| Parameter                    | Recommended value | Absolute maximum |
|------------------------------|-------------------|------------------|
| Maximum Bridge transit delay | 1.0s              | 4.0s             |

## 6.5.7 Undetected frame error rate

The MAC Service introduces a very low undetected frame error rate in transmitted frames. Undetected errors are protected against by the use of an FCS that is appended to the frame by the MAC Sublayer of the source station prior to transmission, and checked by the destination station on reception.

The FCS calculated for a given SDU is dependent on the MAC method employed. It is therefore necessary to recalculate the FCS within a Bridge providing a relay function between IEEE 802 LAN MACs of dissimilar types if differences in the method of calculation and/or the coverage of the FCS, or changes to the data that is within the coverage of the FCS, would lead to a different FCS being calculated for the SDU by the two MAC methods. This introduces the possibility of additional undetected errors arising from the operation of a Bridge. For frames relayed between LANs of the same MAC type, the Bridge shall not introduce an undetected frame error rate greater than that which would have been achieved by preserving the FCS.

NOTE—Application of the techniques described in Annex O allows an implementation to achieve an arbitrarily small increase in undetected frame error rate, even in cases where the data that is within the coverage of the FCS is changed.

## 6.5.8 Maximum Service Data Unit Size

The Maximum Service Data Unit Size that can be supported by an IEEE 802 LAN varies with the MAC method and its associated parameters (e.g., speed, electrical characteristics). It may be constrained by the owner of the LAN. The Maximum Service Data Unit Size supported by a Bridge between two LANs is the smaller of that supported by the LANs. No attempt is made by a Bridge to relay a frame to a LAN that does not support the size of SDU conveyed by that frame.

## 6.5.9 Priority

The MAC Service includes priority as a QoS parameter. MA\_UNITDATA.request primitives with a high priority may be given precedence over other request primitives made at the same station, or at other stations attached to the same LAN and can give rise to earlier MA\_UNITDATA.indication primitives.

1 The MAC Sublayer maps the requested priority onto the priorities supported by the individual MAC  
2 method. The requested priority may be conveyed to the destination station.

3 The transmission delay experienced by a frame in a Bridge can be managed by associating a priority with the  
4 frame.

5 The transmission delay comprises:

- 6 a) A queuing delay until the frame becomes first in line for transmission on the Port, in accordance  
7 with the procedure for selecting frames for transmission described in 8.6.8.
- 8 b) The access delay for transmission of the frame.

9 Queuing delays can be managed using priority. Access delays can be managed using priority in MAC  
10 methods that support more than one priority.

11 The priority associated with a frame can be signaled by means of the priority signaling mechanisms inherent  
12 in some IEEE 802 LAN MAC types. Since not all IEEE 802 LAN MAC types are able to signal the priority  
13 associated with a frame, VLAN Bridges regenerate priority based on a combination of signaled information  
14 and configuration information held in the Bridge.

15 The Bridge maps priority values onto one or more traffic classes; Bridges that support more than one traffic  
16 class are able to support expedited classes of traffic. The Forwarding Process, 8.6, describes the use of  
17 priority and traffic classes in Bridges. Given the constraints placed on frame misordering in a Bridge, as  
18 expressed in 6.5.3, the mappings of priority and traffic class are static.

19 NOTE 1—The term “traffic class,” as used in this standard, is used only in the context of the operation of the priority  
20 handling and queuing functions of the Forwarding Process, as described in 8.6. Any other meanings attached to this term  
21 in other contexts do not apply to the use of the term in this standard.

22 The ability to signal priority in IEEE 802 LANs, coupled with a consistent approach to the mapping of  
23 priority to traffic classes, and of priority to the priority requested from the individual LAN or supporting  
24 service, allows consistent use of priority information to be made, according to the capabilities of the Bridges  
25 and MAC methods that are involved in the transmission path.

26 NOTE 2—This standard defines a frame format and associated procedures that can be used to carry priority information  
27 across LAN MAC types that are not able to signal priority.

28 Under normal circumstances, priority is not modified in transit through the relay function of a Bridge;  
29 however, there may be some circumstances where it is desirable for management purposes to control how  
30 priority is propagated. The Priority Regeneration Table (Table 6-4) provides the ability to map incoming  
31 priority values on a per-Port basis, under management control. In its default state, this table provides an  
32 identity mapping from priority values to Regenerated priority values; i.e., by default, the Regenerated  
33 priority is identical to the incoming priority.

#### 34 **6.5.10 Throughput**

35 The total throughput provided by a network can be significantly greater than that provided by an equivalent  
36 single LAN. Bridges may localize traffic within the network by filtering frames. Filtering services available  
37 in bridged networks are described in 6.16.

38 The throughput between end stations on individual LANs, communicating through a Bridge, can be lowered  
39 by frame discard in the Bridge due to the inability to transmit at the required rate on the LAN forming the  
40 path to the destination for an extended period.

## 1 6.6 Internal Sublayer Service (ISS)

2 The service and control primitives and parameters, the status parameters, and the point-to-point parameters  
3 of the ISS are specified in IEEE Std 802.1AC.

## 4 6.7 Support of the ISS by specific MAC procedures

5 Support of the ISS by MAC Entities that use specific IEEE 802 media access methods is specified in  
6 IEEE Std 802.1AC.

### 7 6.7.1 Support of the ISS by IEEE Std 802.3 (Ethernet)

8 Mapping between M\_CONTROL.requests/indications and IEEE 802.3  
9 MA\_CONTROL.requests/indications is performed as specified in IEEE Std 802.1AC. If the MAC supports  
10 the MAC Merge sublayer specified in IEEE Std 802.3, then PFC M\_CONTROL.requests are mapped onto  
11 the MAC control interface associated with the express MAC (eMAC).

12 If frame preemption (6.7.2) is supported on a Port, then the IEEE 802.3 MAC provides the following two  
13 MAC service interfaces:

- 14 a) A preemptable MAC (pMAC) service interface
- 15 b) An express MAC (eMAC) service interface

16 For priority values that are identified in the frame preemption status table (6.7.2) as *preemptable*, frames that  
17 are selected for transmission shall be transmitted using the pMAC service instance, and for priority values  
18 that are identified in the frame preemption status table as *express*, frames that are selected for transmission  
19 shall be transmitted using the eMAC service instance.

20 In all other respects, the Port behaves as if it is supported by a single MAC service interface. In particular, all  
21 frames received by the Port are treated as if they were received on a single MAC service interface regardless  
22 of whether they were received on the eMAC service interface or the pMAC service interface, except with  
23 respect to frame preemption.

24 If the value of the holdRequest managed object (12.30.1.5) transitions from *release (2)* to *hold (1)*, a  
25 MM\_CTL.request(hold\_req) primitive is issued to the underlying IEEE 802.3 MAC, with a hold\_req  
26 parameter value of HOLD, as described in IEEE Std 802.3. If the value of the holdRequest managed object  
27 (12.30.1.5) transitions from *hold (1)* to *release (2)*, a MM\_CTL.request(hold\_req) primitive is issued to the  
28 underlying IEEE 802.3 MAC, with a hold\_req parameter value of RELEASE.

29 NOTE—This additional material will be moved to IEEE Std 802.1AC in a future revision.

### 30 6.7.2 Frame preemption

31 If the Port supports frame preemption, then a value of frame preemption status is assigned to each value of  
32 priority via a *frame preemption status table*. The possible values of frame preemption status are *express* or  
33 *preemptable*.

34 The frame preemption status table can be changed by management as described in 12.30.1.1. The default  
35 value of frame preemption status is *express* for all priority values.

## 6.8 Enhanced Internal Sublayer Service (EISS)

The EISS is derived from the ISS (IEEE Std 802.1AC) by augmenting that specification with elements necessary to the operation of the tagging and untagging functions of a VLAN Bridge (3.306). Within the attached end station, these elements can be considered either to be below the MAC Service boundary, and pertinent only to the operation of the service provider, or to be local matters not forming part of the peer-to-peer nature of the MAC Service.

The EISS provides the same service status and point-to-point parameters as the ISS (IEEE Std 802.1AC).

### 6.8.1 Service primitives

The unit-data primitives that define this service are:

```

10 EM_UNITDATA.indication      (
11     destination_address,
12     source_address,
13     mac_service_data_unit,
14     priority,
15     drop_eligible,
16     vlan_identifier,
17     frame_check_sequence,
18     service_access_point_identifier,
19     connection_identifier,
20     flow_hash,
21     time_to_live
22 )

23 EM_UNITDATA.request         (
24     destination_address,
25     source_address,
26     mac_service_data_unit,
27     priority,
28     drop_eligible,
29     vlan_identifier,
30     frame_check_sequence,
31     service_access_point_identifier,
32     connection_identifier,
33     flow_hash,
34     time_to_live
35 )

```

The **destination\_address**, **source\_address**, **mac\_service\_data\_unit**, **priority**, **drop\_eligible**, **service\_access\_point\_identifier**, **connection\_identifier**, and **frame\_check\_sequence** parameters are as defined for the ISS.

NOTE—Some of the functions supporting the EISS may result in changes to the `mac_service_data_unit` or other parameters used to construct a frame. The original FCS associated with a frame is invalidated if there are changes to any fields of the frame, if fields are added or removed, or if bit ordering or other aspects of the frame encoding have changed. An invalid FCS is signaled in the EISS by an unspecified value in the `frame_check_sequence` parameter. This signals the need for the FCS to be regenerated according to the normal procedures for the transmitting MAC. Two options for regenerating the FCS under these circumstances are discussed in Annex O.

The **vlan\_identifier** parameter carries the VID.

The **flow\_hash** parameter either is null or carries a value that may be used by the forwarding process in selecting a single forwarding port from a set of available forwarding ports (8.6.3). Transmission order is maintained for all frames from a source to a destination with the same flow hash value. A flow hash value may be retrieved from an F-TAG or otherwise derived from the contents of a service primitive (44.2.2). A flow hash is not required by the MAC Relay Entity, and successful filtering can be provided without this additional information; however, it is required for flow filtering services supported by SPBM with ECMP. Any protocol entity in the interface stack that does not specify use of the flow\_hash assigns the flow\_hash value (if any) supplied with a request from the user of the protocol entity (or with an indication from the provider of the service used by the protocol entity) to the flow\_hash on associated requests made (or indications generated) by the protocol entity.

The **time\_to\_live** parameter either is null or carries a value that may be used to filter frames that have reached their limit of permitted network hops. A time\_to\_live value may be retrieved from an F-TAG in the mac\_service\_data\_unit and processed as described in 44.2.2. Any protocol entity in the interface stack that does not specify use of the time\_to\_live assigns the time\_to\_live value (if any) supplied with a request from the user of the protocol entity (or with an indication from the provider of the service used by the protocol entity) to the time\_to\_live on associated requests made (or indications generated) by the protocol entity.

## 6.8.2 Status parameters

The EISS also makes available the **MAC\_Enabled** and **MAC\_Operational** status parameters that reflect the operational state and administrative controls over each instance of the service provided. The values of these parameters are mapped directly from the values made available by the ISS (IEEE Std 802.1AC).

## 6.8.3 Point-to-point parameters

The EISS also makes available the **operPointToPointMAC** and **adminPointToPointMAC** status parameters that reflect the point-to-point status of each instance of the service provided and provide administrative control over the use of that information. The values of these parameters are mapped directly from the values made available by the ISS (IEEE Std 802.1AC).

## 6.8.4 Control primitives and parameters

The EISS provides two control primitives, an EM\_CONTROL.request and an EM\_CONTROL.indication, and their associated parameters. The values of these parameters are mapped directly to/from the values made available by the corresponding ISS primitives (11.4 of IEEE Std 802.1AC-2016 [B10]).

The EM\_CONTROL.request primitive has the form:

```
EM_CONTROL.request      (
destination_address
opcode
request_operand_list
)
```

The EM\_CONTROL.indication primitive has the form:

```
EM_CONTROL.indication   (
opcode
indication_operand_list
)
```

## 6.9 Support of the EISS

The EISS is supported by tagging and detagging functions that in turn use the ISS (IEEE Std 802.1AC). Any given instance of the EISS shall be supported by using one but not both of the following VLAN tag types:

- a) C-VLAN tag (C-TAG) or
- b) S-VLAN tag (S-TAG)

selected as specified in 9.5.

Each Bridge Port shall support the following parameters for use by these functions:

- c) An Acceptable Frame Types parameter with at least one of the following values:
  - 1) *Admit Only VLAN-tagged frames*
  - 2) *Admit Only Untagged and Priority-tagged frames*
  - 3) *Admit All frames*
- d) A PVID parameter for Port-based VLAN classification

Each Bridge Port may support the following parameters:

- e) A VID Set for Port-and-Protocol-based classification (6.12)
- f) A VID translation table
- g) An Egress VID translation table

All three values for Acceptable Frame Types may be supported; if so, they shall be configurable using the management operations defined in Clause 12, and the default shall be *Admit All Frames*. A frame is treated as Untagged if the initial octets of the `mac_service_data_unit` parameter do not contain a VLAN tag of the type used to support the EISS (9.5), as Priority-tagged if the value contained in the VID field of the VLAN tag is zero, and as VLAN-tagged if the value is nonzero.

NOTE 1—The VID translation tables are for use only at the edge of administrative or control protocol domains, e.g., Network-Network Interfaces, SPB domains, or Root and Leaf interfaces to a rooted-multipoint service, as described in this standard. Control protocols that are designed for operation through ports where VID translation is permitted (e.g., MSTP, MVRP, CFM) explicitly compensate for the translation of VID values carried within their PDUs. Successful operation and maintenance of Bridged Networks depends on the fact that VID values are not translated at other ports or at ports within the operational span of control protocols that do not recognize translation.

The PVID and VID Set shall contain valid VID values (Table 9-2) and may be configured by management. If they have not been explicitly configured, the PVID shall assume the value of the default PVID defined in Table 9-2 and the VID Set shall be empty.

NOTE 2—The default behavior of a Bridge that supports Port-and-Protocol-based classification is the same as that of a Bridge that supports only Port-based classification, since all the Protocol Group Identifiers in the VID Set for each Port assign the same VID as the PVID.

The VID translation table and Egress VID translation table provide a mapping between “local VID” values and “relay VID” values. The local VID is the value encoded in a VLAN tag header in the initial octets of the `mac_service_data_unit` parameter of an ISS service primitive (`M_UNITDATA.indication` or `M_UNITDATA.request`). The relay VID is the value contained in the `vlan_identifier` parameter of an EISS service primitive (`EM_UNITDATA.indication` or `EM_UNITDATA.request`). The VID translation table may be supported by itself, or in combination with the Egress VID translation table. When only the VID translation table is supported it is used for bidirectional mapping between the local VID and the relay VID in both indication and request service primitives. This enforces a symmetric one-to-one translation (i.e., if local VID A maps to relay VID B then relay VID B will map to local VID A). When both tables are supported the VID translation table is used only for mapping the local VID to a relay VID in indication service primitives, and the Egress VID translation table is used for mapping the relay VID to a local VID in request service primitives. This allows asymmetric and many-to-one translations (e.g., for translating to and from SPVIDs at the edge of an SPT Region). Both tables are configurable by management, and the default configuration maps each value of the local VID to the same value for the relay VID, and vice versa. For Bridge Ports at the boundary of an SPBV SPT Region the tables are dynamically modified by the ISIS-SPB.

## 6.9.1 Data indications

On receipt of an M\_UNITDATA.indication primitive from the ISS, the received frame is discarded if:

- a) The initial octets of the mac\_service\_data\_unit do not contain a valid VLAN tag header (9.3) of the type used to support the EISS (9.5), and the Acceptable Frame Types is *Admit Only VLAN-tagged frames*; or
- b) The initial octets of the mac\_service\_data\_unit contain a valid VLAN tag header (9.3) of the type used to support the EISS (9.5), and:
  - 1) The VID value is FFF, reserved in Table 9-2 for implementation use; or
  - 2) The VID translation table is supported and the translated VID value (relay VID) is FFF (indicating local discard); or
  - 3) The VID value is 000 (indicating Priority-tagged), and the Acceptable Frame Types is *Admit Only VLAN-tagged frames*; or
  - 4) The VID value is in the range 001-FFE, and the Acceptable Frame Types is *Admit Only Untagged and Priority-tagged frames*.

Otherwise, an EM\_UNITDATA.indication primitive is invoked, with parameter values determined as follows:

The **destination\_address**, **source\_address**, and **frame\_check\_sequence** parameters carry values equal to the corresponding parameters in the received data indication. The values of the remaining parameters are affected by the contents of the tag header if the frame contains a VLAN tag of the type supported by this instance of the EISS.

The value of the **mac\_service\_data\_unit** parameter is as follows:

- c) If the frame is tagged, then the value used is equal to the value of the received mac\_service\_data\_unit following removal of the tag header.
- d) Otherwise, the value used is equal to the value of the received mac\_service\_data\_unit.

The value of the **vlan\_identifier** parameter is as follows:

- e) The value contained in the VID field, optionally translated using the VID translation table, if the frame is VLAN-tagged.
- f) The value of the PVID for the Port, if Port-and-Protocol-based VLAN classification is not supported and the frame is untagged, Priority-tagged, or the VID translation table is supported and the translated VID value (relay VID) is zero.
- g) As determined by Port-and-Protocol-based VLAN classification (6.12) if that capability is implemented and the frame is untagged or Priority-tagged or the VID translation table is supported and the translated VID value (relay VID) is zero.

The value of the **drop\_eligible** and **priority** parameters are determined as follows:

- h) If the frame is tagged, the value of the drop\_eligible parameter and the received priority value are decoded from the tag header as described in 6.9.3. Otherwise,
- i) The received priority value and the drop\_eligible parameter value are the values in the M\_UNITDATA.indication.
- j) The value of the priority parameter is then regenerated from the received priority, as specified in 6.9.4.

## 6.9.2 Data requests

On invocation of an EM\_UNITDATA.request primitive by a user of the EISS, the frame is discarded if the Egress VID translation table is supported and the translated VID value (local VID) is FFF (reserved in Table 9-2). Otherwise, an M-UNITDATA.request primitive is invoked, with parameter values as follows:

The **destination\_address**, **source\_address**, **drop\_eligible**, and **priority** parameters carry values equal to the corresponding parameters in the received data request.

Unless the Bridge Port is a member of the untagged set (8.8.2) for the VID identified by the **vlan\_identifier** parameter, then a tag header, formatted as necessary for the destination MAC type, is inserted as the initial octets of the **mac\_service\_data\_unit** parameter. The values of the **vlan\_identifier** (optionally translated using the VID translation table or Egress VID translation table), **priority**, and **drop\_eligible** parameters are used to determine the contents of the tag header, in accordance with Clause 9.

If the Bridge Port is a member of the untagged set (8.8.2) for the VID identified by the **vlan\_identifier** parameter, no tag header is inserted.

The remaining octets of the **mac\_service\_data\_unit** parameter are those accompanying the EISS-request. If the data request is a consequence of relaying a frame and the MAC type of the Port differs from that used to receive the frame, they are modified, if necessary, in accordance with the procedures described in ISO/IEC 11802-5, IETF RFC 1042, and IETF RFC 1390.

The value of the **frame\_check\_sequence** parameter is determined as follows:

- a) If the **frame\_check\_sequence** parameter received in the data request either is unspecified or still carries a valid value, then that value is used.
- b) Otherwise, the value used is either unspecified or derived from the received FCS information by modification to take account of the conditions that have caused it to become invalid.

## 6.9.3 Priority Code Point encoding

The **priority** and **drop\_eligible** parameters are encoded in the PCP field of the VLAN tag using the Priority Code Point Encoding Table for the Port, and they are decoded from the PCP using the Priority Code Point Decoding Table. For each Port, the Priority Code Point Encoding Table has 16 entries, corresponding to each of the possible combinations of the eight possible values of priority (0 through 7) with the two possible values of **drop\_eligible** (True or False). For each Port, the Priority Code Point Decoding Table has 8 entries, corresponding to each of the possible PCP values.

Alternative values for each table are specified as rows in Table 6-2 and Table 6-3, with each alternative labeled by the number of distinct priorities that can be communicated, and the number of these for which drop precedence can be communicated. For example, the table entries 6P2D allow six distinct priorities with drop precedence for two. The default values (8P0D) specify a PCP value equal to the priority value and do not support communication of drop precedence in the PCP field. The combination of the **priority** and **drop\_eligible** parameters is shown by the priority alone if **drop\_eligible** is False, and by the priority followed by the letters “DE” if **drop\_eligible** is True.

If the VLAN tag is an S-TAG, then Table 6-2 and Table 6-3 shall be supported. If the VLAN tag is a C-TAG, then the 8P0D row of each table shall be supported, and the remaining rows may be supported.

NOTE—To avoid potential misordering of frames, all Ports on a LAN should select the same row of Table 6-2 and Table 6-3. Interoperability considerations with Bridges supporting only the 8P0D row are discussed in I.8.

**Table 6-2—Priority Code Point encoding**

| priority<br>drop_eligible |                   | 7 | 7DE | 6 | 6DE | 5 | 5DE | 4 | 4DE | 3 | 3DE | 2 | 2DE | 1 | 1DE | 0 | 0DE |
|---------------------------|-------------------|---|-----|---|-----|---|-----|---|-----|---|-----|---|-----|---|-----|---|-----|
| PCP                       | 8P0D<br>(default) | 7 | 7   | 6 | 6   | 5 | 5   | 4 | 4   | 3 | 3   | 2 | 2   | 1 | 1   | 0 | 0   |
|                           | 7P1D              | 7 | 7   | 6 | 6   | 5 | 4   | 5 | 4   | 3 | 3   | 2 | 2   | 1 | 1   | 0 | 0   |
|                           | 6P2D              | 7 | 7   | 6 | 6   | 5 | 4   | 5 | 4   | 3 | 2   | 3 | 2   | 1 | 1   | 0 | 0   |
|                           | 5P3D              | 7 | 7   | 6 | 6   | 5 | 4   | 5 | 4   | 3 | 2   | 3 | 2   | 1 | 0   | 1 | 0   |

**Table 6-3—Priority Code Point decoding**

| PCP                       |                   | 7 | 6 | 5 | 4   | 3 | 2   | 1 | 0   |
|---------------------------|-------------------|---|---|---|-----|---|-----|---|-----|
| priority<br>drop_eligible | 8P0D<br>(default) | 7 | 6 | 5 | 4   | 3 | 2   | 1 | 0   |
|                           | 7P1D              | 7 | 6 | 4 | 4DE | 3 | 2   | 1 | 0   |
|                           | 6P2D              | 7 | 6 | 4 | 4DE | 2 | 2DE | 1 | 0   |
|                           | 5P3D              | 7 | 6 | 4 | 4DE | 2 | 2DE | 0 | 0DE |

1 The values in the Priority Code Point Encoding Table and Priority Code Point Decoding Table may be  
2 modified by management, as described in Clause 12. If this capability is provided, the value of the table  
3 entries shall be independently settable for each Port. The values shall be constrained as follows:

- 4 a) For any two priority values with the same drop\_eligible value, the lower priority shall not map to a  
5 higher PCP than the higher priority.
- 6 b) The lower of any two PCP values shall not map to a higher priority than the higher PCP.
- 7 c) With the exception of values 0 and 1, any priority value combined with drop\_eligible True shall not  
8 map to a higher PCP than the same priority value combined with drop\_eligible False.
- 9 d) With the exception of values 0 and 1, any PCP value shall not map to a priority value combined with  
10 drop\_eligible True if a lower PCP maps to the same priority value combined with drop\_eligible  
11 False.

12 The values may be further constrained, but if the tables can be modified, the default values shown in  
13 Table 6-2 and Table 6-3, and the alternative sets of values in Table 6-2 and Table 6-3 shall be settable.

14 The drop\_eligible parameter may also be encoded in and decoded from the Drop Eligible Indicator (DEI) in  
15 the VLAN tag. Use of the DEI allows the VLAN tag to convey eight distinct priorities, each with a DEI. If  
16 this capability is provided, it shall be independently manageable for each Port by means of a Use\_DEI  
17 parameter. If the Use\_DEI is True for the Port, the drop\_eligible parameter is encoded in the DEI of  
18 transmitted frames, and the drop\_eligible parameter shall be True for a received frame if the DEI is set in the  
19 VLAN tag or the Priority Code Point Decoding Table indicates drop\_eligible True for the received PCP  
20 value. If the Use\_DEI parameter is False, the DEI shall be transmitted as zero and ignored on receipt. The  
21 default value of the Use\_DEI parameter is False.

## 6.9.4 Regenerating priority

The priority of each received frame is regenerated using priority information contained in the frame and the Priority Regeneration Table for the reception Port. For each reception Port, the Priority Regeneration Table has eight entries, corresponding to the eight possible values of priority (0 through 7). Each entry specifies, for the given value of received priority, the corresponding regenerated value.

For untagged frames, the priority parameter signaled in the corresponding M\_UNITDATA.indication is taken to be the received priority. For tagged frames, the priority signaled in the PCP field of the tag header is taken to be the received priority.

NOTE 1—IEEE 802 LAN technologies signal a maximum of eight priority values. Annex I further explains the use of priority values and how they map to traffic classes.

Table 6-4 specifies default regenerated priority values for each of the eight possible values of the received priority. These default values shall be used as the initial values of the corresponding entries of the Priority Regeneration Table for each Port.

**Table 6-4—Priority regeneration**

| Received priority | Default regenerated priority | Range |
|-------------------|------------------------------|-------|
| 0                 | 0                            | 0–7   |
| 1                 | 1                            | 0–7   |
| 2                 | 2                            | 0–7   |
| 3                 | 3                            | 0–7   |
| 4                 | 4                            | 0–7   |
| 5                 | 5                            | 0–7   |
| 6                 | 6                            | 0–7   |
| 7                 | 7                            | 0–7   |

The values in the Priority Regeneration Table may be modified by management, as described in Clause 12. If this capability is provided, the value of the table entries shall be independently settable for each reception Port and for each value of received priority, and the Bridge shall have the capability to use the full range of values in the parameter ranges specified in Table 6-4.

NOTE 2—The regeneration and mapping of priority within the Bridge should be consistent with the end-to-end significance of that priority across the rest of the Bridged Network. The regenerated priority value is used:

~~—Via the traffic class table (8.6.6) to determine the traffic class for a given outbound Port, and~~  
~~—Via fixed, MAC type specific mappings (IEEE Std 802.1AC) to determine the access priority that will be used for certain media access methods.~~

In Bridges that support SRP, an SRP domain boundary port priority regeneration override table is maintained for each reception Port. This table associates a priority value with each SR class supported by the Bridge, and specifies the priority value to be used as the regenerated priority, in preference to the value in the Priority Regeneration table, when the SRPdomainBoundaryPort parameter (35.1.4) for that SR class has the value TRUE. Table 6-5 specifies the default values for priority and regenerated priority for two SR classes, SR class A and SR class B. In cases where only SR class B is supported, only the default value shown in the table for SR Class B is used.

**Table 6-5—Default SRP domain boundary port priority regeneration override values**

| SR class | Default priority | Default regenerated priority for SRP domain boundary Ports | Range |
|----------|------------------|------------------------------------------------------------|-------|
| A        | 3                | 0                                                          | 0–7   |
| B        | 2                | 0                                                          | 0–7   |

The priority values contained in the SRP domain boundary port priority regeneration override table may be modified by management, as described in Clause 12. If this capability is provided, the value of the table entries shall be independently settable for each reception Port and for each supported SR class, and the Bridge shall have the capability to use the full range of values in the parameter ranges specified in Table 6-5.

NOTE 3—The default values specified for the SRP domain boundary port Priority Regeneration Table map inbound PCP values onto the next lowest priority that is available, leaving the remaining priority values unchanged. The consequence of this remapping is that traffic entering an SRP domain that carries the priority value associated with that domain is forwarded by the Bridge at the domain boundary using a lower priority. There is no means of mapping these priority values back to their original values as frames exit from an SRP domain. The default mappings are based on the assumption that normally, two SR classes (A and B) are used to support traffic for which bandwidth has been reserved; if only the lower class (B) is supported, then the default override value for the unsupported A class does not apply.

NOTE 4—The ability for the priority regeneration table to be freely modified by management means that it is possible to create mappings that result in reserved and nonreserved traffic sharing the same priority. This will have unpredictable effects upon the behavior of the network with respect to the worst-case latency that can be assumed for reserved traffic.

## 6.10 Support of the ISS/EISS by PIPs

Each PIP on a BEB uses a single ISS-SAP (IEEE Std 802.1AC) and the I-TAG (9.5) to provide a separate Bridge Port (the VIP) for each backbone service instance configured for the PIP. Each VIP supports either the VLAN-unaware MAC Relay Entity of a T-component or the VLAN-aware MAC Relay Entity of an I-component. A single VIP ISS-SAP is provided to a T-component. An I-component uses an EISS-SAP, supported by its own instance of the functions specified in 6.9 with the S-TAG (9.5), for each VIP ISS-SAP. See Figure 6-2.

The EISS of each Virtual Instance Port (VIP-EISS) shall be supported by an instance of the functions of 6.9 using the S-TAG type (9.5). The ISS of all of the Virtual Instance Ports (VIP-ISS) shall be supported by a single instance of the functions specified in this subclause using the I-TAG type (9.5).

NOTE 1—Higher Layer Entities may interface to any VIP and/or the PIP at the Service Access Points (SAPs) represented by any VIP-ISS and/or the PIP-ISS using the Bridge Port Connectivity specified in 8.5.1. Protocol shims such as CFM MPs may interface at any VIP-EISS using the EISS Multiplex Entity specified in 6.17, or at the PIP-ISS using the Backbone Service Instance Multiplex Entity specified in 6.18. Figure 26-2 shows a PIP with both Bridge Port Connectivity and CFM shims.

Each PIP shall have an individual Backbone Media Access Control (B-MAC) address referred to as the PIP MAC address (26.4) for use by the functions specified in this subclause.

Each VIP shall support the following parameters for use by these functions:

- a) A VIP-ISID parameter for the I-SID of the backbone service instance associated with this VIP
- b) A Default Backbone Destination
- c) An adminPointToPointMAC
- d) An enableConnectionIdentifier

The VIP-ISID shall contain a valid I-SID value (9.7), which is configured by management.

**Figure 6-2—Provider Instance Ports (PIPs)**

1 The Default Backbone Destination parameter contains a MAC address to be used in the destination\_address  
2 parameter of an M\_UNITDATA.request at the PIP-ISS when a backbone destination address cannot be  
3 derived from the connection\_identifier parameter of the M\_UNITDATA.request from the VIP-ISS. The  
4 default value of the Default Backbone Destination is the Backbone Service Instance Group address for the  
5 VIP-ISID (generated by concatenating the Provider Backbone Bridge (PBB) organizationally unique  
6 identifier (OUI) with the VIP-ISID value as specified in 26.4).

7 The adminPointToPointMAC parameter of the VIP-ISS reflects the point-to-point status of the backbone  
8 service instance associated with the VIP. The default value of the adminPointToPointMAC parameter is  
9 ForceFalse. The value may be configured by management to ForceTrue when instantiating a VIP for a  
10 point-to-point backbone service instance. A value of ForceFalse or Auto results in a operPointToPointMAC  
11 value of FALSE; a value of ForceTrue results in a operPointToPointMAC value of TRUE. Whenever the  
12 operPointToPointMAC parameter transitions to FALSE, the value for the Default Backbone Destination  
13 parameter is set to the Backbone Service Instance Group address for the VIP-ISID. When the  
14 operPointToPointMAC parameter is TRUE, the Default Backbone Destination parameter is modified by  
15 subsequent M\_UNITDATA.indications as specified in 6.10.1 (and described in 26.4.1).

16 The enableConnectionIdentifier parameter allows the VIP to use the connection\_identifier parameter to  
17 learn associations between a B-MAC address and a Customer Media Access Control (C-MAC) address. The  
18 default value is TRUE. This parameter should be configured to FALSE at the root node of a  
19 point-to-multipoint TESI.

20 NOTE 2—There is a 1:1 relationship between a given value of the connection\_identifier and a B-MAC address. This  
21 level of indirection is provided to allow the use of the connection\_identifier parameter for other purposes by other types  
22 of Bridge Ports. The relationship between a given connection\_identifier value and a B-MAC address is maintained as  
23 long as any FDB entry contains this value for the connection\_identifier. No ageing mechanism other than that specified  
24 for Dynamic Filtering Entries is implied.

## 6.10.1 Data indications

On receipt of an M\_UNITDATA.indication primitive from the PIP-ISS, if the PIP is congestion aware (5.4.1.4) and the initial octets of the mac\_service\_data\_unit contain a valid CNM encapsulation, the received frame is processed according to 32.16. If the PIP is congestion isolation aware (5.4.7) and the initial octets of the mac\_service\_data\_unit contain a valid CIM encapsulation (49.4.3), the received frame is processed according to 49.4.2.6. Otherwise, the received frame shall be discarded if:

- a) The initial octets of the mac\_service\_data\_unit do not contain a valid I-TAG header; or
- b) The Use Customer addresses (UCA) bit in the I-TAG is not zero; or
- c) The Res2 field in the I-TAG is not zero; or
- d) The I-SID value in the I-TAG does not match the VIP-ISID parameter for one of the VIPs supported by this PIP; or
- e) The destination\_address parameter of the received M\_UNITDATA.indication primitive does not match one of the following:
  - 1) The PIP MAC address; or
  - 2) A Backbone Service Instance Group address; or
  - 3) The broadcast address.

NOTE 1—The generation of I-tagged frames specified in 6.10.2 and the allowed manipulation of backbone addresses specified in 6.11 never result in an I-tagged frame with a broadcast destination address. The broadcast address is included in the previous list on the principle that the broadcast address is a valid address at any reception port by definition.

The received frame may be discarded if:

- f) The source\_address parameter of the received M\_UNITDATA.indication primitive is the PIP MAC address.

Otherwise, an M\_UNITDATA.indication primitive is invoked at the VIP-ISS with a VIP-ISID value matching the I-SID in the I-TAG. The parameter values of the indication are determined as follows:

The **destination\_address** parameter contains the value of the encapsulated C-DA field of the I-TAG.

The **source\_address** parameter contains the value of the encapsulated C-SA field of the I-TAG.

If enableConnectionIdentifier is TRUE, then the **connection\_identifier** parameter references the value of the source\_address parameter (B-SA) of the M\_UNITDATA.indication primitive received from the PIP-ISS; otherwise, the connection\_identifier parameter is null. The connection\_identifier parameter in the M\_UNITDATA.indication primitive received from the PIP-ISS is ignored.

NOTE 2—The connection\_identifier has only local significance meaning that it is used only at a specific PIP. The only requirement imposed by this subclause is that the connection\_identifier uniquely identifies an individual B-MAC address. Whether the connection\_identifier takes the value of that address, or a value from which that address can be determined, is an implementation decision that is not externally observable.

If the value of the operPointToPointMAC parameter of the VIP-ISS is TRUE, then the Default Backbone Destination parameter is set to the value of the source\_address parameter of the M\_UNITDATA.indication primitive.

The **service\_access\_point\_identifier** parameter contains a value that uniquely identifies the VIP within the I-component. This is a local value that is used only within the I-component, and is used by the relay functions (Clause 8) as the port number of the VIP. The service\_access\_point\_identifier parameter received in the M\_UNITDATA.indication primitive is ignored.

The value of the **drop\_eligible** and **priority** parameters are decoded from the I-PCP and I-DEI fields of the I-TAG as described in 6.10.3.

1 The value of the **mac\_service\_data\_unit** parameter is the value of the received `mac_service_data_unit`  
2 following the removal of the I-TAG.

3 The value of the **frame\_check\_sequence** parameter is either unspecified or derived from the received FCS  
4 information modified to take into account the changes to the frame.

### 5 **6.10.2 Data requests**

6 On invocation of an `M_UNITDATA.request` primitive at any VIP-ISS, an `M_UNITDATA.request` primitive  
7 is invoked at the PIP-ISS, with parameter values as follows:

8 If `enableConnectionIdentifier` is `TRUE`, the `connection_identifier` is not null, and the `connection_identifier`  
9 references an address retained by the PIP, then the value for the **destination\_address** is the address  
10 referenced by the `connection_identifier`. Otherwise, the value for the **destination\_address** is the contents of  
11 the Default Backbone Destination parameter of the VIP.

12 The value for the **source\_address** is the PIP MAC address.

13 The **priority** and **drop\_eligible** parameters carry the same value as the corresponding parameter in the  
14 VIP-ISS request.

15 The **connection\_identifier** parameter is `NULL`.

16 The **mac\_service\_data\_unit** parameter is constructed from the `mac_service_data_unit` of the  
17 `M_UNITDATA.request` primitive from the VIP-ISS by prepending an I-TAG as follows:

- 18 a) The encapsulated C-SA field is the value of the `source_address` parameter of the VIP-ISS request.
- 19 b) The encapsulated C-DA field is the value of the `destination_address` parameter of the VIP-ISS  
20 request.
- 21 c) The UCA, Res1, and Res2 fields are all zero.
- 22 d) The I-SID field is the value contained in the VIP-ISID parameter.
- 23 e) The I-PCP and I-DEI fields are encoded from the `priority` and `drop_eligible` parameters of the  
24 VIP-ISS request as specified in 6.10.3.

25 The value of the **frame\_check\_sequence** parameter is either unspecified or derived from the received FCS  
26 information modified to take into account the changes to the frame.

### 27 **6.10.3 Priority Code Point encoding**

28 The encoding (and decoding) of the I-PCP and I-DEI fields from (to) the **priority** and **drop\_eligible**  
29 parameters is accomplished using a Priority Code Point Encoding Table (and Priority Code Point Decoding  
30 Table) as described in 6.9.3.

## 6.11 Support of the EISS by CBPs

The functions specified in this subclause replace the functions specified in 6.9 when the EISS is supported by a CBP in a BEB (Clause 25). See Figure 6-3. The functions specified in this subclause use a single instance of the ISS (IEEE Std 802.1AC) and provide a single instance of the EISS. The EISS shall be supported by functions using both the S-TAG and the I-TAG as specified in 9.5.

NOTE 1—Although the CBP does not transmit or receive S-tagged frames, it supports the S-TAG type in the sense that it is a port on an S-VLAN component and the `vlan_identifier` parameter contains an S-VID.

**Figure 6-3—B-Component CBP**

NOTE 2—Higher Layer Entities may interface to the CBP at the SAP represented by the ISS using the Bridge Port Connectivity specified in 8.5.1. Protocol shims such as CFM MPs may interface at the EISS using the EISS Multiplex Entity specified in 6.17, or at the ISS using the Backbone Service Instance Multiplex Entity specified in 6.18. Figure 26-2 shows a CBP with both Bridge Port Connectivity and CFM shims.

The CBP shall support the following parameters for use by these functions:

- a) A PVID parameter for Port-based B-VLAN classification.  
The PVID shall contain a valid VID value (Table 9-2) and may be configured by management. If it has not been explicitly configured, the PVID shall assume the value of the default PVID defined in Table 9-2.
- b) A Backbone Service Instance table.  
The Backbone Service Instance table is configurable by management and has one entry for each backbone service instance supported on the CBP. The Backbone Service Instance table is used to filter frames containing an I-SID value that is not configured on this CBP. It may also be used to provide backbone service instance-specific assignment of a B-VID, to translate I-SID values, and/or to translate backbone destination addresses. Entries in the Backbone Service Instance table may be set automatically by the protection switching procedures described in 26.10.3.4. The Backbone Service Instance table shall contain the following field for each entry:
- c) Backbone-SID (I-SID). This contains the identifier used in the backbone network for the backbone service instance.

The Backbone Service Instance table may also contain one or more of the following additional fields for each entry:

- d) B-VID (Backbone VLAN Identifier). If the B-VID field is supported, it shall contain a valid VID value (Table 9-2) for that backbone service instance. The default value is the same as the PVID.
- e) Local-SID (Local Service Instance Identifier). This field is used to perform a bidirectional 1:1 mapping between the Backbone-SID (contained in the I-TAG in the `mac_service_data_unit` at the EISS) and the Local-SID (contained in the I-TAG in the `mac_service_data_unit` at the ISS). The default value of the Local-SID field is the value of the Backbone-SID field.

- 1 f) Default Backbone Destination. If this field is present, it is used as the `destination_address` in the  
2 EISS indication when the `destination_address` parameter of the ISS indication is the Backbone  
3 Service Instance Group address. It allows the backbone provider to replace the Backbone Service  
4 Instance Group address with an individual or group address to limit the distribution of the frame  
5 within a B-VLAN. The default value is the Backbone Service Instance Group address.
- 6 NOTE 3—If a CBP is associated with a TESI the Default Backbone Destination field and the B-VID field is  
7 supported.

### 8 6.11.1 Data indications

9 On receipt of an `M_UNITDATA.indication` primitive from the ISS, the received frame shall be discarded if:

- 10 a) The initial octets of the `mac_service_data_unit` do not contain a valid I-TAG; or  
11 b) The `Res2` field in the I-TAG is not zero; or  
12 c) The Local-SID field of the Backbone Service Instance table is supported and the I-SID value in the  
13 I-TAG does not match the Local-SID value in any entry in the Backbone Service Instance table; or  
14 d) The Local-SID field of the Backbone Service Instance table is not supported and the I-SID value in  
15 the I-TAG does not match the Backbone-SID value in any entry in the Backbone Service Instance  
16 table.

17 Otherwise, an `EM_UNITDATA.indication` primitive is invoked at the EISS with parameter values  
18 determined using one entry in the Backbone Service Instance table. If the Local-SID field of the Backbone  
19 Service Instance table is supported then the entry with a Local-SID value that matches the I-SID value in the  
20 I-TAG is selected. Otherwise, the entry with a Backbone-SID value that matches the I-SID value in the  
21 I-TAG is selected. The parameter values are then determined as follows:

22 The `mac_service_data_unit` parameter is determined as follows:

- 23 e) If the Local-SID field of the Backbone Service Instance table is supported, then value of the  
24 `mac_service_data_unit` parameter is the value of the `mac_service_data_unit` parameter of the ISS  
25 indication modified by replacing the value of the I-SID field in the I-TAG with the value of  
26 Backbone-SID field in the selected Backbone Service Instance table entry.
- 27 f) Otherwise, the `mac_service_data_unit` parameter contains the same value as the  
28 `mac_service_data_unit` parameter of the ISS indication.

29 The `destination_address` parameter is determined as follows:

- 30 g) If the `destination_address` in the ISS indication is the Backbone Service Instance Group address and  
31 the Default Backbone Destination field of the Backbone Service Instance table is supported, then the  
32 `destination_address` parameter is the Default Backbone Destination value in the selected Backbone  
33 Service Instance table entry.
- 34 h) Otherwise, if the `destination_address` in the ISS indication is the Backbone Service Instance Group  
35 address and the Local-SID field of the Backbone Service Instance table is supported, then the  
36 `destination_address` parameter is the Backbone Service Instance Group address constructed using  
37 the Backbone-SID value in the selected Backbone Service Instance table entry.
- 38 i) Otherwise, the `destination_address` parameter contains the same value as the `destination_address`  
39 parameter of the ISS indication.

40 The `source_address` parameter contains the same value as the `source_address` parameter of the ISS  
41 indication.

42 The value of the `vlan_identifier` parameter is determined as follows:

- 43 j) If the B-VID field of the Backbone Service Instance table is supported, then the `vlan_identifier`  
44 parameter contains the B-VID value in the selected Backbone Service Instance table entry.
- 45 k) Otherwise, the `vlan_identifier` parameter contains the value of the PVID parameter.

1 The value of the **drop\_eligible** and **priority** parameters are determined as follows:

- 2 l) The value of the **drop\_eligible** parameter and the received\_priority value are decoded from the
- 3 I-DEI and the I-PCP fields of the I-TAG in the mac\_service\_data\_unit as described in 6.11.3.
- 4 m) The value of the **priority** parameter is then regenerated from the received\_priority value, as
- 5 specified for the received\_priority in 6.11.4.

6 The value of the **frame\_check\_sequence** parameter is either unspecified or derived from the received FCS

7 information modified as necessary to take into account changes to the frame.

## 8 6.11.2 Data requests

9 On invocation of an EM\_UNITDATA.request primitive by a user of the EISS, the frame shall be discarded

10 if:

- 11 a) The initial octets of the mac\_service\_data\_unit do not contain a valid I-TAG.
- 12 b) The Res2 field in the I-TAG is not zero.
- 13 c) The I-SID value in the I-TAG does not match the Backbone-SID value in any of the entries in the
- 14 Backbone Service Instance table.

15 Otherwise, an M\_UNITDATA.request primitive is invoked, with parameter values determined using the

16 Backbone Service Instance table entry with a Backbone-SID value that matches the I-SID value in the

17 I-TAG. The parameter values are determined as follows:

18 The value of the **mac\_service\_data\_unit** parameter is determined as follows:

- 19 d) If the Local-SID field of the Backbone Service Instance table is supported, then
- 20 **mac\_service\_data\_unit** parameter contains the value of the mac\_service\_data\_unit parameter of
- 21 the EISS request modified by replacing the I-SID in the I-TAG with the Local-SID value in the
- 22 selected Backbone Service Instance table entry.
- 23 e) Otherwise, the **mac\_service\_data\_unit** parameter contains the same value as the
- 24 mac\_service\_data\_unit parameter of the EISS request.

25 The **destination\_address** parameter is determined as follows:

- 26 f) If the Local-SID field of the Backbone Service Instance table is supported and the
- 27 destination\_address in the EISS request is the address of this CBP, or is a group address, then the
- 28 destination\_address parameter is the Backbone Service Instance Group address constructed from the
- 29 Local-SID value in the selected Backbone Service Instance table entry.
- 30 g) If the Local-SID field of the Backbone Service Instance table is not supported and the
- 31 destination\_address in the EISS request is the address of this CBP, or is a group address, then the
- 32 destination\_address parameter is the Backbone Service Instance Group address constructed from the
- 33 Backbone-SID value in the selected Backbone Service Instance table entry.
- 34 h) Otherwise, the **destination\_address** parameter contains the same value as the destination\_address
- 35 parameter of the EISS request.

36 The **source\_address** parameter contains the same value as the source\_address parameter of the EISS

37 request.

38 The **priority** and **drop\_eligible** parameters carry the same value as the corresponding parameter in the EISS

39 request.

40 The value of the **frame\_check\_sequence** parameter is either unspecified or derived from the received FCS

41 information modified to take into account any changes to the frame.

### 6.11.3 Priority Code Point decoding

The decoding of the I-PCP and I-DEI fields to the **priority** and **drop\_eligible** parameters is accomplished using a Priority Code Point Decoding Table as described in 6.9.3.

### 6.11.4 Regenerating priority

The priority of received frames is regenerated using priority information contained in the I-PCP and the Priority Regeneration table for the reception Port. For each reception Port, the Priority Regeneration table has eight entries, corresponding to the eight possible values of priority (0 through 7). Each entry specifies, for the given value of received\_priority, the corresponding regenerated value. The priority decoded from the I-PCP field of the I-TAG is taken to be the received\_priority.

NOTE—IEEE 802 LAN technologies signal a maximum of eight priority values. Annex I further explains the use of priority values and how they map to traffic classes.

Table 6-4 specifies default regenerated priority values for each of the eight possible values of the received\_priority. These default values shall be used as the initial values of the corresponding entries of the Priority Regeneration table for each Port. The table may be configured as described in 6.9.4.

## 6.12 Protocol VLAN classification

Each instance of the tagging and detagging functions that supports the EISS (6.9), and implements the optional Port-and-Protocol-based VLAN classification, shall implement a VID Set, each member of which associates values of a Protocol Group Identifier (6.12.2) with a VID. Each Untagged and Priority-tagged frame received is assigned a **vlan\_identifier** equal to the VID Set value for the reception Port and the Protocol Group Identifier selected by matching the received frame with a Protocol Template. See Figure 6-4.

**Figure 6-4—Example of operation of Port-and-Protocol-based classification**

1 The **detagged\_frame\_type** parameter indicates the frame format. Its value is determined as follows:

- 2 a) If the frame is Untagged or Priority-tagged, this parameter is present and indicates the link-layer  
3 encapsulation format of the *Detagged Frame*. The Detagged Frame of an Untagged Frame is the  
4 frame itself. The Detagged Frame of a Tagged Frame or Priority-tagged Frame is the frame that  
5 results from untagging the frame in accordance with the frame format described in Clause 9. The  
6 value of **detagged\_frame\_type** is as follows:
  - 7 1) Ethernet, if the Detagged Frame uses EtherType-encapsulated IEEE 802.3 format.
  - 8 2) RFC\_1042, if the Detagged Frame is of the format specified by 9.4 in IEEE Std 802™-2014  
9 [B7] for the encoding of an IEEE 802.3 EtherType Field in an ISO/IEC 8802-2/SNAP header  
10 (this supersedes the original definition, which appeared in IETF RFC 1042 (1988)).
  - 11 3) SNAP\_Other, if the Detagged Frame contains an LLC UI PDU with DSAP and SSAP fields  
12 equal to the LLC address reserved for SNAP and the 5-octet Subnetwork Access Protocol  
13 (SNAP) Protocol Identifier (PID) value is not in either of the ranges used for RFC\_1042 above.
  - 14 4) LLC\_Other, if the Detagged Frame contains both a DSAP and an SSAP address field in the  
15 positions specified by ISO/IEC 8802-2 Logical Link Control, but is not any of the formats  
16 described for LLC frames above.
- 17 b) Else the parameter is not present.

18 The **EtherType** value is present if the **detagged\_frame\_type** parameter is present and has the value Ethernet  
19 or RFC\_1042. Its value is the value of the IEEE 802.3 Length/Type Field present in the Detagged Frame.  
20 The value is determined as follows:

- 21 c) If the **detagged\_frame\_type** parameter is present and has the value Ethernet or RFC\_1042, then this  
22 parameter is present and has the value of the IEEE 802.3 EtherType Field present in the Detagged  
23 Frame.
- 24 d) Else the parameter is not present.

25 The **llc\_saps** parameter is present if the **detagged\_frame\_type** parameter is present and has the value  
26 LLC\_Other. Its value is determined as follows:

- 27 e) If the **detagged\_frame\_type** parameter is present and has the value LLC\_Other, then this parameter  
28 is present and its value is the pair of LLC ISO/IEC 8802-2 DSAP and SSAP address field values.
- 29 f) Else the parameter is not present.

30 NOTE 1—A frame that is encapsulated using values of hex FF/FF in the position where an LLC header is to be expected  
31 (as defined by ISO/IEC 8802-2) is known as a “Novell IPX Raw” encapsulation. Such frames do not conform to  
32 ISO/IEC 8802-2, in that they do not include some of the other required LLC fields. For the purposes of this standard,  
33 they are treated as LLC\_Other, regardless of whether they are legal LLC frames.

34 NOTE 2—Bridges are not required, for the purposes of this standard, to completely verify whether the format of frames  
35 meets ISO/IEC 8802-2. They are required only to recognize the DSAP and SSAP fields of such frames.

36 The **snap\_pid** parameter is present if the **detagged\_frame\_type** parameter is present and has the value  
37 SNAP\_Other. Its value is determined as follows:

- 38 g) If the **detagged\_frame\_type** parameter is present and has the value SNAP\_Other, then the parameter  
39 is present and its value is the contents of the 5 octets following the LLC header, i.e., the PID field.
- 40 h) Else the parameter is not present.

### 1 6.12.1 Protocol Templates

2 In a Bridge that supports Port-and-Protocol-based VLAN classification, a Protocol Template is a tuple that  
3 specifies a protocol to be identified in received frames. A Protocol Template has one of the following  
4 formats:

- 5 a) A value “Ethernet” and a 16-bit IEEE 802.3 EtherType Field value
- 6 b) A value “RFC\_1042” and a 16-bit IEEE 802.3 EtherType Field value
- 7 c) A value “SNAP\_Other” and a 40-bit PID value
- 8 d) A value “LLC\_Other” and a pair of ISO/IEC 8802-2 LSAP values: DSAP and SSAP

9 A Protocol Template matches a frame if:

- 10 e) The frame’s `detagged_frame_type` is Ethernet, the Protocol Template is of type Ethernet, and the  
11 frame’s IEEE 802.3 EtherType Field is equal to the value of the IEEE 802.3 EtherType Field of the  
12 Protocol Template, or
- 13 f) The frame’s `detagged_frame_type` is RFC\_1042, the Protocol Template is of type RFC\_1042 and  
14 the frame’s IEEE 802.3 EtherType Field is equal to the IEEE 802.3 EtherType Field of the Protocol  
15 Template, or
- 16 g) The frame’s `detagged_frame_type` is SNAP\_Other, the Protocol Template is of type SNAP\_Other,  
17 and the frame’s `snap_pid` is equal to the PID of the Protocol Template, or
- 18 h) The frame’s `detagged_frame_type` is LLC\_Other, the Protocol Template is of type LLC\_Other, and  
19 the frame’s `llc_saps` matches the value of the DSAP and SSAP of the Protocol Template.

20 NOTE—If a port does not support Protocol Templates of the frame’s `detagged_frame_type`, then no match will occur.

### 21 6.12.2 Protocol Group Identifiers

22 A Bridge that supports Port-and-Protocol-based VLAN classification shall support Protocol Group  
23 Identifiers.

24 A Protocol Group Identifier, shown as “Group Id” in Figure 6-4, designates a group of protocols that will be  
25 associated with one member of the VID Set of a Port. The association of protocols into groups is established  
26 by the contents of the Protocol Group Database, as described in 6.12.3. The identifier has scope only within  
27 a single Bridge.

28 An implicit Protocol Group Identifier is assigned to frames that match none of the entries in the Protocol  
29 Group Database. Therefore, every incoming frame can be assigned to a Protocol Group Identifier.

### 30 6.12.3 Protocol Group Database

31 A Bridge that supports Port-and-Protocol-based VLAN classification shall support a single Protocol Group  
32 Database. The Protocol Group Database groups together a set of one or more Protocols by assigning them  
33 the same Protocol Group Identifier (6.12.2). Each entry of the Protocol Group Database comprises the  
34 following:

- 35 a) A Protocol Template
- 36 b) A Protocol Group Identifier

37 The Protocol Group Database specifies a mapping from Protocol Templates to Protocol Group Identifiers. If  
38 two entries of the Protocol Group Database contain different Protocol Group Identifiers, then their Protocol  
39 Templates must also be different.

40 The entries of the Protocol Group Database may be configured by management. A Bridge that supports  
41 Port-and-Protocol-based VLAN classification shall support at least one of the Protocol Template formats.

1 An implicit Protocol Group Database entry exists that matches all frames. This entry is invoked for frames  
2 that do not match the template of any of the other entries. It references an implicit Protocol Group Identifier  
3 that selects the PVID on each port. In this way, it is ensured that all incoming frames are matched by a  
4 Protocol Group Identifier and, hence, are assigned to a VID.

5 NOTE—If there are no entries in the Protocol Group Database, then the frame relay behavior of this Bridge is identical  
6 to the frame relay behavior of a Bridge having the same number of Ports that supports only Port-based VLAN  
7 classification.

### 8 6.13 Support of the ISS for attachment to a PBN

9 This standard specifies both Customer Bridges (3.59) and Provider Bridges (3.208). The operation of  
10 Provider Bridges and PBNs is, by design, largely transparent to Customer Bridges and Customer Bridged  
11 Networks (CBNs). Figure 15-1 illustrates the relationship of the service provided by the MAC Sublayer  
12 functionality of Provider Bridges to that used by a Customer Bridge. This subclause enables a mechanism  
13 for a Customer Bridge attached to a PBN to request priority handling of frames.

14 The functions specified in this subclause provide the ISS to the MAC Relay Entity of a Customer Bridge by  
15 making use of the underlying ISS provided by the Media Access Method Convergence function as shown in  
16 Figure 6-5. These functions shall be one of the following:

- 17 a) When Service Access Priority Selection is disabled, the functions shall be null; i.e., each  
18 M\_UNITDATA.request received from the provided ISS results in an M\_UNITDATA.request with  
19 identical parameters presented to the underlying ISS, and each M\_UNITDATA.indication received  
20 from the underlying ISS results in an M\_UNITDATA.indication with identical parameters presented  
21 to the provided ISS.
- 22 b) When Service Access Priority Selection is enabled, the mac\_service\_data\_unit in each  
23 M\_UNITDATA.request is Priority-tagged with an S-TAG header when presented to the underlying  
24 ISS, and if an S-TAG header is present in the mac\_service\_data\_unit parameter in an  
25 M\_UNITDATA.indication received from the underlying ISS, the S-TAG header is removed before  
26 the M\_UNITDATA.indication is presented to the provided ISS.

**Figure 6-5—Service access priority selection**

27 Specification of a null function allows a Customer Bridge without additional functionality to connect to a  
28 PBN.

29 Specification of the Service Access Priority Selection function allows the Customer Bridge Port to request  
30 priority handling of the frame from a Port-based service interface (15.3) to a PBN on the basis of the priority  
31 assigned within the CBN, while allowing for differences in cost and service level ascribed to individual  
32 values of priority within the service provider and customer networks.

### 6.13.1 Data requests

For each M\_UNITDATA.request received from the provided ISS, an M\_UNITDATA.request is presented to the underlying ISS with the following parameters:

The destination\_address, source\_address, and priority parameters are unchanged.

A tag header, formatted as necessary for the destination MAC type, is inserted as the initial octets of the mac\_service\_data\_unit parameter. The Tag Protocol Identification is the Service VLAN Tag EtherType (9.5). The Tag Control Information (TCI) contains a null VID field, and PCP and DEI fields constructed as specified in 6.9.3 using a drop\_eligible value of FALSE and a service\_access\_priority value derived from the priority parameter using Table 6-6.

**Table 6-6—Service Access Priority**

| Received priority | Default service access priority | Range |
|-------------------|---------------------------------|-------|
| 0                 | 0                               | 0–7   |
| 1                 | 1                               | 0–7   |
| 2                 | 2                               | 0–7   |
| 3                 | 3                               | 0–7   |
| 4                 | 4                               | 0–7   |
| 5                 | 5                               | 0–7   |
| 6                 | 6                               | 0–7   |
| 7                 | 7                               | 0–7   |

Table 6-6 specifies default service\_access\_priority values for each of the eight possible values of the priority parameter in the M\_UNITDATA.request received from the provided ISS. These default values shall be used as the initial values of the corresponding entries of the Service Access Priority Table for each Port supporting Service Access Priority Selection. The values in the table may be modified by management. If this capability is provided, the value of the table entries shall be independently settable for each Port and for each value of priority, and the Bridge shall have the capability to use the full range of the values in the parameter ranges specified in the table.

The frame\_check\_sequence parameter is either unspecified or contains a value modified from the received frame\_check\_sequence value taking into account the changes in the mac\_service\_data\_unit parameter.

NOTE—The priority of the original service request made of the customer network can be carried transparently and unchanged across the PBN in the C-TAG.

### 6.13.2 Data indications

For each M\_UNITDATA.indication received from the underlying ISS, an M\_UNITDATA.request is presented to the supported ISS with the following parameters:

The destination\_address and source\_address parameters are unchanged.

1 If the initial octets of the `mac_service_data_unit` do not contain a tag header with the Service VLAN Tag  
2 EtherType value (9.5), then the `mac_service_data_unit` and `frame_check_sequence` parameters are  
3 unchanged. Otherwise,

- 4 a) The `mac_service_data_unit` is detagged by removing the octets of the S-TAG header,
- 5 b) The priority parameter is decoded from the PCP field (6.9.3),
- 6 c) The `drop_eligible` parameter is decoded from the Drop Eligible Indicator field (6.9.3), and
- 7 d) The `frame_check_sequence` parameter is either unspecified or contains a value modified from the  
8 received `frame_check_sequence` value taking into account the changes in the `mac_service_data_unit`  
9 parameter.

## 10 6.14 Support of the ISS within a system

11 A single system can comprise two or more instances of VLAN Bridge components connected by one or  
12 more of their Ports. If those Ports are not otherwise accessible, the ISS may be provided by means outside  
13 the scope of this specification. Figure 15-4 provides an example. Each instance of such an implementation  
14 of the ISS shall support the MAC status and Point-to-point parameters. An `M_UNITDATA.request` at one of  
15 the Ports connected to such an instance of the ISS shall result in `M_UNITDATA.indications` with identical  
16 parameters at all other Ports connected to that instance.

17 For convenience of management, such instances of ISS provision are assigned the LAN MAC Type 802.1.  
18 Management parameters common to MACs of this type are specified in Clause 12.

19 NOTE—The ISS can also be supported at Bridge Ports wholly contained within a system by any IEEE 802 LAN  
20 technology, subject to the system requirements of the particular media access method.

## 21 6.15 Support of the ISS by additional technologies

22 The ISS may be supported by other technologies that provide either an IEEE 802 MAC Service or an  
23 emulated IEEE 802 MAC Service. The technology is responsible for invoking an `M_UNITDATA.indication`  
24 with appropriate parameters (IEEE Std 802.1AC) for each received frame, and transmitting a frame in  
25 response to each `M_UNITDATA.request`. The `mac_service_data_unit` parameter in an  
26 `M_UNITDATA.indication` may include a tag header of a type recognized by the functions using the EISS  
27 (6.8). If multiplexing of multiple virtual instances of the MAC Service is provided, each virtual service must  
28 be:

- 29 a) Identified by the VID field in a tag header of a type recognized by the functions using the EISS, or
- 30 b) Attached to separate instance of the ISS with no tag header in the `mac_service_data_unit`

31 (i.e., the only multiplexing recognized by the functions of the MAC Relay are those identified by a VID).

## 32 6.16 Filtering services in Bridged Networks

33 Bridges provide filtering services that support aspects of the maintenance of QoS—in particular, transit  
34 delay, priority, and throughput. In addition, these services provide a degree of administrative control over the  
35 propagation of particular MAC addresses in the network.

36 The services described are services in the most general sense; i.e., descriptions of functionality available to a  
37 MAC Service user or an administrator to control and access filtering capabilities. The descriptions make no  
38 assumptions about how the service might be realized. There are at least the following possibilities:

- 39 a) Use of existing protocols and mechanisms, defined in IEEE 802 standards and elsewhere.
- 40 b) Use of management functionality, either locally defined or via remote management protocols.
- 41 c) Other means, standardized or otherwise.

## 1 **6.16.1 Purpose(s) of filtering service provision**

2 Filtering services are provided for the purposes described in 6.16.1.1 and 6.16.1.2.

### 3 **6.16.1.1 Administrative control**

4 Filtering services provide administrative control over the use of particular source and destination addresses  
5 in designated parts of the network. Such control allows network managers and administrators to limit the  
6 extent of operation of network layer and other protocols that use individual and group MAC addresses by  
7 establishing administrative boundaries across which specific MAC addresses are not forwarded.

### 8 **6.16.1.2 Throughput and end station load**

9 Filtering services increase the overall throughput of the network, and reduce the load placed on end stations  
10 caused by the reception of frames that are destined for other end stations, by:

- 11 a) Limiting frames destined for specific MAC addresses to parts of the network that, to a high  
12 probability, lie along a path between the source MAC address and the destination MAC address.
- 13 b) Reducing the extent of group addressed frames to those parts of the network that contain end  
14 stations that are legitimate recipients of that traffic.
- 15 c) In Virtual Bridged Networks, reducing the extent of frames on specific VLANs to those parts of the  
16 network that contain stations that are legitimate recipients of traffic on that VLAN.

17 NOTE—Some aspects of the filtering services described in this standard are dependent upon the active participation of  
18 end stations. Where such participation is not possible, those aspects of the filtering services will be unavailable.

## 19 **6.16.2 Goals of filtering service provision**

20 The filtering services provided can be used to:

- 21 a) Allow the MAC Service provider to dynamically learn where the recipients of frames addressed to  
22 individual MAC addresses are located.
- 23 b) Allow end stations that are the potential recipients of MAC frames destined for group MAC  
24 addresses to dynamically indicate to the MAC Service provider which destination MAC address(es)  
25 they wish to receive.
- 26 c) Exercise administrative control over the extent of propagation of specific MAC addresses.

## 27 **6.16.3 Users of filtering services**

28 The filtering services provided are available to the following users:

- 29 a) Network management and administration, for the purposes of applying administrative control.  
30 Interactions between administrators of the network and the filtering service provider may be  
31 achieved by local means or by means of explicit management mechanisms.
- 32 b) End stations, for the purposes of controlling the destination addresses that they will receive.  
33 Interactions between end stations and the filtering service provider may be implicit, as is the case  
34 with the Learning Process (8.7), or by explicit use of filtering service primitives.

## 35 **6.16.4 Basis of service**

36 Filtering in Bridged Networks relies on the establishment of filtering rules, and subsequent filtering  
37 decisions, that are based on the value(s) contained in the Source MAC Address, Destination MAC Address,  
38 or VID fields in MAC frames.

39 NOTE—The filtering services defined by this standard use source address learning, destination address, and VID  
40 filtering.

## 6.16.5 Categories of service

Filtering services in Bridged Networks fall into the following categories:

- a) *Basic Filtering Services.* These services are supported by the Forwarding Process (8.6) and by Static Filtering Entries (8.8.1), Static VLAN Registration Entries (8.8.2), Dynamic Filtering Entries (8.8.3), and Dynamic VLAN Registration Entries (8.8.5) in the FDB. The information contained in the Dynamic Filtering Entries is maintained through the operation of the Learning Process (8.7), while the information contained in the Dynamic VLAN Registration Entries is maintained through the operation of MVRP (11.2) and MIRP (Clause 39).
- b) *Extended Filtering Services.* These services are supported by the Forwarding Process (8.6), and the Static Filtering Entries (8.8.1) and MAC Address Registration Entries (8.8.4) in the FDB. The information contained in the MAC Address Registration Entries is maintained through the operation of MMRP (10.9).

All Bridges shall support Basic Filtering Services and may support Extended Filtering Services.

## 6.16.6 Service configuration

In the absence of explicit information in the FDB, the behavior of the Forwarding Process with respect to the forwarding or filtering of frames destined for group MAC addresses depends upon the categories of service supported by the Bridge.

Basic Filtering Services support the filtering behavior required for regions of a Bridged Network in which potential recipients of multicast frames exist, but where either the recipients or the Bridges are unable to support the dynamic configuration of filtering information for those group MAC addresses, or the recipients have a requirement to receive all traffic destined for group MAC addresses.

Extended Filtering Services support the filtering behavior required for regions of a network in which potential recipients of multicast frames exist, and where both the potential recipients of frames and the Bridges are able to support dynamic configuration of filtering information for group MAC addresses. In order to integrate this extended filtering behavior with the needs of regions of the network that support only Basic Filtering Services, Bridges that support Extended Filtering Services can be statically and dynamically configured to modify their filtering behavior on a per-group MAC address basis, and also on the basis of the overall filtering service provided by each outbound Port with regard to multicast frames. The latter capability permits configuration of the Port's default forwarding or filtering behavior with regard to group MAC addresses for which no specific static or dynamic filtering information has been configured.

Service configuration provides the ability to configure the overall filtering for the following cases:

- a) Bridges that only implement Basic Filtering Services.
- b) Bridges that support Extended Filtering Services in a heterogeneous environment, where some equipment is unable to participate in Dynamic Multicast Filtering, or where some equipment (e.g., routers) has specific needs to see unfiltered traffic.
- c) Bridges that support Extended Filtering Services in a homogeneous environment, where all equipment is able to participate in Dynamic Multicast Filtering.

## 6.16.7 Service definition for Extended Filtering Services

The Filtering Services are described by means of service primitives that define particular types of interaction between MAC Service users and the MAC Service provider across the MAC Service boundary. As these interactions are not defined between peer entities, they are described simply in terms of service requests sent from the MAC Service user to the MAC Service provider.

### 6.16.7.1 Dynamic registration and deregistration services

These services allow MAC Service users dynamic control over the set of destination MAC addresses that they will receive from the MAC Service provider, by:

- a) Registering/deregistering membership of specific Groups associated with those addresses.
- b) Registering/deregistering individual MAC address information.
- c) Registering/deregistering service requirements with regard to the overall forwarding/filtering behavior for Groups.

Provision of these services is achieved by means of MMRP and its associated procedures, as described in 10.9.

NOTE 1—These services can provide the MAC Service user with dynamic control over access to multicast data streams, for example, multiple video channels made available by a server using a different group MAC address for each channel. The ability to both register and deregister Group membership, coupled with the filtering action associated with the Group membership, limits the impact of such services on the bandwidth available in the network. These services can be used to control the reception of other categories of multicast traffic, for similar reasons.

#### REGISTER\_MAC\_ADDRESS (MAC\_ADDRESS)

Indicates to the MAC Service provider that the MAC Service user wishes to receive frames containing the MAC address indicated in the MAC\_ADDRESS parameter as the destination address. The MAC addresses that can be carried by this parameter do not include the following:

- d) Any of the Reserved Addresses identified in Table 8-1, Table 8-2, or Table 8-3.
- e) Any of the MRP Application addresses, as defined in Table 10-1.

#### DEREGISTER\_MAC\_ADDRESS (MAC\_ADDRESS)

Indicates to the MAC Service provider that the MAC Service user no longer wishes to receive frames containing the MAC address indicated in the MAC\_ADDRESS parameter as the destination address.

#### REGISTER\_SERVICE\_REQUIREMENT (REQUIREMENT\_SPECIFICATION)

Indicates to the MAC Service provider that the MAC Service user has a requirement for any devices that support Extended Filtering Services to forward frames in the direction of the MAC Service user in accordance with the definition of the service requirement defined by the REQUIREMENT\_SPECIFICATION parameter. The values that can be carried by this parameter are as follows:

- f) Forward All Groups.
- g) Forward Unregistered Groups.

#### DEREGISTER\_SERVICE\_REQUIREMENT (REQUIREMENT\_SPECIFICATION)

Indicates to the MAC Service provider that the MAC Service user no longer has a requirement for any devices that support Extended Filtering Services to forward frames in the direction of the MAC Service user in accordance with the definition of the service requirement defined by the REQUIREMENT\_SPECIFICATION parameter. The values that can be carried by this parameter are as follows:

- h) Forward All Groups.
- i) Forward Unregistered Groups.

The use of these services can result in the propagation of group MAC address and service requirement information across the spanning tree, affecting the contents of MAC Address Registration Entries (8.8.4) in Bridges and end stations, and thereby affecting the frame forwarding behavior of the Bridges and end stations with regard to multicast frames.

NOTE 2—If the EISS is supported, the Extended Filtering Service primitives issued by the MAC Service user should also include a VID parameter in order to identify the VLAN associated with the MAC\_ADDRESS or REQUIREMENT\_SPECIFICATION specified.

## 6.17 EISS Multiplex Entity

The EISS Multiplex Entity enables shims defined for the ISS to use the EISS. Figure 6-6 illustrates two EISS Multiplex Entities placed back-to-back.

**Figure 6-6—Two back-to-back EISS Multiplex Entities**

An EISS Multiplex Entity has one EISS SAP, and a number of multiplexed SAPs, each either an ISS SAP or an EISS SAP. Each multiplexed ISS SAP is assigned to a single `vlan_identifier` value. Each multiplexed EISS SAP is assigned to one or more `vlan_identifier` values. Every `vlan_identifier` is assigned to some multiplexed SAP. Upon receiving a Request or Indication from its single EISS SAP, the EISS Multiplex Entity uses the `vlan_identifier` to select the corresponding one of its multiplexed SAPs to present the Request or Indication. Similarly, any Request or Indication received from a multiplexed SAP is presented to the single EISS SAP; the `vlan_identifier` parameter presented on the single EISS SAP is the one associated with the multiplexed ISS SAP, or the one obtained from the multiplexed EISS SAP.

Shims can be multiplexed in this fashion to separately serve multiple `vlan_identifiers`. Figure 22-1 illustrates CFM shims deployed in this manner.

The `MAC_Operational` status parameter (IEEE Std 802.1AC) presented to the uppermost EISS-SAP in Figure 6-6 is TRUE if and only if:

- a) The uppermost EISS-SAP's `MAC_Enabled` parameter is TRUE; and
- b) At least one of its multiplexed SAPs' `MAC_Operational` status parameters is TRUE.

The `MAC_Operational` status parameter of each of the lower EISS Multiplex Entity's multiplexed SAPs in Figure 6-6 is computed separately and is TRUE if and only if:

- c) The lowermost EISS-SAP's `MAC_Operational` parameter is TRUE; and
- d) That multiplexed SAP's `MAC_Enabled` parameter is TRUE.

## 6.18 Backbone Service Instance Multiplex Entity

The Backbone Service Instance Multiplex Entity allows shims defined for the ISS to be instantiated per backbone service instance at a SAP that supports multiple backbone service instances. Figure 6-7 illustrates two Backbone Service Instance Multiplex Entities placed back-to-back. A set of back-to-back Backbone Service Instance Multiplex Entities may be used at the ISS of a PIP or CBP to provide per Backbone Service Instance SAPs that support CFM shims at the Backbone Service Instance MD Level as shown in Figure 6-8 and the figures of 26.8.

**Figure 6-7—Two back-to-back Backbone Service Instance Multiplex Entities**

**Figure 6-8—Backbone Service Instance Multiplex Entities with example CFM shims**

NOTE 1—Figure 6-8 shows a representative placement of CFM shims between back-to-back Backbone Service Instance Multiplex Entities. This is not intended to imply any restriction that this is the only possible configuration of MEPs and MIPs.

A Backbone Service Instance Multiplex Entity has one ISS SAP that supports multiple backbone service instances, and a number of multiplexed ISS SAPs each supporting a single backbone service instance. Each multiplexed SAP has a single assigned I-SID value. Every I-SID value is assigned to a multiplexed SAP, and no I-SID value is assigned to more than one multiplexed SAP.

NOTE 2—There are implicitly  $2^{24}$  multiplexed SAPs—one for each potential I-SID value. This does not require any implementation to support  $2^{24}$  SAPs. The combined structure of back-to-back Backbone Service Instance Multiplex Entities is transparent to any frames with an I-SID value corresponding to a multiplexed SAP that does not have a protocol entity (e.g., CFM) instantiated at that SAP.

1 In the multiplexing direction, any Request or Indication received from a multiplexed SAP results in the  
2 generation of a corresponding Request or Indication to the single ISS SAP, with an I-TAG header added to  
3 the `mac_service_data_unit` as specified in 6.18.2. Similarly, in the demultiplexing direction any Request or  
4 Indication received from the single ISS SAP results in the generation of a corresponding Request or  
5 Indication at one of the multiplexed SAPs (determined by the I-SID contained in a I-TAG in the  
6 `mac_service_data_unit`), with the I-TAG removed from the `mac_service_data_unit` as specified in 6.18.1.  
7 When an I-TAG header with the UCA field containing a value of zero is removed, the C\_DA and C\_SA  
8 fields of the I-TAG remain in the `mac_service_data_unit`. In this case, a new EtherType field is prepended so  
9 the `mac_service_data_unit` still begins with a valid EtherType value. The Encapsulated Addresses EtherType  
10 value in Table 6-7 is allocated for this purpose.

**Table 6-7—Encapsulated Addresses EtherType**

| Name                                         | Value |
|----------------------------------------------|-------|
| IEEE 802.1Q Encapsulated Addresses EtherType | 89-10 |

11 NOTE 3—This EtherType value is used only internally at the Backbone Service Multiplex Entity and does not appear in  
12 any frame on a LAN in the PBBN.

### 13 6.18.1 Demultiplexing direction

14 On receipt of an `M_UNITDATA.request` or `M_UNITDATA.indication` primitive from the single ISS SAP,  
15 the received frame shall be discarded if:

- 16 a) The initial octets of the `mac_service_data_unit` do not contain a valid I-TAG; or
- 17 b) The Res2 field in the I-TAG is not zero.

18 Otherwise, an `M_UNITDATA.request` or `M_UNITDATA.indication` primitive is invoked at the multiplexed  
19 ISS SAP corresponding to the I-SID value in the I-TAG. The parameter values are determined as follows:

20 The **connection\_identifier** parameter contains the same value as in the received primitive.

21 The **destination\_address** and **source\_address** parameters are determined as follows:

- 22 c) If the UCA bit is zero, the **destination\_address** and **source\_address** parameters contain the  
23 respective values in the received primitive.
- 24 d) Otherwise, the **destination\_address** and **source\_address** parameters contain the respective values  
25 in the C-DA and C-SA fields of the I-TAG.

26 The value of the **drop\_eligible** and **priority** parameters are decoded from the I-DEI and the I-PCP fields of  
27 the I-TAG header in the `mac_service_data_unit` as described in 6.18.3.

28 The value of the **mac\_service\_data\_unit** parameter is constructed from the value of the received  
29 `mac_service_data_unit` modified as follows:

- 30 e) If the UCA field in the I-TAG is zero, then the I-PCP, I-DEI, UCA, Res1, Res2, and I-SID fields of  
31 the I-TAG are removed and the Backbone Service Instance Tag EtherType value is replaced with the  
32 Encapsulated Addresses EtherType value (Table 6-7).
- 33 f) Otherwise, the entire I-TAG is removed.

34 The value of the **frame\_check\_sequence** parameter is either unspecified or derived from the received FCS  
35 information modified as necessary to take into account changes to the frame.

## 1 6.18.2 Multiplexing direction

2 On receipt of an M\_UNITDATA.request or M\_UNITDATA.indication primitive from any of the  
3 multiplexed ISS SAPs, an M\_UNITDATA.request or M\_UNITDATA.indication primitive is invoked at the  
4 single ISS SAP. The parameter values are determined as follows:

5 The **source\_address**, **priority**, **drop\_eligible**, and **connection\_identifier** parameters contain the same value  
6 as in the received primitive.

7 The **destination\_address** parameter is determined as follows:

- 8 a) If the **destination\_address** in the received primitive is a group address and the UCA bit is set, then  
9 the **destination\_address** parameter contains the Backbone Service Instance Group address  
10 constructed from the I-SID corresponding to the multiplexed ISS SAP at which the primitive was  
11 received.
- 12 b) Otherwise the **destination\_address** parameter contains the same value as in the received primitive.

13 The value of the **mac\_service\_data\_unit** parameter is equal to the value of the received  
14 **mac\_service\_data\_unit** modified as follows:

- 15 c) If the initial two octets of the **mac\_service\_data\_unit** match the Encapsulated Addresses EtherType  
16 value, then these octets are replaced with the Backbone Service Instance Tag EtherType value, and  
17 the I-PCP, I-DEI, UCA, Res1, Res2, and I-SID fields of an I-TAG are inserted following this  
18 EtherType value. The UCA, Res1, and Res2 fields all contain a value of zero. The I-SID field  
19 contains the value of the I-SID corresponding to the multiplexed ISS SAP at which the primitive  
20 was received. The values of the I-PCP and I-DEI fields are encoded from the **drop\_eligible** and  
21 **priority** parameters as specified in 6.18.3.
- 22 d) If the initial two octets of the **mac\_service\_data\_unit** do not match the Encapsulated Addresses  
23 EtherType value, then a complete I-TAG is prepended to the **mac\_service\_data\_unit**. The UCA field  
24 contains a value of one. The Res1 and Res2 fields contain a value of zero. The C-DA and C-SA  
25 fields contain the **destination\_address** and **source\_address** from the received primitive, respectively.  
26 The I-SID field contains the value of the I-SID corresponding to the multiplexed ISS SAP at which  
27 the primitive was received. The values of the I-PCP and I-DEI fields are encoded from the  
28 **drop\_eligible** and **priority** parameters as specified in 6.18.3.

29 The value of the **frame\_check\_sequence** parameter is either unspecified or derived from the received FCS  
30 information modified as necessary to take into account changes to the frame.

## 31 6.18.3 Priority Code Point encoding

32 The encoding (and decoding) of the I-PCP and I-DEI fields from (to) the **priority** and **drop\_eligible**  
33 parameters is accomplished using a Priority Code Point Encoding Table (and Priority Code Point Decoding  
34 Table) as described in 6.9.3.

## 35 6.18.4 Status parameters

36 The MAC\_Operational status parameter (IEEE Std 802.1AC) presented to the uppermost single ISS SAP in  
37 Figure 6-7 is TRUE if and only if:

- 38 a) The uppermost single ISS SAP's MAC\_Enabled parameter is TRUE; and
- 39 b) At least one of its multiplexed SAPs' MAC\_Operational status parameters is TRUE.

40 The MAC\_Operational status parameter of each of the multiplexed SAPs in Figure 6-7 is computed  
41 separately, and is TRUE if and only if:

- 42 c) The lowermost single ISS SAP's MAC\_Operational parameter is TRUE; and
- 43 d) That multiplexed SAP's MAC\_Enabled parameter is TRUE.

## 6.19 TESI Multiplex Entity

The TESI Multiplex Entity allows shims defined for PBB-TE to be instantiated per TESI at a SAP that supports multiple TESI. Figure 6-9 illustrates two TESI Multiplex Entities, placed back-to-back. A set of back-to-back TESI Multiplex Entities may be used at the multiplexed (E)ISS SAPs that are associated with ESP-VIDs on a CBP to provide per TESI SAPs that support CFM shims for PBB-TE MAs as shown in Figure 26-8.

**Figure 6-9—Two back-to-back Up and Down TESI Multiplex Entities**

A TESI Multiplex Entity has one (E)ISS SAP that supports multiple TESI, and a number of multiplexed (E)ISS SAPs each supporting a single TESI. Each multiplexed SAP has destination\_address, source\_address, and vlan\_identifier combinations assigned by the TESI Multiplex Entity. Every destination\_address, source\_address, and vlan\_identifier combination can be assigned to a multiplexed SAP, and no destination\_address, source\_address, and vlan\_identifier combination is assigned to more than one multiplexed SAP.

Upon receiving a Request or Indication from its single (E)ISS SAP, the TESI Multiplex Entity uses the destination\_address, source\_address, and vlan\_identifier to select the corresponding one of its multiplexed SAPs to present the Request or Indication. The Request or Indication presented at the multiplexed SAPs has the same parameters as the original Request or Indication at the Single SAP. Similarly, any Request or Indication received from a multiplexed SAP is transparently presented to the single (E)ISS SAP.

The MAC\_Operational status parameter (6.8.2) presented to the uppermost single (E)ISS SAP in Figure 6-9 is TRUE if and only if:

- a) The uppermost single (E)ISS SAP's MAC\_Enabled parameter is TRUE; and
- b) At least one of its multiplexed SAPs' MAC\_Operational status parameters is TRUE.

The MAC\_Operational status parameter of each of the multiplexed SAPs in Figure 6-9 is computed separately, and is TRUE if and only if:

- c) The lowermost single (E)ISS SAP's MAC\_Operational parameter is TRUE; and
- d) That multiplexed SAP's MAC\_Enabled parameter is TRUE.

The MAC\_Operational parameter of the passive SAP on a PBB-TE MEP is set to FALSE when the PBB-TE MEP declares an errorCCMdefect (20.21.3) or an xconCCMdefect (20.23.3), setting the MAC\_Operational parameter of the associated multiplexed SAP on the TESI Multiplex Entity to FALSE. The MAC\_Operational parameter of the passive SAP on a PBB-TE MEP is set back to TRUE when both defects are cleared, setting back to TRUE the MAC\_Operational parameter of the associated multiplexed SAP.

## 6.20 Support of the ISS with signaled priority

The functions specified in this subclause comprise a shim (3.243, IEEE Std 802.1AC) that uses an ISS SAP supported by a MAC entity (IEEE Std 802.1AC) to provide explicitly signaled priority information to an ISS SAP that supports a VLAN-unaware MAC Relay (Figure 6-10). Signaled priority information is derived from a VLAN tag header (9.3), if such header is present in the `mac_service_data_unit`. Any given instance of the ISS shall be supported by recognizing one but not both of the following VLAN Tag EtherTypes:

- a) C-VLAN tag (C-TAG) or
- b) S-VLAN tag (S-TAG)

The VLAN Tag EtherType is selected as specified in 9.5.

Figure 6-10—Supporting the ISS with signaled priority

### 6.20.1 Data indications

On receipt of an `M_UNITDATA.indication` primitive from the lower ISS SAP (Figure 6-10), an `M_UNITDATA.indication` primitive is invoked at the upper ISS SAP, with parameter values determined as follows:

The **`destination_address`**, **`source_address`**, **`connection_identifier`**, **`mac_service_data_unit`**, and **`frame_check_sequence`** parameters carry values equal to the corresponding parameters in the received data indication.

The value of the **`drop_eligible`** and **`priority`** parameters are determined as follows:

- a) If the initial octets of the `mac_service_data_unit` contain a valid VLAN tag header (9.3) of the type used to support the EISS (9.5), the value of the `drop_eligible` parameter and the received priority value are decoded from the tag header as described in 6.9.3. Otherwise,
- b) The received priority value and the `drop_eligible` parameter value are the values in the received data indication.
- c) The value of the `priority` parameter is then regenerated from the received priority, as specified in 6.9.4.

## 6.20.2 Data requests

On receipt of an M\_UNITDATA.request primitive from the upper ISS SAP (Figure 6-10), an M-UNITDATA.request primitive with identical parameter values is invoked at the lower ISS SAP.

## 6.21 Infrastructure Segment Multiplex Entity

The Infrastructure Segment Multiplex Entity allows shims defined for Segment Endpoint Ports (SEPs) and Segment Intermediate Ports (SIPs) to be instantiated per Infrastructure Segment at a SAP that supports multiple Infrastructure Segments. Figure 6-11 illustrates two Infrastructure Segment Multiplex Entities, placed back-to-back. A set of back-to-back Infrastructure Segment Multiplex Entities may be used at the multiplexed (E)ISS SAPs that are associated with SMP-VIDs on a PNP to provide per Infrastructure Segment SAPs that support CFM shims for Infrastructure Segment MAs as shown in Figure 26-10.

**Figure 6-11—Two back-to-back Up and Down Infrastructure Segment Multiplex Entities**

An Infrastructure Segment Multiplex Entity has one (E)ISS SAP that supports multiple Infrastructure Segment instances, and a number of multiplexed (E)ISS SAPs each supporting a single Infrastructure Segment instance. Each multiplexed SAP has destination\_address, source\_address, and vlan\_identifier combinations assigned by the Infrastructure Segment Multiplex Entity. Every destination\_address, source\_address, and vlan\_identifier combination can be assigned to a multiplexed SAP, and no destination\_address, source\_address, and vlan\_identifier combination is assigned to more than one multiplexed SAP.

Upon receiving a Request or Indication from its single (E)ISS SAP, the Infrastructure Segment Multiplex Entity uses the destination\_address, source\_address, and vlan\_identifier to select the corresponding one of its multiplexed SAPs to present the Request or Indication. The Request or Indication presented at the multiplexed SAPs has the same parameters as the original Request or Indication at the Single SAP. Similarly, any Request or Indication received from a multiplexed SAP is transparently presented to the single (E)ISS SAP.

The MAC\_Operational status parameter (IEEE Std 802.1AC) presented to the uppermost single (E)ISS SAP in Figure 6-9 is TRUE if and only if:

- The uppermost single (E) ISS SAP's MAC\_Enabled parameter is TRUE; and
- At least one of its multiplexed SAPs' MAC\_Operational status parameters is TRUE.

The MAC\_Operational status parameter of each of the multiplexed SAPs in Figure 6-9 is computed separately, and is TRUE if and only if:

- The lowermost single (E)ISS SAP's MAC\_Operational parameter is TRUE; and
- That multiplexed SAP's MAC\_Enabled parameter is TRUE.

1 The MAC\_Operational parameter of the passive SAP on an Infrastructure Segment MEP is set to FALSE  
2 when the Infrastructure Segment MEP declares an errorCCMdefect (20.21.3) or an xconCCMdefect  
3 (20.23.3), setting the MAC\_Operational parameter of the associated multiplexed SAP on the Infrastructure  
4 Segment Multiplex Entity to FALSE. The MAC\_Operational parameter of the passive SAP on an  
5 Infrastructure Segment MEP is set back to TRUE when both defects are cleared, setting back to TRUE the  
6 MAC\_Operational parameter of the associated multiplexed SAP.

## 7 **6.22 PDU and protocol discrimination and media**

8 As described more fully in Clause 9 of IEEE Std 802-2014 [B7], the format of the data parameter passed to  
9 or from a specific MAC procedure (see Figure 6-1 and 6.7) is identified using the first few octets of the  
10 MSDU, by either source and destination LLC addresses or a two-octet EtherType.

11 Length/Type networks have a Length/Type field in the first two octets of the MSDU (e.g., IEEE Std 802.3).  
12 Depending on the value of the Length/Type field (see IEEE Std 802.1AC), the Length/Type field is either an  
13 EtherType or is a Length followed immediately by the LSAPs and Control octets.

14 Networks that do not use a Length/Type field in the MSDU (e.g., some applications of IEEE Std 802.11) can  
15 implement a Media Access Method Dependent Convergence Function to perform any necessary translations  
16 from Length/Type-encoded protocol identifiers. See Clause 13 of IEEE Std 802.1AC-2016 [B10].

17 NOTE—The encoding of tagged frames is clarified in G.3.

## 7. Principles of Virtual Bridged Network operation

This clause establishes the principles and a model of Virtual Bridged Network operation. It defines the context necessary for:

- a) The operation of individual VLAN Bridges (Clause 8);
- b) Their participation in the Spanning Tree Algorithm and Protocol (STP) (Clause 8 of IEEE Std 802.1D, 1998 Edition [B13]), Rapid Spanning Tree Algorithm and Protocol (RSTP) (Clause 13), Multiple Spanning Tree Algorithm and Protocol (MSTP) (Clause 13), Shortest Path Bridging (SPB) (Clause 27), and Path Control and Reservation (PCR) (Clause 45) protocols;
- c) The management of individual Bridges (Clause 12); and
- d) The management of VLAN Topology (Clause 11)

to support, preserve, and maintain the quality of the MAC Service as discussed in Clause 6.

### 7.1 Network overview

The operation of a Virtual Bridged Network, the Bridges, and the LANs that compose that network comprises:

- a) A physical topology comprising LANs, Bridges, and Bridge Ports. Each Bridge Port attaches a LAN to a Bridge and is capable of providing bidirectional connectivity for MAC user data frames. Each LAN is connected to every other LAN by a Bridge and zero or more other LANs and Bridges.
- b) Calculation of one or more active topologies, each a loop-free subset of the physical topology.
- c) Rules for the classification of MAC user data frames that allow each Bridge to allocate, directly or indirectly, each frame to one and only one active topology.
- d) Management control of the connectivity provided for differently classified data frames by the selected active topology.
- e) Implicit or explicit configuration of end station location information, identifying LANs with attached end stations that need to receive user data frames with a given destination address.
- f) Communication of end station location information to allow Bridges to restrict user data frames to LANs in the path provided to their destination(s) by the chosen active topology.

These elements and their interrelationships are illustrated in Figure 7-1.

Figure 7-1—VLAN Bridging overview

1 NOTE 1—The physical and active topologies can be represented as bipartite graphs. Bridges and LANs are nodes in  
2 these graphs (including LANs that are point-to-point links) and the Bridge Ports are edges.

3 NOTE 2—This standard applies the notion of a physical topology to media access control methods, like wireless, where  
4 there is no tangible physical connection between a Bridge and an attached LAN. A Bridge Port models this association  
5 just as for wired connectivity.

6 NOTE 3—Each of the active topologies [see item b)] does not necessarily span the entire network, but does span all  
7 those Bridges and LANs between which data frame connectivity is desired for frames allocated to that active topology.

8 NOTE 4—The destination addressing information associated with a MAC user data frame includes the VLAN  
9 classification of the frame [see item d)].

10 NOTE 5—Implicit configuration [see item d)], or recognition, of end station location includes observation of the source  
11 address of the user data frame transmitted by that station. The user data frame communicates that location information  
12 [see item e)] along the portion of the chosen active topology leading to the frame's destination(s).

## 13 7.2 Use of VLANs

14 VLANs and their VIDs provide a convenient and consistent network-wide reference for VLAN Bridges to:

- 15 a) Identify rules for the classification of user data frames into VLANs.
- 16 b) Effectively extend the source and destination MAC addresses, by treating frames and addressing  
17 information for different VLANs independently.
- 18 c) Identify and select from different active topologies.
- 19 d) Identify configuration parameters that partition a physical network.

20 Taken together these capabilities allow VLAN Bridges to emulate a number of separately manageable, or  
21 virtual, Bridged Networks. A LAN that has been selected by network management to receive frames  
22 assigned to a given VLAN is said to form part of, belong to, or be a member of the VLAN. Similarly, end  
23 stations that are attached to those LANs and that can receive frames assigned to the VLAN are said to be  
24 attached to that VLAN.

25 NOTE—Separate control over the transmission and over the reception of frames to and from LANs and end stations is  
26 possible. To avoid ambiguity, VLAN membership is defined by reception.

27 Inclusion of the VID in VLAN-tagged frames guards against connectivity loops arising from differing  
28 classifications by different Bridges, and permits enhanced classification rules to be used by some Bridges,  
29 while others simply forward the previously classified frames.

30 The VLAN tag allows frames to carry priority information, even if the frame has not been classified as  
31 belonging to a particular VLAN.

## 32 7.3 Active topology

33 Bridges cooperate to calculate one or more loop-free and fully connected active topologies, i.e., spanning  
34 trees. The algorithms and protocols—RSTP (13.4), MSTP (13.5), SPB (Clause 27), PCR (Clause 45)—that  
35 support that calculation provide rapid recovery from network component failure (6.5.1) by using alternate  
36 physical connectivity, without requiring management intervention.

37 The Bridge's forwarding processes constrain the potential path for each user data frame to a single spanning  
38 tree. A Bridge that uses RSTP or STP allocates all frames to a single CST. An MST or SPT Region (13.8,  
39 27.4.1) comprises the transitive closure of Bridges that use MSTP or SPB and that agree on the allocation of  
40 frames with a given VID to a given subtree within the region. That subtree can be an MSTI, a SPT, an  
41 Explicit Tree (ET), or the IST that is the logical continuation of the CST through the region. Interoperability

1 between MST and SPT Bridges and SST Bridges, and between differently configured MST/SPT Bridges, is  
2 achieved by allocating all frames to the CST at region boundaries. Thus the spanning tree for a given frame  
3 can comprise subtrees of the CST together with an MSTI or SPT within each region. Frames with different  
4 VIDs can be assigned to the same or to different trees and subtrees within a region.

5 NOTE—In a stable network, the MSTP and SPB algorithms verify that each MST/SPT Region is fully connected  
6 internally. However, if the CST Root lies outside the region, the region can be partitioned temporarily as necessary to  
7 prevent external connectivity between Bridge Ports at the region boundary from creating a loop. A given region of the  
8 network can be an MST Region, an SPT Region, or both, but the protocol mechanisms that verify connectivity internal  
9 to the region require that regions do not overlap or subset other regions.

## 10 7.4 VLAN topology

11 Typically each of the VIDs for frames assigned to the CST, and to the IST or an MSTI within an MST  
12 Region, supports a different VLAN, and each VLAN is supported by only one VID and only one subtree  
13 within the region. However, frames for VLANs supported by SPB are assigned to the SPT rooted at the  
14 Bridge where they enter an SPT Region, and SPBV requires that each source Bridge for a given VLAN uses  
15 a unique SPVID. To provide interoperability with other regions and end systems that support a VLAN with  
16 a single VID, the VIDs for SPBV VLANs are translated at the SPT Region boundary (6.9, 27.12). SPBM  
17 uses a single VID for all the SPTs for a given VLAN.

18 NOTE 1—Support of a network comprising a single SPT Region with directly attached VLAN-unaware or priority  
19 tagging end stations does not require VID translation. This includes, for example, a PBN or PBBN where the edge of the  
20 network corresponds with the boundary of the SPT Region.

21 Within a given region, the SPTs that support any given shortest path VLAN provide full and symmetric  
22 connectivity (6.3). To allow frames in different VLANs to make use of equal cost shortest paths, multiple  
23 SPT Sets can be used, each providing full symmetric connectivity between all Bridges in the region.

24 Each VLAN may occupy the full extent of the active topology of its associated spanning tree(s) or a  
25 continuously connected subset of that active topology. The connected subset must be continuously  
26 connected; otherwise, the VLAN is split. The maximum extent of the connected subset may be bounded by  
27 management by explicitly excluding certain Bridge Ports from a VLAN's connectivity.

28 At any time the current extent of a VLAN can be further reduced from the maximum to include only those  
29 LANs that provide communication between attached devices, by the use of protocol that allows end stations  
30 to request and release services that use the VLAN. Such a protocol is specified in Clause 11. The dynamic  
31 determination of VLAN extent provides flexibility and bandwidth conservation, at the cost of network  
32 management complexity.

33 NOTE 2—Dynamic determination of VLAN extent is generally preferable to static configuration for bandwidth  
34 conservation, as the latter is error prone and can defeat potential alternate connectivity—requiring active management  
35 intervention to recover from network component failure.

36 NOTE 3—To accommodate end stations that do not participate in the MVRP specified in Clause 11, management  
37 controls associated with each Bridge Port allow the Port to identify the attached LAN as connecting end stations that  
38 require services using specified VLANs.

39 NOTE 4—Where a given VLAN is supported by multiple VIDs, as for SPB, management controls identify the VLAN  
40 by a Base VID (that used when frames are allocated to the CST). Use of this single VID reduces the configuration  
41 burden, particularly when Bridges are added to the SPT Region and further SPVIDs are allocated.

## 1 7.5 Locating end stations

2 Functioning as a distributed system, Bridges within the current extent of a VLAN can, through explicit and  
3 or implicit cooperation, locate those LANs where an attached end station or end stations are intended to  
4 receive frames addressed to a specified individual address or group address. Bridges can thus reduce traffic  
5 by confining frames to the LANs where their transmission is necessary.

6 NOTE 1—Individual Bridges do not determine the precise location of end stations but merely determine which of their  
7 Bridge Ports need to forward frames toward the destination(s). For the system of Bridges this is sufficient to restrict  
8 frames to the paths necessary to reach the destination LANs.

9 As specified in 13.6.2 of IEEE Std 802.1AC-2016 [B10], a Bridge with a Point-to-Multipoint Network port  
10 (PMPN, G.4.2, G.4.3) can detect when an attached PMPN node establishes or breaks a connection to another  
11 PMPN node.

12 The Multiple MAC Registration Protocol (MMRP), specified in Clause 10, allows end stations to advertise  
13 their presence and their desire to join (or leave) a multicast group, or to register an individual MAC address,  
14 in the context of a VLAN. The protocol communicates this information to other Bridges, using the VLAN  
15 and its active topology.

16 NOTE 2—To accommodate end stations that do not participate in MMRP, management controls associated with each  
17 Bridge Port allow the port to identify the attached LAN as connecting end stations that are intended to receive specified  
18 group addresses. The continuous operation of MMRP and the propagation of location information through Bridges using  
19 the current active topology for the VLAN support multicast traffic reduction, while ensuring rapid restoration of  
20 multicast connectivity without management intervention if alternate connectivity is selected following network  
21 component failure.

22 Each end station implicitly advertises its attachment to an individual LAN and its individual MAC address  
23 whenever it transmits a frame. Bridges learn from the source address as they forward the frame along the  
24 active topology to its destination or destinations — or throughout the Bridged Network or VLAN if the  
25 location of the destination or destinations is unknown. The learned information is stored in the FDB (8.8)  
26 and used to filter frames on the basis of their destination addresses.

27 Address information learned from a frame with a given VID can be used to filter frames with other VIDs.  
28 For example, information learned from a frame with any of the VIDs that support SPB for a given VLAN  
29 (i.e., VIDs associated with the same Base VID) is used to filter frames with any of the VIDs for that VLAN.  
30 In some network configurations, it is also necessary to use address information learned in any one of a set of  
31 VLANs to filter frames with VIDs that identify any VLAN in the set (Shared VLAN Learning (SVL),  
32 Clause 3). In other configurations it is necessary or desirable not to share learned information between  
33 certain VLANs (Independent VLAN Learning (IVL), Clause 3) while in some cases it is immaterial whether  
34 address information is shared between VLANs. Annex F discusses the network configuration requirements,  
35 and some of the related interoperability issues.

36 Clause 15 and Clause 16 describe how the mapping of C-VLANs into S-VLANs is accomplished within  
37 PBNs and PBBNs. These networks provide additional mapping facilities to support hierarchies of VLANs  
38 allowing a provider a separate FDB from customers. The conformance definitions of 5.3 have been extended  
39 to support S-VLANs. Clause 25 and Clause 26 describe how the mapping of S-VLANs into backbone  
40 service instances is accomplished within PBBNs.

## 41 7.6 Ingress, forwarding, and egress rules

42 The relay function provided by each Bridge controls the following:

- 1 a) Classification of each received frame as belonging to one and only one VLAN, and discard or  
2 acceptance of the frame for further processing on the basis of that classification and the received  
3 frame format, which can be one of three possible types:
  - 4 1) Untagged, and not explicitly identifying the frame as being associated with a particular VID.
  - 5 2) Priority-tagged, i.e., including a tag header conveying explicit priority information but not  
6 identifying the frames as being associated with a specific VID.
  - 7 3) VLAN-tagged, i.e., explicitly associating the frames with a particular VID.
- 8 This aspect of relay implements the *ingress* rules.
- 9 b) Implementation of the decisions governing where each frame is to be forwarded as determined by  
10 the current extent of the VLAN topology (7.4), station location information (7.5), and the additional  
11 management controls specified in Clause 8. This aspect of relay implements the *forwarding* rules.
- 12 c) Queuing of frames for transmission through the selected Bridge Ports, management of the queued  
13 frames, selection of frames for transmission, and determination of the appropriate frame format  
14 type, VLAN-tagged or untagged. This aspect of relay implements the *egress* rules.

15 The structuring of the relay functionality into the implementation of ingress, forwarding, and egress rules  
16 constitutes a generic approach to the provision of VLAN functionality. All VLAN Bridges can correctly  
17 forward received frames that are already VLAN-tagged. These are classified as belonging to the VLAN  
18 identified by the VID in the tag header. All VLAN Bridges can also classify untagged and priority-tagged  
19 frames received on any given port as belonging to a specified VLAN. In addition to this default Port-based  
20 ingress classification, this standard specifies an optional Port-and-Protocol-based classification.

21 The classification of untagged and priority-tagged frames, and the addition or removal of tag headers, is  
22 performed in support of the EISS (6.9).

23 Frames that carry control information to determine the active topology and current extent of each VLAN,  
24 i.e., spanning tree or SPB and MVRPDUs, and frames from other link constrained protocols, such as  
25 EAPOL and LLDP, are not forwarded. Permanently configured static entries in the FDB (8.2, 8.3, and 8.12)  
26 ensure that such frames are discarded by the Forwarding Process (8.6).

27 NOTE—MRPDUs destined for any MRP application are forwarded or filtered depending on whether the application  
28 concerned is supported by the Bridge, as specified in 8.1.2.

29 The forwarding rules specified for VLAN-tagged frames facilitate the interoperation of VLAN Bridges  
30 conformant to this standard with end stations that directly support attachment of MAC Service users to  
31 VLANs by transmitting VLAN-tagged frames, and with Bridges that are capable of additional proprietary  
32 ingress classification methods.

33 Frames transmitted on a given LAN by a VLAN Bridge for a given VLAN shall be one of the following:

- 34 d) All untagged or
- 35 e) All VLAN-tagged with the same VID or
- 36 f) All VLAN-tagged, each with an SPVID allocated to the Base VID for that VLAN

## 1 8. Principles of Bridge operation

2 This clause:

- 3 a) Explains the principal elements of the operation of Bridges, and the operation of Bridge components
- 4 within systems, and lists the supporting functions.
- 5 b) Establishes a Bridge architecture that governs the provision of these functions.
- 6 c) Provides a model of Bridge operation in terms of processes and entities that support the functions.
- 7 d) Details the addressing requirements in a bridged network.
- 8 e) Specifies the addressing of entities in a Bridge.

### 9 8.1 Bridge operation

10 The principal elements of Bridge operation are:

- 11 a) Relay and filtering of frames (8.1.1).
- 12 b) Maintenance of the information required to make frame filtering and relaying decisions (8.1.2).
- 13 c) Management of the above (Clause 12).

#### 14 8.1.1 Relay

15 A Bridge relays individual MAC user data frames between the separate MACs of the individual LANs  
16 connected to its Ports. The functions that support relaying of frames and maintain the QoS are:

- 17 a) Frame reception (8.5).
- 18 b) Discard on received frame in error (6.5.2).
- 19 c) Discard of frames that do not carry user data (IEEE Std 802.1AC).
- 20 d) Priority and drop eligibility decoding from a VLAN tag, if present, and regeneration of priority, if
- 21 required (6.9).
- 22 e) Assignment of a VID ([VLAN Identifier](#)) to each received frame (6.9).
- 23 f) Ensure that each frame is confined to an active topology (8.6.1).
- 24 g) Frame discard to support management control over the active topology of each VLAN (6.9, 8.6.2,
- 25 8.6.4).
- 26 h) Frame discard following the application of filtering information (8.6.3).
- 27 i) Metering of frames, potentially marking as drop eligible or discarding frames exceeding bandwidth
- 28 limits (8.6.5).
- 29 j) Forwarding of received frames to other Bridge Ports (8.6.6).
- 30 k) Selection of traffic class and queuing of frames by traffic class (8.6.6).
- 31 l) Frame discard to ensure that a maximum Bridge transit delay is not exceeded (6.5.6, 8.6.7).
- 32 m) Preferential discard of drop eligible frames to preserve QoS for other frames (8.6.7).
- 33 n) Selection of queued frames for transmission (8.6.8).
- 34 o) Mapping of SDUs and FCS recalculation, if required (6.5.7).
- 35 p) Frame discard on transmittable SDU size exceeded (6.5.8).
- 36 q) Selection of outbound access priority (6.5.9).
- 37 r) Frame transmission (8.5).

38 ~~A VLAN-unaware MAC Relay Entity, e.g., MAC Bridges and TPMRs, do not support~~ is supported by  
39 ~~the ISS, and not the EISS, and correspondingly the functions that support relaying of frames in a MAC~~  
40 ~~Bridge cannot make use of any parameters explicit to EISS, like the VID. This means in particular that for~~  
41 ~~a MAC Bridge, item e) in the list above is not supported, can support item d), and support and item g) by~~  
42 ~~restricting the active topology for all frames independent of VLAN. would be supported in the form of:~~

- 43 s) ~~Regeneration of priority, if required (6.9.4)~~

- 1 t) ~~Frame discard to support management control over the physical topology of the network~~  
2 ~~and, every other item on the list is supported but~~ Every other listed item is supported without making ~~any~~ use  
3 of, or qualification upon, VLANs.  
4 Note that a TPMR is not a conformant MAC Bridge, so they are called out separately in the revised text above. A  
VLAN-unaware relay can extract and add priority information from and to a VLAN tag as per 6.20, so the prohibition on d) is  
out of date, and RSTP restricts the *active* topology not the *physical* topology of a network (plugs are not pulled out of  
sockets).

8 Figure 8-1 gives an example of the physical topology of a Bridged Network.

Figure 8-1—A Bridged Network

### 9 8.1.2 Filtering and relaying information

10 A Bridge maintains filtering and relaying information for the following purposes:

- 11 a) Duplicate frame prevention: to maintain a loop-free active topology for every frame
- 12 b) Traffic segregation: to separate communication by different sets of network users
- 13 c) Traffic reduction: to confine frames to the path(s) between their source and destination(s)
- 14 d) Traffic expediting: to classify frames in order to expedite time-critical traffic
- 15 e) Frame format conversion: to tag or untag as appropriate for the destination LAN and stations

### 16 8.1.3 Duplicate frame prevention

17 A Bridge filters frames, i.e., does not relay frames received by a Bridge Port to other Bridge Port on that  
18 Bridge, in order to prevent the duplication of frames (6.5.4). The functions that support the use and  
19 maintenance of information for this purpose are:

- 20 a) Configuration and calculation of one or more spanning tree active topologies.
- 21 b) In MST Bridges, explicit configuration to assign VLANs to MSTIs (8.9).
- 22 c) In SPT Bridges: explicit or default selection of shortest path, CIST, or MSTI support for specified  
23 VLANs; and automatic assignment of VLANs to SPTs for shortest path VLANs.

#### 1 8.1.4 Traffic segregation

2 A VLAN Bridge can filter frames to confine them to LANs that belong to the VLAN to which they are  
3 assigned and, thus, define the VLAN's maximum extent (7.4). The functions that support the use and  
4 maintenance of information for this purpose are:

- 5 a) Configuration of a PVID for each Port, to associate a VID with untagged and priority-tagged  
6 received frames (6.9.1), and parameters for Protocol VLAN Classification (6.12) if implemented.
- 7 b) Configuration of Static VLAN Registration Entries (8.8.2).
- 8 c) Configuration of the Enable Ingress Filtering parameter to enable or disable application of Static  
9 VLAN Registration Entries to received frames.

10 A VLAN Bridge can filter frames to partially partition a Virtual Bridged Network. Frames assigned to any  
11 given VID and addressed to specific end stations or groups of end stations can be excluded from relay to  
12 certain Bridge Ports. The functions that support the use and maintenance of information for this purpose are:

- 13 d) Permanent configuration of Reserved Addresses (Table 8-1, Table 8-2, and Table 8-3).
- 14 e) Configuration of Static Filtering Entries (8.8.1) and MAC Address Registration Entries (8.8.4).

15 NOTE—The use of VLANs is generally less error prone and is preferred to filtering using destination addresses if a  
16 Bridged Network is to be partitioned for reasons of scale, efficiency, management, or security. Destination address  
17 filtering is the only mechanism available to MAC Bridges.

#### 18 8.1.5 Traffic reduction

19 A Bridge can filter frames so that LANs not attaching to or forming part of the path between the source and  
20 the potential destination(s) of any given communication do not have to support the transmission of related  
21 frames, potentially improving the quality of the MAC Service for other communications. The functions that  
22 support the use and maintenance of information for this purpose are:

- 23 a) Automatic learning of dynamic filtering information for unicast destination addresses through  
24 observation of source addresses of frames.
- 25 b) Ageing out or flushing of dynamic filtering information that has been learned to support the  
26 movement of end stations and changes in active topology.
- 27 c) Automatic configuration of MAC Address Registration Entries by means of MMRP exchanges.
- 28 d) Explicit configuration of the management controls associated with the operation of MMRP by  
29 means of MAC Address Registration Entries.

30 A VLAN Bridge can also filter frames to confine them to LANs either that have end stations attached to  
31 their assigned VLAN or that connect those LANs and, thus, define the current practical extent of the VLAN  
32 (7.5).

- 33 e) Automatic inclusion and removal of Bridge Ports in the VLAN, through configuration of Dynamic  
34 VLAN Registration Entries by means of MVRP (8.8.5 and 11.2) or MIRP (Clause 39).
- 35 f) Explicit configuration of management controls associated with the operation of MVRP and MIRP  
36 by means of Static VLAN Registration Entries (8.8.2 and 11.2).

37 Item e) and item f) are only supported by VLAN Bridges, while all other items in the list above are  
38 supported by every Bridge.

## 1 8.1.6 Traffic expediting

2 A Bridge classifies frames into traffic classes in order to expedite transmission of frames generated by  
3 critical or time-sensitive services. The function that supports the use and maintenance of information for this  
4 purpose is:

- 5 a) Explicit configuration of traffic class information associated with the Ports of the Bridge.

## 6 8.1.7 Conversion of frame formats

7 A VLAN Bridge adds and removes tag headers (9.3) from frames and performs the associated frame  
8 translations that may be required. The function that supports the use and maintenance of information for this  
9 purpose is:

- 10 a) Explicit configuration of tagging requirements on transmission for each Port (8.8.2, 6.9.2).

11 NOTE—As all incoming frames, including priority-tagged frames, are classified as belonging to a VLAN, the  
12 transmitting Port transmits VLAN-tagged frames or untagged frames. Hence, a station sending a priority-tagged frame  
13 via a Bridge will receive a response that is either VLAN-tagged or untagged, as described in 8.5.

## 14 8.2 Bridge architecture

15 A Bridge comprises at least one Bridge component. A Bridge component comprises the following:

- 16 a) A MAC Relay Entity that interconnects the Bridge's Ports
- 17 b) At least two Ports
- 18 c) Higher layer entities, including at least a Spanning Tree Protocol Entity

19 The VLAN Bridge architecture is illustrated in Figure 8-2. The MAC Relay Entity handles the media access  
20 method-independent functions of relaying frames among Bridge Ports, filtering frames, and learning  
21 filtering information. It uses the EISS (6.8, 6.9) provided by each Bridge Port.

22 The architecture of a VLAN-unaware MAC Bridge is illustrated in Figure 6-1

NOTE—The notation “IEEE Std 802.n” in this figure indicates that the specifications for these functions can be found in the relevant standard for the media access method concerned; for example, n would be 3 (IEEE Std 802.3) in the case of Ethernet.

**Figure 8-2—VLAN Bridge architecture**

1 The MAC Bridge architecture is illustrated in Figure 8-3. The main difference with the VLAN  
2 Bridge architecture is that it does not use the EISS and the VLAN-unaware MAC relay entity is supported  
3 by the ISS.

**Figure 8-3—MAC Bridge architecture**

4 Each Bridge Port also functions as an end station and shall provide the MAC Service to an LLC Entity that  
5 operates LLC Type 1 procedures to support protocol identification, multiplexing, and demultiplexing, for  
6 PDU transmission and reception by the Spanning Tree Protocol Entity and other higher layer entities. Other  
7 types of LLC procedures can also be supported for use by other protocols. The Bridge Port provides  
8 additional MSAPs if those are explicitly required by the specifications of the attached higher layer entities.  
9 Each instance of the MAC Service is provided to a distinct LLC Entity that supports protocol identification,  
10 multiplexing, and demultiplexing, for PDU transmission and reception by one or more higher layer entities.

11 NOTE—For simplicity of specification, this standard refers to a single LLC Entity that can provide both the procedures  
12 specified by ISO/IEC 8802-2 and EtherType protocol discrimination in the cases where the media access method for the  
13 attached LAN supports the latter.

14 If the Bridge Port can be directly attached to an IEEE 802 LAN, an instance of the MAC for that LAN type  
15 is permanently associated with the Port, handles the media access method-specific functions (MAC protocol  
16 and procedures), and provides an instance of the ISS as specified in IEEE Std 802.1AC to support frame  
17 transmission and reception by the other processes and entities that compose the Port.

18 Figure 8-2 illustrates a VLAN Bridge, and Figure 8-3 illustrates a MAC Bridge, with two Ports, each  
19 directly connected to a LAN.

## 1 8.3 Model of operation

2 The model of operation is simply a basis for describing the functionality of the Bridge. It is in no way  
3 intended to constrain real implementations of a Bridge; these may adopt any internal model of operation  
4 compatible with the externally visible behavior that this standard specifies. Conformance of equipment to  
5 this standard is purely in respect of observable protocol.

6 The processes and entities that model the operation of a Bridge Port include the following:

- 7 a) A Bridge Port Transmit and Receive Process (8.5) that:
  - 8 1) Receives and transmits frames from and to the attached LAN (8.5, 6.8, 6.9,  
9 IEEE Std 802.1AC).
  - 10 2) Can filter received frames if the VLAN tag is absent, or present, or conveys a null VID.
  - 11 3) Classifies received frames into VLANs, assigning each a VID value.
  - 12 4) Determines the format, VLAN-tagged or untagged, of transmitted frames.
  - 13 5) Delivers and accepts frames to and from the MAC Relay Entity and LLC Entities.
- 14 b) The LLC Entity or Entities that support Higher Layer Entities such as the following:
  - 15 1) Spanning Tree Protocol
  - 16 2) Multiple Registration Protocol (MRP)
  - 17 3) Bridge Management
  - 18 4) Linktrace response
- 19 c) Zero or more CFM entities, each of which can be one of the following:
  - 20 1) An MA Endpoint (MEP) or
  - 21 2) An MA Intermediate Point (MIP) or
  - 22 3) A Linktrace Output Multiplexer (LOM)

23 As Bridge Ports on MAC Bridges provide only the ISS, item a2), item a3), and item a4) in the list above are  
24 not supported by MAC Bridges.

- 25 d) The Forwarding Process (8.6) that:
  - 26 1) Enforces loop-free active topologies for all frames (8.1.3, 8.4, 8.6.1);
  - 27 2) Filters frames using their VID and destination MAC addresses (8.1.4, 8.6.2, 8.6.3, 8.6.4);
  - 28 3) Optionally, classifies and meters received frames that are to be relayed to other Bridge Ports  
29 (8.6.5);
  - 30 4) Forwards received frames that are to be relayed to other Bridge Ports (8.6.6, 8.6.7, 8.6.8).
- 31 e) The Learning Process (8.7) that observes the source addresses of frames received on each Port and  
32 updates the FDB (8.1.5, 8.4).
- 33 f) The FDB (8.8) that holds filtering information and supports queries by the Forwarding Process  
34 about whether frames with given values of VID and destination MAC address field can be  
35 forwarded to a given Port.

36 NOTE 1—The processes and entities that model the operation of the VLAN-unaware MAC Relays on MAC Bridges are  
37 the same as the ones described above but excluding any use or qualification based on VID values.

38 NOTE 2—In Figure 8-4, Figure 8-5, Figure 8-6, and Figure 8-7, the EISS is used by the VLAN-aware MAC Relay  
39 entities and the ISS is used by the VLAN-unaware MAC Relay entities.

1 Figure 8-4 illustrates a single instance of frame relay between the Ports of a Bridge with two Ports.

**Figure 8-4—Relaying MAC frames**

2 Figure 8-5 illustrates the inclusion of information carried by a single frame, received on one of the Ports of a  
3 Bridge with two Ports, in the FDB.

**Figure 8-5—Observation of network traffic**

1 Figure 8-6 illustrates the operation of the Spanning Tree Protocol Entity.

### Figure 8-6—Operation of Spanning Tree Protocol Entity

<sup>2</sup> Figure 8-7 illustrates the operation of the MRP Entity (8.11).

### Figure 8-7—Operation of MRP

3 Higher Layer Entities that require only one point of attachment for the Bridge as a whole may attach to an  
4 LLC Entity that uses an instance of the MAC Service provided by a Management Port. A Management Port  
5 does not use an instance of the ISS to attach to a network but uses the Bridge Port Transmit and Receive  
6 Process and the MAC Relay Entity to provide connectivity to other Bridge Ports and the attached LANs.

7 NOTE 3—Management port functionality may also be provided by an end station connected to an IEEE 802 LAN that is  
8 wholly contained within the system that incorporates the Bridge. The absence of external connectivity to the LAN means  
9 that the management port is always forwarding.

Figure 8-8 illustrates the reception and transmission by an entity attached to a Management Port.

**Figure 8-8—Management Port transmission and reception**

Figure 8-9 illustrates the operation of the IPS Control entity. The IPS Control entity functions as an intermediary between the Bridge Management entity and the FDB for operations related to TESIs associated with an IPG. Infrastructure Segment MEPs associated with an IPG communicate the operational state of the associated Infrastructure Segment to the IPS control entity (26.11.3).

**Figure 8-9—Infrastructure Segment MEP placement in a PNP**

## 8.4 Active topologies, learning, and forwarding

An *active topology* is the connectivity provided, for frames with a specified set of VID, destination address, and source address values, by interconnecting the LANs and Bridges in a bridged network with *forwarding* Bridge Ports.

1 The distributed spanning tree algorithms and protocols, i.e., RSTP (Clause 13), MSTP (Clause 13), and  
2 ISIS-SPB (Clause 27), construct one or more active topologies, each simply and fully connected for frames  
3 being associated with any given VLAN and transmitted from any end station to any other. The *forwarding*  
4 and *learning* performed by each Bridge Port for each spanning tree is dynamically managed by RSTP,  
5 MSTP, or ISIS-SPB to prevent temporary loops and reduce excessive traffic in the network while  
6 minimizing denial of service following any change in the *physical topology* of the network.

7 PBB-TE enables construction of active topologies by the external agent that is responsible for setting up  
8 Ethernet Switched Paths (ESPs).

9 Any port that is not enabled, i.e., has MAC\_Operational (IEEE Std 802.1AC) False or has been excluded  
10 from the active topology by management setting of the Administrative Bridge Port State to Disabled, has  
11 both forwarding and learning disabled for all spanning trees and ESPs.

12 If the Bridge Port is enabled, PBB-TE disables learning and enables forwarding for all frames allocated to  
13 each ESP-VID. An external agent manages the FDB to control the forwarding of frames with particular  
14 values of ESP-VID and destination MAC address.

15 The term Port State summarizes per-tree combinations of forwarding and learning, and any additional  
16 per-tree variables used by a given spanning tree protocol to enforce the active topologies it has calculated,  
17 and is used by RSTP and MSTP as follows. Any port that has learning and forwarding disabled is assigned  
18 the Port State *Discarding*. A Port that has learning enabled but forwarding disabled has the Port State  
19 *Learning*, and a Port that both learns and forwards frames has the Port State *Forwarding*. However, the  
20 RSTP and MSTP state machines (Clause 13) do not control the Port State directly but use independent  
21 forwarding and learning variables for each tree.

22 ISIS-SPB controls both forwarding and learning variables for each SPT and Bridge Port directly when used  
23 to support Shortest Path Bridging VID (SPBV, Clause 27) just like RSTP and MSTP. ISIS-SPB disables  
24 learning and sets forwarding to TRUE when supporting Shortest Path Bridging MAC (SPBM, Clause 27).

25 RSTP constructs a single spanning tree, the CST, and maintains a single Port State for each Bridge Port. SST  
26 Bridges allocate all frames to that single spanning tree irrespective of their VLAN classification or source  
27 and destination MAC addresses.

28 MSTP constructs multiple spanning trees, the CIST and additional MSTIs, and maintains a Port State for  
29 each spanning tree for each Port. An MST Bridge allocates all frames classified as belonging to a given  
30 VLAN to the CIST or to one of the MSTIs using the MST Configuration Table. An MSTID of 0 identifies  
31 the CIST. A reserved MSTID value (TE-MSTID) is used to identify VIDs for use by PBB-TE with ESPs.  
32 Further MSTID values are used to identify the use of SPBV or SPBM. A single VID is used to identify  
33 frames assigned to any given VLAN that is supported by the CIST or an MSTI. That VID is used by the  
34 Forwarding Process (8.6) to identify the spanning tree for the relayed frame, and thus identifies the  
35 applicable Port State.

36 ISIS-SPB constructs symmetric (Clause 3) SPTs rooted at each Bridge within an SPT Region, and maintains  
37 independent forwarding and learning variables for each SPT for each Bridge Port.

38 Each frame classified as belonging to a VLAN supported by SPBV, is allocated to an SPT rooted at the  
39 Bridge that first relays the frame into the Region. If a C-VLAN, S-VLAN, or B-VLAN is supported by  
40 SPBV (Clause 27) the frame is assigned a Shortest Path VLAN Identifier (SPVID) that is used by the  
41 Forwarding Process (8.6) to identify both the VLAN and the SPT, and thus identifies the applicable learning  
42 and forwarding values.

1 If a B-VLAN is supported by SPBM, (Clause 27) the frame is assigned a B-VID value that identifies the  
2 frame as subject to SPBM and identifies the B-VLAN and the SPT Set (Clause 3). The SPT is identified  
3 (from among those in that set) by the source address of the frame (B-SA), which identifies the SPT root.  
4 When ISIS-SPB sets forwarding True for that SPT, a Dynamic Filtering Entry for that B-VID, source  
5 address tuple is included in the FDB so that it passes the active topology enforcement check (8.6.1). An  
6 individual destination address identifies the SPT that is rooted at that destination and belongs to the SPT Set  
7 identified by the VID. If relaxed ingress checking (45.3.1) is supported, then a MAC Address Registration  
8 Entry is included in the FDB for that VID, individual destination address tuple if there is any source whose  
9 path to the destination in that SPT is via the given Bridge. The Port Map of those MAC Address Registration  
10 entries comprises only the ports that are upstream for a given individual destination address (45.3.1). If a  
11 B-VLAN is supported by SPBM, learning is disabled for all frames for that B-VID.

12 Figure 8-6 illustrates the operation of the Spanning Tree Protocol Entity, which operates the spanning tree  
13 algorithm and its related protocols, and its modification of Port state information as part of determining the  
14 active topology of the network.

15 Figure 8-4 illustrates the Forwarding Process's use of the Port State: first, for a Port receiving a frame, to  
16 determine whether the received frame is to be relayed through any other Ports; and second, for another Port  
17 in order to determine whether the relayed frame is to be forwarded through that particular Port.

18 Figure 8-5 illustrates the use of the Port state information for a Port receiving a frame, in order to determine  
19 whether the station location information is to be incorporated in the FDB.

## 20 8.5 Bridge Port Transmit and Receive

21 The Bridge Port Transmit and Receive process supports the attachment of the Bridge Port to a network. It  
22 comprises the following functions:

- 23 a) In a VLAN Bridge component, mapping between the EISS (6.8) provided to the MAC Relay Entity,  
24 and the ISS (IEEE Std 802.1AC), adding, recognizing, interpreting, and removing VLAN tags as  
25 specified in 6.9 and illustrated in Figure 8-10.
- 26 b) In a MAC Bridge component, an optional shim (IEEE Std 802.1AC) that uses and provides the ISS  
27 (IEEE Std 802.1AC), recognizing and interpreting VLAN tags as specified in 6.20 and illustrated in  
28 Figure 8-11.
- 29 c) Connectivity, as specified in 8.5.1 (for non-TPMR Bridges) or 8.5.2 (for TPMRs), between the  
30 following ISS access points:
  - 31 1) That provided by the MAC Entity for the LAN attached to the Port, as specified in  
32 IEEE Std 802.1AC.
  - 33 2) That supporting the MAC Relay Entity.
  - 34 3) One or more that support Higher Layer Entities attached to the Port (8.5.3).

35 A single Port for a Bridge, known as the Management Port, may support Higher Layer Entities without  
36 providing a point of attachment to a LAN (see Figure 8-8).

### 37 8.5.1 Bridge Port connectivity

38 Each M\_UNITDATA.indication provided by the ISS access point for an attached LAN [(1) in Figure 8-10]  
39 shall result in a corresponding M\_UNITDATA.indication with identical parameters at each of the access  
40 points supporting the MAC Relay and Higher Layer Entities [(2), (3a) and (3b)]. Each  
41 M\_UNITDATA.request from the ISS access point supporting the MAC Relay Entity shall result in a  
42 corresponding M\_UNITDATA.indication with identical parameters at each of the access points for the  
43 Higher Layer Entities [(3a) and (3b)], and a corresponding M\_UNITDATA.request with identical parameters  
44 at the access point for the LAN [(1)]. Each M\_UNITDATA.request from an ISS access point supporting a

1 Higher Layer Entity shall result in a corresponding M\_UNITDATA.indication with identical parameters at  
2 the access points for the MAC Relay Entity, and at other access points for Higher Layer Entities, and a  
3 corresponding M\_UNITDATA.request with identical parameters at the access point for the LAN.

**Figure 8-10—Bridge Port Transmit and Receive**

4 NOTE—Figure 8-10 shows the relative position of the Bridge Port Transmit and Receive process and the VLAN  
5 tagging function (6.9) for a Customer Bridge or Provider Bridge that does not support CFM. For the relative positioning  
6 of these functions in a Bridge supporting CFM, see Figure 8-9. For the relative positioning of these functions in a BEB,  
7 see Figure 26-2.

8 The MAC\_Enabled, MAC\_Operational, and operPointToPointMAC status parameters for the ISS access  
9 point for the MAC Relay Entity and Higher Layer Entities [(2), (3a), and (3b) in Figure 8-10] shall take the  
10 same value as that for the LAN (1) if that is present, and shall be True otherwise (i.e., if the Port is a  
11 Management Port).

12 The consequence of the above connectivity is that frames relayed to a Bridge Port are both submitted to that  
13 Port's MAC Service users and transmitted on the attached LAN (see 8.13.9).

#### 14 8.5.2 TPMR Port connectivity

15 Each M\_UNITDATA.indication provided by the ISS access point for an attached LAN [(1) in Figure 8-11]  
16 shall result in a corresponding M\_UNITDATA.indication with identical parameters at each of the access  
17 points supporting the MAC Relay and Higher Layer Entities [(2), (3a), and (3b)].

**Figure 8-11—TPMR Port Transmit and Receive**

18 Each M\_UNITDATA.request from the ISS access point supporting the MAC Relay Entity (2) or a Higher  
19 Layer Entity [(3a) or (3b)] shall result in a corresponding M\_UNITDATA.request with identical parameters  
20 at the access point for the LAN (1).

1 The MAC\_Enabled, MAC\_Operational, and operPointToPointMAC status parameters for the ISS access  
2 point for the MAC Relay Entity and Higher Layer Entities [(2), (3a), and (3b) in Figure 8-11] shall take the  
3 same value as for the LAN (1).

4 NOTE—These connectivity rules allow a higher layer entity to “listen” on both TPMR Ports to be able to determine the  
5 LAN on which a particular frame was received, and ensure that any frames sent by a higher layer entity are propagated  
6 only on the LAN associated with the Port on which the frame is transmitted. This differs from the propagation rules for  
7 other Bridges, where frames transmitted by a higher layer entity are also submitted to the forwarding process, and frames  
8 transmitted by the Forwarding Process on a given Port are received by any higher layer entity associated with that Port.

### 9 8.5.3 Support of Higher Layer Entities

10 The MAC Service is provided to a Higher Layer Entity using one of ISS access points provided for that  
11 purpose by the Bridge Port Connectivity function (8.5.1) or the TPMR Port Connectivity function (8.5.2).

12 Each ISS M\_UNITDATA.indication with a destination MAC address that is either the individual address of  
13 an MSAP provided by the Bridge Port or a group address used by the attached LLC Entity shall cause an  
14 MA\_UNITDATA.indication at that MSAP with destination address, source address, MSDU, and priority  
15 parameters identical to those in the M\_UNITDATA.indication. No other indications or frames give rise to  
16 indications to the MAC Service user.

17 Each MA\_UNITDATA.request at the MSAP shall result in an M\_UNITDATA.request at the ISS access  
18 point with identical destination address, source address, MSDU, and priority parameters.

19 NOTE 1—Appropriate selection of the PVID for a Management Port facilitates attachment of an Internet Protocol (IP)  
20 stack supporting an SNMP Management Agent to any selected VID relayed by the Bridge. This function is not  
21 supported in Bridges that do not support the EISS, such as TPMRs.

22 NOTE 2—Higher Layer Entities attached to a Bridge Port can use the VLAN tag of received frames to achieve  
23 VLAN-awareness.

## 24 8.6 The Forwarding Process

25 Each frame submitted to the MAC Relay Entity shall be forwarded subject to the constituent functions of the  
26 Forwarding Process (Figure 8-12). Each function is described in terms of the action taken for a given frame  
27 received on a given Port (termed “the reception Port”). The frame can be forwarded for transmission on  
28 some Ports (termed “transmission Ports”) and discarded without being transmitted at the other Ports.

29 NOTE 1—IEEE Std 802.1Q, 2003 Edition, included frame formatting and FCS recalculation functions within the  
30 Forwarding Process. This standard now places those functions below the EISS interface, to allow the specification of  
31 additional methods for Bridge Port support of the EISS.

32 NOTE 2—IEEE Std 802.1D-2004 [B14], included priority mapping functions within the Forwarding Process. This  
33 standard now places this function below the ISS interface.

34 NOTE 3—The Forwarding Process models the MAC relay function and does not take into consideration what may occur  
35 once frames are passed to the Bridge Port for transmission. Conformant implementations of some media access methods  
36 can vary the transmission order in apparent violation of the transmission selection rules when observing frames on the  
37 medium. It may therefore not be possible to test conformance to this standard for some implementations simply by  
38 relating observed LAN traffic to the functionality of the forwarding process; tests also have to allow for the (conformant)  
39 behavior of the MAC.

40 Figure 8-4 illustrates the operation of the Forwarding Process in a single instance of frame relay between the  
41 Ports of a Bridge with two Ports.

Figure 8-12—Forwarding process functions

## 8.6.1 Active topology enforcement

To prevent data loops and unwanted learning of source MAC addresses, the Forwarding Process determines the values (TRUE or FALSE) of the learning and forwarding controls (8.4) appropriate to each received frame and Bridge Port. If learning is TRUE for the reception Port and ingress filtering (8.6.2) would not cause the received frame to be discarded, the source address and VID are submitted to the Learning Process.

~~NOTE 1—VIDs are not applicable to MAC Bridges and only the source address is submitted to the Learning Process.~~

~~NOTE 1—In a VLAN-unaware MAC Bridge, the Learning Process is supported by Bridge Ports that provide the ISS, which does not include a VID parameter. The VLAN-unaware Forwarding Process does not use VID as part of its operation and the data structure maintained omit this parameter.~~

~~If forwarding is TRUE for the reception Port, and either the EVBMode parameter value (40.4) for the Port is not “EVB Bridge” or the value of the operReflectiveRelayControl parameter for the Port is FALSE, each Bridge Port, other than the reception Port, with forwarding TRUE is identified as a potential transmission Port. If forwarding is TRUE for the receiving Port and the EVBMode parameter value (40.4) for the Port is “EVB Bridge” and the operReflectiveRelayControl parameter value for the Port is TRUE, each Bridge Port, including the reception Port, with forwarding TRUE is identified as a potential transmission Port.~~

~~The text shown as removed above was amended by 802.1Qbg-2012. The effect of the change was to almost entirely obscure the original sense, which continues to be relevant in all cases except that of an Edge Virtual Bridge (EVB). It also leaves bridging behavior undefined when EVB specific parameters are not present. Amendments addressing specific subjects should not be written to convert the entire subject to the benefit of the amendment and the detriment of other established uses. The paragraph added immediately below restores the text prior to the Qbg amendment and is followed by a paragraph that specifically addresses the EVB requirement.~~

~~If forwarding is TRUE for the reception Port, each Bridge Port, other than the reception Port, with forwarding TRUE is identified as a potential transmission Port.~~

1 Edge Virtual Bridging (Clause 40) can use reflective relay (8.6.1). If forwarding is TRUE for the reception  
2 Port and the EVBMode parameter value (40.4) for the Port is “EVB Bridge” and the  
3 operReflectiveRelayControl parameter value for the Port is TRUE, the reception Port is also identified as a  
4 potential transmission Port.

5 In an edge relay (ER), the forwarding process ~~may~~can set learning FALSE for all frames.

6 An SST Bridge supports a single active topology, the CST. For each Bridge Port, RSTP determines a single  
7 value for forwarding and a single value for learning (8.4) for all frames.

8 Bridges with MST, PBB-TE, or SPB capabilities use the VID of the received frame to determine forwarding  
9 and learning for that frame for each Bridge Port that is enabled, i.e., has MAC\_Operational True and an  
10 Administrative Bridge Port State of Enabled, as follows:

11 If the Bridge supports PBB-TE, and the VID is an ESP-VID, forwarding is TRUE and learning is FALSE.  
12 Control over the active topology of each ESP is provided by configuration of Static Filtering Entries in the  
13 FDB (8.8.1, 25.10.1).

14 If the Bridge uses MSTP to configure the CIST, and the VID identifies a VLAN assigned to the CIST,  
15 forwarding and learning are as determined by MSTP (Clause 13) for the CIST.

16 If the Bridge uses MSTP to configure MSTIs, and the VID identifies a VLAN assigned to an MSTI  
17 calculated by MSTP, forwarding and learning are as determined by MSTP for that MSTI.

18 If the Bridge uses ISIS-SPB to configure the CIST, and the VID identifies a VLAN assigned to the CIST,  
19 forwarding and learning take the value of forwarding determined by ISIS-SPB (Clause 28) for the CIST.

20 If the Bridge uses ISIS-SPB, and the VID is used by SPBV as an SPVID, both forwarding and learning take  
21 the value of forwarding determined by ISIS-SPB for the SPT identified by that SPVID.

22 If the Bridge uses ISIS-SPB and the VID identifies a VLAN supported by SPBM, then for that VID:

- 23 — Learning is False for all Bridge Ports.
- 24 — Forwarding is True for the reception Port if and only if a Dynamic Filtering Entry for the frame’s  
25 source address exists and specifies Forward for that Port or a MAC Address Registration Entry for  
26 the frame’s individual destination address exists and specifies Forward for that Port.
- 27 — Forwarding is True for all other Bridge Ports.

28 NOTE 2—Effective control over the egress component of an SPT for VLANs supported by SPBM is provided by  
29 ISIS-SPB configuration of (a) a Dynamic Filtering Entry for the VLAN’s VID and Root MAC address (for unicast  
30 frames); and (b) MAC Address Registration Entries for the VID- and SPT-specific group MAC addresses (for multicast  
31 frames); and (c) a MAC Address Registration Entry for the VID to filter “All Unregistered Group Addresses” at all  
32 Ports.

33 All Bridges other than SST Bridges implement the MST Configuration Table (8.9.1). The use of VIDs to  
34 determine learning and forwarding, as required by this clause, shall be consistent with that table as follows.  
35 VIDs allocated by the MST Configuration Table (8.9.1) of value:

- 36 — CIST-MSTID (0x000) are CIST VIDs.
- 37 — SPBM-MSTID (0xFFC) are Base VIDs supported by SPBM.
- 38 — SPBV-MSTID (0xFFD) are Base VIDs supported by SPBV.
- 39 — TE-MSTID (0xFFE) are ESP-VIDs supported by PBB-TE.
- 40 — SPVID-Pool-MSTID (0xFFF) are VIDs reserved for use by ISIS-SPB as SPVIDs.
- 41 — All VIDs allocated to other values of MSTID are assigned to the MSTI identified by that MSTID.

42 NOTE 3—While the MST Configuration Table is capable of detailing the configuration of each SPVID, it captures the  
43 allocation of Base VIDs only. Individual allocation of SPVIDs are captured in the ISIS-SPB database, the SPB ECT  
44 Static Entry (12.25.4), and in the port VID translation tables. By specifying only the type of VID and its allocation to  
45 SPB, backwards compatibility with STP, RSTP, and MSTP is maintained.

### 1 8.6.1.1 Requirements for the use of reflective relay

2 VEPA ERs (8.6.3.1) used in EVB (Clause 40) require reflective relay (40.4, 8.6.1) to be enabled on an  
3 attached EVB Bridge SBP in order to ensure that all VSIs connected to the VEPA ER are able to receive  
4 frames transmitted on one of the other VSIs. The following requirements ensure that a device operates  
5 correctly when using reflective relay:

- 6 a) The operation of the device shall be such that it prevents the establishment of loops, i.e., the device  
7 shall not both request and provide reflective relay on the same port.
- 8 b) The device shall ensure that any frame that it transmits on a given port, and that is reflected back to  
9 the device through the attached Bridge Port, is filtered by the device in order to prevent it being  
10 delivered to the originating port.
- 11 c) Any device requesting reflective relay is responsible for performing frame replication as necessary  
12 for delivery to multiple ports.

13 NOTE—Information that can be used to assist in meeting these requirements is the source MAC address and the FID  
14 derived from the VID.

### 15 8.6.2 Ingress filtering

16 Each Port may support an Enable Ingress Filtering parameter. A frame received on a Port that is not in the  
17 member set (8.8.10) associated with the frame's VID shall be discarded if this parameter is set. The default  
18 value for this parameter is reset, i.e., Disable Ingress Filtering, for all Ports. Any Port that supports setting  
19 this parameter shall also support resetting it. The parameter may be configured by the management  
20 operations defined in Clause 12.

21 This function is not applicable to VLAN-unaware MAC Relays.

### 22 8.6.3 Frame filtering

23 The Forwarding Process takes filtering decisions, i.e., reduces the set of potential transmission Ports (8.6.1),  
24 for each received frame on the basis of:

- 25 a) Destination MAC address
- 26 b) VID
- 27 c) Flow hash
- 28 d) The information contained in the FDB for that MAC address and VID
- 29 e) The default Group filtering behavior for the potential transmission Port (8.8.6)

30 in accordance with the definition of the FDB entry types (8.8.1, 8.8.3, and 8.8.4). The required behavior is  
31 summarized in 8.8.6, 8.8.9, Table 8-10, Table 8-11, and Table 8-12. Item b), specifying a VID value, is not  
32 applicable to VLAN-unaware MAC Relays. Flow hash is applicable only on Bridges supporting flow  
33 filtering (44.2).

34 Each of the reserved MAC addresses specified in Table 8-1 shall be permanently configured in the FDB in  
35 C-VLAN components and ERs. Each of the reserved MAC addresses specified in Table 8-2 shall be  
36 permanently configured in the FDB in S-VLAN components. Each of the reserved MAC addresses specified  
37 in Table 8-3 shall be permanently configured in the FDB in TPMR components. The FDB entries for  
38 reserved MAC addresses shall specify filtering for all Bridge Ports and all VIDs. Management shall not  
39 provide the capability to modify or remove entries for reserved MAC addresses.

40 The addresses in Table 8-1, Table 8-2, and Table 8-3 determine the scope of propagation of PDUs within a  
41 Bridged Network, as follows:

- 42 f) The *Nearest Bridge* group address is an address that no conformant TPMR component, S-VLAN  
43 component, C-VLAN component, or MAC Bridge can forward. PDUs transmitted using this

destination address, or any of the other addresses that appear in all three tables, can therefore travel no further than those stations that can be reached via a single individual LAN from the originating station. Hence the Nearest Bridge group address is also known as the Individual LAN Scope group address.

g) The **Nearest non-TPMR** Bridge group address is an address that no conformant S-VLAN component, C-VLAN component, or MAC Bridge can forward; however, this address is relayed by a TPMR component. PDUs using this destination address, or any of the other addresses that appear in both Table 8-1 and Table 8-2 but not in Table 8-3, will be relayed by any TPMRs but will propagate no further than the nearest S-VLAN component, C-VLAN component, or MAC Bridge.

h) The **Nearest Customer Bridge** group address is an address that no conformant C-VLAN component or MAC Bridge can forward; however, it is relayed by TPMR components and S-VLAN components. PDUs using this destination address, or any of the other addresses that appear in Table 8-1 but not in either Table 8-2 or Table 8-3, will be relayed by TPMR components and S-VLAN components but will propagate no further than the nearest C-VLAN component or MAC Bridge.

NOTE 1—The reserved MAC addresses specified in Table 8-1, Table 8-2, and Table 8-3 determine the span of connectivity for the protocol frames using the address; they do not identify the protocol. The protocols are identified by the EtherType field following the address fields.

NOTE 2—An instance of IEEE 802.1AX™ Link Aggregation Control Protocol (LACP) intended to operate between non-TPMR Bridges, even through a TPMR, can use the Nearest non-TPMR Bridge group address. See K.2 for discussion of the use of TPMRs in a link using LACP.

1

**Table 8-1—C-VLAN and MAC Bridge component Reserved addresses**

| Assignment                                                                        | Value             |
|-----------------------------------------------------------------------------------|-------------------|
| Bridge Group Address,<br>Nearest Customer Bridge group address <sup>a</sup>       | 01-80-C2-00-00-00 |

| IEEE 802.3 Slow_Protocols_Multicast address                                       | 01-80-C2-00-00-02 |
| Nearest non-TPMR Bridge group address                                             | 01-80-C2-00-00-03 |
| IEEE MAC-specific Control Protocols group address                                 | 01-80-C2-00-00-04 |
| Reserved for future standardization                                               | 01-80-C2-00-00-05 |
| Reserved for future standardization                                               | 01-80-C2-00-00-06 |
| MEF Forum ELMI protocol group address <sup>b</sup>                                | 01-80-C2-00-00-07 |
| Provider Bridge Group Address                                                     | 01-80-C2-00-00-08 |
| Reserved for future standardization                                               | 01-80-C2-00-00-09 |
| Reserved for future standardization                                               | 01-80-C2-00-00-0A |
| EDE-SS PEP Address (IEEE Std 802.1AE)                                             | 01-80-C2-00-00-0B |
| Reserved for future standardization                                               | 01-80-C2-00-00-0C |
| Provider Bridge MVRP Address                                                      | 01-80-C2-00-00-0D |
| Individual LAN Scope group address <sup>c</sup> ,<br>Nearest Bridge group address | 01-80-C2-00-00-0E |
| Reserved for future standardization                                               | 01-80-C2-00-00-0F |

<sup>a</sup> As stated in 13.41, in a Provider Edge Bridge, a C-VLAN component supporting a single service instance (i.e., with a single PEP) may forward (not filter) frames with the Nearest Customer Bridge Address as the destination address.

<sup>b</sup> This address is not exclusively reserved for this purpose; other uses are reserved for future standardization.

<sup>c</sup> It is intended that no IEEE 802.1 relay device will be defined that will forward frames that carry this destination address.

**Table 8-2—S-VLAN component Reserved addresses**

| Assignment                                                                        | Value             |
|-----------------------------------------------------------------------------------|-------------------|
| IEEE MAC-specific Control Protocols group address                                 | 01-80-C2-00-00-01 |
| IEEE 802.3 Slow_Protocols_Multicast address                                       | 01-80-C2-00-00-02 |
| Nearest non-TPMR Bridge group address                                             | 01-80-C2-00-00-03 |
| IEEE MAC-specific Control Protocols group address                                 | 01-80-C2-00-00-04 |
| Reserved for future standardization                                               | 01-80-C2-00-00-05 |
| Reserved for future standardization                                               | 01-80-C2-00-00-06 |
| MEF Forum ELMI protocol group address <sup>a</sup>                                | 01-80-C2-00-00-07 |
| Provider Bridge Group Address <sup>b</sup>                                        | 01-80-C2-00-00-08 |
| Reserved for future standardization                                               | 01-80-C2-00-00-09 |
| Reserved for future standardization                                               | 01-80-C2-00-00-0A |
| Individual LAN Scope group address <sup>c</sup> ,<br>Nearest Bridge group address | 01-80-C2-00-00-0E |

<sup>a</sup> This address is not exclusively reserved for this purpose; other uses are reserved for future standardization.

<sup>b</sup> It is intended that no IEEE 802.1 protocol or device will be defined that will require the inclusion of this address in the FDB to prevent or restrict its use for communication between a port of a Provider Bridge's S-VLAN component and the S-VLAN component of the nearest Provider Bridge.

<sup>c</sup> It is intended that no IEEE 802.1 relay device will be defined that will forward frames that carry this destination address.

**Table 8-3—TPMR component Reserved addresses**

| Assignment                                                                        | Value             |
|-----------------------------------------------------------------------------------|-------------------|

<sup>a</sup> It is intended that no IEEE 802.1 relay device will be defined that will forward frames that carry this destination address.

### 1 8.6.3.1 Virtual edge port aggregator (VEPA) filtering

2 A VEPA ER filters frames as follows.

3 If the receiving port is a DRP, then the URP shall be selected as the only transmission Port.

4 If the receiving port is a URP, then in addition to the filtering specified in 8.6.3, if there is a filtering entry  
5 that specifies forwarding for the source MAC address and VLAN of the frame for any DRP, then that DRP  
6 shall be removed from the list of potential transmission Ports.

## 8.6.4 Egress filtering

This function is not applicable to VLAN-unaware MAC Relays.

Any Port that is not in the member set (8.8.10) for the frame's VID is removed from the set of potential egress Ports.

## 8.6.5 Flow classification and metering

The Forwarding Process can apply flow classification and metering to frames that are received on a Bridge Port and have one or more potential transmission ports. Bridge Ports and end stations may support Per-Stream Filtering and Policing (PSFP), Asynchronous Traffic Shaping (ATS) filtering and eligibility time assignment, Congestion Isolation (CI), or the general flow classification rules specified in 8.6.5.1.

NOTE—The general flow classification and metering specification was added to this standard by IEEE Std 802.1Q-2005, PSFP by IEEE Std 802.1Qci-2017, ATS by IEEE Std 802.1Qcr-2020, and CI by IEEE Std 802.1Qcz-2023.

PSFP, ATS, and CI share common per-stream classification and metering elements, as shown in Figure 8-13. The Stream identification function specified in IEEE Std 802.1CB can be used to associate received frames with these elements.

Figure 8-13—Flow classification and metering

### 1 8.6.5.1 General flow classification and metering

2 Bridges that implement general flow classification and metering can identify subsets of traffic (frames), each  
3 subject to the same flow metering and forwarding. Flow classification rules may be based on the following:

- 4 a) Destination MAC address
- 5 b) Source MAC address
- 6 c) VID
- 7 d) Priority

8 Item c), specifying a VID value, is not applicable to VLAN-unaware MAC Relays.

9 Frames classified using the same set of classification rules are subject to the same flow meter. The flow  
10 meter can change the drop\_eligible parameter associated with each frame and can discard frames on the  
11 basis of the following parameters for each received frame and previously received frames, and the time  
12 elapsed since those frames were received:

- 13 e) The received value of the drop\_eligible parameter
- 14 f) The mac\_service\_data\_unit size

15 The flow meter shall not base its decision on the parameters of frames received on other Bridge Ports, or on  
16 any other parameters of those Ports. The bandwidth profile algorithm described in the MEF Forum  
17 Technical Specification 10.3 (MEF 10.3) should be used.

18 NOTE 1—The flow meter described here can encompass a number of meters, each with a simpler specification.  
19 However, given the breadth of implementation choice permitted, further structuring to specify, for example, that frames  
20 can bypass a meter or are subject only to one of a number of meters provides no additional information.

21 NOTE 2—Although flow metering is applied after egress (Figure 8-12), the meter(s) operate per reception Port, not per  
22 potential transmission Port(s).

### 23 8.6.5.2 Per-stream classification and metering

24 When Per-Stream Filtering and Policing (PSFP), Asynchronous Traffic Shaping (ATS), or Congestion  
25 Isolation (CI) is used, filtering and policing decisions for received frames are made, and subsequent queuing  
26 (8.6.6) and transmission selection decisions (8.6.8) supported, as follows:

- 27 a) Each received frame can be associated with a stream filter, as specified in 8.6.5.3. If a matching  
28 stream filter is specified (8.6.5.3), that is used to process the frame. Wildcard stream filters can be  
29 configured to match and discard frames not associated with a specified stream. If no matching  
30 stream filter is found, the frame is queued for transmission as specified in 8.6.6.
- 31 b) If the stream filter specifies maximum SDU size filtering (8.6.5.3.1), that is used to process the  
32 frame. The frame can be discarded if a maximum SDU size is exceeded. The ATS scheduler state  
33 machine operation (8.6.11) assumes that the sizes of frames that it processes are less than or equal to  
34 the associated CommittedBurstSize parameter (8.6.11.3.5).
- 35 c) The stream filter specifies a stream gate (8.6.5.4), that is used to process the frame. The frame can be  
36 discarded if it is received outside of permitted reception intervals or a given data limit within a  
37 reception interval is exceeded. The frame's priority can be mapped to an internal priority value  
38 (IPV) that can influence subsequent queuing decisions (8.6.6).
- 39 d) If the stream filter specifies a flow meter (8.6.5.5), that is used to process the frame. The frame can  
40 be discarded or marked as drop eligible if a traffic limit of a flow meter is exceeded. A given stream  
41 filter can be configured with flow meters and an ATS scheduler if both PSFP and ATS are supported.
- 42 e) If the stream filter specifies an ATS scheduler (8.6.5.6), that is used to process the frame. It  
43 computes an eligibility time for the frame for subsequent use by the ATS transmission selection  
44 algorithm (8.6.8.5). The frame can be discarded if a maximum eligibility time is exceeded  
45 (8.6.11.3.13).

### 8.6.5.2.1 PSFP support

Each Bridge component or end station that implements PSFP shall support stream filtering, maximum SDU size filtering, stream gating, and flow metering, with the following:

- a) A single *Stream Filter Instance Table* (8.6.5.3).
- b) A single *Stream Gate Instance Table* (8.6.5.4).
- c) A single *Flow Meter Instance Table* (8.6.5.5).

The relationship between stream filters, stream gates, flow meters for streams subject to PSFP processing (as identified by the stream filter) is illustrated by Figure 8-14 for a number of streams.

Figure 8-14—Per-stream classification for PSFP

### 1 8.6.5.2.2 ATS support

2 Each Bridge component that implements ATS shall support stream filtering, maximum SDU size filtering,  
3 stream gates supporting IPV assignment, ATS schedulers, and ATS scheduler groups, with the following:

- 4 a) A single *Stream Filter Instance Table* (8.6.5.3).
- 5 b) A single *Stream Gate Instance Table* (8.6.5.4).
- 6 If the Bridge component does not support PSFP in addition to ATS, each stream gate only supports  
7 IPV assignment (8.6.5.4). IPV can be used as part of adjusting per-hop delay bounds to meet specific  
8 networks' end-to-end delay requirements.
- 9 c) A single *ATS Scheduler Instance Table* (8.6.5.6).
- 10 d) A single *ATS Scheduler Group Instance Table* (8.6.5.6).
- 11 e) An *ATS Port Parameter Table* for each Bridge Port (8.6.5.6).

12 NOTE 1—The operation of ATS schedulers (8.6.11) provides policing capabilities similar to those provided by flow  
13 meters (8.6.5.5). This handling of improper traffic can be sufficient, such that no additional flow meters are required.

14 NOTE 2—For bridges with support for ATS, and without support for PSFP, stream gates of ATS traffic will never close.  
15 In this case, stream gates are only used for IPV assignment.

16 NOTE 3—In presence of state changes of stream gates associated with ATS traffic, the asynchronous nature of ATS  
17 traffic can require that state changes of multiple of these associated gates are executed simultaneously.

18 The relationship between stream filters, stream gates, and ATS schedulers for streams subject to ATS  
19 processing is illustrated by Figure 8-15.

20 ATS support in end stations is provided by a modified variant of per-stream classification and metering for  
21 ATS, as specified in 47.1.

**KEY**

*Discard*: Frame discarding abilities and parameters (Clause 8.6.5.3.1, Clause 8.6.5.4, 8.6.5.6).

CBS: CommittedBurstSize parameter (8.6.5.6, 8.6.11.3.5).

CIR: CommittedInformationRate parameter (8.6.5.6, 8.6.11.3.6).

Figure 8-15—Per-stream classification and metering for ATS

### 8.6.5.2.3 CI Support

Each Bridge component or an end station that implements Congestion Isolation supports stream identification and stream gates to allow traffic class modification, with the following:

- a) A single Stream Filter Instance Table (8.6.5.3).
- b) A single Stream Gate Instance Table (8.6.5.4).

The relationship between stream filters and stream gates for streams subject to CI processing (as identified by the stream filter) is illustrated by Figure 8-16 for a number of streams.

**Figure 8-16—Per-stream classification and assignment for CI**

Congestion isolation uses two stream filter instances from the stream filter instance table (8.6.5.3) to select stream gate instances that will modify the priority of flows. One stream filter instance is used to modify the priority of congesting flows from the monitored queue to the congesting queue. The other stream filter instance is used to modify the priority of congesting flows from the congesting queue back to the monitored queue. There are no *filter specifications* used by congestion isolation.

The *stream\_handle* and *priority* parameters associated with a received frame select the stream filter instance of congestion isolation for a particular monitored traffic class. The purpose of the stream filter is to select the stream gate instance that will modify the priority of congesting flow frames so they will traverse the congesting queue. The absence of a *stream\_handle* and the *priority* parameter associated with a received frame select the stream gate instance that will modify the priority of received frames back to the priority of the monitored queue.

**NOTE**—Changes to the frame's priority are intended to persist (see 49.2.4 and 49.2.6) by modifying the Priority Code Point (see 6.9.3) or other indicators used to select the traffic class, such as the Differentiated Services Code Point (see IETF RFC 2474). As noted in 6.8.1, modification to a frame will require the FCS to be regenerated. Options for regenerating the FCS are discussed in Annex O.

1 Congestion isolation uses two stream gate instances from the stream gate instance table (8.6.5.4) to modify  
2 the priority of flows. The operational and an administrative *stream gate state* (8.6.10.4, 8.6.10.5, 12.31.3) is  
3 set to Open for Congestion Isolation and the *GateClosedDueToInvalidRxEnable* and  
4 *GateClosedDueToOctetsExceededEnable* parameters are set to FALSE. The internal priority value (IPV) is  
5 used in place of the priority value associated with the frame to determine the frame's traffic class, using the  
6 Traffic Class Table as specified in 8.6.6. The *stream gate control list* feature is not used by Congestion  
7 Isolation and is set to null.

### 8 8.6.5.3 Stream filtering

9 A received frame can be associated with a stream filter using the frame's *stream\_handle* and *priority*  
10 parameters. The *stream\_handle* is a sub-parameter of the *connection\_identifier* parameter of the ISS (6.6),  
11 provided by the stream identification function specified in IEEE Std 802.1CB.

12 Each stream filter comprises the following:

- 13 a) An integer *stream filter identifier*.
- 14 b) A *stream\_handle* specification, either:
  - 15 1) A single value, as specified in IEEE Std 802.1CB.
  - 16 2) A wildcard, that matches any *stream\_handle*.
  - 17 3) If congestion isolation is supported, a null-handle, that matches when no *stream\_handle* is  
18 provided.
- 19 c) A *priority* specification, either:
  - 20 1) A single priority value.
  - 21 2) A wildcard value that matches any priority value.
- 22 d) Maximum SDU size filtering (8.6.5.3.1) information, comprising:
  - 23 1) An integer *Maximum SDU size*, in octets. A value of 0 disables maximum SDU size filtering  
24 for this stream filter.
  - 25 2) A boolean *StreamBlockedDueToOversizeFrameEnable* parameter.
  - 26 3) A boolean *StreamBlockedDueToOversizeFrame* parameter.
- 27 e) An integer *stream gate identifier* (8.6.5.4).
- 28 f) An integer *flow meter instance identifier* (8.6.5.5).  
29 If this parameter is absent, frames associated with the stream filter are not subject to flow metering.
- 30 g) An integer *ATS scheduler instance identifier* (8.6.5.6).  
31 If this parameter is absent, frames associated with the stream filter are not subject to ATS scheduling  
32 and transmission selection.

33 Each stream filter also comprises the following counters for frames associated with the stream filter:

- 34 h) *MatchingFramesCount*: all frames associated with that stream filter.
- 35 i) *PassingSDUCount*: frames passing the maximum SDU size filter (8.6.5.3.1).
- 36 j) *NotPassingSDUCount*: frames not passing the maximum SDU size filter (8.6.5.3.1).
- 37 k) *PassingFrameCount*: frames passing the associated stream gate (8.6.5.4).
- 38 l) *NotPassingFrameCount*: frames not passing the stream gate (8.6.5.4).
- 39 m) *RedFramesCount*: frames discarded by the flow meter (8.6.5.5).

1 The *stream filter identifier* uniquely identifies the stream filter, indexing a *Stream Filter Instance Table* of up  
2 to *MaxStreamFilterInstances* stream filters. Each received frame is associated with the stream filter with the  
3 lowest *stream filter identifier* whose *stream\_handle* and *priority* specification match the frame's parameters,  
4 and the *MatchingFramesCount* is incremented for that filter.

5 NOTE 1—The use of *stream\_handle* and *priority*, along with the wild-carding rules previously stated, allow  
6 configuration possibilities that go beyond the selection of individual streams, for example, per-priority filtering and  
7 policing, or per-priority per-reception Port filtering and policing can be configured using these rules.

8 NOTE 2—If it is desired to discard frames that do not match any other stream filter, rather than such frames being  
9 processed without filtering, a stream filter can be placed at the end of the table with *stream\_handle* and *priority*  
10 specifications both wild-carded and the stream gate identifier of a permanently closed stream gate.

11 NOTE 3—A discarded frame is not processed or counted by subsequent elements of the forwarding process. As a  
12 consequence, implementations can internally represent all counters [items h) through m) above] by the four counters  
13 *MatchingFramesCount* [item h) above], *NotPassingSDUCount* [item j) above], *NotPassingFrameCount* [item l) above],  
14 and *RedFramesCount* [item m) above].

### 15 8.6.5.3.1 Maximum SDU Size Filtering

16 If the SDU size of a frame exceeds the value of the associated stream filter's Maximum SDU size parameter,  
17 the frame is discarded and that stream filter's *NotPassingSDUCount* is incremented. If the stream filter's  
18 *StreamBlockedDueToOversizeFrameEnable* parameter is configured to be TRUE, the  
19 *StreamBlockedDueToOversizeFrame* parameter is set to TRUE and all subsequent frames will be discarded  
20 until *StreamBlockedDueToOversizeFrame* is administratively reset to FALSE.

21 Otherwise, the stream filter's *PassingSDUCount* is incremented (see 8.6.5.3). The default configuration of  
22 both *StreamBlockedDueToOversizeFrameEnable* and *StreamBlockedDueToOversizeFrame* is FALSE.

23 NOTE—The Maximum SDU size is defined per stream filter and can therefore differ from the *queueMaxSDU* specified  
24 in 8.6.8.4. As *queueMaxSDU* is applied after the flow classification and metering, it is possible that a frame that passes  
25 the Maximum SDU size filter will later be discarded because its SDU size exceeds *queueMaxSDU*.

### 26 8.6.5.4 Stream gating

27 Stream gates can discard frames whose reception times contradict a given time schedule. Stream gates can  
28 also map the frame's priority to an internal priority value (IPV) that is used to make subsequent queuing  
29 decisions (8.6.6), while retaining the frame's original priority for transmission.

30 NOTE 1—The IPV facilitates ATS per-hop delay bound adjustment to satisfy specific networks' end-to-end delay  
31 requirements. Annex T (CQF) describes another IPV use case. Another use case is the ability to isolate congesting flows  
32 to a congesting flow queue as specified by Congestion Isolation (Clause 49).

33 Each stream gate comprises the following:

- 34 a) An integer *stream gate instance identifier*.
- 35 b) An administrative and an operational *stream gate state* parameter. These parameters take the  
36 following values:
  - 37 1) Open: Frames are permitted to pass through the stream gate.
  - 38 2) Closed: Frames are not permitted to pass through the stream gate.
- 39 c) An administrative and an operational *internal priority value specification* parameter. These  
40 parameters take the following values:
  - 41 1) Null, in this case the received frame's priority parameter is used as the IPV.
  - 42 2) A specific IPV for the frame.

43 The *stream gate instance identifier* uniquely identifies the stream gate, indexing a *Stream Gate Instance*  
44 *Table* of up to *MaxStreamGateInstances* stream gates.

45 If PSFP are supported, each stream gate also includes the following:

- 46 d) An administrative and an operational *stream gate control list*.

- e) A boolean *GateClosedDueToInvalidRxEnable* parameter.
- f) A boolean *GateClosedDueToInvalidRx* parameter.
- g) A boolean *GateClosedDueToOctetsExceededEnable* parameter.
- h) A boolean *GateClosedDueToOctetsExceeded* parameter.

An instance of the stream gate control state machine (8.6.10) determines the operational values of the *stream gate state* and the *internal priority value specification* [items b) and c) above] by the cyclical execution of the control operations (see Table 8-4) specified in the stream gate's *stream gate control list* [item d) above]. The administrative *stream gate state* and *internal priority value specification* parameters are used to determine the initial values of the corresponding operational parameters, and the administrative *stream gate control list* parameter allows configuration of a new control list prior to enabling its use in a running system.

If a frame is passed by a stream gate, the *PassingFrameCount* of the stream filter (8.6.5.3) associated with that frame is incremented. The *NotPassingFrameCount* is incremented if the frame is discarded.

**Table 8-4—Stream gate control operations**

| Operation name | Parameter(s)                                         | Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SetGateAndIPV  | StreamGateState, IPV, TimeInterval, IntervalOctetMax | The StreamGateState parameter specifies a desired state, <i>open</i> or <i>closed</i> , for the stream gate, and the IPV parameter specifies a desired value of the IPV associated with the stream. On execution, the StreamGateState and IPV parameter values are used to set the operational values of the stream gate state and internal priority value specification parameters for the stream. After <i>TimeInterval</i> ticks (8.6.9.4.16) has elapsed since the completion of the previous stream gate control operation in the stream gate control list, control passes to the next stream gate control operation. The optional IntervalOctetMax parameter specifies the maximum number of MSDU octets that are permitted to pass the gate during the specified TimeInterval. If the IntervalOctetMax parameter is omitted, there is no limit on the number of octets that can pass the gate. |

Stream gates are able to permanently discard frames and thus effectively override the operational gate state (i.e., the stream gate behaves as if the operational stream gate state is Closed). This capability is provided in case a frame is discarded due to a closed gate state [8.6.5.4 item b)], and in case a frame is discarded because there are insufficient octets left (i.e., the value of the IntervalOctetsLeft parameter, as specified in 8.6.10.8, is lower than the frame length).

- i) Permanent frame discarding due to a frame received during a closed gate state is enabled if the *GateClosedDueToInvalidRxEnable* parameter is TRUE, and disabled if this parameter is FALSE. If enabled and any frame is discarded, then the *GateClosedDueToInvalidRx* parameter is set to TRUE, and all subsequent frames are discarded as long as the *GateClosedDueToInvalidRxEnable* and *GateClosedDueToInvalidRx* parameters are TRUE. Changes of the *GateClosedDueToInvalidRxEnable* parameter and transitions from TRUE to FALSE of the *GateClosedDueToInvalidRx* parameter are administrative actions.
- j) Permanent frame discarding due to insufficient left octets is enabled if the *GateClosedDueToOctetsExceededEnable* parameter is TRUE, and disabled if this parameter is FALSE. If enabled and any frame is discarded because there are insufficient octets left, then the *GateClosedDueToOctetsExceeded* parameter is set to TRUE, and all subsequent frames are discarded as long as the *GateClosedDueToOctetsExceededEnable* and *GateClosedDueToOctetsExceededEnable* parameters are TRUE. Changes of the *GateClosedDueToOctetsExceededEnable* parameter and transitions from TRUE to FALSE of the *GateClosedDueToOctetsExceeded* parameter are administrative actions.

1 Per default, permanent frame discarding is disabled and all associated parameters have the default value  
2 FALSE.

3 NOTE 2—Permanent frame discarding allows the detection of incoming frames during time periods when the stream  
4 gate is in the closed state and exceptionally large ingress bursts to result in the stream gate behaving as it is in a  
5 permanently closed state, until such a time as management action is taken to reset the condition. The intent is to support  
6 applications where the transmission and reception of frames across the network is coordinated such that frames are  
7 received only when the stream gate is open with a limited overall amount of ingress octets. Hence, frames received by  
8 the stream gate when it is in the closed state and unexpected amounts of ingress octets represent invalid receive  
9 conditions.

### 10 8.6.5.5 Flow metering

11 The flow meters specified by this subclause (8.6.5.5) implement the parameters and algorithm specified in  
12 *Bandwidth Profile Parameters and Algorithm* in MEF 10.3 with the additions described in this subclause.

13 Each flow meter comprises the following:

- 14 a) An integer *flow meter identifier*.
- 15 b) An integer *Committed information rate (CIR)*, in bits per second (MEF 10.3).
- 16 c) An integer *Committed burst size (CBS)*, in octets (MEF 10.3).
- 17 d) An integer *Excess Information Rate (EIR)*, in bits per second (MEF 10.3).
- 18 e) An integer *Excess burst size (EBS) per bandwidth profile flow*, in octets (MEF 10.3).
- 19 f) A *Coupling flag (CF)*, which takes the value 0 or 1 (MEF 10.3).
- 20 g) A *Color mode (CM)*, which takes the value *color-blind* or *color-aware* (MEF 10.3).
- 21 h) A boolean *DropOnYellow* parameter.
- 22 i) A boolean *MarkAllFramesRedEnable* parameter.
- 23 j) A boolean *MarkAllFramesRed* parameter.

24 Each frame has a predetermined color for subsequent processing by a flow meter. If this color is determined  
25 by the *drop\_eligible* parameter (6.9.1), the color is determined as follows:

- 26 k) If the *drop\_eligible* parameter is FALSE, the color is green.
- 27 l) If the *drop\_eligible* parameter is TRUE, the color is yellow.

28 NOTE 1—This standard specifies the relationship among frame length, media-dependent overhead, ATS scheduler  
29 operation, and the associated parameters in 8.6.11. In contrast, the operation and parameters of flow meters in 8.6.5.5 are  
30 as specified by MEF 10.3.

31 NOTE 2—Envelope and Rank, as defined in MEF 10.3, are not used by the flow meters described in this subclause; i.e.,  
32 the reduced functionality algorithm described in 12.2 of MEF 10.3 is used.

33 The *flow meter identifier* uniquely identifies the flow meter instance, indexing a *Flow Meter Instance Table*  
34 of up to *MaxFlowMeterInstances* flow meters.

35 The *DropOnYellow* parameter indicates whether frames marked yellow by the MEF 10.3 algorithm are  
36 discarded or marked as drop eligible:

- 37 m) A value of TRUE indicates that yellow frames are discarded.
- 38 n) A value of FALSE indicates that the *drop\_eligible* parameter of yellow frames is set to TRUE.

39 NOTE 3—Changing the value of the *drop\_eligible* parameter may change the contents of the frame, depending on how  
40 the frame is tagged when transmitted, which may then require updating the *frame\_check\_sequence*. Mechanisms for  
41 conveying information from ingress to egress that the *frame\_check\_sequence* may require updating are implementation  
42 dependent.

43 Flow meters can permanently discard all frames after an initial frame has been discarded. This capability is  
44 enabled if the *MarkAllFramesRedEnable* parameter is TRUE, and disabled if this parameter is FALSE. If  
45 enabled and the flow meter discards a frame, then the *MarkAllFramesRed* parameter is set to TRUE, and all

1 subsequent frames are discarded as long as the `MarkAllFramesRedEnable` and `MarkAllFramesRed`  
2 parameters are TRUE.

3 Changes of the `MarkAllFramesRedEnable` parameter and transitions from TRUE to FALSE of the  
4 `MarkAllFramesRed` parameter are administrative actions. Per default, permanent frame discarding is  
5 disabled and both associated parameters have the default value FALSE.

6 Each time a flow meter discards a frame, the `RedFramesCount` counter of the originating stream filter  
7 (8.6.5.3) is increased.

#### 8 **8.6.5.6 ATS eligibility time assignment**

9 Asynchronous Traffic Shaping (ATS) schedulers assign eligibility times to frames which are then used for  
10 traffic regulation by the ATS transmission selection algorithm (8.6.8.5).

11 NOTE 1—ATS schedulers, as defined in this subclause (8.6.5.6), realize the computational part of the overall traffic  
12 shaping operation of ATS. The complete operation is provided in combination with the ATS transmission selection  
13 algorithm (8.6.8.5), which uses the assigned eligibility times to regulate the traffic for transmission.

14 Each ATS scheduler comprises the following:

- 15 a) An integer *scheduler identifier*.
- 16 b) An integer *scheduler group identifier*.
- 17 c) An integer *CommittedBurstSizeParameter* parameter, in bits (8.6.11.3.5).
- 18 d) An integer *CommittedInformationRate* parameter, in bits per second (8.6.11.3.6).
- 19 e) An internal *bucket empty time* state variable, in seconds (8.6.11.3.3).

20 ATS schedulers are organized in *ATS scheduler groups*. There is one ATS scheduler group per reception Port  
21 per upstream traffic class, where the latter refers to the transmitting traffic class in the device connected to  
22 the given reception Port. All ATS schedulers that process frames from a particular reception Port and a  
23 particular upstream traffic class are in the respective ATS scheduler group.

24 Each ATS scheduler group comprises the following:

- 25 f) An integer *scheduler group identifier*.
- 26 g) An integer *MaximumResidenceTime* parameter, shared by all ATS schedulers in a scheduler group,  
27 in nanoseconds (8.6.11.3.13).
- 28 h) An internal *group eligibility time* state variable, shared by all ATS schedulers in a scheduler group,  
29 in seconds (8.6.11.3.10).

30 NOTE 2—The organization of ATS schedulers into groups results in a non-decreasing ordering of eligibility times of  
31 successive frames associated with a single group. This permits frames of one group to be queued in FIFO order.

32 Each ATS scheduler assigns eligibility times to the associated frames, and discards frames in exceptional  
33 situations. The underlying operations are performed by an ATS scheduler state machine (8.6.11) associated  
34 with an ATS scheduler. This state machine updates the associated bucket empty time and group eligibility  
35 time state variables based on the `CommittedBurstSize`, the `CommittedInformationRate`, the  
36 `MaxResidenceTime`, the frame arrival times, and the frame lengths (including media-specific overhead).

37 Each Port is associated with the following variable for ATS schedulers:

- 38 i) An integer *DiscardedFramesCount* of frames discarded by the ATS schedulers associated with that  
39 reception Port.

1 Each Bridge component provides an *ATS Scheduler Instance Table* of up to *MaxSchedulerInstances* ATS  
2 schedulers, an *ATS Scheduler Group Instance Table* of up to *MaxSchedulerGroupInstances* ATS scheduler  
3 groups, and a *ATS Scheduler Port Parameter Table* shared by all ATS schedulers associated with a reception  
4 Port.

5 NOTE 3—Whether ATS scheduler instances, ATS scheduler group instances, the scheduler instance table, and the  
6 scheduler group instance table are located in reception ports or in transmission ports is implementation specific.

### 7 8.6.6 Queuing frames

8 The Forwarding Process shall queue each received frame to each of the potential transmission Ports (8.6.1,  
9 8.6.3, 8.6.4).

10 NOTE 1—The Forwarding Process is modeled as receiving a frame as the parameters of a data indication and  
11 transmitting through supplying the parameters of a data request. Queuing a frame awaiting transmission amounts to  
12 placing the parameters of a data request on an outbound queue.

13 The Forwarding Process provides storage for queued frames, awaiting an opportunity to submit these for  
14 transmission. The order of frames received on the same Bridge Port shall be preserved for:

- 15 a) Unicast frames with a given VID, priority, flow hash, and destination address and source address  
16 combination.
- 17 b) Multicast frames with a given VID, priority, flow hash, and destination address.

18 Flow hash is applicable only on Bridges supporting flow filtering (44.2).

19 The Forwarding Process provides one or more queues for a given Bridge Port, each corresponding to a  
20 distinct traffic class. Each frame is mapped to a traffic class using the Traffic Class Table for the Port. The  
21 priority value used for this mapping is determined as follows:

- 22 c) If stream gates are unsupported (8.6.5.4), the frame's priority is used.
- 23 d) If stream gates are supported and the IPV specification assigned to the frame is the null value, the  
24 frame's priority is used.
- 25 e) If stream gates are supported and the IPV specification assigned to the frame is an IPV, this IPV is  
26 used.

27 Traffic class tables may be managed. Table 8-5 shows the recommended mapping for the number of classes  
28 implemented, in implementations that do not support the credit-based shaper transmission selection  
29 algorithm (8.6.8.2). The requirements for priority to traffic class mappings in implementations that support  
30 the credit-based shaper transmission selection algorithm are defined in 34.5. Up to eight traffic classes may  
31 be supported, allowing separate queues for each priority.

32 NOTE 2—Different Ports can use different numbers of traffic classes. Ports with media access methods that support a  
33 single transmission priority, such as Ethernet, can support more than one traffic class.

34 NOTE 3—A queue in this context is not necessarily a single FIFO data structure. A queue is a record of all frames of a  
35 given traffic class awaiting transmission on a given Bridge Port. The transmission selection algorithm (8.6.8) determines  
36 which traffic class, among those classes with frames available for transmission, provides the next frame for transmission.  
37 A variety of queue structures such as a single FIFO, or a set of FIFOs with one for each VLAN or priority, is allowed.

38 In a congestion-aware Bridge (Clause 30) or a congestion isolation aware Bridge (Clause 49), the act of  
39 queuing a frame for transmission on a Bridge Port can result in the Forwarding Process generating a CNM or  
40 a CIM. The CNM and CIM are injected back into the Forwarding Process (8.6.1) as if they had been  
41 received on that Bridge Port.

42 If PSFP is supported (8.6.5.2), and the IPV associated with the stream filter that passed the frame is anything  
43 other than the null value, then that IPV is used to determine the traffic class of the frame, in place of the  
44 frame's priority, via the Traffic Class Table specified in 8.6.6. In all other respects, the queuing actions  
45 specified in 8.6.6 are unchanged.

**Table 8-5—Recommended priority to traffic class mappings**

|                                                                |             | Number of available traffic classes |   |   |   |   |   |   |   |
|----------------------------------------------------------------|-------------|-------------------------------------|---|---|---|---|---|---|---|
|                                                                |             | 1                                   | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Priority                                                       | 0 (Default) | 0                                   | 0 | 0 | 0 | 0 | 1 | 1 | 1 |
|                                                                | 1           | 0                                   | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
|                                                                | 2           | 0                                   | 0 | 0 | 1 | 1 | 2 | 2 | 2 |
|                                                                | 3           | 0                                   | 0 | 0 | 1 | 1 | 2 | 3 | 3 |
|                                                                | 4           | 0                                   | 1 | 1 | 2 | 2 | 3 | 4 | 4 |
|                                                                | 5           | 0                                   | 1 | 1 | 2 | 2 | 3 | 4 | 5 |
|                                                                | 6           | 0                                   | 1 | 2 | 3 | 3 | 4 | 5 | 6 |
|                                                                | 7           | 0                                   | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| NOTE—The rationale for these mappings is discussed in Annex I. |             |                                     |   |   |   |   |   |   |   |

<sup>1</sup> The IPV is used only to determine the traffic class associated with a frame, and hence select an outbound queue; for all other purposes, the received priority is used.

### 8.6.7 Queue management

A frame queued for transmission on a Port shall be removed from that queue:

- a) Following a transmit data request. No further attempt shall be made to transmit the frame on that Port even if the transmission is known to have failed.
- b) If that is necessary to ensure that the maximum Bridge transit delay (6.5.6) will not be exceeded at the time at which the frame would subsequently be transmitted.
- c) If the transmission Port is no longer forwarding for that frame (8.4, 8.6.1). Frames entering the queue subsequent to the transition out of the Forwarding state (e.g., CFM frames from Down MPs, as described in 22.1, Figure 22-4, and Figure 22-7) are not discarded.

NOTE—CFM frames may be excepted, and not removed from the queue, on a transition out of the Forwarding state (see 22.1.3).

The frame can be removed from the queue, and not subsequently transmitted:

- d) If the time for which buffering is guaranteed has been exceeded for that frame
- e) By a queue management algorithm that attempts to improve the QoS provided by deterministically or probabilistically managing the queue depth based on the current and past queue depths.

Removal of a frame from a queue for any particular Port does not affect queuing of that frame for transmission on any other Port.

The probability of removing a frame with drop\_eligible set shall not be less than that of removing a frame with drop\_eligible False, all other conditions being equal. If a queue management algorithm is implemented, it should preferentially discard frames with drop\_eligible True. If a Bridge supports encoding or decoding of drop\_eligible from the PCP field of a VLAN tag (6.9.3) on any of its Ports, then it shall implement a boolean parameter Require Drop Encoding on each of its Ports with default value FALSE. If Require Drop Encoding is True and the Bridge Port cannot encode particular priorities with drop\_eligible, then frames queued with those priorities and drop\_eligible True shall be discarded and not transmitted.

## 1 8.6.8 Transmission selection

2 For each Port, frames are selected for transmission on the basis of the traffic classes that the Port supports  
3 and the operation of the transmission selection algorithms supported by the corresponding queues on that  
4 Port. For a given Port and traffic class, frames are selected from the corresponding queue for transmission if  
5 and only if:

- 6 a) The operation of the transmission selection algorithm supported by that queue determines that there  
7 is a frame available for transmission; and
- 8 b) For each queue corresponding to a numerically higher value of traffic class supported by the Port,  
9 the operation of the transmission selection algorithm supported by that queue determines that there  
10 is no frame available for transmission.

11 In a port of a Bridge or station that supports PFC, a frame of priority  $n$  is not available for transmission if  
12 that priority is paused, i.e., if `Priority_Paused[n]` is TRUE (see 36.1.3.2) on that port. When Transmission  
13 Selection is running above Link Aggregation, a frame of priority  $n$  is not available for transmission if that  
14 priority is paused on the physical port to which the frame is to be distributed.

15 NOTE 1—Two or more priorities can be combined in a single queue. In this case if one or more of the priorities in the  
16 queue are paused, it is possible for frames in that queue not belonging to the paused priority to not be scheduled for  
17 transmission.

18 NOTE 2—Mixing PFC and non-PFC priorities in the same queue results in non-PFC traffic being paused causing  
19 congestion spreading, and therefore is not recommended.

20 In a port of a Bridge or station that supports frame preemption, a frame of priority  $n$  is not available for  
21 transmission if that priority is identified in the frame preemption status table (6.7.2) as preemptable and  
22 either the `holdRequest` object (12.30.1.5) is set to the value *hold*, or the transmission of a prior preemptable  
23 frame has yet to complete because it has been interrupted to allow the transmission of an express frame.

24 The strict priority transmission selection algorithm defined in 8.6.8.1 shall be supported by all Bridges as the  
25 default algorithm for selecting frames for transmission. The credit-based shaper transmission selection  
26 algorithm defined in 8.6.8.2, the ETS algorithm defined in 8.6.8.3, and the ATS transmission selection  
27 algorithm defined in 8.6.8.5 may be supported in addition to the strict priority algorithm. Further  
28 transmission selection algorithms, selectable by management means, may be supported as an  
29 implementation option so long as the requirements of 8.6.6 are met.

30 The Transmission Selection Algorithm Table for a given Port assigns, for each traffic class that the Port  
31 supports, the transmission selection algorithm that is to be used to select frames for transmission from the  
32 corresponding queue. Transmission Selection Algorithm Tables may be managed, and allow the  
33 identification of vendor-specific transmission selection algorithms. The transmission selection algorithms  
34 are identified in the Transmission Selection Algorithm Table by means of integer identifiers, as defined in  
35 Table 8-6.

36 A recommended configuration of the Transmission Selection Algorithm Tables for use with the credit-based  
37 shaper transmission selection algorithms is specified in 34.5. When the enhancements for scheduled traffic  
38 are supported, additional requirements to determine whether a frame is available for transmission apply, as  
39 specified in 8.6.8.4.

**Table 8-6—Transmission selection algorithm identifiers**

| Transmission selection algorithm                                                   | Identifier                                                                                                                                                                                             |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### 8.6.8.1 Strict priority algorithm

For a given queue that supports strict priority transmission selection, the algorithm determines that there is a frame available for transmission if the queue contains one or more frames. The order in which frames are selected for transmission from the queue shall maintain the ordering requirement specified in 8.6.6.

#### 8.6.8.2 Credit-based shaper algorithm

For a given queue that supports credit-based shaper transmission selection, the algorithm determines that a frame is available for transmission if the following conditions are all true:

- a) The queue contains one or more frames.
- b) The *transmitAllowed* signal for the queue is TRUE.

The order in which frames are selected for transmission from the queue shall maintain the ordering requirement specified in 8.6.6.

The following external parameters are associated with each queue that supports the operation of the credit-based shaper algorithm:

- c) ***portTransmitRate***. The transmission rate, in bits per second, that the underlying MAC Service that supports transmission through the Port provides. The value of this parameter is determined by the operation of the MAC.
- d) ***idleSlope***. The rate of change of *credit*, in bits per second, when the value of *credit* is increasing (i.e., while *transmit* is FALSE and the transmission gate for the queue is open [8.6.8.4]). The value of *idleSlope* can never exceed *portTransmitRate*. If the enhancements for scheduled traffic (8.6.8.4) are not supported, or if GateEnabled is FALSE (8.6.9.4.14), the value of *idleSlope* for a given queue is equal to the value of the *operIdleSlope(N)* parameter for that queue, as defined in 34.3. If the enhancements for scheduled traffic (8.6.8.4) are supported, and GateEnabled is TRUE (8.6.9.4.14), then:

$$idleSlope = (operIdleSlope(N) \times OperCycleTime / GateOpenTime)$$

1 where *OperCycleTime* is as defined in 8.6.9.4.19 and *GateOpenTime* is equal to the total amount of  
2 time during the gating cycle that the gate state for the queue is Open.

3 NOTE 1—When scheduled traffic operation is enabled, *credit* is accumulated only while the gate is open; therefore, the  
4 effective data rate of the *idleSlope* is increased to reflect the duty cycle for the transmission gate associated with the  
5 queue; however, the value of *operIdleSlope(N)* for the queue remains unchanged.

6 The following internal parameters are associated with each queue that supports the credit-based shaper  
7 algorithm:

8 e) ***transmit***. Takes the value TRUE for the duration of a frame transmission from the queue; FALSE  
9 when any frame transmission from the queue has completed. If the credit-based shaper algorithm is  
10 used in combination with frame preemption (6.7.2), *transmit* only takes the value TRUE while the  
11 frame is actually being transmitted by the MAC. If the frame transmission is delayed or interrupted  
12 (e.g., the frame is a preemptable frame and its transmission is interrupted to allow the transmission  
13 of an express frame from a different queue, or the frame is an express frame and there is a delay  
14 before transmission can start because a preemptable frame was being transmitted) *transmit* takes the  
15 value FALSE until transmission of the frame commences or is resumed. *Transmit* also takes the  
16 value FALSE during the transmission of any overhead that is a consequence of frame preemption;  
17 i.e., any additional frame overhead that is added to the preemptable frame when preemption occurs.

18 NOTE 2—The consequence of this is that any overhead associated with preemption does not come out of the reserved  
19 bandwidth for the credit-based shaper.

20 f) ***credit***. The transmission credit, in bits, that is currently available to the queue. If, at any time, there  
21 are no frames in the queue, and the *transmit* parameter is FALSE, and *credit* is positive, and the  
22 transmission gate for the queue is open (8.6.8.4), and there is no preemptable frame from this queue  
23 for which transmission is in progress but has been interrupted, then *credit* is set to zero.

24 NOTE 3—The condition that the *transmit* parameter is FALSE and a preemptable frame or part-frame is waiting in the  
25 MAC for transmission can only occur if the credit-based shaper algorithm is used in combination with Preemption.

26 g) ***sendSlope***. The rate of change of *credit*, in bits per second, when the value of *credit* is decreasing  
27 (i.e., while *transmit* is TRUE). The value of *sendSlope* is defined as follows:

$$28 \quad \textit{sendSlope} = (\textit{idleSlope} - \textit{portTransmitRate})$$

29 h) ***transmitAllowed***. Takes the value TRUE when the *credit* parameter is zero or positive; FALSE when  
30 the *credit* parameter is negative.

31 NOTE 4—The value of *credit* is naturally constrained by the operating parameters for the algorithm, and also by the  
32 operation of any higher priority queues that use this algorithm. The lowest value that *credit* can reach depends on  
33 *sendSlope* and the largest frame that will be transmitted from the queue. This largest frame size is a consequence of the  
34 type of traffic that is being transmitted using the queue, rather than a limit imposed by the algorithm or by management.  
35 The highest value that can be accumulated in *credit* depends on *idleSlope* and the length of time that the algorithm may  
36 have to wait when the queue is not empty and there is other traffic being transmitted through the Port; for any given  
37 queue, that length of time is bounded, as discussed in Annex L, which also illustrates how the algorithm operates under  
38 varying conditions, and how its operation affects the maximum latency that can be experienced by SR traffic.

39 NOTE 5—In order for the credit-based shaper algorithm to operate as intended, it is necessary for all traffic classes that  
40 support the algorithm to be numerically higher than any traffic classes that support the strict priority algorithm defined in  
41 8.6.8.1. The mapping of priorities onto traffic classes, and the choice of traffic classes that support particular  
42 transmission selection algorithms, is defined in 34.5.

43 Traffic classes using the credit-based shaper algorithm shall not use PFC and shall ignore the setting of the  
44 bits related to such classes in the PFC Enable bit vector (see D.2.10.6)

### 8.6.8.3 ETS algorithm

If ETS is enabled for a traffic class, transmission selection is performed based on the allocation of bandwidth to that traffic class. Bandwidth is distributed among ETS traffic classes that support ETS algorithm such that each traffic class is allocated available bandwidth in proportion to its TCBandwidth (see Clause 37).

For a given queue that supports ETS, the algorithm determines that there is a frame available for transmission if the following conditions are all true:

- The queue contains one or more frames.
- The ETS algorithm (37.3) determines that a frame should be transmitted from the queue.
- There are no frames available for transmission for any queues running strict priority or credit-based shaper algorithms.

The order in which frames are selected for transmission from the queue shall maintain the ordering requirement specified in 8.6.6.

### 8.6.8.4 Enhancements for scheduled traffic

A Bridge or an end station may support enhancements that allow transmission from each queue to be scheduled relative to a known timescale. In order to achieve this, a transmission gate is associated with each queue; the state of the transmission gate determines whether or not queued frames can be selected for transmission (see Figure 8-17). For a given queue, the transmission gate can be in one of two states:

- Open*: Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the queue.
- Closed*: Queued frames are not selected for transmission.

**Figure 8-17—Transmission selection with gates**

A *gate control list* associated with each Port contains an ordered list of gate operations. Each gate operation changes the transmission gate state for the gate associated with each of the Port's traffic class queues and allows associated control operations to be scheduled. In an implementation that does not support enhancements for scheduled traffic, all gates are assumed to be permanently in the *open* state. Table 8-7 identifies the gate operation types, their parameters, and the actions that result from their execution. The state machines that control the execution of the gate control list, along with their variables and procedures, are specified in 8.6.9.

**Table 8-7—Gate operations**

| Operation name      | Parameter(s)            | Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SetGateStates       | GateState, TimeInterval | The <i>GateState</i> parameter indicates a value, <i>open</i> or <i>closed</i> , for each of the Port's queues. The gates are immediately set to the states indicated in the <i>GateState</i> parameter. This causes gate-close events (3.108) and/or gate-open events (3.109) to occur for any queue where the new <i>GateState</i> represents a change of state relative to the current state of the gate. After <i>TimeInterval</i> ticks (8.6.9.4.16) have elapsed since the completion of the previous gate operation in the gate control list, control passes to the next gate operation.                                                                                                                                                                   |
| Set-And-Hold-MAC    | GateState, TimeInterval | Performs all of the actions defined for the SetGateStates operation; in addition, the start of this operation marks the point in the sequence of gate operations at which the MAC associated with the port is to have stopped transmitting preemptable frames. This is achieved by setting the holdRequest managed object to the value <i>hold (1)</i> , at holdAdvance (Table 12-33) nanoseconds in advance of this point for the hold to have taken effect at this point. If frame preemption is not supported or not enabled (preemptionActive is FALSE), this operation behaves the same as SetGateStates.                                                                                                                                                    |
| Set-And-Release-MAC | GateState, TimeInterval | Performs all of the actions defined for the SetGateStates operation; in addition, the start of this operation marks the point in the sequence of gate operations at which the MAC associated with the port is permitted to resume transmitting preemptable frames; if an express frame is currently being transmitted by the MAC, the release takes effect at the end of that transmission. This is achieved by setting the holdRequest managed object to the value <i>release (2)</i> , at releaseAdvance (Table 12-33) nanoseconds in advance of this point for the release to have taken effect at this point. <sup>a</sup> If frame preemption is not supported or not enabled (preemptionActive is FALSE), this operation behaves the same as SetGateStates. |

<sup>a</sup> The releaseAdvance parameter allows the timing of when the release command is issued to vary depending upon the constraints of a particular implementation. Its value should be less than the minimum frame size so that release does not occur too early and interfere with transmission of the last express frame.

1 In addition to the other checks carried out by the transmission selection algorithm, a frame on a traffic class  
2 queue is not available for transmission [as required for tests (a) and (b) in 8.6.8] if the transmission gate is in  
3 the closed state or if there is insufficient time available to transmit the entirety of that frame, plus the  
4 media-dependent overhead specified in 12.4.2.2, before the next gate-close event (3.108) associated with  
5 that queue (Figure 8-18).

6 NOTE 1—For example, in the case of IEEE 802.3 media, the media-dependent overhead prior to the gate-close event  
7 includes the preamble of a potentially following frame from a different traffic class.

8 A per-traffic class counter, TransmissionOverrun (12.29.1.1.2), is incremented if the implementation detects  
9 that a frame from a given queue is still being transmitted by the MAC when the gate-close event for that  
10 queue occurs.

11 NOTE 2—There can be reasons why the frame size, and therefore the length of time needed for its transmission, is  
12 unknown. For example, where frame preemption is supported and there is no way of telling in advance how many times  
13 a given frame will be preempted before its transmission is complete. It is desirable that the schedule for such traffic is  
14 designed to accommodate the intended pattern of transmission without overrunning the next gate-close event for the  
15 traffic classes concerned.

**Figure 8-18—Frame timing at gate-close events**

NOTE 3— It is assumed that the implementation can determine the time at which the next gate-close event will occur from the sequence of gate events. In the normal case, this can be achieved by inspecting the sequence of gate operations in OperControlList (8.6.9.4.18) and associated variables. However, when a new configuration is about to be installed, it would be necessary to inspect the contents of both the OperControlList and the AdminControlList (8.6.9.4.2) and associated variables in order to determine the time of the next gate-close event, as the gating cycle for the new configuration may differ in size and phasing from the old cycle.

A per-traffic class queue queueMaxSDU parameter defines the maximum service data unit size for each queue; frames that exceed queueMaxSDU are discarded [item b8) in 6.5.2]. The value of queueMaxSDU for each queue is configurable by management (12.29); its default value is the maximum SDU size supported by the MAC procedures employed on the LAN to which the frame is to be relayed [item b3) in 6.5.2].

NOTE 4—The use of PFC is likely to interfere with a traffic schedule, because PFC is transmitted by a higher layer entity (see Clause 36).

In order for an end station to support the scheduled transmission of frames, it is necessary for its behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in the Bridges to which it connects. In effect, the requirements for an end station are for its transmission selection to operate as if it is a single outbound Port of a Bridge that supports scheduled traffic. There are no particular requirements for end station support for the reception of scheduled traffic; only for the transmission of scheduled traffic.

#### 8.6.8.5 ATS transmission selection algorithm

For a given queue that supports ATS transmission selection, a frame is eligible for transmission if the assigned eligibility time (8.6.5.6, 8.6.11.3.2) is earlier than or at the current time.

The current time is determined by the TransmissionSelection Clock, which is an implementation specific local system clock function.

Frames are selected for transmission in ascending order of the assigned eligibility times. Transmission selection of frames with identical assigned eligibility times shall maintain the ordering requirement specified in 8.6.6.

NOTE—In the case of frames with non-identical eligibility times, the ordering requirement from 8.6.6 is automatically satisfied due the operation of the ATS scheduler state machines (8.6.11), which assign eligibility times in a non-decreasing order.

### 1 8.6.8.6 Enhancements for congestion isolation

2 A Bridge component or an end station may support enhancements to isolate the frames of congesting flows  
3 to a designated congesting traffic class. During the isolation of a congesting flow it may be possible for  
4 frames of the same flow to queue in both the congesting and non-congesting traffic class. The transmission  
5 gate associated with each monitored non-congesting queue and each congesting queue can be used to meet  
6 the ordering requirements of 8.6.6. The state of the transmission gate determines whether or not queued  
7 frames can be selected for transmission. For a given queue, the transmission gate can be either *Open* or  
8 *Closed* as described in 8.6.8.4.

9 The need to control the transmission gate depends upon the transmission selection algorithm used and the  
10 technique for determining when to return a congesting flow to non-congesting status. Congestion isolation  
11 specifies that congesting and non-congesting queues use the same Active Queue Management (AQM)  
12 approach and the same transmission selection algorithm. Additionally, the congesting queues have lower  
13 priority than the monitored non-congesting queues.

14 When the transmission selection algorithm is strict priority and the technique for returning a congesting flow  
15 to non-congesting status is only when the congesting queue is empty, the state of the transmission gate can  
16 be set to *Open*. When the transmission selection algorithm is anything other than strict priority or the  
17 technique for returning a congesting flow to non-congesting status allows for congesting frames to exist in  
18 the congesting queue during the transition, the state of the transmission gate is controlled by the  
19 `cipGateControl` (49.4.1.4.1) variable. An example implementation of setting `cipGateControl` to provide  
20 transmission gate control for the purposes of ensuring ordering can be seen in Annex X.

21 Congestion isolation controls the transmission gate of the congesting and non-congesting queues to maintain  
22 the order of congesting flow frames. As a consequence, transmission gates used for congestion isolation  
23 cannot be used for other purposes.

### 24 8.6.9 Scheduled traffic state machines

25 The execution of the gate operations in a Port's gate control list (8.6.8.4) is controlled by three state  
26 machines:

- 27 a) The Cycle Timer state machine (8.6.9.1)
- 28 b) The List Execute state machine (8.6.9.2)
- 29 c) The List Config state machine (8.6.9.3)

30 One instance of each state machine is instantiated for each Port that supports the enhancements for  
31 scheduled traffic.

32 The Cycle Timer state machine initiates the execution of the gate control list and ensures that the gating  
33 cycle time defined for the Port is maintained.

34 The List Execute state machine executes the gate operations in the gate control list, in sequence, and  
35 establishes the appropriate time delay between each operation.

36 The List Config state machine manages the process of updating the current active schedule, interrupting the  
37 operation of the other two state machines while the update process is performed, and restarting them once  
38 the new schedule has been installed.

39 The state machine notation is specified in Annex E.

40 An overview of the state machines, showing their relationships and the variables that are used by them, can  
41 be seen in Figure 8-19.

**NOTATION:**

Variables are shown both within the machine where they are initialized and between machines where they are used to communicate information. In the latter case the arrow styles, running from one machine to another, provide an overview of how the variables are used:

—————▶ Not changed by the target machine, this variable communicates between state machines for the same port.

—————▷ Set (or cleared) by the originating machine, cleared (or set) by the target machine, communicates between machines for the same port.

**Figure 8-19—Scheduled traffic state machines—overview and relationships**

### 1 8.6.9.1 Cycle Timer state machine

2 The Cycle Timer state machine shall implement the function specified by the state diagram in Figure 8-20  
3 and the attendant definitions in 8.6.9.4.

**Figure 8-20—Cycle Timer state machine**

4 NOTE 1—Since the origin of the PTP timescale is 1 January 1970 00:00:00 TAI, CycleStartTime will be larger than  
5  $1.3 \times 10^{18}$  ns. If sufficient precision is not maintained when computing N, CycleStartTime will not be an integer  
6 multiple of OperCycleTime, which could result in misalignment of the cycles at ports on different bridges.

7 NOTE 2—If AdminBaseTime is set to the same time in the past in all bridges and end stations, OperBaseTime is always  
8 in the past, and all cycles start synchronized. Using AdminBaseTime in the past is appropriate when you can start  
9 schedules prior to starting the application that uses the schedules. Use of AdminBaseTime in the future is intended to  
10 change a currently running schedule in all bridges and end stations to a new schedule at a future time. Using  
11 AdminBaseTime in the future is appropriate when schedules must be changed without stopping the application.

### 8.6.9.2 List Execute state machine

The List Execute state machine shall implement the function specified by the state diagram in Figure 8-21 and the attendant definitions in 8.6.9.2.1, 8.6.9.2.2, and 8.6.9.4.

Figure 8-21—List Execute state machine

#### 8.6.9.2.1 ExecuteOperation()

The ExecuteOperation() procedure is responsible for fetching the next gate operation from the OperControlList, along with any parameters associated with it, and performing actions based upon the gate operation that has been fetched. The value of the ListPointer variable (8.6.9.4.15) is used as an index into OperControlList. The procedure processes the operation according to its operation name (Table 8-7) as follows:

- If the operation name is SetGateStates, then the GateState parameter value associated with the operation is assigned to the OperGateStates variable (8.6.9.4.21), and the TimeInterval parameter value associated with the operation is assigned to the TimeInterval variable (8.6.9.4.23). If the TimeInterval parameter value associated with the operation was 0, the TimeInterval variable is assigned the value 1.
- If the operation name is unrecognized, then the ListPointer variable (8.6.9.4.15) is assigned the value of the OperControlListLength variable (8.6.9.4.22) and the TimeInterval variable (8.6.9.4.23) is assigned the value 0.
- If there is no TimeInterval parameter associated with the operation, then the TimeInterval variable is assigned the value 0.

#### 8.6.9.2.2 SetGateStates()

This procedure sets the gate state for each of the Port's queues as specified by the value of the OperGateStates variable (8.6.9.4.21).

NOTE—If the OperGateStates value differs from the previous gate states, the SetGateStates() procedure causes gate-open and/or gate-close events to occur (3.108, 3.109). It is possible that, on a given queue, the maximum time interval between any gate-open event and a subsequent gate-close event is smaller than the value of queueMaxSDU, in

1 which case, frames that are too long to transmit but are shorter than queueMaxSDU could be queued on that queue. Such  
2 frames would never be transmitted, but would eventually be discarded because they exceed the maximum frame lifetime  
3 (6.5.2, 6.5.6). It should also be noted that a Bridge is allowed to discard frames that could never be transmitted [item b8)  
4 in 6.5.2].

### 5 8.6.9.3 List Config state machine

6 The List Config state machine shall implement the function specified by the state diagram in Figure 8-22  
7 and the attendant definitions in 8.6.9.3.1 and 8.6.9.4.

**Figure 8-22—List Config state machine**

#### 8 8.6.9.3.1 SetConfigChangeTime()

9 The SetConfigChangeTime() procedure determines the time at which the administrative values of the cycle  
10 configuration variables are to be copied across to the operational variables. The procedure sets the  
11 ConfigChangeTime variable (8.6.9.4.9) to the start time, based upon the values of AdminBaseTime  
12 (8.6.9.4.1) and AdminCycleTime (8.6.9.4.3), according to the following rules:

- 13 a) If:
  - 14 AdminBaseTime  $\geq$  CurrentTime (8.6.9.4.10)
  - 15 (i.e., AdminBaseTime specifies the current time or a future time)
  - 16 Then:
  - 17 ConfigChangeTime = AdminBaseTime
- 18 b) If:
  - 19 (AdminBaseTime < CurrentTime) and (GateEnabled = FALSE)
  - 20 (i.e., AdminBaseTime specifies a time in the past, and the current schedule is stopped)
  - 21 Then:
  - 22 ConfigChangeTime = (AdminBaseTime + N\*AdminCycleTime)
  - 23 where N is the smallest integer for which the relation
  - 24 ConfigChangeTime  $\geq$  CurrentTime
  - 25 would be TRUE.
- 26 c) If:
  - 27 (AdminBaseTime < CurrentTime) and (GateEnabled = TRUE)
  - 28 (i.e., AdminBaseTime specifies a time in the past, and the current schedule is running)
  - 29 Then:
  - 30 Increment ConfigChangeError counter (12.29.1)
  - 31 ConfigChangeTime = (AdminBaseTime + N\*AdminCycleTime)
  - 32 where N is the smallest integer for which the relation
  - 33 ConfigChangeTime  $\geq$  CurrentTime
  - 34 would be TRUE.

## 1 8.6.9.4 State machine variables

### 2 8.6.9.4.1 AdminBaseTime

3 The administrative value of base time, expressed as an IEEE 1588 precision time protocol (PTP) [B17]  
4 timescale (see IEEE Std 802.1AS™). This value can be changed by management, and is used by the List  
5 Config state machine (8.6.9.3) to set the value of OperBaseTime (8.6.9.4.17).

6 NOTE—Time is expressed in the PTP timescale as the number of seconds, nanoseconds, and fractional nanoseconds that  
7 have elapsed since 1 January 1970 00:00:00 TAI.

### 8 8.6.9.4.2 AdminControlList

9 The administrative version of the gate control list for the Port. This value can be changed by management,  
10 and is used by the List Config state machine (8.6.9.3) to set the value of OperControlList (8.6.9.4.18).

### 11 8.6.9.4.3 AdminCycleTime

12 The administrative value of the duration of the gating cycle for the Port (3.110). This value can be changed  
13 by management, and is used by the List Config state machine (8.6.9.3) to set the value of OperCycleTime  
14 (8.6.9.4.19). The AdminCycleTime variable is a rational number of seconds, defined by an integer  
15 numerator and an integer denominator.

### 16 8.6.9.4.4 AdminCycleTimeExtension

17 An integer number of nanoseconds, defining the maximum amount of time by which the gating cycle for the  
18 Port (3.110) is permitted to be extended when a new cycle configuration is being installed. This  
19 administrative value can be changed by management, and is used by the List Config state machine (8.6.9.3)  
20 to set the value of OperCycleTimeExtension (8.6.9.4.20).

### 21 8.6.9.4.5 AdminGateStates

22 The initial state of the gate associated with each queue for the Port is set by the List Execute state machine  
23 (8.6.9.2), and is determined by the value of the AdminGateStates variable. The default value of  
24 AdminGateStates is *open* for all queues. The value of AdminGateStates can be changed by management.

### 25 8.6.9.4.6 AdminControlListLength

26 This value can be changed by management, and is used by the List Config state machine (8.6.9.3) to set the  
27 value of OperControlListLength (8.6.9.4.22).

### 28 8.6.9.4.7 ConfigChange

29 A Boolean variable that acts as a start signal to the List Config state machine (8.6.9.3) that the administrative  
30 variable values for the Port are ready to be copied into their corresponding operational variables. This  
31 variable is set TRUE by management and is set FALSE by the List Config state machine.

### 32 8.6.9.4.8 ConfigPending

33 A Boolean variable, set TRUE by the List Config state machine (8.6.9.3) to signal that there is a new cycle  
34 configuration awaiting installation. The variable is set FALSE when the List Config state machine has  
35 installed the new configuration. The variable is used by the Cycle Timer state machine (8.6.9.1) to control  
36 the length of the cycle that immediately precedes the first cycle that uses the new configuration values. This  
37 value can be read by management, as specified in 12.29.1.

#### 1 **8.6.9.4.9 ConfigChangeTime**

2 The time at which the administrative variables that determine the cycle are to be copied across to the  
3 corresponding operational variables, expressed as a PTP timescale. The value of this variable is set by the  
4 SetConfigChangeTime() procedure (8.6.9.3.1) in the List Config state machine (8.6.9.3).

#### 5 **8.6.9.4.10 CurrentTime**

6 The current time maintained by the local system, expressed as a PTP timescale (see IEEE Std 802.1AS).  
7 NOTE 1—Other sources of times can be used to provide a value for the time. The implementation has to ensure that the  
8 same view of time is shared by the implementation and whatever entity is responsible for establishing the time schedule.  
9 The described mechanisms will work also with other formats of time.  
10 NOTE 2—A discontinuity in time will have a predictable effect upon the operation of the state machines, as a  
11 consequence of their definitions. The implementer and/or user is advised to understand what those effects could be, and  
12 either limit such discontinuities or ensure that the results will not adversely affect the application.

#### 13 **8.6.9.4.11 CycleStart**

14 A Boolean variable used as a signal from the Cycle Timer state machine (8.6.9.1) to the List Execute state  
15 machine to start executing the gate control list. Set TRUE by the Cycle Timer state machine and set FALSE  
16 by the List Execute state machine (8.6.9.2).

#### 17 **8.6.9.4.12 CycleStartTime**

18 The time at which the next gate control list execution cycle is to start, expressed as a PTP timescale. The  
19 value of this parameter is set by the Cycle Timer state machine (8.6.9.1).

#### 20 **8.6.9.4.13 ExitTimer**

21 A timer that implements the delay associated with the currently executing gate operation, expressed as an  
22 integer number of nanoseconds. The value is set by the operation of the List Execute state machine (8.6.9.2).

#### 23 **8.6.9.4.14 GateEnabled**

24 A Boolean variable that indicates whether the operation of the state machines is enabled (TRUE) or disabled  
25 (FALSE). This variable is set by management. The default value of this variable is FALSE.

#### 26 **8.6.9.4.15 ListPointer**

27 An integer used as a pointer to entries in the OperControlList (8.6.9.4.18), each entry consisting of a gate  
28 operation with its associated parameters (Table 8-7). A value of zero points at the first entry in the list; a  
29 value of (OperControlListLength – 1) points at the last entry.

#### 30 **8.6.9.4.16 Tick**

31 A Boolean variable, set to TRUE by an implementation-specific system clock function at one nanosecond  
32 intervals, that controls the decrementing of the ExitTimer variable (8.6.9.4.13). This variable is set FALSE  
33 by the operation of the List Execute state machine (8.6.9.2).

34 NOTE—While the state machine is documented on the basis of a nanosecond clock “tick,” it is anticipated that real  
35 implementations will use a wide variety of clocks that differ in frequency accuracy and granularity. Hence, the  
36 management parameters specified in 12.29 allow a management station to discover the characteristics of an  
37 implementation’s cycle timer clock (TickGranularity) and to set the parameters for the gating cycle accordingly.

#### 1 **8.6.9.4.17 OperBaseTime**

2 The operational value of base time, expressed as a PTP timescale (see IEEE Std 802.1AS). This variable is  
3 used by the List Config state machine (8.6.9.3).

#### 4 **8.6.9.4.18 OperControlList**

5 The active Gate Control List for the Port; the List Execute state machine executes this list. This list is  
6 populated dynamically from the AdminControlList (8.6.9.4.2) under the control of the List Config state  
7 machine (8.6.9.3).

#### 8 **8.6.9.4.19 OperCycleTime**

9 The operational value of the duration of the gating cycle for the Port (3.110). This variable is set  
10 dynamically from the AdminCycleTime variable (8.6.9.4.3) under the control of the List Config state  
11 machine (8.6.9.3). OperCycleTime is used by the Cycle Timer state machine (8.6.9.1) to enforce the cycle  
12 time for the Port. The OperCycleTime variable is a rational number of seconds, defined by an integer  
13 numerator and an integer denominator.

#### 14 **8.6.9.4.20 OperCycleTimeExtension**

15 An integer number of nanoseconds, defining the maximum amount of time by which the gating cycle for the  
16 Port (3.110) is permitted to be extended when a new cycle configuration is installed. This operational value  
17 is set by the List Config state machine (8.6.9.3) to the value of AdminCycleTimeExtension (8.6.9.4.4). The  
18 value of OperCycleTimeExtension is used by the Cycle Timer state machine (8.6.9.1).

#### 19 **8.6.9.4.21 OperGateStates**

20 The current state of the gate associated with each queue for the Port. OperGateStates is set by the List  
21 Execute state machine (8.6.9.2), and its initial value is determined by the value of the AdminGateStates  
22 variable (8.6.9.4.5).

#### 23 **8.6.9.4.22 OperControlListLength**

24 This variable is set dynamically from the AdminControlListLength parameter (8.6.9.4.6) under the control  
25 of the List Config state machine (8.6.9.3). OperControlListLength indicates the number of entries in the  
26 OperControlList and is used by the List Execute state machine (8.6.9.2) to determine when the end of the list  
27 has been reached.

#### 28 **8.6.9.4.23 TimeInterval**

29 Set to the value of the TimeInterval parameter associated with the currently executing gate operation. Used  
30 in the operation of the List Execute state machine (8.6.9.2).

### 31 **8.6.10 Stream gate control state machines**

32 The execution of the gate operations in a stream gate control list (8.6.5.4) is controlled by the three state  
33 machines specified in 8.6.9:

- 34 a) The Cycle Timer state machine (8.6.9.1)
- 35 b) The List Execute state machine (8.6.9.2)
- 36 c) The List Config state machine (8.6.9.3)

One instance of each state machine is instantiated for each stream gate control list associated with instances of stream gates in a Bridge component that supports stream gates. An overview of the operation of these state machines can be found in Figure 8-19.

The operation of these state machines is as defined in 8.6.9, with the exception of the definitions of the `ExecuteOperation()` procedure, the `SetGateStates()` procedure, the `ListPointer` variable, the `AdminGateStates` variable, and the `OperGateStates` variable; amended versions of these definitions appear in 8.6.10.1 through 8.6.10.5. Table 8-8 shows the correspondence between the procedures/variables used in 8.6.9 and the stream gate versions of these procedures/variables.

Three additional variables needed by the `ExecuteStreamGateOperation` procedure are defined in 8.6.10.6 and 8.6.10.7.

**Table 8-8—Scheduled Traffic and Stream Gate procedures/variables**

| Procedure/variable name in 8.6.9            | StreamGate procedure/variable name                   |
|---------------------------------------------|------------------------------------------------------|
| <code>ExecuteOperation()</code> (8.6.9.2.1) | <code>ExecuteStreamGateOperation()</code> (8.6.10.1) |
| <code>SetGateStates()</code> (8.6.9.2.2)    | <code>SetStreamGateStates()</code> (8.6.10.2)        |
| <code>ListPointer</code> (8.6.9.4.15)       | <code>StreamGateListPointer</code> (8.6.10.3)        |
| <code>AdminGateStates</code> (8.6.9.4.5)    | <code>StreamGateAdminGateStates</code> (8.6.10.4)    |
| <code>OperGateStates</code> (8.6.9.4.21)    | <code>StreamGateOperGateStates</code> (8.6.10.5)     |

#### 8.6.10.1 `ExecuteStreamGateOperation()`

The `ExecuteStreamGateOperation()` procedure is responsible for fetching the next gate operation from the `OperControlList`, along with any parameters associated with it, and performing actions based upon the gate operation that has been fetched. The value of the `StreamGateListPointer` variable (8.6.9.2.2) is used as an index into `OperControlList`. The procedure processes the operation according to its operation name (Table 8-4) as follows:

- a) If the operation name is `SetGateAndIPV`, then the `StreamGateState` parameter value associated with the operation is assigned to the `StreamGateOperGateStates` variable (8.6.10.5), the `IPV` parameter value is assigned to the `OperIPV` variable (8.6.10.7), and the `TimeInterval` parameter value associated with the operation is assigned to the `TimeInterval` variable (8.6.9.4.23). If the `TimeInterval` parameter value associated with the operation was 0, the `TimeInterval` variable is assigned the value 1. If there is an `IntervalOctetMax` parameter associated with the gate operation, then that parameter value is used to set the value of the `IntervalOctetsLeft` variable (8.6.10.8); otherwise, the `IntervalOctetsLeft` variable is set to a value greater than the maximum possible number of octets that the gate could pass during `TimeInterval`.
- b) If the operation name is unrecognized, then the `StreamGateListPointer` variable (8.6.9.4.15) is assigned the value of the `OperControlListLength` variable (8.6.9.4.22) and the `TimeInterval` variable (8.6.9.4.23) is assigned the value 0.
- c) If there is no `TimeInterval` parameter associated with the operation, then the `TimeInterval` variable is assigned the value 0.

#### 8.6.10.2 `SetStreamGateStates()`

This procedure sets the stream gate state as specified by the value of the `StreamGateOperGateStates` variable (8.6.9.4.21).

### 1 8.6.10.3 StreamGateListPointer

2 An integer used as a pointer to entries in the OperControlList (8.6.9.4.18), each entry consisting of a stream  
3 gate control operation with its associated parameters (Table 8-4). A value of zero points at the first entry in  
4 the list; a value of (OperControlListLength – 1) points at the last entry.

### 5 8.6.10.4 StreamGateAdminGateStates

6 The initial state of the gate associated with the stream gate is set by the List Execute state machine (8.6.9.2)  
7 and is determined by the value of the StreamGateAdminGateStates variable. The default value of  
8 StreamGateAdminGateStates is open. The value of StreamGateAdminGateStates can be changed by  
9 management.

### 10 8.6.10.5 StreamGateOperGateStates

11 The current state of the gate associated with the stream gate. StreamGateOperGateStates is set by the List  
12 Execute state machine (8.6.9.2), and its initial value is determined by the value of the  
13 StreamGateAdminGateStates variable (8.6.10.4).

### 14 8.6.10.6 AdminIPV

15 The initial value of the OperIPV variable (8.6.10.7) associated with the stream gate is determined by the  
16 value of the AdminIPV variable. The default value of AdminIPV variable is the null value. The value of the  
17 AdminIPV variable can be changed by management.

### 18 8.6.10.7 OperIPV

19 The current value of the IPV associated with the stream gate. The initial value of OperIPV is set equal to the  
20 value of the AdminIPV variable (8.6.10.6) by the Cycle Timer state machine (8.6.9.1) with the operational  
21 cycle configuration variables when the state machines are initialized, when GateEnabled (8.6.9.4.14) is  
22 FALSE, and at ConfigChange Time (8.6.9.4.9). Subsequently, if there is a stream gate control list associated  
23 with the stream gate instance, its value is controlled by the contents of the operational stream gate control  
24 list and the operation of the List Execute state machine (8.6.9.2).

### 25 8.6.10.8 IntervalOctetsLeft

26 The current value of the IntervalOctetsLeft parameter indicates how many more MSDU octets can be passed  
27 by the stream gate during the current TimeInterval. This variable is initialized by the  
28 ExecuteStreamGateOperation() procedure (8.6.10.1). If a frame that would otherwise pass the gate is larger  
29 than the current value of IntervalOctetsLeft, it is treated as if the gate is in the *closed* state; i.e., it is  
30 discarded. If a frame that would otherwise pass the gate is smaller than the current value of  
31 IntervalOctetsLeft, the number of MSDU octets is subtracted from the value of IntervalOctetsLeft.

### 32 8.6.11 ATS Scheduler state machines

33 The ATS scheduler state machine operation is based on the ATS scheduler clocks (8.6.11.1), which is in  
34 relationship to transmission selection clocks (8.6.8.5). The state machine operation is specified by the  
35 ProcessFrame(frame) procedure (8.6.11.3) and the therein used state variables (8.6.11.3.3, 8.6.11.3.10).  
36 Parameters used by the ProcessFrame(frame) procedure are as defined in 8.6.5.6. Each arriving frame causes  
37 invocation of the ProcessFrame(frame) procedure.

### 1 8.6.11.1 ATS Scheduler Clocks

2 An ATS scheduler clock is an implementation specific local system clock function. It is used to determine  
3 the arrival time of frames (8.6.11.3.1). A Bridge component may utilize one or more ATS scheduler clock  
4 instances. In the case of multiple scheduler clock instances, all ATS scheduler instances associated with the  
5 same reception Port share the same ATS scheduler clock instance (i.e., the arrival time of all frames received  
6 from a particular reception port is determined by the same ATS scheduler clock instance).

### 7 8.6.11.2 Relationship between ATS Scheduler Clocks and Transmission Selection Clocks

8 ATS scheduler clocks and transmission selection clocks (8.6.8.5) run at the same long term rate with  
9 bounded offset variation. A difference between an arbitrary instant of time  $t_{FA}$ , as recognized by an ATS  
10 scheduler clock instance, and the same instant of time  $t_{TS}$ , as recognized by a transmission selection clock  
11 instance, may be observed during the processing of a frame. The time difference may vary over a sequence  
12 of frames, which is characterized by the following equation:

$$13 \quad \text{ClockOffsetMin} \leq t_{TS} - t_{FA} \leq \text{ClockOffsetMax}$$

14 where ClockOffsetMin and ClockOffsetMax are implementation specific constants that limit the variation.  
15 The range is characterized by ClockOffsetVariationMax (12.31.8.3) as follows:

$$16 \quad \text{ClockOffsetVariationMax} = \text{ClockOffsetMax} - \text{ClockOffsetMin}$$

17 NOTE 1—ClockOffsetMin and ClockOffsetMax capture implementation specific properties such as the resolution of the  
18 associated clocks, associated rounding errors, constant offsets between clocks, Bridge-internal synchronization  
19 inaccuracies in presence of different underlying oscillators, and similar.

20 A pair of a scheduler clock instance and a transmission selection clock instance has an implementation  
21 specific nominal rate, and a maximal absolute deviation from this nominal rate during operation, as  
22 characterized by the ClockRateDeviationMax parameter (Clause 12.31.8.4).

23 NOTE 2—ClockRateDeviationMax captures implementation specific properties such as oscillator rate deviation,  
24 numeric resolution for the operations specified in 8.6.11.3, and similar.

25 NOTE 3—ATS scheduler clocks and transmission selection clocks provide a model to express different sources of delay,  
26 delay variation, and inaccuracy. It is not required to implement different multiple physical oscillators/clocks (i.e., ATS  
27 scheduler clocks and transmission selection clocks can actually be the same physical clock or can be generated from the  
28 same oscillator), but the model captures the properties of implementations with and without different physical  
29 oscillators/clocks in a unified manner.

### 1 8.6.11.3 ProcessFrame(frame)

2 This procedure computes eligibility time, assigns the eligibility times to frames, and updates the ATS  
3 scheduler state machine variables.

4 The procedure is described by the following pseudo-code in a neutral manner: The arithmetic precision, and  
5 the resolution of variables, are implementation specific, unless externally visible by management (12.31).  
6 The impact of the associated inaccuracies is discussed in Annex V.

```

7 ProcessFrame(frame) {
8     lengthRecoveryDuration    = length(frame) /
9                               CommittedInformationRate;
10    emptyToFullDuration        = CommittedBurstSize /
11                                CommittedInformationRate;
12    schedulerEligibilityTime    = BucketEmptyTime +
13                                lengthRecoveryDuration;
14    bucketFullTime              = BucketEmptyTime +
15                                emptyToFullDuration;
16    eligibilityTime              = max(arrivalTime(frame),
17                                     GroupEligibilityTime,
18                                     schedulerEligibilityTime);
19
20    if (eligibilityTime <= (arrivalTime(frame) + MaxResidenceTime/1.0e9)){
21        // The frame is valid
22        GroupEligibilityTime = eligibilityTime;
23        BucketEmptyTime      = (eligibilityTime < bucketFullTime) ?
24                                schedulerEligibilityTime :
25                                schedulerEligibilityTime + eligibilityTime - bucketFullTime;
26        AssignAndProceed(frame, eligibilityTime);
27    } else {
28        // The frame is invalid
29        Discard(frame);
30    }
31 }
```

#### 32 8.6.11.3.1 arrivalTime(frame)

33 The arrival time of the frame, in seconds. The arrival time refers to the instant of time at which the  
34 associated ATS scheduler clock instance recognizes the arrival of the entire frame.

35 The point at which this recognition happens on the path between reception Ports and transmission Ports is  
36 implementation dependent. The earliest option is when the frame passes the boundary between the network  
37 physical medium and a reception Port, the latest option is during invocation of the ProcessFrame procedure.

38 For all frames arriving at all reception Ports, the arrival time is determined relative to the frame end. The  
39 maximum delay between the time a frame passes the boundary between the network physical medium and  
40 its subsequent recognition by the associated ATS scheduler clock instance is implementation specific, and is  
41 characterized by the ArrivalRecognitionDelayMax parameter (12.31.8.5).

42 The order of all frames associated with one ATS scheduler group at the boundary between the network  
43 physical medium and a reception Port is the same as the order of the arrival times determined for these  
44 frames.

45 NOTE—For example, the arrival time of frames may be determined based on invocation of the  
46 M\_UNITDATA.indication service primitive of the ISS (6.6), as specified in IEEE Std 802.1AC.

#### 47 8.6.11.3.2 AssignAndProceed(frame, eligibilityTime)

48 This procedure calculates an assigned eligibility time parameter (assignedEligibilityTime) that is used by the  
49 ATS transmission selection algorithm (8.6.8.5).

1 The assignedEligibilityTime is derived from the eligibilityTime parameter. Its calculation accounts for  
2 variations between the associated ATS scheduler clock and transmission selection clock instances, and for  
3 processing delays through the forwarding process, as detailed in the following.

4 Any frame may experience an additional, non-negative, processing delay, between its arrival time  
5 recognition by the associated ATS scheduler clock instance and the time at which it is queued and becomes  
6 available for transmission selection (8.6.8.5). This delay may vary per frame, thus that there is a delay  
7 variation over a sequence of frames. The processing delay is characterized by the following equation:

$$8 \quad \text{ProcessingDelayMin} \leq \text{processingDelay}(\text{frame}) \leq \text{ProcessingDelayMax}$$

9 where ProcessingDelayMin (12.31.8.6) and ProcessingDelayMax (12.31.8.7) are implementation specific  
10 parameters, and processingDelay(frame) denotes the processing delay of an actual frame, including any  
11 potential delay introduced by the operation of the associated ATS scheduler state machine instance.

12 The assigned eligibility time is calculated as follows:

$$13 \quad \text{assignedEligibilityTime} = \text{eligibilityTime} + \text{ClockOffsetMin} + \text{ProcessingDelayMax}$$

#### 14 **8.6.11.3.3 BucketEmptyTime**

15 A variable that embodies the current state of the ATS scheduler instance. This variable is initialized with a  
16 time earlier than CommittedBurstSize/CommittedInformationRate in the past, as perceived by the ATS  
17 Scheduler Clock.

#### 18 **8.6.11.3.4 bucketFullTime**

19 A temporary variable used when updating BucketEmptyTime after determining a frame's  
20 schedulerEligibilityTime. The prior value of BucketEmptyTime plus the emptyToFullDuration.

#### 21 **8.6.11.3.5 CommittedBurstSize**

22 The committed burst size of the ATS scheduler instance, in bits (8.6.5.6).

#### 23 **8.6.11.3.6 CommittedInformationRate**

24 The committed information rate of the ATS scheduler instance, in bits per second (8.6.5.6).

#### 25 **8.6.11.3.7 Discard(frame)**

26 This procedure discards the frame and increases the DiscardedFramesCount counter of the associated  
27 reception port (8.6.5.6). The procedure is called in exceptional situations only (e.g., misbehavior of the  
28 connected upstream system).

#### 29 **8.6.11.3.8 eligibilityTime**

30 The eligibility time of the frame, without taking the implementation specific device-internal timing  
31 properties of the forwarding process into account. These timing properties are taken into account by the  
32 AssignAndProceed(frame) procedure (8.6.11.3.2).

#### 33 **8.6.11.3.9 emptyToFullDuration**

34 The duration CommittedBurstSize/CommittedInformationRate.

1 **8.6.11.3.10 GroupEligibilityTime**

2 A state variable that contains the most recent value of the eligibilityTime variable from the previous frame,  
3 as processed by any ATS scheduler instance in the same ATS scheduler group, in seconds.

4 The GroupEligibilityTime variable is initialized with a time earlier or equal to the current time, as perceived  
5 by the ATS scheduler clock.

6 **8.6.11.3.11 length(frame)**

7 The length of the frame, including all media-dependent overhead (12.4.2.2), in bits.

8 **8.6.11.3.12 lengthRecoveryDuration**

9 The duration  $\text{length}(\text{frame})/\text{CommittedInformationRate}$ .

10 **8.6.11.3.13 MaxResidenceTime**

11 The MaximumResidenceTime parameter of the ATS scheduler group instance associated with the ATS  
12 scheduler instance, in nanoseconds (8.6.5.6). The parameter limits the duration for which frames can reside  
13 in a Bridge.

14 NOTE—A consistent setup of MaxResidenceTime parameter can be determined by the per hop delay bound, which is a  
15 result of the timing analysis (Annex V).

16 **8.6.11.3.14 schedulerEligibilityTime**

17 A temporary variable used in the calculation of a frame's eligibilityTime. The prior value of  
18 BucketEmptyTime plus the lengthRecoveryDuration for the frame.

## 1 8.7 The Learning Process

2 The Learning Process receives the source MAC addresses and VIDs, or only the source MAC addresses in  
3 the case of VLAN-unaware MAC Relays, of received frames from the Forwarding Process, subject to active  
4 topology enforcement (8.6.1) and the application of ingress filtering (8.6.2). The Learning Process is not  
5 invoked (8.6.1) for frames whose VID is an ESP-VID or identifies a VLAN supported by SPBM.

6 When invoked, the Learning Process shall create or update a Dynamic Filtering Entry (8.8.3) that specifies  
7 the reception Port for the frame's source address and, in the case of VLAN Bridge components, the frame's  
8 VID, if and only if the source address is an individual address, i.e., is not a group address, the resulting  
9 number of entries would not exceed the capacity of the FDB, and the filtering utility criteria for the receiving  
10 Bridge Port are met, as specified below.

11 If the FDB is already filled to capacity, but a new entry would otherwise be made, then an existing entry ~~may~~  
12 [can](#) be removed to make room for the new entry.

13 The purpose of filtering utility criteria is to reduce the capacity requirements of the FDB and to reduce the  
14 time for which service can be denied (6.5.1) by retaining filtering information learned prior to a change in  
15 the physical topology of the network. Filtering utility criteria shall be applied to the learning and retention of  
16 information for each FID (8.8.8). In Bridges other than EVB Bridges (5.23), enhanced filtering utility  
17 criteria may be implemented for any Bridge Port as specified below (8.7.2); if implemented, both the default  
18 (8.7.1) and the enhanced criteria shall be selectable by management. In EVB Bridges, the enhanced filtering  
19 utility criteria shall be implemented for all Bridge Ports, and the default filtering utility criteria shall not be  
20 implemented.

21 Figure 8-5 illustrates the operation of the Learning Process in the inclusion of station location information  
22 carried by a single frame, received on one of the Ports of a Bridge, in the FDB.

### 23 8.7.1 Default filtering utility criteria

24 The default for a VLAN Bridge is that the member set (8.8.10) for the frame's VID includes at least one  
25 Port.

26 NOTE—If the member set for a given VID is empty, that VID is not currently active, and the Bridge will filter all frames  
27 destined for that VID, regardless of their destination address.

28 The default filtering utility criteria are always met for MAC Bridges.

### 29 8.7.2 Enhanced filtering utility criteria

30 For a VLAN Bridge, the enhanced criteria are satisfied if at least one VID that uses the FID includes the  
31 reception Port and at least one other Port with a Port State of Learning or Forwarding in its member set, and:

- 32 a) The `operPointToPointMAC` parameter is FALSE for the reception Port, or
- 33 b) Ingress for the VID is permitted through a third Port, or
- 34 c) The reception Port has reflective relay enabled (40.4.2).

35 NOTE—The third port can, but is not required to, be in the member set.

36 For a MAC Bridge, the enhanced criteria are satisfied if there exists at least one Port different than the  
37 reception Port with a Port State of Learning or Forwarding, and:

- 38 d) The `operPointToPointMAC` parameter is FALSE for the reception Port, or
- 39 e) There exists third Port with a Port State of Learning or Forward, or
- 40 f) The reception Port has reflective relay enabled (40.4.2).

### 8.7.3 Ageing of Dynamic Filtering Entries

Dynamic Filtering Entries shall be automatically removed after a specified time, the Ageing Time, has elapsed since the entry was created or last updated by the Learning Process.

The ageing out of Dynamic Filtering Entries ensures that end stations that have been moved to a different part of the network will not be permanently prevented from receiving frames. It also takes account of changes in the active topology of the network that can cause end stations to appear to move from the point of view of the Bridge; i.e., the path to those end stations subsequently lies through a different Bridge Port.

The Ageing Time may be set by management (Clause 12). A range of applicable values and a recommended default is specified in Table 8-9; this is suggested to remove the need for explicit configuration in most cases. If the value of Ageing Time can be set by management, the Bridge shall have the capability to use values in the range specified, with a granularity of 1 s.

**Table 8-9—Ageing time parameter value**

| Parameter   | Recommended default value | Range              |
|-------------|---------------------------|--------------------|
| Ageing time | 300.0 s                   | 10.0–1 000 000.0 s |

NOTE—The granularity is specified in order to establish a common basis for the granularity expressed in the management operations defined in Clause 12, not to constrain the granularity of the actual timer supported by a conformant implementation. If the implementation supports a granularity other than 1 s, then it is possible that the value read back by management following a Set operation will not match the actual value expressed in the Set.

The STP specified in Clause 8 of IEEE Std 802.1D, 1998 Edition [B13], includes a procedure for notifying all Bridges in the network of topology change. It specifies a short value for the Ageing Timer, to be enforced for a period after any topology change (8.3.5 of IEEE Std 802.1D, 1998 Edition [B13]). While the topology is not changing, this procedure allows normal ageing to accommodate extended periods during which addressed end stations do not generate frames themselves, perhaps through being powered down, without sacrificing the ability of the network to continue to provide service after automatic configuration.

## 8.8 The Filtering Database (FDB)

The FDB supports queries by the Forwarding Process to determine whether received frames, with given values of, destination MAC address, and for VLAN Bridge components, VID, are to be forwarded through a given potential transmission Port (8.6.1, 8.6.3, 8.6.4). It can also be used, by SPBM (8.6.1), to determine whether received frames with given values of source B-MAC address and B-VID, are to be forwarded from a given reception Port. The FDB contains filtering information in the form of filtering entries that are either:

- a) Static, and explicitly configured by management action; or
- b) Dynamic, and automatically entered into the FDB by the normal operation of the Bridge and the protocols it supports.

Two entry types are used to represent static filtering information. The Static Filtering Entry represents static information in the FDB for individual and for group MAC addresses. It allows administrative control of:

- c) Forwarding of frames with particular destination addresses.
- d) The inclusion in the FDB of dynamic filtering information associated with Extended Filtering Services, and use of this information.

1 The FDB shall contain entries of the Static Filtering Entry type.

2 The Static VLAN Registration Entry represents all static information in the FDB for VLANs. It allows  
3 administrative control of:

- 4 e) Forwarding of frames with particular VIDs.
- 5 f) The inclusion/removal of tag headers in forwarded frames.
- 6 g) The inclusion in the FDB of dynamic VLAN membership information, and use of this information.

7 The FDB associated with VLAN Bridge components may contain entries of the Static VLAN Registration  
8 Entry type. The Static VLAN Registration Entry type is not applicable to MAC Bridge components.

9 Static filtering information is added to, modified, and removed from the FDB only under explicit  
10 management control except when PBB-TE IPS is deployed, in which case the static filtering information for  
11 traffic associated with IPGs configured on the Bridge is added to, modified, and removed from the FDB only  
12 under the direction of IPS Control (26.11.3). It shall not be automatically removed by any ageing  
13 mechanism. Management of static filtering information may be carried out by use of the remote  
14 management capability provided by Bridge Management (8.12) using the operations specified in Clause 12.

15 Four entry types are used to represent dynamic filtering information:

- 16 h) Each Dynamic Filtering Entry specifies the Port through which a frame with a given individual  
17 MAC address, and in the case of VLAN Bridge components, VID, has been or can be received.  
18 Dynamic Filtering Entries can be created and updated by the Learning Process (8.7) and by  
19 ISIS-SPB. Entries that are updated by the Learning Process are subject to ageing and removal by the  
20 FDB.

21 NOTE 1—ISIS-SPB has to create the Dynamic Filtering Entries for VLANs supported by SPBM, since learning is not  
22 used. Initial creation of these entries does no harm for VLANs supported by SPBV (when learning is used) as it can  
23 reduce flooding of frames to unknown destinations.

- 24 i) MAC Address Registration Entries support the registration of MAC addresses. They are created,  
25 updated, and removed by MMRP in support of Extended Filtering Services (8.8.4 and Clause 10)  
26 and by ISIS-SPB. If the `Restricted_MAC_Address_Registration` management control (10.12.2.3) is  
27 TRUE, then the creation of a MAC Address Registration Entry by MMRP is not permitted unless a  
28 Static Filtering Entry exists that permits dynamic registration for the Group concerned.
- 29 j) Dynamic VLAN Registration Entries are used to specify the Ports on which VLAN membership has  
30 been dynamically registered. They are not applicable to MAC Bridge components. They are created,  
31 updated, and removed by MVRP, MIRP, and ISIS-SPB, in support of automatic VLAN membership  
32 configuration (Clause 11 and Clause 39). The MVRP controlled Dynamic VLAN Registration  
33 Entries are subject to the state of the `Restricted_VLAN_Registration` management control  
34 (11.2.3.2.3). If the value of this control is TRUE, then the creation of a Dynamic VLAN Registration  
35 Entry is not permitted unless a Static VLAN Registration Entry exists that permits dynamic  
36 registration for the VID concerned.
- 37 k) Dynamic Reservation Entries are used to specify the Ports on which stream reservations have been  
38 made. They are created, updated, and removed by the operation of SRP defined in Clause 35.

39 Static Filtering Entries and MAC Address Registration Entries comprise:

- 40 l) A MAC address specification.
- 41 m) A VID.
- 42 n) A Port Map, with a control element for each outbound Port to specify filtering for, that MAC address  
43 specification, and in the case of VLAN Bridge components, that VID.

44 Item m), and any reference to VIDs, are not applicable to MAC Bridge components.

1 Dynamic Filtering Entries comprise:

- 2 o) A MAC address specification.
- 3 p) A locally significant FID (see 8.8.8).
- 4 q) A Port Map, with a control element for each outbound Port to specify filtering for, that MAC address
- 5 specification, and in the case of VLAN Bridge components, for the VID(s) allocated to that FID.

6 Item p) and any reference to VIDs and FIDs are not applicable to MAC Bridge components.

7 The Port Map in Static and Dynamic Filtering Entries may contain a **connection\_identifier** (8.8.12) for each  
8 outbound Port.

9 Static and Dynamic VLAN Registration Entries comprise:

- 10 r) A VID.
- 11 s) A Port Map, with a control element for each outbound Port to specify filtering for the VID.

12 Static and Dynamic VLAN Registration Entries are not applicable to MAC Bridge components.

13 Dynamic Reservation Entries comprise:

- 14 t) A MAC address specification.
- 15 u) A VID.
- 16 v) A Port Map, with a control element for each outbound Port to specify filtering for that MAC address
- 17 specification, and in the case of VLAN Bridge components, in the VLAN specified by the VID.

18 Dynamic filtering information may be read by use of the remote management capability provided by Bridge  
19 Management (8.12) using the operations specified in Clause 12.

20 The Filtering Services supported by a Bridge (Basic and Extended Filtering Services) determine the default  
21 behavior of the Bridge with respect to the forwarding of frames destined for group MAC addresses. In  
22 Bridges that support Extended Filtering Services, the default forwarding behavior for group MAC addresses,  
23 for each Port, and for each VID, can be configured both statically and dynamically by means of Static  
24 Filtering Entries and/or MAC Address Registration Entries that can carry the following MAC address  
25 specifications:

- 26 w) All Group Addresses, for which no more specific Static Filtering Entry exists.
- 27 x) All Unregistered Group Addresses (i.e., all group MAC addresses for which no MAC Address
- 28 Registration Entry exists), for which no more specific Static Filtering Entry exists.

29 NOTE 2—The All Group Addresses specification in item w), when used in a Static Filtering Entry with an appropriate  
30 control specification, provides the ability to configure a Bridge that supports Extended Filtering Services to behave as a  
31 Bridge that supports only Basic Filtering Services on some or all of its Ports. This might be done for the following  
32 reasons:

- 33 — The Ports concerned serve “legacy” devices that wish to receive multicast traffic, but are unable to register
- 34 Group membership.
- 35 — The Ports concerned serve devices that need to receive all multicast traffic, such as routers or diagnostic
- 36 devices.

37 The FDB shall support the creation, updating, and removal of Dynamic Filtering Entries by the Learning  
38 Process (8.7). In Bridges that support Extended Filtering Services, the FDB shall support the creation,  
39 updating, and removal of MAC Address Registration Entries by MMRP (Clause 10). In Bridges that support  
40 SPBM, Dynamic Filtering Entries are populated by ISIS-SPB (Clause 28). In Bridges that support SPBV the  
41 Dynamic Filtering Entries are created and updated by the Learning Process (8.7) and the use of ISIS-SPB for  
42 this operation is optional (28.12.9).

43 SPB (27.10) allocates SPVIDs dynamically to support shortest path bridging of frames assigned to one or  
44 more VLANs, each identified by a Base VID (Clause 3). A Static Filtering Entry should not be created for  
45 an SPVID, irrespective of whether that SPVID is currently used, and SPVIDs should not be used in

1 registration protocols that create MAC Address Registration Entries or Dynamic VLAN Registration  
2 Entries. In an SPT Bridge, configuration or registration of an FDB entry with the Base VID of a VLAN  
3 supported by SPBV shall cause the Bridge to filter frames as if that entry was also present for every one of  
4 the SPVIDs for that Base VID.

5 In Bridges that support SRP, the FDB shall support the creation, updating, and removal of Dynamic  
6 Reservation Entries by SRP (Clause 35).

7 Figure 8-4 illustrates use of the FDB by the Forwarding Process in a single instance of frame relay between  
8 the Ports of a Bridge with two Ports.

9 Figure 8-5 illustrates the creation or update of a dynamic entry in the FDB by the Learning Process. The  
10 entries in the FDB, associated with VLAN Bridge components, allow MAC address information to be  
11 learned independently for each VID or set of VIDs, by relating a MAC address to the VID or set of VIDs on  
12 which that address was learned.

13 NOTE 3—The ability to create VLAN-dependent FDB entries allows a VLAN Bridge to support multiple end stations  
14 with the same individual MAC address residing on different VLANs. It also supports end stations with multiple  
15 interfaces, each using the same individual MAC address, as long as not more than one end station or interface that uses a  
16 given MAC address resides in a given VLAN.

17 Figure 8-6 illustrates the operation of the Spanning Tree Protocol Entity (8.10), which operates STP, and its  
18 notification of the FDB of changes in active topology signaled by that protocol.

19 There are no standardized constraints on the size of the FDB in an implementation for which conformance to  
20 this standard is claimed. The PICS proforma in Annex A requires the following to be specified for a given  
21 implementation:

- 22 y) The total number of entries (Static Filtering Entries, Dynamic Filtering Entries, MAC Address  
23 Registration Entries, Static VLAN Registration Entries, Dynamic VLAN Registration Entries, and  
24 Dynamic Reservation Entries) that the implementation of the FDB can support.
- 25 z) Of that total number, the total number of VLAN Registration Entries (static and dynamic) that the  
26 FDB can support.

### 27 8.8.1 Static Filtering Entries

28 A Static Filtering Entry specifies:

- 29 a) A MAC address specification, comprising
  - 30 1) An individual MAC address, or
  - 31 2) A group MAC address, or
  - 32 3) All Individual Addresses, for which no more specific Filtering Entry exists, or
  - 33 4) All Group Addresses, for which no more specific Static Filtering Entry exists, or
  - 34 5) All Unregistered Group Addresses, for which no more specific Static Filtering Entry exists.
- 35 b) A VID specification, comprising:
  - 36 1) The VID of a specific VLAN to which the static filtering information applies, or
  - 37 2) The wildcard VID (Table 9-2), indicating that the static filtering information applies to all VIDs  
38 for which no specific Static Filtering Entry exists.
- 39 c) A Port Map, containing a control element for each outbound Port, specifying that a frame with a  
40 destination MAC address, and in the case of VLAN Bridge components, VID that meets this  
41 specification is to be:
  - 42 1) Forwarded, independently of any dynamic filtering information held by the FDB, or
  - 43 2) Filtered, independently of any dynamic filtering information, or

- 1           3) Forwarded or filtered on the basis of dynamic filtering information, or on the basis of the  
2           default Group filtering behavior for the outbound Port (8.8.6) if no dynamic filtering  
3           information is present specifically for the MAC address.

4 The Port Map may contain a connection\_identifier (8.8.12) for each outbound Port.

5 MAC Bridges shall have the capability to support the first two values for the MAC address specification,  
6 and all three values for each control element for all Static Filtering Entries [i.e., shall have the capability to  
7 support item a1), item a2), item c1), item c2), and item c3)]. All VLAN Bridges shall have the capability to  
8 support the first two values for the MAC address specification, both values of the VID specification, and all  
9 three values for each control element for all Static Filtering Entries [i.e., shall have the capability to support  
10 item a1), item a2), item b1), item b2), item c1), item c2), and item c3)]. All Bridges supporting PBB-TE or  
11 SPT Bridges shall, in addition, support item a3) and item a4) for ESP-VIDs (8.9) or VIDs identifying  
12 VLANs supported by SPBM, respectively, and shall always have in their FDBs Static Filtering Entries  
13 specifying item a3) and item a4), and a Port Map specifying filtering for each outbound port, for every  
14 ESP-VID or SPBM VID, respectively.

15 A Bridge that supports Extended Filtering Services shall have the capability to support item a1), item a2),  
16 item a4), and item a5) for the MAC address specification and all three control element values for all Static  
17 Filtering Entries.

18 For a given MAC address specification, a separate Static Filtering Entry with a distinct Port Map may be  
19 created for each VID from which frames are received by the Forwarding Process.

20 In addition to controlling the forwarding of frames, Static Filtering Entries provide the Registrar  
21 Administrative Control values for MMRP (Clause 10). Static configuration of forwarding of a specific  
22 destination MAC address to an outbound port indicates Registration Fixed on that port, which indicates a  
23 desire to receive the specific frames even in the absence of dynamic information. Static configuration of  
24 filtering of frames that might otherwise be sent to an outbound port indicates Registration Forbidden. The  
25 absence of a Static Filtering Entry for a MAC address, or the configuration of forwarding or filtering on the  
26 basis of dynamic filtering information, indicates Normal Registration.

## 27 **8.8.2 Static VLAN Registration Entries**

28 A Static VLAN Registration Entry specifies:

- 29   a) The VID to which the static filtering information applies.  
30   b) A Port Map, consisting of a control element for each outbound Port, specifying:  
31       1) The Registrar Administrative Control values for MVRP (Clause 11) and MIRP (Clause 39) for  
32       the VID. In addition to providing control over the operation of MVRP and MIRP, these values  
33       can also directly affect the forwarding behavior of the Bridge, as described in 8.8.10. The  
34       values that can be represented are:  
35           i) Registration Fixed (New ignored), or  
36           ii) Registration Fixed (New propagated), or  
37           iii) Registration Forbidden, or  
38           iv) Normal Registration.  
39       2) Whether frames are to be VLAN-tagged or untagged when transmitted. The entries in the Port  
40       Map that specify untagged transmission compose the untagged set for the VID. The untagged  
41       set is empty if no Static VLAN Registration Entry exists for the VID.

42 Static VLAN Registration Entries are not applicable to MAC Bridge components.

1 A separate Static VLAN Registration Entry with a distinct Port Map may be created for each VID. All  
2 Bridges shall be capable of supporting all values for each control element for all Static VLAN Registration  
3 Entries; however, the ability to support more than one untagged VID on egress on any given Port is optional  
4 (see 5.4).

5 NOTE 1—In other words, it is possible to configure any VID as untagged on egress, but it is not necessarily possible to  
6 configure more than one VID as untagged on egress. It is an implementation option about whether only a single  
7 untagged VID per Port on egress is supported or whether multiple untagged VIDs per Port on egress are supported.  
8 When a single untagged VID per Port is supported, that VID is not necessarily the same as the PVID.

9 The initial state of the Permanent Database contains a Static VLAN Registration Entry for the VID  
10 corresponding to the Default PVID (Table 9-2). The Port Map in this entry specifies Registration Fixed and  
11 forwarding untagged for all Ports of the Bridge. This entry may be modified or removed from the Permanent  
12 Database by means of the management operations defined in Clause 12 if the implementation supports these  
13 operations.

14 NOTE 2—This initial state causes the default tagging state for the PVID to be untagged, and for all other VIDs to be  
15 tagged, unless otherwise configured; however, the management configuration mechanisms allow any VID (including the  
16 PVID) to be specified as VLAN-tagged or untagged on any Port.

17 NOTE 3—For VLANs supported by SPBV the Filtering specified by a static VLAN registration entry for the Base VID  
18 is applied for all SPVIDs associated with that Base VID.

### 19 8.8.3 Dynamic Filtering Entries

20 A Dynamic Filtering Entry specifies:

- 21 a) An individual MAC address.
- 22 b) The FID, an identifier assigned by the MAC Bridge (8.8.8) to identify a set of VIDs for which no  
23 more than one Dynamic Filtering Entry can exist for any individual MAC address.  
24 NOTE 1—An FID identifies a set of VIDs among which Shared VLAN Learning (SVL) (3.247) takes place.  
25 Any pair of FIDs identifies two sets of VIDs between which Independent VLAN Learning (IVL) (3.120) takes  
26 place. The allocation of FIDs by a Bridge is described in 8.8.8.
- 27 c) A Port Map specifying forwarding for the destination MAC address and FID to a single Port or, in  
28 the case of ECMP with flow filtering (44.1, 44.2), to a set of Ports from which one must be selected.

29 Item b), and any reference to FIDs and VIDs in the list above, are not applicable to MAC Bridge  
30 components.

31 The Port Map may contain a **connection\_identifier** (8.8.12) for each outbound Port.

32 Dynamic Filtering Entries can be created, updated, and removed by the Learning Process (8.7). They shall  
33 be automatically removed after a specified time, the Ageing Time (8.7.3), has elapsed since the entry was  
34 created or last updated.

35 Dynamic Filtering Entries can also be created and updated by SPB (Clause 27). ISIS-SPB (Clause 28)  
36 refreshes these entries, so they are not aged out by the normal operation of the Learning Process. These  
37 entries are used by SPBM (Clause 27) to support both unicast loop mitigation (6.5.4.2) and multicast loop  
38 prevention (6.5.4.1) for active topology enforcement (8.6.1) as well as to locate end stations. Entries  
39 indicating a set of potential forwarding ports from which one must be selected are used by ECMP with flow  
40 filtering. SPBV updates Dynamic Filtering Entries by the normal Learning Process, but they may also be  
41 controlled by ISIS-SPB. This allows entries for the higher layer entities in a Bridge (see Figure 8-12) to be  
42 populated rapidly after any topology change.

43 ~~No more than one Dynamic Filtering Entry shall be created in the FDB for a given combination of MAC~~  
44 ~~address and FID. Dynamic Filtering Entries cannot be created or updated by management.~~

45 NOTE 2—Dynamic Filtering Entries may be read by management (Clause 12). In the case of VLAN Bridge  
46 components, the FID is represented in the management Read operation by any one of the VIDs that it represents. For a  
47 given VID, the set of VIDs that share the same FID may also be determined by management.

## 1 8.8.4 MAC Address Registration Entries

2 A MAC Address Registration Entry specifies:

- 3 a) A MAC address specification, comprising:
  - 4 1) An individual MAC address, or
  - 5 2) A group MAC address, or
  - 6 3) All Group Addresses, for which no more specific Static Filtering Entry exists, or
  - 7 4) All Unregistered Group Addresses, for which no more specific Static Filtering Entry exists.
- 8 b) The VID for which the dynamic filtering information was registered.
- 9 c) A Port Map, consisting of a control element for each outbound Port, which specifies forwarding  
10 (Registered) or filtering (Not registered) of frames destined to the MAC address and, in the case of  
11 VLAN Bridge components, the VID.

12 Item b) and any reference to VIDs, in the list above, are not applicable to MAC Bridge components.

13 MAC Address Registration Entries are created, modified, and deleted by the operation of MMRP  
14 (Clause 10) or by ISIS-SPB. No more than one MAC Address Registration Entry shall be created in the FDB  
15 for a given combination of MAC address specification and VID.

16 NOTE—It is possible to have a Static Filtering Entry that has values of Forward or Filter on some or all Ports that mask  
17 the dynamic values held in a corresponding MAC Address Registration Entry. The values in the MAC Address  
18 Registration Entry will continue to be updated by MMRP; hence, subsequent modification of that entry to allow the use  
19 of dynamic filtering information on one or more Ports immediately activates the true MMRP registration state that was  
20 hitherto masked by the static information.

21 The creation of MAC Address Registration Entries by MMRP is subject to the  
22 Restricted\_MAC\_Address\_Registration management control (10.12.2.3). If the value of this control is  
23 TRUE, a dynamic entry for a given MAC address may only be created if a Static Filtering Entry already  
24 exists for that MAC address, in which the Registrar Administrative Control value is Normal Registration.

## 25 8.8.5 Dynamic VLAN Registration Entries

26 A Dynamic VLAN Registration Entry specifies:

- 27 a) The VID to which the dynamic filtering information applies.
- 28 b) A Port Map with a control element for each outbound Port specifying whether the VID is registered  
29 on that Port.

30 NOTE—Dynamic VLAN Registration Entries can be accessed by ingress ports or egress ports.

31 Dynamic VLAN Registration Entries are not applicable to MAC Bridge components.

32 A separate Dynamic VLAN Registration Entry with a distinct Port Map may be created for each VID from  
33 which frames are received by the Forwarding Process.

34 The creation of Dynamic VLAN Registration Entries is subject to the Restricted\_VLAN\_Registration  
35 management control (11.2.3.2.3). If the value of this control is TRUE, a dynamic entry for a given VID may  
36 only be created if a Static VLAN Registration Entry already exists for that VID, in which the Registrar  
37 Administrative Control value is Normal Registration.

## 1 8.8.6 Default Group filtering behavior

2 Forwarding and filtering of group-addressed frames may be managed by specifying defaults for each VID  
3 and outbound Port, or just outbound Ports in the case of MAC Bridges. The behavior of each of these  
4 defaults, as modified by the control elements of more explicit FDB entries applicable to a given frame's  
5 MAC address, VID, and outbound Port, is as follows:

6 NOTE 1—As stated in 8.8.1 for VLAN Bridge components, for a given MAC address, there may be separate Static  
7 Filtering Entries with a distinct Port Map for each VID.

- 8 a) *Forward All Groups*. The frame is forwarded, unless an explicit Static Filtering Entry specifies  
9 filtering independent of any dynamic filtering information.
- 10 b) *Forward Unregistered Groups*. The frame is forwarded, unless:
  - 11 1) An explicit Static Filtering Entry specifies filtering independent of any dynamic filtering  
12 information; or
  - 13 2) An explicit Static Filtering Entry specifies forwarding or filtering on the basis of dynamic  
14 filtering information, and an applicable explicit MAC Address Registration Entry exists  
15 specifying filtering; or
  - 16 3) An applicable explicit Static Filtering Entry does not exist, but an applicable MAC Address  
17 Registration Entry specifies filtering.
- 18 c) *Filter Unregistered Groups*. The frame is filtered unless:
  - 19 1) An explicit Static Filtering Entry specifies forwarding independent of any dynamic filtering  
20 information; or
  - 21 2) An explicit Static Filtering Entry specifies forwarding or filtering on the basis of dynamic  
22 filtering information, and an applicable explicit MAC Address Registration Entry exists  
23 specifying forwarding; or
  - 24 3) An applicable explicit Static Filtering Entry does not exist, but an applicable MAC Address  
25 Registration Entry specifies forwarding.

26 In Bridges that support only Basic Filtering Services, the default Group filtering behavior is Forward All  
27 Groups for all Ports of the Bridge, for all VIDs.

28 NOTE 2—Forward All Groups corresponds directly to the behavior specified in IEEE Std 802.1D, 1993 Edition [B12]  
29 when forwarding group MAC addressed frames for which no static filtering information exists in the FDB. Forward All  
30 Groups makes use of information contained in Static Filtering Entries for specific group MAC addresses, but overrides  
31 any information contained in MAC Address Registration Entries. Forward Unregistered Groups is analogous to the  
32 forwarding behavior of a Bridge with respect to individual MAC addresses. If there is no static or dynamic information  
33 for a specific group MAC address, then the frame is forwarded; otherwise, the frame is forwarded in accordance with the  
34 statically configured or dynamically learned information.

35 In Bridges that support Extended Filtering Services, the default Group filtering behavior for each outbound  
36 Port, and in the case of VLAN Bridge components, for each VID, is determined by the following  
37 information contained in the FDB:

- 38 d) Any Static Filtering Entries that are applicable to that VID in the case of VLAN Bridge components,  
39 with a MAC address specification of All Group Addresses or All Unregistered Group Addresses.
- 40 e) Any MAC Address Registration Entries that are applicable to that VID in the case of VLAN Bridge  
41 components, with a MAC address specification of All Group Addresses or All Unregistered Group  
42 Addresses.

43 The means whereby this information determines the default Group filtering behavior is specified in 8.8.9,  
44 Table 8-11, and Table 8-12.

45 NOTE 3—The result is that the default Group filtering behavior, applicable in the case of VLAN Bridge components for  
46 each VID, can be configured for each Port of the Bridge via Static Filtering Entries, determined dynamically via MAC  
47 Address Registration Entries created/updated by MMRP (Clause 10), or both. For example, in the absence of any static  
48 or dynamic information in the FDB for All Group Addresses or All Unregistered Group Addresses, the default Group  
49 filtering behavior will be Filter Unregistered Groups on all Ports, for all VIDs. Subsequently, the creation of a Dynamic

1 MAC Address Registration Entry for All Unregistered Group Addresses indicating “Registered”, for a given VID in the  
2 case of VLAN Bridge components, on a given Port would cause that Port to exhibit Forward Unregistered Groups  
3 behavior, for that VID in the case of VLAN Bridge components. Similarly, creating a Static Filtering Entry for All Group  
4 Addresses indicating “Registration Fixed” on a given Port, in the case of VLAN Bridge components for that VID, would  
5 cause that Port to exhibit Forward All Groups behavior.

6 Hence, by using appropriate combinations of “Registration Fixed,” “Registration Forbidden,” and “Normal  
7 Registration” in the Port Maps of Static Filtering Entries for the All Group Addresses and All Unregistered Group  
8 Addresses address specifications, it is possible, for a given Port, and in the case of VLAN Bridge components, VID, to:

- 9 — Fix the default Group filtering behavior to be just one of the three behaviors described above; or
- 10 — Restrict the choice of behaviors to a subset of the three, and allow MMRP registrations (or their absence) to  
11 determine the final choice; or
- 12 — Allow any one of the three behaviors to be adopted, in accordance with any registrations received via MMRP.

### 13 8.8.7 Dynamic Reservation Entries

14 A Dynamic Reservation Entry specifies the following:

- 15 a) A group MAC address or an individual MAC address.
- 16 b) The VID for which the dynamic reservation information was registered.
- 17 c) A Reservation Port Map, consisting of a control element for each outbound Port that specifies  
18 forwarding (reservation information exists for this Port) or filtering (reservation information does  
19 not exist for this Port) of frames for this Port. The initial value shall be filtering.

20 Dynamic Reservation Entries are created, modified, and deleted by the operation of SRP. No more than one  
21 Dynamic Reservation Entry shall be created in the FDB for a given combination of MAC address and VID.

### 22 8.8.8 Allocation of VIDs to FIDs

23 The allocation of VIDs to FIDs within a VLAN Bridge determines how learned individual MAC address  
24 information is used in forwarding and filtering decisions. If two VIDs are allocated to the same FID learned  
25 information is shared, i.e., an individual MAC address learned following receipt of a frame affects the  
26 forwarding or filtering of a subsequent frame with the same address as its destination address if either of the  
27 two VIDs have been assigned to each of the two frames. If two VIDs are allocated to different FIDs learned  
28 information is independent, i.e., an individual MAC address for frames that have one of the VIDs assigned  
29 does not affect forwarding or filtering of frames with the other VID. IVL can allow two separate stations to  
30 use the same MAC address, provided they use different VLANs, and also allows frames transmitted by a  
31 single station to be assigned to independent active topologies. SVL allows support of a single VLAN by  
32 multiple VIDs, enabling further control over the filtering of frames for that VLAN, and allowing SPB to  
33 support the VLAN with a set of symmetric trees while still using learning. Further considerations for the use  
34 of IVL and/or SVL are described in Annex F (informative).

35 A VLAN Bridge shall support either SVL or IVL, and may support both. If IVL is not supported the Bridge  
36 shall support a single FID. If IVL is supported, the number of FIDs shall be the same as the maximum  
37 number of VLANs supported by the implementation. For the purposes of the management operations, FIDs  
38 are numbered from 1 through N, where N is the maximum number of FIDs supported by the  
39 implementation. A Bridge that supports both SVL and IVL shall be capable of allocating any VID to any  
40 FID, through configuration of the VID to FID allocation table. Following any set of management operations  
41 designed to change the allocation of VIDs to FIDs, whether initiated by an administrative request or as a  
42 consequence of other aspects of the Bridge’s operation, the value of any FID that is in use should be the  
43 same as that of one of the VIDs allocated to that FID. One exception to this rule is the allocation of SPVIDs  
44 to FIDs for SPBV (Clause 27). SPVIDs that are allocated are associated with a Base VID’s FID. The  
45 learning behavior of SPVIDs assigned to a FID is determined by the learning behavior of the associated  
46 Base VID’s FID (27.11).

1 The VID to FID allocation table may be read and modified by means of the management operations defined  
2 in Clause 12. For each VID supported by the implementation, the allocation table indicates one of the  
3 following:

- 4 a) The VID is currently not allocated to any FID, or
- 5 b) A fixed allocation has been defined (via management), allocating this VID to a specific FID, or
- 6 c) A dynamic allocation has been defined, allocating this VID to a specific FID.

7 An SPT Bridge can dynamically allocate VIDs, that have been reserved for use as SPVIDs, to FIDs.

8 An MST Bridge shall support IVL and may support SVL. An MST Bridge shall be capable of allocating any  
9 FID to any MSTID through configuration of the FID to MSTID Allocation Table (12.12.2). An SPT Bridge  
10 supports both IVL and SVL.

### 11 8.8.9 Querying the FDB

12 If a frame is assigned to a VLAN supported by SPBM, then the Filtering Database is queried upon reception  
13 of the frame by the ingress port for ingress checking and the frame is forwarded or filtered. If single port  
14 admittance ingress checking (6.5.4.2) is applied, then the frame is forwarded only if a Dynamic Filtering  
15 Entry for that VID, source address tuple specifies forward for the ingress port; otherwise, the frame is  
16 filtered. If relaxed ingress checking (45.3.1) is applied, then the frame is forwarded only if the ingress port is  
17 in the Port Map of the MAC Address Registration Entry for that VID, individual destination address tuple;  
18 otherwise, the frame is filtered.

19 If the VID assigned to a relayed frame identifies a VID or an ESP with a given outbound Bridge Port in its  
20 member set (8.8.10), the FDB entries that are applicable to the frame's destination MAC address and VID  
21 determine whether the frame is filtered or forwarded through that Bridge Port. More than one entry can  
22 apply to a given frame. This subclause (8.8.9) specifies the effect of combining applicable entries, and of the  
23 absence of certain types of entries (not all possible entries are necessarily present). For an overview of the  
24 different types of entries, see the introductory text of 8.8.

25 The FDB entries associated with a VLAN Bridge component, applicable to a frame whose destination MAC  
26 address is a specific individual MAC address are the Dynamic Filtering Entry (if present) with that MAC  
27 address and the FID to which the frame's VID is allocated (8.8.8), and all Static Filtering Entries (if any)  
28 with that MAC address, or with "All Individual MAC Address," as their MAC address specification and a  
29 VID that is also allocated to that FID, as their VID specification. An entry with a wildcard VID applies only  
30 if there is no applicable Static Filtering Entry for a specific VID. Table 8-10 specifies the result of  
31 combining this information for an individual MAC address and a given outbound Bridge Port, and can be  
32 summarized as follows:

- 33 — IF any static entry for a VID allocated to the FID specifies Forward, THEN Forward.
- 34 — ELSE IF any static entry for a VID allocated to the FID specifies Filter, THEN Filter.
- 35 — ELSE IF a static entry for the wildcard VID specifies Forward, THEN Forward.
- 36 — ELSE IF a static entry for the wildcard VID specifies Filter, THEN Filter.
- 37 — ELSE IF dynamic (learned filtering information) entry for the FID specifies Filter, THEN Filter
- 38 — ELSE Forward.

39 Table 8-10 is also applicable to MAC Bridge components but in this case there is no specific qualification on  
40 FIDs in the FDB entries and the result of combining this information for an individual MAC address and a  
41 given outbound Bridge Port can be summarized as follows:

- 42 — IF any static entry specifies Forward, THEN Forward.
- 43 — ELSE IF any static entry specifies Filter, THEN Filter.
- 44 — ELSE IF dynamic (learned filtering information) entry specifies Filter, THEN Filter.

**Table 8-10—Combining Static and Dynamic Filtering Entries for an individual MAC address**

| Filtering Information | Control Elements in any Static Filtering Entry or Entries for this individual MAC address, FID, and outbound Port specify: |                                                                                   |                                                                                                                                                                                                                                                                       |        |                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|------------------------------------|
|                       | Forward<br>(Any Static Filtering Entry for this Address/FID/Port specifies Forward)                                        | Filter<br>(No Static Filtering Entry for this Address/FID/Port specifies Forward) | Use Dynamic Filtering Information (No Static Filtering Entry for this Address/FID/Port specifies Forward or Filter), or no Static Filtering Entry present. Dynamic Filtering Entry Control Element for this individual MAC address, FID, and outbound Port specifies: |        |                                    |
|                       |                                                                                                                            |                                                                                   | Forward                                                                                                                                                                                                                                                               | Filter | No Dynamic Filtering Entry present |
| Result                | Forward                                                                                                                    | Filter                                                                            | Forward                                                                                                                                                                                                                                                               | Filter | Forward                            |

1 — ELSE Forward.

2 The FDB entries applicable (if present) to a frame whose destination MAC address is a specific group MAC  
3 address are the Static Filtering Entries and MAC Address Registration Entries (for the frame's VID and for  
4 the wildcard VID) whose address specification is that group MAC address or "All Group Addresses" or "All  
5 Unregistered Group Addresses." A Static Filtering Entry for a wildcard VID applies only if there is no  
6 applicable Static Filtering Entry for a specific VID, MAC Address Registration Entries do not use wildcard  
7 VID. Table 8-11 specifies the results, Registered or Not Registered for a given outbound Bridge Port, of  
8 combining the entries for the "All Group Addresses" and for combining the entries for "All Unregistered  
9 Group Addresses." Table 8-12 combines these results with the entries for the specific group MAC address.  
10 The result of Table 8-11 for "All Group Addresses" can be summarized as follows:

- 11 — IF a static entry for "All Group Addresses" and the frame's VID specifies Forward (Registration  
12 Fixed), THEN "All Group Addresses" is Registered.
- 13 — ELSE IF a static entry for "All Group Addresses" and the frame's VID specifies Filter (Registration  
14 Forbidden), THEN "All Group Addresses" is Not Registered.
- 15 — ELSE IF a dynamic (MAC Address Registration) entry for "All Group Addresses" and the frame's  
16 VID specifies Forward (Registered), THEN "All Group Addresses" is Registered.
- 17 — ELSE "All Group Addresses" is NOT Registered.

18 NOTE 1—The result for "All Unregistered Group Addresses" is given by substituting that address specification for "All  
19 Group Address" throughout the summary.

20 The result of Table 8-12 can be summarized as follows:

- 21 — IF a static entry for the specific group address and the frame's VID specifies Forward, THEN  
22 Forward.
- 23 — ELSE IF a static entry for the specific group address and the frame's VID specifies Filter, THEN  
24 Filter.
- 25 — ELSE IF a static entry for the specific group address and the wildcard VID specifies Forward,  
26 THEN Forward.
- 27 — ELSE IF a static entry for the specific group address and the wildcard VID specifies Filter, THEN  
28 Filter.
- 29 — ELSE IF the Table 8-11 result for "All Group Addresses" is Registered, THEN Forward.
- 30 — ELSE IF the Table 8-11 result for "All Unregistered Group Addresses" is Registered, THEN  
31 Forward.

**Table 8-11—Combining Static Filtering Entry and MAC Address Registration Entry for “All Group Addresses” and “All Unregistered Group Addresses”**

| Filtering Information | Static Filtering Entry Control Element<br>for this group MAC address, VID, and outbound Port specifies: |                                 |                                                                                                                                                                                                 |                         |                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|-------------------------------------------|
|                       | Registration Fixed (Forward)                                                                            | Registration Forbidden (Filter) | Use MAC Address Registration Information, or no Static Filtering Entry present.<br>MAC Address Registration Entry Control Element for this group MAC address, VID, and outbound Port specifies: |                         |                                           |
|                       |                                                                                                         |                                 | Registered (Forward)                                                                                                                                                                            | Not Registered (Filter) | No MAC Address Registration Entry present |
| Result                | Registered                                                                                              | Not Registered                  | Registered                                                                                                                                                                                      | Not Registered          | Not Registered                            |

- 1 — ELSE IF a dynamic (MAC Address Registration) entry for the specific group address and the
- 2 frame’s VID specifies Forward, THEN Forward.
- 3 — ELSE Filter.

4 Table 8-11 and Table 8-12 are also applicable to MAC Bridge components but in this case there is no  
5 specific qualification on VIDs in the FDB entries and the result of combining this information for an  
6 individual MAC address and a given outbound Bridge Port can be summarized as follows:

- 7 — IF a static entry for the specific group address specifies Forward, THEN Forward.
- 8 — ELSE IF a static entry for the specific group address specifies Filter, THEN Filter.
- 9 — ELSE IF a static entry for the specific group address specifies Forward, THEN Forward.
- 10 — ELSE IF a static entry for the specific group address specifies Filter, THEN Filter.
- 11 — ELSE IF the Table 8-11 result for “All Group Addresses” is Registered, THEN Forward.
- 12 — ELSE IF the Table 8-11 result for “All Unregistered Group Addresses” is Registered, THEN
- 13 Forward.
- 14 — ELSE IF a dynamic (MAC Address Registration) entry for the specific group address specifies
- 15 Forward, THEN Forward.
- 16 — ELSE Filter.

17 When forwarding or filtering a frame with a destination group MAC address, a VLAN Bridge may:

- 18 a) Ignore the allocation of VIDs to FID, and use Table 8-12 directly for the frame’s VID; or
- 19 b) Take the same decision for all VIDs allocated to any given FID, forwarding if Table 8-12 specifies
- 20 Forward for any VID allocated to the same FID as the frame’s VID, and filtering otherwise.

21 For a given destination MAC address and VID, a Dynamic Reservation Entry (8.8.7) may be present in the  
22 FDB, indicating, by means of its port map, which Ports have valid bandwidth reservations. If a Dynamic  
23 Reservation Entry exists in the FDB for that MAC address and VID, the port map in the  
24 Dynamic Reservation Entry is used to prevent frames being forwarded on Ports where no reservation exists.

**Table 8-12—Forwarding or Filtering for specific group MAC addresses**

|                                                                                  |                |                                                                                               |                | Static Filtering Entry Control Element for this group MAC address, VID, and outbound Port specifies: |                                 |                                                                                                                                                                                              |                                       |                                           |
|----------------------------------------------------------------------------------|----------------|-----------------------------------------------------------------------------------------------|----------------|------------------------------------------------------------------------------------------------------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|-------------------------------------------|
|                                                                                  |                |                                                                                               |                | Registration Fixed (Forward)                                                                         | Registration Forbidden (Filter) | Use MAC Address Registration Information, or no Static Filtering Entry present. MAC Address Registration Entry Control Element for this group MAC address, VID, and outbound Port specifies: |                                       |                                           |
|                                                                                  |                |                                                                                               |                |                                                                                                      |                                 | Registered (Forward)                                                                                                                                                                         | Not Registered (Filter)               | No MAC Address Registration Entry present |
| All Group Addresses control elements for this VID and Port specify (Table 8-11): | Not Registered | All Unregistered Group Addresses control elements for this VID and Port specify (Table 8-11): | Not Registered | Forward                                                                                              | Filter                          | Forward                                                                                                                                                                                      | Filter (Filter Unregistered Groups)   | Filter (Filter Unregistered Groups)       |
|                                                                                  |                |                                                                                               | Registered     | Forward                                                                                              | Filter                          | Forward                                                                                                                                                                                      | Forward (Forward Unregistered Groups) | Forward (Forward Unregistered Groups)     |
|                                                                                  | Registered     |                                                                                               |                | Forward                                                                                              | Filter                          | Forward (Forward All Groups)                                                                                                                                                                 | Forward (Forward All Groups)          | Forward (Forward All Groups)              |

1 Table 8-13 combines the output of Table 8-10 (for an individual MAC address) or Table 8-12 (for a group  
2 MAC address) with a Dynamic Reservation Entry to specify forwarding, or filtering, of a frame with that  
3 destination MAC address and VID through an outbound Port.

**Table 8-13—Forwarding or Filtering with Dynamic Reservation Entries**

|                                                                                                                                                             |         | Dynamic Reservation Entry Control Element for this individual or group MAC address, VID, and outbound Port specifies: |        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------|--------|
|                                                                                                                                                             |         | Forward                                                                                                               | Filter |
| Output of Table 8-10 (individual MAC address) or Table 8-12 (group MAC address) for this group or individual MAC address, VID, and outbound Port specifies: | Forward | Forward                                                                                                               | Filter |
|                                                                                                                                                             | Filter  | Filter                                                                                                                | Filter |

4 NOTE 2—Where a group MAC address is used as the destination address for reserved traffic, the reservation  
5 mechanisms used by SRP will prevent reservations being made for multiple streams using the same combination of  
6 MAC address and VID. The Dynamic Reservation Entry can then control which Port(s) the stream associated with the  
7 MAC address and VID is permitted to be transmitted through. The restriction preventing multiple streams from using the  
8 same group MAC address/VID is necessary because those different streams may be destined for different destination  
9 Ports; if the restriction was not imposed, it would not be possible to distinguish which frames belong to which streams  
10 and therefore through which Ports they should be transmitted.

#### 11 8.8.10 Determination of the member set for a VID

12 The VLAN configuration information contained in the FDB of a VLAN Bridge component for a given VID  
13 may include a Static VLAN Registration Entry (8.8.2) and/or a Dynamic VLAN Registration Entry (8.8.5).  
14 This information defines the member set, the Ports through which members of the VLAN identified by that  
15 VID can be reached.

16 For a given VID, the FDB can contain a Static VLAN Registration Entry, a Dynamic VLAN Registration  
17 Entry, both, or neither. Table 8-14 combines Static VLAN Registration Entry and Dynamic VLAN  
18 Registration Entry information for a VID and Port to give a result *member*, or *not member*, for the Port. The  
19 member set for a given VID consists of all Ports for which the result is member.

**Table 8-14—Determination of whether a Port is in a VID's member set**

| Filtering Information | Static VLAN Registration Entry Control Element for this VID and Port specifies: |                        |                                                                                                                                                     |                |                                            |
|-----------------------|---------------------------------------------------------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|----------------|--------------------------------------------|
|                       | Registration Fixed                                                              | Registration Forbidden | Normal Registration, or no Static VLAN Registration Entry present. Dynamic VLAN Registration Entry Control Element for this VID and Port specifies: |                |                                            |
|                       |                                                                                 |                        | Registered                                                                                                                                          | Not Registered | No Dynamic VLAN Registration Entry present |
| Result                | Member                                                                          | Not member             | Member                                                                                                                                              | Not member     | Not member                                 |

20 The Forwarding Process uses the member set to apply ingress (8.6.2) and egress rules (8.6.4) for the VID.

### 1 8.8.11 Permanent Database

2 The Permanent Database provides fixed storage for a number of Static Filtering Entries and Static VLAN  
3 Registration Entries. The FDB shall be initialized with the FDB entries contained in this fixed data store.

4 Entries may be added to and removed from the Permanent Database under explicit management control,  
5 using the management functionality defined in Clause 12. Changes to the contents of Static Filtering Entries  
6 or Static VLAN Registration Entries in the Permanent Database do not affect forwarding and filtering  
7 decisions taken by the Forwarding Process or the egress rules until such a time as the FDB is reinitialized.

8 NOTE 1—This aspect of the Permanent Database can be viewed as providing a “boot image” for the FDB, defining the  
9 contents of all initial entries, before any dynamic filtering information is added.

10 NOTE 2—Subclause 10.12.2.3 defines an initial state for the contents of the Permanent Database, required for the  
11 purposes of MMRP operation.

### 12 8.8.12 Connection\_Identifier

13 A connection\_identifier may be associated with the Bridge Port value maintained in a Dynamic Filtering  
14 Entry of the FDB for Bridge Ports that generate EM\_UNITDATA.indications with a non-null  
15 connection\_identifier parameter (e.g., a VIP as specified in 6.10). The connection\_identifier has no effect on  
16 the Bridge operation specified in this clause other than being stored in the FDB and conveyed across the  
17 EISS as a parameter in an EM\_UNITDATA.request or EM\_UNITDATA.indication (6.8.1).

18 When the result of an FDB query (8.8.9) for a particular frame is that the frame will be forwarded, and the  
19 FDB entry determining that result has a connection\_identifier, then that connection\_identifier is included in  
20 the EM\_UNITDATA.request. For a given VID and MAC address, a connection\_identifier can be included in  
21 a Dynamic Filtering Entry of the FDB. The FDB entry that determines a filtering or forwarding result is  
22 specified in Table 8-10. If there are no entries for that MAC address and VID in the FDB, then a null value  
23 for the connection\_identifier is used in the EM\_UNITDATA.request.

24 When an EM\_UNITDATA.indication with a non-null connection\_identifier is received from an ingress port,  
25 and the Learning Process identifies or creates a Dynamic Filtering Entry for that frame’s source address and  
26 VID, the connection\_identifier is included in the entry created for that port in the FDB.

## 27 8.9 MST, SPB, and ESP configuration information

28 In order to support multiple spanning trees, and SPB, all the Bridges in an MST or SPT Region have to be  
29 configured with assignments of VIDs to spanning trees.

30 The combination of the VID to FID allocations (8.8.8) and the FID to MSTI allocations (8.9.3) defines a  
31 mapping of VIDs to spanning trees, MSTIDs, represented by the MST Configuration Table (8.9.1). If an  
32 MSTID is included in the MSTI List (12.12.1), frames with VIDs allocated to that MSTID will be supported  
33 by an MSTI calculated by MSTP (Clause 13). If the MSTID is not included in the MSTI List, and is not a  
34 reserved MSTID, those frames will be supported by the IST.

35 A Bridge supporting PBB-TE can assign specific VID values to ESPs but can also support any of the  
36 spanning tree protocols. This is achieved by allocating the VIDs associated with the PBB-TE ESPs to a  
37 special MSTID, the TE-MSTID.

38 An SPT Bridge can allocate any given VLAN to the CIST, or to the reserved MSTIs, as well as supporting  
39 SPB for other VLANs within an SPT Region. The assignment of VLANs and VIDs to MSTIs is subject to  
40 similar considerations and constraints as for MST Bridges. In addition to the Base VID used to identify

1 frames for the VLAN when transmitted on the CST outside the region, each VLAN supported by SPBV uses  
2 a number of dynamically allocated shortest path VIDs (SPVIDs), one for each SPT Bridge participating in  
3 the VLAN within the region.

4 The network administrator allocates enough SPVIDs for SPBV to avoid unintentionally excluding Bridges  
5 from the topology. The details of SPVID allocation, including mitigation of the consequences of not  
6 allocating enough SPVIDs, are specified in 27.10.

7 Administratively, by not translating from Base VID to SPVID, an SPBV VLAN can be forced to the IST.  
8 When there is no shortage of SPVIDs and the MST Configuration Identifiers (MCIDs) match but the Base  
9 VID algorithms disagree the algorithm defaults to the spanning tree. This behavior allows SPBV to change  
10 the Equal Cost Tree (ECT) Algorithms.

11 Dynamic SPVID allocation is supported by ISIS-SPB and allows the addition of Bridges to existing SPT  
12 Regions without disruptive configuration changes, as well as allowing supporting auto configuration of  
13 SPB in simple networks where all user data is assigned to a VLAN identified by the default PVID of 1  
14 (Table 9-2). However, prior to SPVID allocation, all Bridges in an SPT Region have to agree which VLANs  
15 are to be shortest path bridged, and which SPT Set (ECT Algorithm) is to be used for each of those VLANs.  
16 By default, all VLANs whose Base VID is allocated to MSTID 0xFFD will be supported by SPBV using the  
17 SPB default ECT Algorithm. The SPT configuration information can also specify that frames for SPBV and  
18 SPBM be supported by another specified SPB ECT Algorithm as specified by configuration (12.25.4,  
19 Table 28-1).

20 NOTE—The use of MSTIDs to support allocation of Base VIDs to SPB allows the per VLAN components of the  
21 necessary information to be conveyed in the MST Configuration Digest, thus avoiding any need for a separate digest.  
22 However, the digest is not specific about how the VIDs are mapped to specific SPTs, just that they are allocated to SPBV,  
23 SPBM, or SPVIDs.

## 24 8.9.1 MST Configuration Table

25 The MST Configuration Table specifies an MSTID for each possible VID.

26 In an MST Bridge, each MSTID identifies the MSTI to which the VID is allocated and an MSTID of zero  
27 identifies the CIST.

28 The combination of the VID to FID allocations (8.8.8) and the FID to MSTID allocations (8.9.3) define a  
29 mapping of VIDs to MSTIDs summarized in the MST Configuration Table (8.9.1).

## 30 8.9.2 MST configuration identification

31 For two or more MST Bridges to be members of the same MST Region (3.174), it is necessary for those  
32 Bridges to support the same MST Region configuration and to be interconnected only by means of LANs,  
33 with all intervening Bridges being members of the region or being transparent to the BPDUs of the members  
34 of the region. Two MST Region configurations are considered to be the same if the correspondence between  
35 VIDs and MSTIDs is identical in both configurations and they use the same information to identify the  
36 configuration, including the same Configuration Name.

37 NOTE 1—If two adjacent MST Bridges consider themselves to be in the same MST Region despite having different  
38 mappings of VIDs to MSTIDs, then the possibility exists of undetectable loops arising within the MST Region.

39 In order to ensure that adjacent MST Bridges are able to determine whether they are part of the same MST  
40 Region, the MST BPDU supports the communication of an MCID (13.8).

41 NOTE 2—As the MCID is smaller than the mapping information that it summarizes, there is a small but finite  
42 possibility that two MST Bridges will assume that they have the same MST Region Configuration when this is not  
43 actually the case. However, given the size of the identifier, this standard assumes that this possibility is sufficiently small  
44 that it can safely be ignored. Appropriate use of the Configuration Name and Revision Level portions of the identifier  
45 can remove the possibility of an accidental match between MCIDs that are derived from different configurations within  
46 a single administrative domain (see 13.8).

### 1 8.9.3 FID to MSTI Allocation Table

2 The FID to MSTI Allocation Table defines, for all FIDs that the Bridge supports, the MSTID to which the  
3 FID is allocated.

- 4 a) The IST is identified by the reserved MSTID value 0.
- 5 b) The use of PBB-TE is identified by the reserved MSTID value TE-MSTID (0xFFE).
- 6 c) Each MSTID in the MSTI List identifies an MSTI.
  - 7 The reserved MSTID values 0 and TE-MSTID, SPBV-MSTID, SPBM-MSTID and
  - 8 SPVID-Pool-MSTID are never used in the MSTI List.
- 9 d) The following MSTID values identify the method used to support the VLANs identified by the Base  
10 VIDs allocated to those MSTIDs:
  - 11 1) 0xFFC—SPBM-MSTID.
  - 12 2) 0xFFD—SPBV-MSTID.
  - 13 3) 0xFFF—SPVID-Pool-MSTID: Allocated to FIDs that are not used to filter frames including
  - 14 SPVIDs for SPBV.

15 NOTE—MSTIDs that are present in the MSTI List (12.12) identify spanning tree instances supported by MSTP.  
16 MSTIDs identify (indirectly) VLANs that are supported by SPB.

### 17 8.9.4 SPT Configuration Identification

18 For two or more SPT Bridges to be members of the same SPT Region (Clause 3), it is necessary for those  
19 Bridges to support the same SPT Region configuration and to be interconnected only by means of LANs,  
20 with all intervening Bridges being members of the region or being transparent to the BPDUs and/or SPB  
21 Hello PDUs of the members of the region. This requirement is identical to that for MST Regions: a given  
22 SPT Region can support selected MSTIs as well as SPTs. MCIDs only specify the VIDs that are configured.

23 Two SPT Region configurations are considered to be the same if they have the same MST Region  
24 configuration or alternate MST Region configuration, they agree on the VLANs that are to be shortest path  
25 bridged and they use the same ISIS-SPB. Furthermore by using ISIS-SPB they agree on which SPT Set is to  
26 be used for each of these VLANs (Clause 27).

27 The MST Region information captures the VIDs for SPB but it does not capture the operational state of the  
28 VIDs for SPB. This allows allocation of SPVIDs and upgrade of multiple ECT Algorithms without change  
29 to the MST Region when sufficient pre-allocation of VIDs has been configured. However, in situations  
30 where the network grows beyond the current allocation of VIDs, the options are to temporarily create a  
31 region boundary as the new configuration is deployed or allow in-service upgrades by making changes that  
32 are compatible with the current MST region configuration.

33 To support in-service upgrade from one set of VID to MSTID allocations to another, SPT Bridges support a  
34 second (auxiliary) MCID (28.9). Two such Bridges consider themselves to be in the same MST Region  
35 provided that at least one of their MCIDs matches with one of their neighbors. In this way, a new  
36 configuration can be incrementally introduced without time constraints, and put into operation, all the while  
37 maintaining operation as a single SPT Region.

### 38 8.10 Spanning Tree Protocol Entity

39 Figure 8-6 illustrates the operation of the Spanning Tree Protocol Entity, including the reception and  
40 transmission of frames containing BPDUs, the modification of the state information associated with  
41 individual Bridge Ports, and the notification of the FDB of changes in active topology.

1 A given MST Bridge is not required to support all of the spanning trees that exist within the MST bridged  
2 network. That is, the number of spanning trees operated by the Spanning Tree Protocol Entity in a given  
3 Bridge may be different from the number operated by that in another Bridge. However, as a direct  
4 consequence of the conditions stated in 8.9.2, the number of instances of the spanning tree protocol operated  
5 by a given MST Bridge is the same for all Bridges that are members of a given MST Region.

6 The ISIS-SPB Entity comprises an instance of IS-IS with SPB extensions as specified in Clause 28. The  
7 ISIS-SPB Entity is described, for the purposes of management, as distinct from the Spanning Tree Protocol  
8 Entity. Nonetheless, the ISIS-SPB and Spanning Tree Protocol Entities that calculate active topologies for  
9 the same Bridge Port use the same ISS SAP (ISS-SAP, 8.5, 27.2), and the same individual MAC address.  
10 However, ISIS-SPB uses one of the group MAC addresses in Table 8-15 and does not use the group MAC  
11 addresses used by the spanning tree protocol specified in Table 8-1. The ISIS-SPB Entity uses the state  
12 machines and state machine variables supported by the Spanning Tree Protocol Entity (Clause 27, 13.6) and  
13 calculates the Agreement Digest that the Spanning Tree Protocol Entity transmits in SPT BPDUs and/or  
14 SPB Hello PDUs.

## 15 **8.11 MRP entities**

16 The MRP entities operate the algorithms and protocols associated with the MRP Applications supported by  
17 the Bridge and consist of the set of MRP Participants for those MRP Applications (Clause 10).

18 Figure 8-7 illustrates the operation of an MRP entity, including the reception and transmission of frames  
19 containing MRPDUs, the use of control information contained in the FDB, and the notification of the FDB  
20 of changes in filtering information.

## 21 **8.12 Bridge Management Entity**

22 Remote management capabilities (as opposed to management via a console or other device attached directly  
23 to a Bridge) are modeled as performed by a Bridge Management Entity supported by a protocol stack as  
24 described in 8.13.7. To facilitate interoperable remote management, the Bridge Management Entity should  
25 use either the SMIPv2 MIB modules specified in Clause 17 with SNMP or the YANG modules specified in  
26 Clause 48 with a network configuration protocol, e.g., NETCONF, RESTCONF.

## 27 **8.13 Addressing**

28 All MAC Entities communicating across a bridged network use 48-bit MAC addresses (IEEE Std 802).  
29 These can be universally administered addresses or a combination of universally administered and locally  
30 administered addresses.

### 31 **8.13.1 End stations**

32 Frames transmitted between end stations using the MAC Service carry the MAC address of the source and  
33 destination peer end stations in the source and destination address fields of the frames, respectively. The  
34 address, or other means of identification, of a Bridge is not carried in frames transmitted between peer users  
35 for the purpose of frame relay in the network.

36 In the absence of explicit filters configured via management as Static Filtering Entries, or via MMRP as  
37 MAC Address Registration Entries (8.8, Clause 10), frames with a destination address of the broadcast  
38 address or any other group address that is not a Reserved Address (8.6.3) are assigned by a VLAN Bridge  
39 component a VID and relayed throughout the VLAN identified by that VID.

### 8.13.2 Bridge Ports

A separate individual MAC address is associated with each instance of the MAC Service provided to an LLC Entity. That MAC address is used as the source address of frames transmitted by the LLC Entity.

Media access method-specific procedures can require the transmission and reception of frames that use an individual MAC address associated with the Bridge Port, but neither originate from nor are delivered to a MAC Service user. Where an individual MAC address is associated with the provision of an instance of the MAC Service by the Port, that address can be used as the source and/or the destination address of such frames, unless the specification of the media access method-specific procedures requires otherwise.

### 8.13.3 Use of LLC by Spanning Tree Protocol Entities

Spanning Tree Protocol Entities use the DL\_UNITDATA.request and DL\_UNITDATA.indication primitives (ISO/IEC 8802-2) provided by individual LLC Entities associated with each Bridge Port to transmit and receive BPDUs (Clause 14). The source\_address and destination\_address parameters of the DL\_UNITDATA.request shall both denote the standard LLC address assigned to the Bridge spanning tree protocol (Table 8-15). Each DL\_UNITDATA request primitive gives rise to the transmission of an LLC UI command PDU, which conveys the BPDU in its information field.<sup>25</sup>

**Table 8-15—Standard LLC address assignment**

| Assignment                                                                                                                                                                                                                                                                                                                | Value    |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| Bridge spanning tree protocol                                                                                                                                                                                                                                                                                             | 01000010 |
| IS-IS PDUs                                                                                                                                                                                                                                                                                                                | 11111110 |
| NOTE—Code Representation: The least significant bit (LSB) of the value shown is the right-most. The bits increase in significance from right to left. It should be noted that the code representation used here has been chosen in order to maintain consistency with the representation used elsewhere in this standard. |          |

A Protocol Identifier field, present in all BPDUs (Clause 14), serves to identify different protocols supported within the scope of the LLC address assignment. Further values of this field are reserved for future standardization. A Spanning Tree Protocol Entity that receives a BPDU with an unknown PID shall discard that PDU.

IS-IS PDUs are LLC (encoded with a DSAP and SSAP of 0xFE (section 7.5 of ISO/IEC 10589:2002), then a single byte indicating Control 0x03 (see ISO/IEC/IEEE 8802-2) immediately followed by a IS-IS PDU starting with an Interdomain Routing Protocol Discriminator equal to 0x83 (section 5.3 of ISO/IEC 9577:1999).

### 8.13.4 Reserved MAC addresses

Any frame with a destination address that is a reserved MAC address shall not be forwarded by a Bridge. Reserved MAC addresses for MAC Bridge components and C-VLAN components, for S-VLAN components, and for TPMR components are specified in Table 8-1, Table 8-2, and Table 8-3, respectively. These group MAC addresses are reserved for assignment to standard protocols, according to the criteria for such assignments.<sup>26</sup>

<sup>25</sup> Administration of LLC address assignments is the responsibility of the IEEE Registration Authority (IEEE RA). A full list of standard LLC address assignments, and the criteria for assignment, can be found on the IEEE RA Website at <https://standards.ieee.org/regauth/index.html>.

### 1 8.13.5 Group MAC addresses for spanning tree entity

2 A Spanning Tree Protocol Entity uses an instance of the MAC Service provided by each of the Bridge's  
3 Ports to transmit frames addressed to the Spanning Tree Protocol Entities of all the other Bridges attached to  
4 the same LAN as that Port.

#### 5 8.13.5.1 Group MAC addresses for spanning tree protocols

6 Spanning tree protocols use a reserved address for peer to peer communication between entities of the same  
7 type.

8 A universally administered standard group MAC address, known as the Bridge Group Address, has been  
9 assigned (Table 8-1) for use by C-VLAN components for this purpose.

10 It is essential to the operation of the spanning tree protocols that frames with this destination address both  
11 reach all peer protocol entities attached to the same LAN and do not reach protocol entities attached to other  
12 LANs. The Bridge Group Address is therefore included in the block of MAC Bridge and C-VLAN  
13 components reserved MAC addresses and is always filtered by Customer Bridges and C-VLAN components  
14 of Provider Edge Bridges (8.6.3).

15 As a network of Provider Bridges needs to appear to attached Customer Bridges as if it was a single LAN,  
16 frames addressed to the Bridge Group Address are forwarded by S-VLAN components. Provider Bridges  
17 also use a spanning tree protocol to provide one or more loop-free active topologies, so a distinct universally  
18 administered standard group MAC address, the Provider Bridge Group Address, which can be confined to  
19 the LANs that their Bridge Ports attach, has been assigned (Table 8-2). The Provider Bridge Group Address  
20 is included in both the C-VLAN component and the S-VLAN component reserved MAC addresses and is  
21 always filtered by all Bridges (8.6.3).

22 The source MAC address field of frames transmitted by Spanning Tree Protocol Entities contains the  
23 individual MAC address for the Bridge Port used to transmit the frame.

#### 24 8.13.5.2 Group MAC addresses for SPB

25 ISIS-SPB use a group address for ISIS-SPB peer to peer communication. ISIS-SPB is configured to use only  
26 one of the addresses listed in Table 8-16. All other addresses in this table will be ignored by IS-IS and will  
27 not be filtered by the MAC Relay. The choice of which address is used depends on the environment.

28 Table 8-16 lists the various addresses that may be configured for ISIS-SPB. Table 8-17 lists the deployment  
29 environments for SPB. The usage of ISIS-SPB is described in Clause 28. These addresses are from a  
30 reserved address space. These addresses have the property that:

- 31 a) Where a given address in the set is used by a Bridge component to support ISIS-SPB, frames  
32 destined for that address shall not be forwarded by that Bridge component; i.e., a Static Filtering  
33 Entry for that address is maintained for that group MAC address in order to prevent the forwarding  
34 of frames destined for that address.
- 35 b) Where a given address in the set is not used by a Bridge component to support ISIS-SPB, frames  
36 destined for that address received on any Port that is part of a given active topology shall be  
37 forwarded by that Bridge component on all other Ports that are part of that active topology.

---

<sup>26</sup> Administration of standard group MAC address assignments is the responsibility of the IEEE Registration Authority (IEEE RA). A full list of standard group MAC address assignments, and the criteria for assignment, can be found on the IEEE RA Website at <https://standards.ieee.org/regauth/index.html>.

**Table 8-16—ISIS-SPB reserved addresses**

| Assignment                               | Value                          |
|------------------------------------------|--------------------------------|
| All Level 1 Intermediate Systems         | 01-80-C2-00-00-14 <sup>a</sup> |
| All Level 2 Intermediate Systems         | 01-80-C2-00-00-15 <sup>a</sup> |
| All Intermediate Systems                 | 09-00-2B-00-00-05 <sup>a</sup> |
| All Provider Bridge Intermediate Systems | 01-80-C2-00-00-2E              |
| All Customer Bridge Intermediate Systems | 01-80-C2-00-00-2F              |

<sup>a</sup> The first three addresses are existing IS-IS addresses (Table 9 of ISO/IEC 10589:2002).

<sup>1</sup> An SPT Bridge, whether it is running SPBV, or SPBM, or both, uses a single group MAC address.

<sup>2</sup> Table 8-17 provides the reference for the possible environments.

<sup>3</sup> In Provider Bridge only environments, for SPBV the address should be the allocated All Provider Bridge Intermediate Systems address.

<sup>5</sup> In Customer Bridge only environments where only SPBV is supported the address should be the All Customer Bridge Intermediate Systems address.

<sup>7</sup> In SPBM or SPBV deployments where only Provider backbone components are configured the use of addresses is flexible as indicated in Table 8-17. To allow peering with other systems capable of using IS-IS for IP, the existing IS-IS addresses may be used.

**Table 8-17—ISIS-SPB Recommended Address Usage**

| Network Deployment                                   | Level 1           | Level 2           | All Levels                             |
|------------------------------------------------------|-------------------|-------------------|----------------------------------------|
| SPT Bridges Peering with other IS-IS-capable systems | 01-80-C2-00-00-14 | 01-80-C2-00-00-15 | 09-00-2B-00-00-05                      |
| SPT Bridges PBBs only                                | 01-80-C2-00-00-14 | 01-80-C2-00-00-15 | 09-00-2B-00-00-05 or 01-80-C2-00-00-2E |
| SPT Bridges in SPBV mode for S-VLANs Provider Bridge | 01-80-C2-00-00-2E |                   |                                        |
| SPT Bridges in SPBV mode for C-VLANs Customer Bridge | 01-80-C2-00-00-2F |                   |                                        |

### 10 8.13.6 Group MAC addresses for MRP Applications

<sup>11</sup> An MRP Entity that supports a given MRP Application transmits frames addressed to all other MRP Entities that implement the same MRP Application. The peers of each such entity bound a region of the network that contains no peers, commonly a single LAN in the case where all Bridges attached to the LAN implement the application.

<sup>15</sup> Universally administered standard group MAC addresses are assigned to MRP applications, from a set of universally administered group MAC addresses, known as MRP application addresses, as shown in Table 10-1; these addresses are for use by VLAN components that support the MRP applications concerned.

1 FDB entries for each MRP application address assigned to an application that is supported by a VLAN  
2 component should be configured in the FDB so frames for that application are confined to the peer region,  
3 while addresses for applications that are not supported should not be included. These group MAC addresses  
4 are reserved for assignment to standard protocols, according to the criteria for such assignments (see 8.13.4).

5 When an MRP Application operates among both Customer and Provider Bridges, a distinct universally  
6 administered group MAC address is assigned for use by both C-VLAN components and S-VLAN  
7 components. MMRP is such an application, and uses the Customer and Provider Bridge MMRP Address  
8 assigned in Table 10-1. When an MRP application operates separately among Customer Bridges or among  
9 Provider Bridges, different distinct universally administered group MAC addresses are assigned for use by  
10 C-VLAN components and for use by S-VLAN components. MVRP is such an application; C-VLAN  
11 components use the Customer Bridge MVRP address assigned in Table 10-1, while S-VLAN components  
12 use the Provider Bridge MVRP address assigned in Table 8-1. Note that because the Provider Bridge MVRP  
13 address is selected from the set of addresses that appear in Table 8-1 but not Table 8-2, it will always be  
14 filtered by C-VLAN components. Although the Provider Bridge MVRP Address is not selected from  
15 Table 10-1, an S-VLAN component should treat this as an MRP Application Address and configure an FDB  
16 entry to filter frames with this address.

17 An MRP Entity that supports a given MRP Application uses the individual MAC address for the Bridge Port  
18 through which the PDU is transmitted (8.13.2) as the source\_address field of MAC frames conveying  
19 MRPDUs for that application.

### 20 8.13.7 Bridge Management Entities

21 Network configuration and management protocols typically use IP as a network layer protocol. SNMP can  
22 also be supported directly over an IEEE 802 LAN, as specified in IETF RFC 4789. The management  
23 protocol stack and address used shall be supported by a single LLC Entity attached to a Bridge Port. The  
24 Port should be a Management Port for the Bridge, as described in 8.3 and Figure 8-8, but may be a Port  
25 attached to a LAN, as described in 8.13.9, Figure 8-25, and Figure 8-26.

26 NOTE—A universally administered standard group MAC address, known as the All LANs Bridge Management Group  
27 Address with a value of 01-80-C2-00-00-10 was assigned and recorded in the 1990 Edition of this standard. That address  
28 should not be used for Bridge management or for any other purpose.

### 29 8.13.8 Unique identification of a Bridge

30 A unique EUI-48 Universally Administered MAC address, termed the Bridge Address, shall be assigned to  
31 each Bridge. The Bridge Address may be the individual MAC address of a Bridge Port; in which case, use of  
32 the address of the lowest numbered Bridge Port (Port 1) is recommended.

33 NOTE—RSTP (Clause 13) and MSTP (Clause 13) require that a single unique identifier be associated with each Bridge.  
34 That identifier is derived from the Bridge Address as specified in 14.2.5.

### 35 8.13.9 Points of attachment and connectivity for Higher Layer Entities

36 The Higher Layer Entities in a Bridge, such as the Spanning Tree Protocol Entity (8.10), MRP entities  
37 (8.11), the ISIS-SPB Entity (Clause 28), and Bridge Management (8.12), are modeled as attaching directly  
38 to one or more individual LANs connected by the Bridge's Ports, in the same way that any distinct end  
39 station is attached to the network. While these entities and the relay function of the Bridge use the same  
40 individual MAC entities to transmit and receive frames, the addressing and connectivity to and from these  
41 entities is the same as if they were attached as separate end stations "outside" the Port or Ports where they  
42 are actually attached. Figure 8-23 is functionally equivalent to Figure 8-2 but illustrates this logical  
43 separation between the points of attachment used by the Higher Layer Entities and those used by the MAC  
44 Relay Entity.

**Figure 8-23—Logical points of attachment of the Higher Layer and Relay Entities**

1 Figure 8-24 depicts the information used to control the forwarding of frames from one Bridge Port to  
2 another (the Port States and the content of the FDB) as a series of switches (shown in the open, disconnected  
3 state) inserted in the path provided by the MAC Relay Entity. For the Bridge to forward a given frame  
4 between two Ports, all three switches must be in the closed state. While showing Higher Layer Entities  
5 sharing the point of attachment to each LAN used by each Bridge Port to forward frames, this figure further  
6 illustrates a point made by Figure 8-23. Controls placed in the forwarding path have no effect on the ability  
7 of a Higher Layer Entity to transmit and receive frames to or from a given LAN using a direct attachment to  
8 that LAN (e.g., from entity A to LAN A); they only affect the path taken by any indirect transmission or  
9 reception (e.g., from entity A to or from LAN B).

**Figure 8-24—Effect of control information on the forwarding path**

10 The functions provided by Higher Layer Entities can be categorized as requiring either:

- 11 a) A single point of attachment to the Bridged Network, providing connectivity to stations attached to  
12 the network at any point (subject to administrative control), as does Bridge Management; or
- 13 b) A distinct point of attachment to each individual LAN attached by a Bridge Port, providing  
14 connectivity only to peer entities connected directly to that LAN, as do the Spanning Tree Protocol  
15 Entity and the MRP entity.

1 In the latter case, it is essential that the function associate each received and transmitted frame with a point  
2 of attachment. Frames transmitted or received via one point of attachment are not to be relayed to and from  
3 other Ports and attached LANs, so the MAC addresses (8.13.4) used to reach these functions are  
4 permanently configured in the FDB.

5 NOTE 1—Addresses used to reach functions with distinct points of attachment are generally group MAC addresses.

6 NOTE 2—A single higher layer entity can incorporate both a function requiring a single point of attachment and a  
7 function requiring distinct points of attachment. The two functions are reached using different MAC addresses.

8 Figure 8-25 illustrates forwarding path connectivity for frames destined for Higher Layer Entities requiring  
9 per-Port points of attachment. Configuration of the Permanent Database in all Bridges to prevent relay of  
10 frames addressed to these entities means that they receive frames only via their direct points of attachment  
11 (i.e., from LAN A to entity A, and from LAN B to entity B), regardless of Port states.

**Figure 8-25—Per-Port points of attachment**

12 Figure 8-26 and Figure 8-27 illustrate forwarding path connectivity for frames destined for a Higher Layer  
13 Entity requiring a single point of attachment. In both figures, the FDB permits relay of frames, as do the Port  
14 states in Figure 8-26 where frames received from LAN B are relayed by the Bridge to the entity and to  
15 LAN A.

**Figure 8-26—Single point of attachment—relay permitted**

16 In Figure 8-27, frames received from LAN A are received by the entity directly, but frames received from  
17 LAN B are not relayed by the Bridge and will only be received by the entity if another forwarding path is  
18 provided between LANs A and B. If the Discarding Port state shown resulted from spanning tree  
19 computation (and not from disabling the Administrative Bridge Port State), such a path will exist via one or  
20 more Bridges. If there is no active spanning tree path from B to A, the network has partitioned into two  
21 separate Bridged Networks, and the Higher Layer Entity shown is reachable only via LAN A.

**Figure 8-27—Single point of attachment—relay not permitted**

1 Specific Higher Layer Entities can take notice of the Administrative Bridge Port State, as required by their  
2 specification. The Spanning Tree Protocol Entity is one such example—BPDUs are never transmitted or  
3 received on Ports with an Administrative Bridge Port State of Disabled.

4 If a Bridge Port's MAC Entity is not operational, a Higher Layer Entity directly attached at the Port will not  
5 be reachable, as Figure 8-28 illustrates. The Spanning Tree Protocol Entity ensures that the Port State is  
6 Discarding if the MAC\_Operational (IEEE Std 802.1AC) is FALSE even if the Administrative Bridge Port  
7 State is Enabled.

**Figure 8-28—Effect of Port State**

8 Port-based network access control (IEEE Std 802.1X) and MAC Security (IEEE Std 802.1AE) can be used  
9 to provide a further level of control over the connectivity provided by a Bridge Port to the MAC Relay  
10 Entity and the Higher Layer Entities within a Bridge. Port-based network access control creates two distinct  
11 SAPs for the LAN: the Controlled Port and the Uncontrolled Port. MAC\_Operational is TRUE for the  
12 Controlled Port only when criteria for authentication, authorization, and secure connectivity have been  
13 satisfied; while MAC\_Operational for the Uncontrolled Port is the same as that for direct access to the LAN.  
14 Both the Spanning Tree Protocol Entity and the MAC Relay Entity attach to the Controlled Port, thus  
15 ensuring that the connectivity seen by each of those entities is the same. If MAC\_Operational for the  
16 Controlled Port is FALSE, the Spanning Tree Protocol Entity will ensure that both forwarding and learning  
17 (8.4) will be FALSE for that Port (i.e., the Port State will be Discarding). The Uncontrolled Port supports the  
18 operation of protocol entities such as the Port Access Entity (PAE) specified by IEEE Std 802.1X, that  
19 participate in the authentication exchanges necessary before Controlled Port connectivity is permitted or that  
20 distribute other unsecured information.

**Figure 8-29—Controlled and Uncontrolled Port connectivity**

1 Figure 8-29 illustrates the connectivity provided to Higher Layer Entities if the MAC entity is physically  
2 capable of transmitting and receiving frames but MAC\_Operational is FALSE for the Controlled Port.  
3 Higher Layer Entity A and the PAE are connected to an Uncontrolled Port and can transmit and receive  
4 frames using the MAC entity associated with the Port for LAN A, which Higher Layer Entity B cannot.  
5 None of the three entities can transmit or receive to or from LAN B.

6 NOTE 3—Reference should be made to IEEE Std 802.1X-2010 or later.

7 NOTE 4—The administrative and operational state values associated with the MAC, the Port's authorization state, and  
8 the Bridge Port State equate to the ifAdminStatus and ifOperStatus parameters associated with the corresponding  
9 interface definitions; see IETF RFC 2863.

10

#### 11 8.13.10 VLAN attachment and connectivity for Higher Layer Entities

12 In VLAN Bridges, two more switches appear in the forwarding path, corresponding to the actions taken by  
13 the Forwarding Process (8.6) in applying the ingress and egress rules (8.6.2 and 8.6.4), as illustrated in  
14 Figure 8-30.

**Figure 8-30—Ingress/egress control information in the forwarding path**

15 As with Port state information, the configuration of the ingress and egress rules does not affect the reception  
16 of frames received on the same LAN as a Higher Layer Entity's point of attachment. For example, the  
17 reception of a frame by Higher Layer Entity A that was transmitted on LAN A is unaffected by the ingress or

egress configuration of either Port. However, for Higher Layer Entities that require only a single point of attachment, the ingress and egress configuration affects the forwarding path. For example, frames destined for Higher Layer Entity A that are transmitted on LAN B would be subjected to the ingress rules that apply to Port B and the egress rules that apply to Port A.

The decision about whether frames transmitted by Higher Layer Entities are VLAN-tagged or untagged depends on the Higher Layer Entity concerned and the connectivity that it requires:

- a) Spanning Tree Bridge Protocol Data Units (ST BPDUs) transmitted by the Spanning Tree Protocol Entity are not forwarded by Bridges and must be visible to all other Spanning Tree Protocol Entities attached to the same LAN. Such frames shall be transmitted untagged.  
NOTE—Any BPDUs or MVRPDUs that carry a tag header are not recognized as well-formed BPDUs or MVRPDUs and are not forwarded by the Bridge.
- b) The definition of the MVRP application (11.2.3) calls for all MVRP frames to be transmitted untagged for similar reasons.
- c) The definition of the MMRP application (Clause 10) calls for all MMRP frames originating from VLAN devices to be transmitted VLAN-tagged, in order for the VID in the tag to be used to identify the VLAN context in which the registration applies.
- d) It may be necessary for PDUs transmitted for Bridge Management (8.12) to be VLAN-tagged in order to achieve the necessary connectivity for management in a Virtual Bridged Network. This is normally achieved by routing a packet containing the PDU to the routed subnet associated with the VLAN. Transmission of the packet through the router interface to that VLAN and subsequent forwarding of the resulting frame by VLAN Bridges ensures that the frame is correctly VLAN-tagged, as required.

### 8.13.11 CFM entities

CFM entities reside in shims. The entities in a CFM shim inspect every frame that passes through either of the shim's two SAPs, and decides whether to pass that frame through to the other SAP, process it, or both. The decision whether pass it through is not dependent on the destination\_address, but the decision whether to process the frame is dependent on the destination\_address (see Clause 19). A CFM entity shall discard any frame, directed to it by reason of its VID and MD Level, whose destination\_address parameter does not correspond to a MAC address recognized by that CFM entity.

Any given CFM entity is configured to recognize one or more individual MAC addresses, and one or more group MAC addresses, in received frames, and to use one or more individual MAC address or one or more group MAC addresses for transmitted frames. The individual MAC address is unique, within a bridged network, to a specific Bridge, though not necessarily to a single Bridge Port (J.6). For VLAN-based and backbone service instances, the group MAC addresses are selected from Table 8-18 and Table 8-19 according to the MD Level and OpCode fields in the CFM PDU header. For these service instances, Loopback Messages (LBMs, 20.2), Loopback Replies (LBRs, 20.2), and Linktrace Replies (LTRs, 20.3) are carried in unicast frames while Continuity Check Messages (CCMs, 20.1) use addresses from Table 8-18, and Linktrace Messages (LTMs, 20.3) use addresses from Table 8-19. In the case of TESI, all CFM messages use the individual MAC addresses or the group MAC addresses that are associated with the monitored service (20.1, 20.2, 20.3).

NOTE—The group destination MAC addresses in Table 8-18 are there primarily to make it possible for Bridges built prior to this standard to process CFM. This restriction on the choice of group destination MAC addresses to be used on a CFM PDU is relaxed for ESP-VIDs. See 22.8.

**Table 8-18—CCM group destination MAC addresses**

| 01-80-C2-00-00-3y |                       |
|-------------------|-----------------------|
| MD Level of CCM   | Four address bits “y” |
| 7                 | 7                     |
| 6                 | 6                     |
| 5                 | 5                     |
| 4                 | 4                     |
| 3                 | 3                     |
| 2                 | 2                     |
| 1                 | 1                     |
| 0                 | 0                     |

**Table 8-19—LTM group destination MAC addresses**

| 01-80-C2-00-00-3y |                       |
|-------------------|-----------------------|
| MD Level of LTM   | Four address bits “y” |
| 7                 | F                     |
| 6                 | E                     |
| 5                 | D                     |
| 4                 | C                     |
| 3                 | B                     |
| 2                 | A                     |
| 1                 | 9                     |
| 0                 | 8                     |

## 9. Tagged frame format

This clause specifies the format of the tags added to and removed from user data frames by the tag encoding and decoding functions that support the EISS (6.8, 6.9, 6.10, 6.11) and the Backbone Service Instance Multiplex Entity (6.18). It:

- a) Reviews the purpose of tagging, and the functionality provided.
- b) Specifies generic rules for the representation of tag fields and their encoding in the octets of an MSDU.
- c) Specifies a general tag format, comprising a Tag Protocol Identifier (TPID), Tag Control Information (TCI), with additional information as signaled in the TCI.
- d) Specifies the format of the TPID for each IEEE 802 media access control method.
- e) Describes the types of tags that can be used, including the following:
  - 1) A C-TAG used at ports on a C-VLAN component
  - 2) An S-TAG used at ports on an S-VLAN component
  - 3) An I-TAG used at PIPs on an I-component and CBPs on a B-component
- f) Documents the allocation of EtherType values to identify the types of tag specified in this standard.
- g) Specifies the format of the TCI and additional information for each tag type.

Further analysis of the frame formats and the format translations that can occur when frames are tagged or untagged when relayed between different media access control methods can be found in Annex G.

### 9.1 Purpose of tagging

Tagging a frame with a VLAN tag:

- a) Allows a VID to be conveyed, facilitating consistent VLAN classification of the frame throughout the network and enabling segregation of frames assigned to different VIDs.
- b) Allows priority (IEEE Std 802.1AC, 6.8) to be conveyed with the frame when using IEEE 802 LAN media access control methods that provide no inherent capability to signal priority.

### 9.2 Representation and encoding of tag fields

In this subclause, octets are numbered starting from 1 and increasing in the order in which they are encoded in the sequence of octets that constitute an MSDU.

Where bits in consecutive octets are used to encode a binary number in a single field, the lower octet number encodes the more significant bits of the field, and the LSB of the lower octet number and the most significant bit (MSB) of the next octet both form part of the field.

Where the value of a field comprising a sequence of octets is represented as a sequence of two-digit hexadecimal values separated by hyphens (e.g., A1-5B-03), the leftmost hexadecimal value (A1 in this example) appears in the lowest numbered octet of the field and the rightmost hexadecimal value (03 in this example) appears in the highest numbered octet of the field.

The bits in an octet are numbered from 1 to 8, where 1 is the LSB.

When the terms set and reset are used in the text to indicate the values of single-bit fields, set is encoded as a binary 1 and reset as a binary 0 (zero).

- 1 When the encoding of a field or a number of fields is represented using a diagram,
- 2 a) Octets are shown with the lowest numbered octet nearest the top of the page, the octet numbering  
3 increasing from the top to bottom; or
  - 4 b) Octets are shown with the lowest numbered octet nearest the left of the page, the octet numbering  
5 increasing from left to right;
  - 6 c) Within an octet, bits are shown with bit 8 to the left and bit 1 to the right.

### 7 9.3 Tag format

8 Each tag comprises the following sequential information elements:

- 9 a) A Tag Protocol Identifier (TPID) (9.4)
- 10 b) Tag Control Information (TCI) that is dependent on the tag type (9.5, 9.6)
- 11 c) Additional information, if and as required by the tag type and TCI

12 The tag encoding function supports each EISS (6.8) instance by using an instance of the ISS to transmit and  
13 receive frames and encodes the above information in the first and subsequent octets of the MSDU that will  
14 accompany an ISS M\_UNITDATA.request, immediately prior to encoding the sequence of octets that  
15 constitute the corresponding EISS M\_UNITDATA.request's MSDU. On reception the tag decoding function  
16 is selected by the TPID and decodes the TCI and additional information octets (if present) prior to issuing an  
17 EISS M\_UNITDATA.indication with an MSDU that comprises the subsequent octets.

### 18 9.4 TPID formats

19 The TPID includes an EtherType value that is used to identify the frame as a tagged frame and to select the  
20 correct tag decoding functions. Such an EtherType is known as the Tag EtherType. The TPID is EtherType  
21 encoded, i.e., is two octets in length and contains only the assigned EtherType value.

### 22 9.5 Tag Protocol identification

23 The following types of tags are specified:

- 24 a) A C-TAG, for general use by C-VLAN Bridges (5.9) and C-VLAN components of Provider Edge  
25 Bridges (5.10.1).
- 26 b) An S-TAG, reserved for use by S-VLAN Bridges (5.10), the S-VLAN component of Provider Edge  
27 Bridges (5.10.1) and BEBs (5.12), and C-VLAN Bridges signaling priority to a PBN or a PBBN  
28 (6.13).
- 29 c) An I-TAG, reserved for use by BEBs (5.7, 5.8, 5.12).

30 NOTE—The S-TAG is identical to the B-TAG (see 25.2).

31 A distinct EtherType has been allocated (Table 9-1) for use in the TPID field (9.4) of each tag type so they  
32 can be distinguished from each other, and from other protocols.

**Table 9-1—IEEE 802.1Q™ EtherType allocations**

| Tag Type                              | Name                                                                 | Value |
|---------------------------------------|----------------------------------------------------------------------|-------|
| Customer VLAN Tag                     | IEEE 802.1Q Tag Protocol EtherType (802.1QTagType)                   | 81-00 |
| Service VLAN Tag or Backbone VLAN Tag | IEEE 802.1Q Service Tag EtherType (802.1QSTagType)                   | 88-A8 |
| Backbone Service Instance Tag         | IEEE 802.1Q Backbone Service Instance Tag EtherType (802.1QITagType) | 88-E7 |

## 9.6 VLAN Tag Control Information (TCI)

The VLAN TCI field (Figure 9-1) is two octets in length and encodes the vlan\_identifier, drop\_eligible, and priority parameters of the corresponding EISS M\_UNITDATA.request as unsigned binary numbers.

**Figure 9-1—VLAN TCI format**

The VID is encoded in a 12-bit field. A VLAN Bridge may not support the full range of VID values but shall support the use of all VID values in the range 0 through a maximum N, less than or equal to 4094 and specified for that implementation. Table 9-2 identifies VID values that have specific meanings or uses.

**Table 9-2—Reserved VID values**

| VID value (hexadecimal) | Meaning/Use                                                                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                       | The null VID. Indicates that the tag header contains only priority information; no VID is present in the frame. This VID value shall not be configured as a PVID or a member of a VID Set, or configured in any FDB entry, or used in any Management operation. |
| 1                       | The default PVID value used for classifying frames on ingress through a Bridge Port. The PVID value of a Port can be changed by management.                                                                                                                     |
| 2                       | The default SR_PVID value used for SRP [35.2.1.4 item i)] Stream related traffic. The SR_PVID value of a Port can be changed by management.                                                                                                                     |
| FFF                     | Reserved for implementation use. This VID value shall not be configured as a PVID or a member of a VID Set, or transmitted in a tag header. This VID value may be used to indicate a wildcard match for the VID in management operations or FDB entries.        |

NOTE 1—There is a distinction between the range of VIDs that an implementation can support and the maximum number of active VIDs supported at any one time. An implementation supports only 16 active VIDs, for example, may use VIDs chosen from anywhere in the identifier space, or from a limited range. The latter can result in difficulties where different Bridges in the same network support different maximums. It is recommended that new implementations of this standard support the full range of VIDs, even if the number of active VIDs is limited.

The priority and drop\_eligible parameters are conveyed in the 3-bit PCP field and the DEI field as specified in 6.9.3.

NOTE 2—Previous versions of this standard used bit 5 of octet 1 of the TCI in C-TAGs as a Canonical Format Indicator (CFI). Bridges conformant to this version of the standard will not interoperate with Bridges that set the CFI as a result of inserting C-TAGs in frames received from an IEEE 802.5™ Token Ring LAN. Bridges conformant to this version of the standard will interoperate with Bridges that forward bit 5 of octet 1 as a CFI but do not have 802.5 Token Ring interfaces.

## 9.7 Backbone Service Instance Tag Control Information (I-TAG TCI)

The I-TAG TCI field (Figure 9-2) is 16 octets in length and encodes the priority, drop\_eligible, destination\_address, and source\_address parameters of the corresponding service request primitive as unsigned binary numbers. I-TAGs are encoded and decoded at PIPs and CBPs of BEBs as specified in 6.10, 6.11, and 6.18.

Figure 9-2—I-TAG TCI format

The I-TAG TCI contains the following fields:

- a) *I-PCP (Priority Code Point)*—This 3-bit field encodes the priority and drop\_eligible parameters of the service request primitive associated with this frame using the same encoding as specified for VLAN tags in 6.9.3. The PBBN operates on the priority associated with the B-TAG.
- b) *I-DEI (Drop Eligible Indicator)*—This 1-bit field carries the drop\_eligible parameter of the service request primitive associated with this frame. The PBBN operates on the drop eligibility associated with the B-TAG.
- c) *UCA (Use Customer Addresses)*—A single-bit flag that, when containing a value of one, signals a Backbone Service Instance Multiplex Entity (6.18) to use the addresses contained in the C-DA and C-SA fields.
- d) *Res1 (Reserved 1)*—This 1-bit field is reserved for future standardization. The Res1 field contains a value of zero when the tag is encoded, and is ignored when the tag is decoded.
- e) *Res2 (Reserved 2)*—This 2-bit field is reserved for future standardization. The Res2 field contains a value of zero when the tag is encoded. The frame will be discarded if this field contains a nonzero value when the tag is decoded.
- f) *I-SID (Backbone Service Instance Identifier)*—This 24-bit field carries the identifier of the backbone service instance.
- g) *C-DA (Encapsulated Customer Destination MAC address)*—Contains the address in the destination\_address parameter of the service request primitive associated with this frame. The address is represented using the Hexadecimal Representation as specified in IEEE Std 802 with the octet containing the I/G bit in the lowest numbered octet of the field.
- h) *C-SA (Encapsulated Customer Source MAC address)*—Contains the address in the source\_address parameter of the service request primitive associated with this frame. The address is represented using the Hexadecimal Representation as specified in IEEE Std 802 with the octet containing the I/G bit in the lowest numbered octet of the field.

<sup>1</sup> The I-SID is encoded in a 24-bit field. Table 9-3 identifies I-SID values that have specific meanings or uses.

**Table 9-3—Reserved I-SID values**

| I-SID value<br>(hexadecimal) | Meaning/Use                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                            | Reserved for implementation use. This I-SID value shall not be configured as an identifier for a backbone service instance or transmitted in an I-TAG header. This I-SID value may be used in management and control operations, e.g., to indicate a deleted or null I-SID in ISIS-SPB TLVs (see Clause 28). |
| 1                            | Default value—Unassigned ISID on a VIP.                                                                                                                                                                                                                                                                      |
| 2 through FE                 | Reserved for future standardization.                                                                                                                                                                                                                                                                         |
| FF                           | SPBM default I-SID.                                                                                                                                                                                                                                                                                          |
| FFFFFF                       | Reserved for implementation use. This I-SID value shall not be configured as an identifier for a backbone service instance or transmitted in an I-TAG header. This I-SID value may be used to indicate a wildcard match for the I-SID in management operations.                                              |

<sup>2</sup> NOTE—There is a distinction between the range of I-SIDs that an implementation can support, and the maximum  
<sup>3</sup> number of active backbone service instances supported at any one time. An implementation that supports only  $2^{16}$  active  
<sup>4</sup> backbone service instances, for example, may use I-SIDs chosen from anywhere in the identifier space. Implementations  
<sup>5</sup> of this standard support the full range of I-SIDs, even if the number of active backbone service instances is limited.

## 10. Multiple Registration Protocol (MRP) and Multiple MAC Registration Protocol (MMRP)

The Multiple Registration Protocol allows participants in an MRP application to register attributes with other participants in a Bridged Network. The definition of attribute types, their values, and the semantics associated with values when registered, are specific to each MRP application.

This clause:

- a) Provides an overview of the use of MRP within a bridged network (10.1).
- b) Describes the architecture of MRP participants for end stations and Bridge Ports (10.2).
- c) Specifies registration propagation between the per-Port Participants in a Bridge (10.3).
- d) Details requirements to be met by the MRP design (10.4).
- e) Details requirements for interoperability between MRP participants (10.5).
- f) Provides an overview of protocol operation (10.6).
- g) Provides a detailed specification of the protocol (10.7).
- h) Describes the structure of PDUs exchanged between MRP participants (10.8).

Subclauses 10.9 through 10.12 define an MRP application, the Multiple MAC Registration Protocol (MMRP), that registers attributes of two types—MAC addresses and Group service requirements. Values of these attributes control MAC address filtering by MMRP participants.

Clause 11 defines a second MRP application, the Multiple VLAN Registration Protocol (MVRP), that registers VLAN membership information.

Clause 35 defines a third MRP application, the Multiple Stream Registration Protocol (MSRP), that registers data Stream characteristics and reserves Bridge resources as appropriate to provide QoS guarantees.

Clause 39 defines a fourth MRP application, the Multiple I-SID Registration Protocol (MIRP), that serves as an alternative to MVRP for per-VLAN flushing of learned MAC address information in I-components.

### 10.1 MRP overview

MRP allows a participant in a given MRP application to make or withdraw *declarations* of *attributes*, and for those declarations (or withdrawals) to result in the *registration* (or removal of registrations) of those attributes with the other MRP Participants for that application.

A declaration by an MRP Participant for an end station or Bridge Port is recorded by an Applicant state machine for the declared attribute and Port. Changes in the Applicant state machine's variables trigger the transmission of MRPDUs to communicate the declaration (or withdrawal).

A registration is recorded by a Registrar state machine for the attribute at each participating end station and Bridge Port that receives the MRPDU. Removal of a given attribute registration occurs only if all the other participants connected to the same LAN withdraw the declaration.

1 Attributes registered on Bridge Ports that are part of the applicable *active topology* (8.4, 10.3.1) are declared  
2 on all the other Bridge Ports that are also part of that active topology. Hence, a given declaration is  
3 propagated to all application participants, and registered in each Bridge on those Ports that are “nearest” to  
4 the source or sources of the declaration within the active topology.

5 NOTE—Unless otherwise stated, the following description assumes operation within the Base Spanning Tree Context  
6 (see 10.3.1). While registration can occur on any Bridge Port, regardless of Port State (8.4), propagation follows the  
7 spanning tree active topology. All the Bridge Ports shown in Figure 10-1, Figure 10-2, and Figure 10-3 are in the  
8 Forwarding Port State.

9 Figure 10-1 illustrates the result of a single end station making a declaration, and shows the Bridge Ports that  
10 also make declarations to propagate the attribute. The attribute is propagated to all LANs in the Bridged  
11 Network, but the directional nature of the propagation results in registration only on Bridge Ports that  
12 receive a declaration of that attribute from the attached LAN.

**Figure 10-1—Example—Attribute value propagation from one station**

13 Figure 10-2 illustrates the result of different end stations declaring the same attribute on different LANs. All  
14 end stations register the attribute, and some Bridges register it on more than one Port.

15 The set of Bridge Ports and end stations that both declare and register a given attribute defines the subset of  
16 the active topology that connects all the participants interested in that attribute. A registration can be  
17 regarded as a pointer to participants that have declared that attribute, as illustrated in Figure 10-3 (using the  
18 same set of declarations and registrations that were illustrated in Figure 10-2).

19 Situations where it is desirable to form “reachability trees” are generally good candidates for the use of  
20 MRP. For example, if the attribute in Figure 10-3 is a group MAC address that is used as a destination  
21 address for a video data stream, and it is deemed desirable for that video data to be sent only to the subset of  
22 the active topology that contains end stations that have declared that attribute, then an end station that is the  
23 source of that video stream could use the presence or absence of a registration as an indication of whether to  
24 send the data on the LAN to which it is attached. Any Bridge receiving the data could determine on which  
25 Ports the data should be forwarded.

Figure 10-2—Example—Attribute value propagation from two stations

Figure 10-3—Example—Registrations as pointers to the sources of declarations

- 1 VLAN Bridges that do not support MRP are transparent to MRP exchanges, and forward received MRPDUs
- 2 on all Ports in the active topology. Similarly, VLAN Bridges that do not implement a given MRP application
- 3 are transparent to MRP exchanges destined for that application, and forward any such received MRPDUs on
- 4 all Ports that are participating in the active topology for the VLAN concerned.

1 MRP operates only on Ports that are MAC\_Operational (IEEE Std 802.1AC). If the Port is operating as a  
2 network access port (IEEE Std 802.1X), MRP uses the controlled port (8.13.9). On any Port whose  
3 MAC\_Operational parameter is FALSE, any MRP entity shall not transmit MRPDUs, and shall discard,  
4 without processing, any received MRPDUs.

5 MRP provides a means to mark initial attribute declarations and propagated attribute declarations as “new,”  
6 signaling to the recipient of the declaration that the attribute value is being newly declared, or is being  
7 redeclared following a change in the underlying topology. The rules applied to the marking and propagation  
8 of newly declared values in this way are common to all MRP Applications; however, the action taken on  
9 receipt of an attribute declaration marked as “new” is specific to each MRP Application. For example,  
10 MMRP (10.9) makes no use of the “new” marking, whereas MVRP (Clause 11) uses the “new” marking to  
11 permit FDB entries to be flushed on a per-VID basis following a topology change.

## 12 10.2 MRP architecture

13 An MRP Participant consists of an application component and an MRP Attribute Declaration (MAD)  
14 component. The application component is responsible for the semantics associated with attribute values and  
15 their registration, including the use of explicitly signaled new declarations, and uses the following two  
16 primitives to request MAD to make or withdraw attribute declarations:

17 MAD\_Join.request (attribute\_type, attribute\_value, new)

18 MAD\_Leave.request (attribute\_type, attribute\_value)

19 where *attribute\_type* specifies the type of the attribute declaration, and *attribute\_value* specifies the instance  
20 of that type, and the Boolean *new* parameter indicates an explicit new declaration.

21 Within a Bridge, a per application MRP Attribute Propagation (MAP) component (10.3) propagates  
22 information between the per-Port Participants, using the same request and indication primitives. If the value  
23 of *tcDetected* (13.25) for the Port and MAP Context (10.3.1) associated with the MRP Participant is  
24 nonzero, then the value of the *new* parameter in the propagated MAD\_Join.request is set TRUE.

25 The MAD component executes MRP (10.6, 10.7), generating MRP messages for transmission and  
26 processing messages received from other Participants, and uses the following two primitives to notify its  
27 application component of a change in Attribute registration:

28 MAD\_Join.indication (attribute\_type, attribute\_value, new)

29 MAD\_Leave.indication (attribute\_type, attribute\_value)

30 One such Participant, per MRP application, exists for each point of attachment to a LAN where Attributes  
31 for that application are to be declared or registered, i.e., one Participant per application in an end station, and  
32 one per application per Port in a Bridge. The encoding of Attribute values in MRPDUs and their subsequent  
33 decoding is application specific, within the general structure specified in 10.8, and each MRPDU conveys  
34 messages generated by the MAD component for a single application.

35 Figure 10-4 illustrates the components of MRP Participants in a two-Port Bridge and an end station.

36 For each MRP application, the following are defined:

- 37 a) A set of Attribute types used by the application.
- 38 b) The Attribute values permitted for each Attribute type.
- 39 c) The semantics associated with each Attribute type and value.
- 40 d) The use made of MAP Contexts by the application.
- 41 e) The group MAC address and EtherType for protocol exchanges between application Participants.

- 1 f) The structure and encoding of the Attribute types and values in MRPDUs.
- 2 g) The requirements for MRP state machine support in end stations and Bridges.
- 3 h) The circumstances, if any, in which the application makes use of the “new” declaration capability.
- 4 NOTE 1—Not all applications of MRP will make use of the “new” declaration capability.
- 5 i) If the application makes use of the “new” declaration capability, the semantics that new registrations carry in that application.
- 6 j) The number of attribute values out of the possible range of values for which the application is expected to be capable of maintaining current state information.
- 7 NOTE 2—In some applications, such as MVRP, the failure of one Bridge in a network to maintain state for all possible attribute values would have major consequences for the integrity of the network. For such applications,
- 8 the application definition will mandate the ability to track the state of all possible attribute values.
- 9
- 10
- 11

Figure 10-4—MRP architecture

### 10.3 MRP Attribute Propagation (MAP)

The MAP function enables propagation of attributes registered on Bridge Ports across the network to other participants. Each MRP application specifies the operation of the MAP function. This subclause specifies the operation of the MAP function for the MMRP application, the MVRP application (11.2.1), and the MSRP application (35.2). In addition, 35.2.4 specifies additional MSRP attribute processing rules that modify the MAP function defined below.

For a given MRP application and MAP Context (10.3.1), and for the set of Ports that have a Port State (8.4) of Forwarding for that MAP Context, and for the set of attributes associated with that MAP Context:

- a) Any MAD\_Join.indication, or any MAD\_Join.request issued by the MRP application, received by MAP from a given Port in the set is propagated as a MAD\_Join.request to the instance(s) of MAD associated with each other Port in the set. If the value of tcDetected (13.25) for the given Port and MAP Context is nonzero, then the value of the *new* parameter in the propagated MAD\_Join.request

1 is set TRUE, regardless of the value of this parameter in the indication or request that is being  
2 propagated.

3 b) Any MAD\_Leave.indication, or any MAD\_Leave.request issued by the MRP application, received  
4 by MAP from a given Port in the set is propagated as a MAD\_Leave.request to the instance(s) of  
5 MAD associated with each other Port in the set (Port P, say) if and only if no registration now exists  
6 for that Attribute on any other Port in the set excluding P.

7 These rules propagate attribute registrations through any given Port if any other Port has seen a registration  
8 for that attribute, and propagate deregistrations if all other Ports are now deregistered.

9 As the set of Ports with a Port State of Forwarding for a given MAP Context can change dynamically, for  
10 example as a result of spanning tree reconfiguration, MAP operates as follows after such a change:

11 c) If a Port is added to the set, and that Port has registered an attribute (i.e., a MAD\_Join.indication or  
12 MAD\_Join.request has occurred more recently than any MAD\_Leave.indication or  
13 MAD\_Leave.request for the attribute), then MAD\_Join.requests are propagated to the MAD  
14 instances for each of the other Ports in the set.

15 d) If a Port is added to the set, but that Port has not declared an attribute that other Ports in the set have  
16 registered, then MAD\_Join.requests are propagated by those other Ports to the MAD instance for  
17 that Port.

18 e) If a Port is removed from the set, and that Port has registered an attribute and no other Port has, then  
19 MAD\_Leave.requests are propagated to the MAD instances for each of the other Ports in the set.

20 NOTE—If a Port is removed from the set, and that Port has declared one or more attributes, then this Port  
21 transmits a Leave message (see 10.6) for every attribute that it has declared.

22 f) If a Port is removed from the set, and that Port has registered an attribute that another Port has also  
23 registered, then a MAD\_Leave.request is propagated to the MAD instance for that other Port.

### 24 10.3.1 MAP Context

25 For a given Port of an MRP-aware Bridge and MRP application supported by that Bridge, an instance of an  
26 MRP Participant can exist for each *MRP Attribute Propagation Context (MAP Context)* understood by the  
27 Bridge. A MAP Context identifies the set of Bridge Ports that form the applicable *active topology* (8.4).

28 Examples of MAP Contexts are as follows:

29 a) The active topology formed by the operation of RSTP (Clause 13). This MAP Context provides the  
30 same connectivity as the spanning tree in each Bridge and is known as the *Base Spanning Tree*  
31 *Context*.

32 b) The active topology formed by the subset of Bridge Ports, and the underlying spanning tree, that  
33 support a given VID. This MAP Context is known as a *VLAN Context*.

34 NOTE—This standard uses the Base Spanning Tree Context and VLAN Contexts to define the operation of MMRP and  
35 MVRP; however, other MAP Contexts may be used for other applications, or for extending MMRP functionality.

36 MRP exchanges can occur on all of the Ports of a Bridge; however propagation across a Bridged Network of  
37 attribute registrations for a given application uses only those Bridge Ports that are part of the active topology  
38 identified by the MAP Context. Each MRP application specification identifies the contexts it can operate  
39 within and assigns MAP Context identifiers for use in conjunction with the operation of MRP and its  
40 administrative controls (10.7.2, 10.7.3).

41 A MAP Context identifier of 0 always identifies the *Base Spanning Tree Context*. The MRP application  
42 specifies how the MAP Context of each MRPD is identified if any other context is used.

### 10.3.1.1 MAD and Port role changes

A spanning tree provides a loop-free active topology connecting all the Bridges and all the LANs in a network. Hence, any Bridge Port that forwards frames connects two otherwise disconnected parts of the topology. Each Alternate Port on a Bridge A (say) connects to a LAN that has a Port of another Bridge with a better priority vector than A can supply; hence, each of A's Alternate Ports is a potential connection to part of the network that is not connected to any of A's Designated Ports, all LANs and Bridges in any such part having an equal or worse priority vector than A. Therefore, an Alternate Port on A potentially connects to the part of the network connected to by A's Root Port. Since any part of the network is fully connected, in the absence of registration controls, A's Alternate Port will have registered the same attributes as its Root Port.

For implementations running over RSTP or MSTP, this gives rise to the risk of information loops when Port roles change; because of the store and forward nature of attribute propagation and the potentially rapid transitions of Port roles (compared to the relatively slow transitions that occurred with STP), these can arise even when there are no data loops.

To prevent such information loops from occurring, the information held by MAD's Registrars for a Port (i.e., information registered on a Port as a result of protocol activity on the LAN to which that Port is connected) is discarded whenever the Port transitions from an Alternate port or Root Port role to become a Designated Port. No such discard is needed for changes in the other direction, i.e., changes from Designated Port to Root Port or Alternate Port.

## 10.4 Requirements to be met by MRP

MRP establishes, maintains, withdraws, and disseminates attribute declarations and registrations among the MRP Participants attached to a Bridged Network. The protocol meets the following requirements for Applicant and Registrar behavior, error recovery, performance, scalability, compatibility with non-MRP-aware devices, and the load imposed on Bridges, end stations, and the network:

- a) Participants can issue declarations for MRP application attributes (10.2, 10.3, 10.7.3, and 10.7.7).
- b) Participants can withdraw declarations for attributes (10.2, 10.3, 10.7.3, and 10.7.7).
- c) Each Bridge propagates declarations to MRP Participants (10.3).
- d) MRP Participants can track the current state of declaration and registration of attributes on each Port of the participant device (10.7.7 and 10.7.8).
- e) MRP Participants can remove state information relating to attributes that are no longer active within part or all of the network, e.g., as a result of the failure of a participant (10.7.8 and 10.7.9).
- f) The latency involved in issuing, propagating, or revoking attribute declarations, is small (i.e., comparable to the frame propagation delay) and increases linearly as a function of the diameter of the network (10.7.7, 10.7.8, and 10.7.9).
- g) MRP is resilient in the face of the failure of MRP Participants.
- h) MRP is resilient in the face of single packet loss.
- i) MRP will operate correctly in networks where:
  - 1) All Bridges support both Basic and Extended Filtering Services; or where
  - 2) Some Bridges support only Basic Filtering Services and some both Basic and Extended Filtering Services (10.5, 10.7.7, 10.7.8, and 10.7.9).
- j) The communications bandwidth consumed on any particular LAN by Applicants and Registrars in exchanging MRPDUs will be a small percentage of the total available bandwidth, and independent of the total traffic supported by the network. The bandwidth consumed will be a function of the number of attributes registered.

## 10.5 Requirements for interoperability between MRP Participants

To ensure the interoperability of MRP, the following are required:

- a) All MRP applications use a group MAC address as the destination address of MRPDUs, selected in accordance with the stated requirements of the MRP application concerned for the type of Bridge component in which the application is implemented. The addresses used may be taken from the set of addresses specified in Table 10-1, or taken from the set of reserved addresses specified in Table 8-1, Table 8-2, and Table 8-3, or other group MAC addresses, chosen according to the particular properties required by the application concerned.  
NOTE 1—The addresses in Table 8-1, Table 8-2, Table 8-3, and Table 10-1 differ from other group MAC addresses in terms of the scope of transmission within a network, as a consequence of the forwarding/filtering decisions that are taken relative to them by different types of Bridge component.
- b) Table 10-1 specifies a set of group MAC addresses, some that have been assigned for use by existing applications defined in this standard, and others reserved for future standardization. Addresses in this set have the property that:
  - 1) Where a given address in the set is used by a Bridge component to support an MRP application, frames destined for that address shall not be forwarded by that Bridge component; i.e., a Static Filtering Entry for that address is maintained for that group MAC address in order to prevent the forwarding of frames destined for that address.
  - 2) Where a given address in the set is not used by a Bridge component to support any MRP application, frames destined for that address received on any Port that is part of a given active topology shall be forwarded by that Bridge component on all other Ports that are part of that active topology.

**Table 10-1—MRP application addresses**

| Assignment <sup>a</sup>                   | Value             |
|-------------------------------------------|-------------------|
| Customer and Provider Bridge MMRP address | 01-80-C2-00-00-20 |
| Customer Bridge MVRP address              | 01-80-C2-00-00-21 |
| Reserved                                  | 01-80-C2-00-00-22 |
| Reserved                                  | 01-80-C2-00-00-23 |
| Reserved                                  | 01-80-C2-00-00-24 |
| Reserved                                  | 01-80-C2-00-00-25 |
| Reserved                                  | 01-80-C2-00-00-26 |
| Reserved                                  | 01-80-C2-00-00-27 |
| Reserved                                  | 01-80-C2-00-00-28 |
| Reserved                                  | 01-80-C2-00-00-29 |
| Reserved                                  | 01-80-C2-00-00-2A |
| Reserved                                  | 01-80-C2-00-00-2B |
| Reserved                                  | 01-80-C2-00-00-2C |
| Reserved                                  | 01-80-C2-00-00-2D |
| All Provider Bridge Intermediate Systems  | 01-80-C2-00-00-2E |
| All Customer Bridge Intermediate Systems  | 01-80-C2-00-00-2F |

<sup>a</sup> MIRP is an MRP application, but is not assigned an address from this table (39.2.1.5, 39.2.1.6).

- c) The transmission and reception of MRPDUs between MRP Participants, formatted as defined for the application using the generic PDU format defined in 10.8, shall use LLC procedures. Each MRP application uses a unique EtherType value in order to identify the application protocol. Table 10-2 specifies the EtherType values assigned to existing applications.

**Table 10-2—MRP EtherType values**

| Assignment     | Value |
|----------------|-------|
| MMRP EtherType | 88-F6 |
| MVRP EtherType | 88-F5 |
| MSRP EtherType | 22-EA |
| MIRP EtherType | 89-29 |

NOTE 2—For the purposes of this standard, the expression “use LLC procedures” includes making use of the service provided by link layer protocol entities that support protocol discrimination by means of an EtherType value.

- d) MRPDUs, i.e., frames with the destination MAC addresses selected as specified in item a) and the EtherType values specified in item c), that are destined for applications supported by a Bridge component, and that are not well formed (i.e., are not structured and encoded as defined in 10.8 and with attribute types and values encoded as defined by the MRP application), shall be discarded on receipt.

## 10.6 Protocol operation

This subclause provides an informal introduction. The definitive specification of MRP is contained in 10.7 and 10.8.

MRP is a simple, fully distributed, many-to-many protocol, that supports efficient, reliable, and rapid declaration and registration of attributes by multiple participants on shared and virtual shared media. MRP also incorporates optimizations to speed attribute declarations and withdrawals on point-to-point media. Correctness of MRP operation is independent of the relative values of protocol timers, and the protocol design is based primarily on the exchange of idempotent protocol state rather than commands.

A full MRP Participant maintains Registrar and Applicant state machines for each Attribute of interest, and a LeaveAll state machine and PeriodicTransmission state machine for the participant as a whole.

The job of the Registrar is to record declarations of the attribute made by other Participants on the LAN. It does not send any protocol messages, as the Applicant looks after the interests of all would-be Participants.

The job of the Applicant is twofold:

- a) To ensure that this Participant’s declaration is correctly registered by other Participants’ Registrars.
- b) To prompt other Participants to reregister after one withdraws a declaration.

NOTE 1—Applicant-Only implementations are concerned only with item a).

The basic design of MRP is oriented to LAN environments, where there is generally a low probability of frame loss, and ensures that timely registration of attributes is unaffected unless at least two out of a set of immediately related frames are lost. The LeaveAll state machine periodically ensures that Participants reregister attributes, thus guarding against an extended failure to register or deregister. In potentially lossy

1 environments such as service instances supported by PBNs, where frame losses are temporally correlated,  
2 the PeriodicTransmission machine ensures successful registration without immediately contributing to  
3 congestive loss.

4 If one Applicant has both declared and registered an Attribute, other Applicants do not need to reiterate the  
5 declaration. MRP messages convey both Applicant and Registrar state to allow suppression of such repeated  
6 declarations. The Applicant state machine distinguishes between Active Participants (that have sent a  
7 message or messages to make a declaration), Passive Participants (that require registration, but have not had  
8 to declare the attribute so far to register it, and will not have to explicitly deregister), and Observers (that do  
9 not require registration at present, but track the attribute's registration in case they do and become Passive  
10 Participants). The following four distinct messages communicate the transmitting participant's state for an  
11 Attribute:

- 12 — Empty—Not declared, and not registered.
- 13 — In—Not declared, but registered.
- 14 — JoinEmpty—Declared, but not registered.
- 15 — JoinIn—Declared and registered.

16 One message communicates a withdrawal of a prior declaration, so that Registrars do not have to track  
17 individual Applicants:

- 18 — Leave—Previously registered, but now withdrawn.

19 A further message conveys a declaration from a new Participant, or a Participant newly added to the active  
20 topology reached through a Bridge Port. This information is propagated by the MAP component, and so  
21 includes additional registrations elsewhere in the bridged network:

- 22 — New—Newly declared, and possibly not previously registered.

23 The LeaveAll state machine uses the following single message that applies to all Attributes.

- 24 — LeaveAll—All registrations will shortly be deregistered; Participants need to reregister.

25 The Registrar for each Attribute actually implements the following three states for the Attribute:

- 26 — IN—Registered.
- 27 — LV—Previously registered, but now being timed out.
- 28 — MT—Not registered.

29 A single timer, the leavetimer, is associated with each Registrar and operates in the LV state. In that state,  
30 MRP messages for the Attribute report it as unregistered (using Empty or Join Empty) but the MAD Leave  
31 indication is delayed until the leavetimer expires and the state transitions to MT.

32 NOTE 2—The accuracy required for the leavetimer is sufficiently coarse to permit the use of a single operating system  
33 timer per Participant with 2 bits of state for each Registrar.

34 The Applicant for each Attribute implements states that record whether it wishes to make a new declaration,  
35 to maintain or withdraw an existing declaration, or has no declaration to make. It also records whether it has  
36 actively made a declaration, or has been passive, taking advantage of or simply observing the declarations of  
37 others. It counts the New, JoinIn, and JoinEmpty messages it has sent, and JoinIn messages sent by others, to  
38 ensure that at least two such messages have been sent since it last received a LeaveAll or Leave message,  
39 and at least one since it last received a JoinEmpty or Empty message. This ensures that each of the other  
40 Participant's Registrars for the Attribute either have received (assuming no packet loss) two Join or New  
41 messages or have reported the Attribute as registered. The Applicant state machine (Table 10-3) uses the  
42 following states:

- 43 — VO—Very anxious Observer. The applicant is not declaring the attribute, and has not received a  
44 JoinIn message since the state machine was initialized, or since last receiving a Leave or LeaveAll.

- 1 — VP—Very anxious Passive. The applicant is declaring the attribute, but has neither sent a Join nor  
2 received a JoinIn since the state machine was initialized, or since last receiving a LeaveAll or Leave.
- 3 — VN—Very anxious New. The applicant is declaring the attribute, but has not sent a message since  
4 receiving a MAD Join request for a new declaration.
- 5 — AN—Anxious New. The applicant is declaring the attribute, and has sent a single New message  
6 since receiving the MAD Join request for the new declaration.
- 7 — AA—Anxious Active. The applicant is declaring the attribute, and has sent a Join message, since the  
8 last Leave or LeaveAll, but either has not received another JoinIn or In, or has received a subsequent  
9 message specifying an Empty registrar state.
- 10 — QA—Quiet Active. The applicant is declaring the attribute and has sent at least one of the required  
11 Join or New messages since the last Leave or LeaveAll, has seen or sent the other, and has received  
12 no subsequent messages specifying an Empty registrar state.
- 13 — LA—Leaving Active. The applicant has sent a Join or New message since last receipt of a Leave or  
14 LeaveAll, but has subsequently received a MAD Leave request and has not yet sent a Leave  
15 message.
- 16 — AO—Anxious Observer. The applicant is not declaring the attribute, but has received a JoinIn since  
17 last receiving a Leave or LeaveAll.
- 18 — QO—Quiet Observer. The applicant is not declaring the attribute, but has received two JoinIns since  
19 last receiving a Leave or LeaveAll, and at least one since last receiving a message specifying an  
20 Empty registrar state.
- 21 — AP—Anxious Passive. The applicant is declaring the attribute, and has not sent a Join or a New  
22 since last receiving a Leave or a LeaveAll but has received messages as for the Anxious Observer  
23 state.
- 24 — QP—Quiet Passive. The applicant is declaring the attribute, and has not sent a Join or a New since  
25 last receiving a Leave or a LeaveAll but has received messages as for the Quiet Observer state.
- 26 — LO—Leaving Observer. The applicant is not declaring the attribute, and has received a Leave or  
27 LeaveAll message.

28 If an Applicant receives a Leave or LeaveAll message it will send a JoinEmpty or Empty message, and that  
29 message will prompt any other Applicants that are declaring the attribute to send a JoinIn. An Applicant that  
30 sends a LeaveAll message will also ensure that an Empty message is sent to prompt other Applicants to  
31 repeat their declaration. Thus, if any Participant's Registrar deregisters an Attribute, at least two messages  
32 will be lost before another Participant's Applicant fails to make a required redeclaration.

33 To facilitate and encourage the transmission of timely protocol information and the encoding of messages  
34 for multiple Attributes within the same MRPDU, rather than the use and subsequent queuing of multiple  
35 PDUs prior to transmission, PDU transmission is specified in terms of requests for a transmission  
36 opportunity, and the Applicant and LeaveAll state machines specify the necessary addition of messages to an  
37 MRPDU when that opportunity occurs. Whenever a state machine transitions to a state that requires  
38 transmission of a message, a transmit opportunity is requested if one is not already pending. The message  
39 actually transmitted (if any) is that appropriate to the state of the machine when the opportunity is presented.

40 NOTE 3—Specifying transmit opportunity requests and their subsequent use is also intended to aid correct  
41 implementation in systems where a transmission is not possible immediately, e.g., shortly after whole or part of the  
42 system is initialized when other claims on system resources take precedence or interfaces are not yet available.

43 To support the efficient encoding of many messages in a single MRPDU, the number of message types has  
44 been kept to the minimum consistent with protocol goals and requirements, and the state machines specify  
45 both whether it is necessary to send a message and a message type that can always be sent—thus removing  
46 the need for a further “no message” encoding. The MRPDU structure and compact encoding (10.8) allows  
47 all potential attributes for certain MRP applications, e.g., MVRP (Clause 11), to be encoded in a single  
48 IEEE 802.3 frame and this further promotes protocol efficiency through ready detection of missing  
49 registrations. Protocol efficiency and correct registration are further supported by encoding a LeaveAll

1 message (if required) at the beginning of the MRPDU, and by using an Applicant state machine that  
2 minimizes state changes for those Attributes whose redeclaration can be encoded in the same PDU—if the  
3 LeaveAll is received by another Participant so also will be the redeclaration, and sequential processing of  
4 the encoded messages by the recipient will ensure that the registration is uninterrupted. Applicant states for  
5 Attributes that cannot be redeclared in the same PDU allow for receipt of the LeaveAll but loss of the  
6 redeclaration.

7 LeaveAll messages are transmitted to ensure that any failure to withdraw a declaration does not result in an  
8 unwanted permanent registration—perhaps the system or process responsible for the registration has been  
9 removed from the LAN or has ceased to operate. Attributes registered by the Participant transmitting the  
10 LeaveAll as well as those receiving it are therefore timed out. The LeaveAll state machine (10.7.9) for the  
11 Participant operates a single timer, the leaveAllTimer, that causes a transmit opportunity to be requested  
12 when it expires, and transmission of a LeaveAll at the next opportunity. Reception of a LeaveAll message  
13 from another Participant causes the timer to be restarted without generating a message, thus suppressing  
14 multiple LeaveAll messages from Participants connected to the same LAN.

15 NOTE 4—In the face of changing inputs, arbitrary loss, delay, reordering, and unsignaled interruption in participation,  
16 no protocol will meet its objectives. What can be said is that the objectives will be met after a known period of operation  
17 within specified limits, and what failures are most likely otherwise. MRP favors ensuring that registrations are made, at  
18 the expense of tolerating prolonged registrations. Thus, the LeaveAll mechanism, when it has an effect, most often  
19 implements “garbage collection.” At the same time it will also ensure that failed registrations are (re-)established. These  
20 objectives cannot be ensured if the LeaveAllTime is set to zero; therefore, it is recommended to set the LeaveAllTime to  
21 a nonzero value as soon as is practicable.

22 When MRP Participants are connected by a shared or virtual shared medium, protocol performance is  
23 improved and the effect on other protocols using the LAN minimized if the Participants transmit at different  
24 times, avoiding a multicast storm and allowing some to optimize their transmissions based on messages  
25 received. A request for a transmit opportunity starts a randomized join timer, with a maximum value chosen  
26 to ensure successful reregistration(s) within a Leave time period (10.7.4), and the transmit opportunity is  
27 offered when the timer expires. If more messages are to be sent than can fit in a single PDU, a further  
28 transmit opportunity is requested.

29 When two MRP Participants are connected by a point-to-point medium or service instance delaying  
30 MRPDU transmission provides no benefit. In bridged networks it is desirable to transmit without delay,  
31 minimizing the denial of service that might occur while registration changes propagate after reconfiguration,  
32 and maximizing the benefit from using protocols such as RSTP and MSTP. When operPointToPointMAC  
33 (IEEE Std 802.1AC) is TRUE, transmit opportunities are scheduled immediately on request, subject to rate  
34 limiting (10.7.4).

35 Use of point-to-point service connecting at most two Participants allows further protocol optimization, e.g.,  
36 receipt of an In message does acknowledge registration. However, not all LAN media support reliable  
37 determination of point-to-point status, particularly if nonstandard bridge-like devices are present. When  
38 operating in point-to-point mode, MRP avoids behavior that could cause failure, potentially continuous  
39 rapid exchanges of messages, or flapping registrations if there are more than two Participants. This standard  
40 permits simple point-to-point subset implementations of MRP, but these will successfully operate on shared  
41 media—albeit at reduced efficiency.

42 NOTE 5—IEEE Std 802.1AE (MAC Security) can ensure that there are at most two communicating Participants.

43 In certain contexts, often encountered in PBNs or PBBNs, it is necessary to control the VLAN entries in the  
44 FDB using Static VLAN Registration Entries, and retain only the ability to signal the need to flush learned  
45 MAC Address Entries via MRP. A New-Only Participant supports this need by implementing only a part of  
46 the Applicant and Registrar state machines, but not implementing the LeaveAll state machine, and by  
47 transmitting and receiving only New messages. It is also possible to simplify an MRP Participant that only  
48 wishes to make declarations; for example, for an end station that uses MMRP (10.9) to declare a need to  
49 receive group addressed frames, but is not a source of such frames, and therefore does not need to support  
50 source pruning by registering declarations from other Participants. Such an Applicant-Only Participant does

1 not implement the Registrar or LeaveAll state machines, never sends LeaveAll, Empty, or JoinEmpty  
2 messages (which would elicit unnecessary Joins from its peer Participants), and does not implement the  
3 administrative controls defined in 10.7.2 and 10.7.3. The following five types of MRP implementation  
4 conform to this standard:

- 5 — Full Participant
- 6 — Full Participant, point-to-point subset
- 7 — New-Only Participant
- 8 — Applicant-Only Participant
- 9 — Applicant-Only point-to-point subset, also referred to as the Simple-Applicant Participant

10 While Simple-Applicant and Full Participant point-to-point subset implementations can operate on shared  
11 media, their initial Join and Leave messages are not suppressed. Significant additional, and unnecessary,  
12 traffic can result from attaching several such implementations to the same shared medium. Devices that do  
13 not perform registration should use an Applicant-Only Participant rather than a Simple-Applicant  
14 Participant.

15 NOTE 6—At the time of the development of this standard the LAN MACs most commonly used were point-to-point but  
16 the use of virtual shared media was increasing.

## 17 10.7 Protocol specification

18 The operation of MRP as executed by the MRP Attribute Declaration (MAD, 10.2) component of an MRP  
19 Participant is represented by the following state machines:

- 20 a) A per-Attribute Applicant state machine (10.7.7)
- 21 b) A per-Attribute Registrar state machine (10.7.8)
- 22 c) A LeaveAll state machine for the Participant as a whole (10.7.9)
- 23 d) A PeriodicTransmission state machine for the Participant as a whole (10.7.10)

24 These state machines are specified as compact state tables, and make use of the following:

- 25 e) Notational conventions and abbreviations for protocol events, actions, and timer operations (10.7.1)
- 26 f) Registrar Administrative Controls (10.7.2)
- 27 g) Applicant Administrative Controls (10.7.3)
- 28 h) Protocol timers (10.7.4)
- 29 i) Protocol event definitions (10.7.5)
- 30 j) Protocol action definitions (10.7.6)

31 A Full Participant implements the complete Applicant state machine (Table 10-3) and the Registrar state  
32 machine (Table 10-4) for each Attribute declared, registered, or tracked, together with a single instance of  
33 the LeaveAll state machine (Table 10-5) and the PeriodicTransmission state machine (Table 10-6).

34 The point-to-point subset of the Full Participant implements the same state machines, but omits certain  
35 Applicant state machine states and actions as specified by Table 10-3.

36 A New-Only Participant implements the Applicant state machine, with the omission of certain states and  
37 actions, as specified in Table 10-3, and the Registrar state machine (Table 10-4), for each Attribute declared,  
38 registered, or tracked, but does not implement the LeaveAll state machine (Table 10-5) or the  
39 PeriodicTransmission state machine (Table 10-6). Applications that permit both Full Participants and New-  
40 Only Participants define managed objects (12.9) to make the selection on a per-Port basis.

1 An Applicant-Only Participant implements the Applicant state machine, with the omission of certain states  
2 and actions as specified by Table 10-3, for each Attribute declared, registered, or tracked, together with a  
3 single instance of the PeriodicTransmission state machine (Table 10-6).

4 The point-to-point subset of the Applicant-Only Participant (the Simple-Applicant Participant) implements  
5 the same state machines, but omits certain Applicant state machine states and actions as specified by  
6 Table 10-3.

7 NOTE—Conceptually, per-Attribute state is maintained for all possible values of all Attribute types that are defined for  
8 a given application; however, in real implementations of MRP, it is likely that the range of possible Attribute values in  
9 some applications will preclude this, and the implementation will limit the state to those Attribute values in which the  
10 Participant has an immediate interest, either as a Member or as a likely future Member.

11 Timer values, their relationships, and default values are described in 10.7.11 and Table 10-7, protocol  
12 management statistics accumulated by each MAD component in 10.7.12, and interoperability considerations  
13 for potentially misordering networks in 10.7.13.

14 The encoding of MRP messages in MRPUs is specified in 10.8, which also specifies the parsing and checks  
15 applied to received PDUs.

## 16 10.7.1 Notational conventions and abbreviations

17 The following conventions are used in the abbreviations used in this subclause:

|          |                                                           |
|----------|-----------------------------------------------------------|
| 18 rXXX  | receive PDU XXX                                           |
| 19 sXXX  | send PDU XXX                                              |
| 20 txXXX | transmit opportunity                                      |
| 21 XXX!  | state machine event                                       |
| 22 !XXX  | “Not XXX”; i.e., logical NOT applied to the condition XXX |

23 The following abbreviations are used in the state machine descriptions. For their meaning, see 10.7.5 and  
24 10.7.6.

25 Protocol events:

|                          |                                                                                  |
|--------------------------|----------------------------------------------------------------------------------|
| 26 <b>Begin!</b>         | Initialize state machine (10.7.5.1)                                              |
| 27 <b>New!</b>           | A new declaration (10.7.5.4)                                                     |
| 28 <b>Join!</b>          | Declaration without signaling new registration (10.7.5.5)                        |
| 29 <b>Lv!</b>            | Withdraw a declaration (10.7.5.6)                                                |
| 30 <b>tx!</b>            | Transmission opportunity without a LeaveAll (10.7.5.7)                           |
| 31 <b>txLA!</b>          | Transmission opportunity with a LeaveAll (10.7.5.8)                              |
| 32 <b>txLAF!</b>         | Transmission opportunity with a LeaveAll, and with no room (Full) (10.7.5.9)     |
| 33 <b>rNew!</b>          | receive New message (10.7.5.14)                                                  |
| 34 <b>rJoinIn!</b>       | receive JoinIn message (10.7.5.15)                                               |
| 35 <b>rIn!</b>           | receive In message (10.7.5.18)                                                   |
| 36 <b>rJoinMt!</b>       | receive JoinEmpty message (10.7.5.16)                                            |
| 37 <b>rMt!</b>           | receive Empty message (10.7.5.19)                                                |
| 38 <b>rLv!</b>           | receive Leave message (10.7.5.17)                                                |
| 39 <b>rLA!</b>           | receive a LeaveAll message (10.7.5.20)                                           |
| 40 <b>Flush!</b>         | Port role changes from Root Port or Alternate Port to Designated Port (10.7.5.2) |
| 41 <b>Re-Declare!</b>    | Port role changes from Designated to Root Port or Alternate Port (10.7.5.3)      |
| 42 <b>periodic!</b>      | A periodic transmission event occurs (10.7.5.10)                                 |
| 43 <b>leavetimer!</b>    | leavetimer has expired (10.7.5.21)                                               |
| 44 <b>leavealltimer!</b> | leavealltimer has expired (10.7.5.22)                                            |
| 45 <b>periodictimer!</b> | periodictimer has expired (10.7.5.23)                                            |

1 Protocol actions:

|                         |                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------|
| 2 <b>New</b>            | send a New indication to MAP and the MRP application (10.7.6.12)                         |
| 3 <b>Join</b>           | send a Join indication to MAP and the MRP application (10.7.6.13)                        |
| 4 <b>Lv</b>             | send a Lv indication to MAP and the MRP application (10.7.6.14)                          |
| 5 <b>sN</b>             | send a New message (10.7.6.2)                                                            |
| 6 <b>sJ</b>             | send a JoinIn or JoinMT message (10.7.6.3)                                               |
| 7 <b>sL</b>             | send a Lv message (10.7.6.4)                                                             |
| 8 <b>s</b>              | send an In or an Empty message (10.7.6.5)                                                |
| 9 <b>[s]</b>            | send an In or an Empty message, if required for optimization of the encoding (10.7.6.5)  |
| 10 <b>[sL]</b>          | send a Lv message, if required for optimization of the encoding (10.7.6.4)               |
| 11 <b>[sJ]</b>          | send a Join message, if required for optimization of the encoding (10.7.6.3)             |
| 12 <b>sLA</b>           | send a Leave All message (10.7.6.6)                                                      |
| 13 <b>periodic</b>      | Periodic transmission event (10.7.6.7).                                                  |
| 14 <b>leavetimer</b>    | Leave period timer (10.7.4.2)                                                            |
| 15 <b>leavealltimer</b> | Leave All period timer (10.7.4.3)                                                        |
| 16 <b>periodictimer</b> | Periodic Transmission timer (10.7.4.4)                                                   |
| 17 <b>-x-</b>           | Inapplicable event/state combination. No action or state transition occurs in this case. |

18 Timers are used in the state machine descriptions in order to cause actions to be taken after defined time  
19 periods have elapsed. The following terminology is used in the state machine descriptions to define timer  
20 states and the actions that can be performed upon them:

- 21 a) A timer is said to be *running* if the most recent action to be performed upon it was a *start*.
- 22 b) A running timer is said to have *expired* when the time period associated with the timer has elapsed  
23 since the most recent start action took place.
- 24 c) A timer is said to be *stopped* if it has expired or if the most recent action to be performed upon it was  
25 a *stop* action.
- 26 d) A *start* action sets a stopped timer to the running state, and associates a time period with the timer.  
27 This time period supersedes any periods that might have been associated with the timer by previous  
28 start events.
- 29 e) A *stop* action sets a timer to the stopped state.

30 The following abbreviations are used for the state names in the state tables and state diagrams:

31 **Registrar states** (see 10.6):

|              |         |
|--------------|---------|
| 32 <b>IN</b> | In      |
| 33 <b>LV</b> | Leaving |
| 34 <b>MT</b> | Empty   |

35 **Applicant and Simple-Applicant states** (see 10.6):

|              |                       |
|--------------|-----------------------|
| 36 <b>VO</b> | Very anxious Observer |
| 37 <b>VP</b> | Very anxious Passive  |
| 38 <b>VN</b> | Very anxious New      |
| 39 <b>AN</b> | Anxious New           |
| 40 <b>AA</b> | Anxious Active        |
| 41 <b>QA</b> | Quiet Active          |
| 42 <b>LA</b> | Leaving Active        |
| 43 <b>AO</b> | Anxious Observer      |
| 44 <b>QO</b> | Quiet Observer        |
| 45 <b>AP</b> | Anxious Passive       |
| 46 <b>QP</b> | Quiet Passive         |
| 47 <b>LO</b> | Leaving Observer      |

## 1 10.7.2 Registrar Administrative Controls

2 Associated with each instance of the Registrar state machines are *Registrar Administrative Control*  
3 parameters. These parameters allow administrative control to be exercised over the registration state of each  
4 Attribute value, and hence, via the propagation mechanism provided by MAP, allow control to be exercised  
5 over the propagation of declarations.

- 6 a) *Normal Registration*. The Registrar responds to incoming MRP messages as specified by  
7 Table 10-4.
- 8 b) *Registration Fixed (New ignored)*. The Registrar ignores all MRP messages, and remains IN  
9 (registered).
- 10 c) *Registration Fixed (New propagated)*. The Registrar ignores all MRP messages except New, and  
11 remains IN (registered).
- 12 d) *Registration Forbidden*. The Registrar ignores all MRP messages, and remains MT (unregistered).

13 The default value of this parameter is *Normal Registration*.

14 If the value of this parameter is *Registration Fixed (New ignored)* or *Registration Fixed (New propagated)*,  
15 In and JoinIn messages are sent. If the value of this parameter is *Registration Forbidden*, Empty or  
16 JoinEmpty messages are sent. If the value of this parameter is *Registration Fixed (New propagated)*, only  
17 New messages are accepted.

18 NOTE—The Registrar Administrative Controls are realized by means of the contents of the Port Map parameters of  
19 static entries in the FDB for all MRP applications. In the case of MMRP, the static entries concerned are Static Filtering  
20 Entries (8.8.1); in the case of MVRP and MIRP, the static entries concerned are Static VLAN Registration Entries  
21 (8.8.2). The contents of the Port Map parameters in static entries can be modified by means of the management  
22 operations defined in Clause 12. In the absence of such control information for a given attribute, the default value  
23 “Normal Registration” is assumed.

## 24 10.7.3 Applicant Administrative Controls

25 An overall control parameter for each Applicant state machine, the *Applicant Administrative Control*,  
26 determines whether the Applicant state machine participates in MRP exchanges.

- 27 a) *Normal Participant*. The state machine participates normally in MRP exchanges.
- 28 b) *New-Only Participant*. The state machine sends only New MRP messages.
- 29 c) *Non-Participant*. The state machine does not send any MRP messages.

30 The default value of this parameter is Normal Participant.

31 NOTE 1—The Applicant Administrative Control parameters can be modified for any MRP application by means of the  
32 management operations defined in Clause 12. In the absence of such information for a given attribute, the default value  
33 “Normal Participant” is assumed.

34 NOTE 2—The Applicant Administrative Control parameters can be set per attribute type (see 12.9.2).

## 35 10.7.4 Protocol timers

### 36 10.7.4.1 jointimer

37 The Join Period Timer, jointimer, controls the interval between transmit opportunities that are applied to the  
38 Applicant state machine. An instance of this timer is required on a per-Port, per-MRP Participant basis. The  
39 value of JoinTime used to initialize this timer is determined in accordance with 10.7.11.

### 40 10.7.4.2 leavetimer

41 The Leave Period Timer, leavetimer, controls the period of time that the Registrar state machine will wait in  
42 the LV state before transiting to the MT state. An instance of the timer is required for each state machine that  
43 is in the LV state. The Leave Period Timer is set to the value LeaveTime when it is started; LeaveTime is  
44 defined in Table 10-7.

#### 1 **10.7.4.3 leavealltimer**

2 The Leave All Period Timer, `leavealltimer`, controls the frequency with which the LeaveAll state machine  
3 generates LeaveAll PDUs. The timer is required on a per-Port, per-MRP Participant basis. If LeaveAllTime  
4 is zero, the Leave All Period Timer is not started; otherwise, the Leave All Period Timer is set to a random  
5 value,  $T$ , in the range  $\text{LeaveAllTime} < T < 1.5 \times \text{LeaveAllTime}$  when it is started. LeaveAllTime is defined  
6 in Table 10-7.

#### 7 **10.7.4.4 periodictimer**

8 The Periodic Transmission timer, `periodictimer`, controls the frequency with which the PeriodicTransmission  
9 state machine generates periodic! events. The timer is required on a per-Port basis. The Periodic  
10 Transmission timer is set to one second when it is started.

### 11 **10.7.5 Protocol event definitions**

12 Unless stated otherwise in these event definitions, MRPDU reception in a Bridge can occur through all Ports  
13 of a Bridge, and events generated as a result of such reception affect only those state machines that are  
14 associated with the Port through which the PDU was received.

#### 15 **10.7.5.1 Begin!**

16 The state machine is initialized or reinitialized.

#### 17 **10.7.5.2 Flush!**

18 A Flush! event signals to the Registrar state machine that there is a need to rapidly deregister information on  
19 the Port associated with the state machine as a result of a topology change that has occurred in the network  
20 topology that supports the propagation of MRP information. If the network topology is maintained by means  
21 of the spanning tree protocol state machines, then, for the set of Registrar state machines associated with a  
22 given Port and spanning tree instance, this event is generated when the Port Role changes from either Root  
23 Port or Alternate Port to Designated Port.

24 When a Flush! event occurs for a given Port and spanning tree instance, a `leavealltimer!` event (10.7.5.22) is  
25 also signaled to the LeaveAll state machine for that Port and spanning tree instance.

#### 26 **10.7.5.3 Re-declare!**

27 A Re-declare! event signals to the Applicant and Registrar state machines that there is a need to rapidly  
28 redeclare registered information on the Port associated with the state machines as a result of a topology  
29 change that has occurred in the network topology that supports the propagation of MRP information. If the  
30 network topology is maintained by means of the spanning tree protocol state machines, then, for the set of  
31 Applicant and Registrar state machines associated with a given Port and spanning tree instance, this event is  
32 generated when the Port Role changes from Designated Port to either Root Port or Alternate Port.

#### 33 **10.7.5.4 New!**

34 A new declaration is made. The event is deemed to have occurred if the MAD Service User issues a  
35 `MAD_Join.request` service primitive for the Attribute instance associated with that state machine, indicating  
36 a new declaration.

#### 37 **10.7.5.5 Join!**

38 A declaration is made. The event is deemed to have occurred if the MAD Service User issues a  
39 `MAD_Join.request` service primitive for the Attribute instance associated with that state machine.

1 **10.7.5.6 Lv!**

2 A declaration is withdrawn. The event is deemed to have occurred if the MAD Service User issues a  
3 MAD\_Leave.request service primitive for the Attribute instance associated with that state machine.

4 **10.7.5.7 tx!**

5 A transmission opportunity occurs, without a LeaveAll being signaled by the LeaveAll state machine.

6 NOTE—The tx! event is modified by the behavior of the LeaveAll state machine. If the LeaveAll state machine has  
7 signaled LeaveAll, then tx! is modified to txLA! (see 10.7.5.8).

8 **10.7.5.8 txLA!**

9 A transmission opportunity occurs, with a LeaveAll being signaled by the LeaveAll state machine.

10 **10.7.5.9 txLAF!**

11 A transmission opportunity occurs, with a LeaveAll being signaled by the LeaveAll state machine, and with  
12 no room available in the PDU.

13 **10.7.5.10 periodic!**

14 This event indicates to the Applicant state machine that the timer used to stimulate periodic transmission has  
15 expired.

16 **10.7.5.11 periodicEnabled!**

17 This event indicates to the Periodic Transmission state machine that it has been enabled by management  
18 action (12.9.3).

19 **10.7.5.12 periodicDisabled!**

20 This event indicates to the Periodic Transmission state machine that it has been disabled by management  
21 action (12.9.3).

22 **10.7.5.13 Message reception events**

23 For an instance of the Applicant state machine or the Registrar state machine, a message reception event is  
24 deemed to have occurred if an MRPDU (10.8) is received, and the following conditions are true:

- 25 a) The PDU was addressed to an MRP application (the MRP application address, Table 10-1, or MRP  
26 address, 39.2.1.6) and had an EtherType (Table 10-2) in accordance with that of the MRP  
27 application associated with the state machine.
- 28 b) The PDU contains a Message (10.8.1) in which the Attribute Type is the type associated with the  
29 state machine.
- 30 c) The Message contains a VectorAttribute (10.8.1.2) where the range defined by the FirstValue and  
31 NumberOfValues includes the attribute value associated with the state machine.

32 The specific type of message reception event is determined by the event value (10.8.2.5) associated with the  
33 state machine. The possible message reception event types are specified in 10.7.5.14 through 10.7.5.20.

34 **10.7.5.14 rNew!**

35 For an instance of the Applicant or Registrar state machine, a message reception event (10.7.5.13) occurs,  
36 and the event value (10.8.2.5) associated with the state machine specifies the New message.

1 **10.7.5.15 rJoinIn!**

2 For an instance of the Applicant or Registrar state machine, a message reception event (10.7.5.13) occurs,  
3 and the event value (10.8.2.5) associated with the state machine specifies the JoinIn message.

4 **10.7.5.16 rJoinMt!**

5 For an instance of the Applicant or Registrar state machine, a message reception event (10.7.5.13) occurs,  
6 and the event value (10.8.2.5) associated with the state machine specifies the JoinMt message.

7 **10.7.5.17 rLv!**

8 For an instance of the Applicant or Registrar state machine, a message reception event (10.7.5.13) occurs,  
9 and the event value (10.8.2.5) associated with the state machine specifies the Lv message.

10 **10.7.5.18 rIn!**

11 For an instance of the Applicant or Registrar state machine, a message reception event (10.7.5.13) occurs,  
12 and the event value (10.8.2.5) associated with the state machine specifies the In message.

13 **10.7.5.19 rMt!**

14 For an instance of the Applicant or Registrar state machine, a message reception event (10.7.5.13) occurs,  
15 and the event value (10.8.2.5) associated with the state machine specifies the Mt message.

16 **10.7.5.20 rLA!**

17 For an instance of the Applicant state machine, the Registrar state machine, or the LeaveAll state machine,  
18 the rLA! event is deemed to have occurred if either:

- 19 a) The LeaveAll state machine associated with that instance of the Applicant or Registrar state  
20 machine performs the sLA action (10.7.6.6); or
- 21 b) An MRPDU (10.8) is received, and the following conditions are true:
  - 22 1) The PDU's destination MAC address and EtherType are in accordance with the definition of  
23 the MRP application associated with the state machine.
  - 24 2) The PDU contains a Message (10.8.1) in which the Attribute Type is the type associated with  
25 the state machine.
  - 26 3) The Message contains a LeaveAllEvent (10.8.2.6) that carries the value LeaveAll.

27 NOTE—The LeaveAll state machine operates on a per-application (not per-Attribute Type) basis, but the LeaveAll  
28 message operates on a per-Attribute Type basis. Hence, when the LeaveAll state machine issues a LeaveAll, it must  
29 generate a LeaveAll Attribute for each Attribute Type supported by the application concerned.

30 **10.7.5.21 leavetimer!**

31 For an instance of the Registrar state machine, the leavetimer! event is deemed to have occurred when the  
32 leavetimer associated with that state machine expires.

33 **10.7.5.22 leavealltimer!**

34 For an instance of the LeaveAll state machine, the leavealltimer! event is deemed to have occurred either  
35 when the leavealltimer associated with that state machine expires or when a Flush! event (10.7.5.2) occurs  
36 for the Port and spanning tree instance associated with that state machine.

37 **10.7.5.23 periodictimer!**

38 For an instance of the PeriodicTransmission state machine, the periodictimer! event is deemed to have  
39 occurred when the periodictimer associated with that state machine expires.

## 1 10.7.6 Protocol Action definitions

### 2 10.7.6.1 MRPDU transmission actions

3 Unless stated otherwise in these action definitions, MRPDU transmission as a result of the operation of a  
4 state machine in a Bridge occurs only through the Port associated with that state machine. MRPDUs shall be  
5 transmitted using the destination MAC address and EtherType value defined by the MRP application  
6 associated with the state machine.

7 When the action specifies the transmission of attribute state information, an MRPDU, formatted as defined  
8 in 10.8.1, is transmitted so that:

- 9 a) The PDU contains a Message (10.8.1.2) that carries an Attribute Type (10.8.2.2) that corresponds to  
10 the type of attribute associated with the state machine concerned.
- 11 b) The Message contains a VectorAttribute (10.8.2.10) in which the FirstValue (10.8.2.7) and  
12 NumberOfValues (10.8.2.8) defines a range of attribute values that includes the attribute value  
13 associated with the state machine.
- 14 c) The Vector (10.8.2.10) encodes an AttributeEvent value in the vector position corresponding to the  
15 attribute value for this state machine. The choice of AttributeEvent value is determined by the  
16 specific transmission action, as defined below.

17 NOTE—As explained in 10.8.2.10.1 each attribute in a vector is associated with its own individual state machine. A  
18 naive implementation of MRP can therefore be quite inefficient.

19 In the case of LeaveAll transmission actions, the LeaveAll event value specified by the transmission action  
20 is encoded in the NumberOfValues field of the VectorAttribute.

### 21 10.7.6.2 sN

22 The AttributeEvent value New is encoded in the Vector as specified in 10.7.6.1.

### 23 10.7.6.3 sJ, [sJ]

24 If the Registrar state is IN, then the AttributeEvent value JoinIn is encoded in the Vector as specified in  
25 10.7.6.1.

26 If the Registrar state is MT or LV, then the AttributeEvent value JoinMt is encoded in the Vector as specified  
27 in 10.7.6.1.

28 NOTE—The [sJ] variant indicates that the action is only necessary in cases where transmitting the value, rather than  
29 terminating a vector and starting a new one, makes for more optimal encoding; i.e., transmitting the value is not  
30 necessary for correct protocol operation.

### 31 10.7.6.4 sL

32 The AttributeEvent value Lv is encoded in the Vector as specified in 10.7.6.1.

### 33 10.7.6.5 s, [s]

34 If the Registrar state is IN, then the AttributeEvent value In is encoded in the Vector as specified in 10.7.6.1.

35 If the Registrar state is MT or LV, then the AttributeEvent value Mt is encoded in the Vector as specified in  
36 10.7.6.1.

37 NOTE—In the [s] variant, this value is transmitted only if its inclusion makes for more optimal encoding; i.e.,  
38 transmitting the value is not necessary for correct protocol operation.

### 39 10.7.6.6 sLA

40 The LeaveAll event value specified by the transmission action is encoded in the NumberOfValues field of  
41 the VectorAttribute as specified in 10.7.6.1.

1 The sLA action also gives rise to a rLA! event (10.7.5.20) against all instances of the Applicant state  
2 machine, or the Registrar state machine, associated with the MRP participant.

### 3 **10.7.6.7 periodic**

4 Causes a periodic! event (10.7.5.10) against all Applicant state machines associated with the participant.

### 5 **10.7.6.8 Start leavetimer**

6 Causes leavetimer to be started, in accordance with the definition of the timer in 10.7.4.2.

### 7 **10.7.6.9 Stop leavetimer**

8 Causes leavetimer to be stopped.

### 9 **10.7.6.10 Start leavealltimer**

10 When LeaveAllTime is nonzero, this causes leavealltimer to be started, in accordance with the definition of  
11 the timer in 10.7.4.3.

### 12 **10.7.6.11 Start periodictimer**

13 Causes periodictimer to be started, in accordance with the definition of the timer in 10.7.4.4.

### 14 **10.7.6.12 New**

15 This action causes a MAD\_Join.indication primitive to be issued to the MAD Service User, indicating the  
16 Attribute instance corresponding to the state machine concerned, with the *new* parameter set TRUE.

### 17 **10.7.6.13 Join**

18 This action causes a MAD\_Join.indication primitive to be issued to the MAD Service User, indicating the  
19 Attribute instance corresponding to the state machine concerned, with the *new* parameter set FALSE.

### 20 **10.7.6.14 Lv**

21 This action causes a MAD\_Leave.indication primitive to be issued to the MAD Service User, indicating the  
22 Attribute instance corresponding to the state machine concerned.

## 23 **10.7.7 Applicant state machine**

24 A full MRP Participant maintains a single instance of the Applicant state machine (Table 10-3) for each  
25 Attribute value for which the Participant needs to maintain state information.

## 26 **10.7.8 Registrar state machine**

27 A full MRP Participant maintains a single instance of this state machine for each Attribute value that is  
28 currently registered, or that the Registrar state machine is in the process of deregistering.

29 NOTE—As with the Applicant, state information is conceptually maintained for all possible values of all Attribute types  
30 that are defined for a given application; however, in real implementations of MRP, it is likely that the range of possible  
31 Attribute values in some applications will preclude this, and the implementation will limit the state to those Attribute  
32 values in which the Participant has an immediate interest. In the case of simple devices that have no interest in what  
33 other Participants have registered, it may be appropriate for that device to ignore Registrar operation altogether.

34 The detailed operation of this state machine is described in Table 10-4.

**Table 10-3—Applicant state table**

|       |                             | STATE               |                 |                     |                       |                 |                  |                 |                    |                    |                   |                 |                 |
|-------|-----------------------------|---------------------|-----------------|---------------------|-----------------------|-----------------|------------------|-----------------|--------------------|--------------------|-------------------|-----------------|-----------------|
|       |                             | VO <sup>11,12</sup> | VP <sup>6</sup> | VN <sup>6, 12</sup> | AN <sup>6, 12</sup>   | AA <sup>6</sup> | QA <sup>12</sup> | LA <sup>6</sup> | AO <sup>3,11</sup> | QO <sup>3,11</sup> | AP <sup>3,6</sup> | QP <sup>3</sup> | LO <sup>6</sup> |
| EVENT | Begin! <sup>12</sup>        | —                   | VO              | VO                  | VO                    | VO              | VO               | VO              | VO                 | VO                 | VO                | VO              | VO              |
|       | New! <sup>12</sup>          | VN                  | VN              | —                   | —                     | VN              | VN               | VN              | VN                 | VN                 | VN                | VN              | VN              |
|       | Join!                       | VP                  | —               | —                   | —                     | —               | —                | AA              | AP                 | QP                 | —                 | —               | VP              |
|       | Lv!                         | —                   | VO              | LA                  | LA                    | LA              | LA               | —               | —                  | —                  | AO                | QO              | —               |
|       | rNew!                       | —                   | —               | —                   | —                     | —               | —                | —               | —                  | —                  | —                 | —               | —               |
|       | rJoinIn!                    | AO <sup>4</sup>     | AP <sup>4</sup> | —                   | —                     | QA              | —                | —               | QO                 | —                  | QP                | —               | —               |
|       | rIn!                        | —                   | —               | —                   | —                     | QA <sup>5</sup> | —                | —               | —                  | —                  | —                 | —               | —               |
|       | rJoinMt!    rMt!            | —                   | —               | —                   | —                     | —               | AA               | —               | —                  | AO                 | —                 | AP              | VO              |
|       | rLv!    rLA!    Re-declare! | LO <sup>1</sup>     | —               | —                   | VN                    | VP <sup>9</sup> | VP <sup>9</sup>  | — <sup>10</sup> | LO <sup>1</sup>    | LO <sup>1</sup>    | VP                | VP              | —               |
|       | periodic!                   | —                   | —               | —                   | —                     | —               | AA               | —               | —                  | —                  | —                 | AP              | —               |
|       | tx! <sup>7, 12</sup>        | [s]<br>—            | sJ<br>AA        | sN<br>AN            | sN<br>QA <sup>8</sup> | sJ<br>QA        | [sJ]<br>—        | sL<br>VO        | [s]<br>—           | [s]<br>—           | sJ<br>QA          | [s]<br>—        | s<br>VO         |
|       | txLA! <sup>2</sup>          | [s]<br>LO           | s<br>AA         | sN<br>AN            | sN<br>QA              | sJ<br>QA        | sJ<br>—          | [s]<br>LO       | [s]<br>LO          | [s]<br>LO          | sJ<br>QA          | sJ<br>QA        | [s]<br>—        |
|       | txLAF! <sup>2</sup>         | LO                  | VP              | VN                  | VN                    | VP              | VP               | LO              | LO                 | LO                 | VP                | VP              | —               |

**Notes to the table:**

- <sup>1</sup> Applicant-Only participants exclude the LO state, and transition to VO.
- <sup>2</sup> These events do not occur for Applicant-Only participants.
- <sup>3</sup> Point-to-point subset participants exclude the AO, QO, AP, and QP states.
- <sup>4</sup> Ignored (no transition) if point-to-point subset or if operPointToPointMAC is TRUE.
- <sup>5</sup> Ignored (no transition) if operPointToPointMAC is FALSE. See MRP Design Notes below.
- <sup>6</sup> Request opportunity to transmit on entry to VN, AN, AA, LA, VP, AP, and LO states.
- <sup>7</sup> If the MRDPDU is full and cannot convey a required message there is no change of state and an additional transmit opportunity is requested if that has not been done already.
- <sup>8</sup> QA if the Registrar is IN, and AA otherwise. See MRP Design Notes below.

**MRP design notes:**

- <sup>5</sup> On shared media the receipt of In does not confirm registration by all Participants, and the In could have been sent by an Applicant-Only participant.
- <sup>8</sup> Since New messages do not convey registrar state, a Leave could have been received without an Empty or JoinEmpty prompt being sent, the transition to AA guards against loss of that Leave by another Applicant.
- <sup>9</sup> The design accepts a small possibility of a continued registration (after rLv! if a Lv! occurs before a further Join is sent) in return for not accumulating many Active participants when Join!s and Lv!s are frequent. rLv! processing is deliberately not optimized for point-to-point.
- <sup>10</sup> If a Leave has been received, the Registrar for the transmitting participant is very probably IN, as this Applicant has not yet sent a Leave, so the pending Leave is required. The small savings from avoiding transmission of Leaves pending on receipt of LeaveAlls does not merit distinguishing the rLv! and rLA! cases.
- <sup>11</sup> The VO, AO, and QO states represent states where the attribute is neither being declared by the Participant nor being registered by any other station on the LAN. In implementations where dynamic creation and discarding of state machines is desirable, the state machine can be discarded when in any of these states, pending a future requirement to declare or register that attribute value.
- <sup>12</sup> A New-Only Participant recognizes only the Begin!, New!, and tx! events, and ignores all others, so can only reach the VO, VN, AN, and QA states.

**Table 10-4—Registrar state table**

|              |                                                         | STATE                  |                              |                 |
|--------------|---------------------------------------------------------|------------------------|------------------------------|-----------------|
|              |                                                         | IN                     | LV                           | MT              |
| <b>EVENT</b> | <b>Begin!</b>                                           | MT                     | MT                           | MT              |
|              | <b>rNew!</b>                                            | New<br>IN              | New<br>Stop leavetimer<br>IN | New<br>IN       |
|              | <b>rJoinIn!   <br/>rJoinMt!</b>                         | IN                     | Stop leavetimer<br>IN        | Join<br>IN      |
|              | <b>rLv!   <br/>rLA!   <br/>txLA!   <br/>Re-declare!</b> | Start leavetimer<br>LV | -x-                          | -x-             |
|              | <b>Flush!</b>                                           | Lv<br>MT               | Lv<br>MT                     | MT              |
|              | <b>leavetimer!</b>                                      | -x-                    | Lv<br>MT                     | MT <sup>a</sup> |

<sup>a</sup>If operPointToPointMAC is TRUE, proceed directly to the Lv/MT transition as defined in the LV State for the leavetimer! Event. This avoids the delay resulting from the leavetimer. If operPointToPointMAC is FALSE, the state machine is executed as shown.

## 1 10.7.9 LeaveAll state machine

2 A single LeaveAll state machine exists for each full MRP Participant. Leave All messages generated by this  
3 state machine also generate LeaveAll events against all the Applicant and Registrar state machines  
4 associated with that Participant and Port; hence, LeaveAll generation is treated by those state machines in  
5 the same way as reception of a LeaveAll message from an external source.

6 If the LeaveAllTime is changed from a value of zero to a nonzero value, a Begin! event shall be signaled to  
7 the LeaveAll state machine to cause it to reinitialize.

8 The detailed operation of this state machine is described in Table 10-5.

## 9 10.7.10 PeriodicTransmission state machine

10 A single PeriodicTransmission state machine exists for each Port. Periodic Transmission events are  
11 generated on a regular basis, against all Applicant state machines that are associated with that Port.

12 The detailed operation of this state machine is described in Table 10-6.

**Table 10-5—LeaveAll state table**

|       |                | STATE                          |                                |
|-------|----------------|--------------------------------|--------------------------------|
|       |                | Active <sup>a</sup>            | Passive                        |
| EVENT | Begin!         | Start leavealltimer<br>Passive | Start leavealltimer<br>Passive |
|       | tx!            | sLA<br>Passive                 | -x-                            |
|       | rLA!           | Start leavealltimer<br>Passive | Start leavealltimer<br>Passive |
|       | leavealltimer! | Start leavealltimer<br>Active  | Start leavealltimer<br>Active  |

<sup>a</sup> Request opportunity to transmit on entry to the Active state

**Table 10-6—PeriodicTransmission state table**

|       |                   | STATE                                     |                               |
|-------|-------------------|-------------------------------------------|-------------------------------|
|       |                   | Active                                    | Passive                       |
| EVENT | Begin!            | Start periodictimer<br>Active             | Start periodictimer<br>Active |
|       | periodicEnabled!  | -x-                                       | Start periodictimer<br>Active |
|       | periodicDisabled! | Passive                                   | -x-                           |
|       | periodictimer!    | Start periodictimer<br>periodic<br>Active | -x-                           |

### 1 10.7.11 Timer values

2 MRP *correctness* is not critically dependent on the values of protocol timers. However, the protocol operates  
3 more efficiently, and with less likelihood of unwanted deregistrations, if the following relationships are  
4 maintained between timer values used by peer Participants:

- 5 a) LeaveTime should be at least twice the maximum JoinTime, plus six times the timer resolution, to  
6 allow reregistration after a Leave or LeaveAll even if a message is lost.
- 7 b) To minimize the volume of rejoining traffic generated following a LeaveAll, the value chosen for  
8 LeaveAllTime should be large relative to LeaveTime.

9 The default timer values (Table 10-7) maintain these relationships. They may be modified on a per-Port  
10 basis by means of the management functionality defined in Clause 12.

11 NOTE—The default values for the MRP timers are independent of media access method or data rate. This is a deliberate  
12 choice, made in the interests of maximizing the “plug and play” characteristics of the protocol.

13 Implementation of the timers for MRP shall be based on a timer resolution of 1 centisecond or less.

**Table 10-7—MRP timer parameter default values**

| Parameter    | Value (centiseconds) |
|--------------|----------------------|
| JoinTime     | 20                   |
| LeaveTime    | 60–100               |
| LeaveAllTime | 1000                 |

1 If operPointToPointMAC (IEEE Std 802.1AC) is TRUE, a request for a transmit opportunity should result  
2 in such an opportunity as soon as is practicable, given other system constraints, and shall occur within the  
3 value specified for JoinTime subject to not more than three such transmission opportunities occurring in any  
4 period of  $1.5 \times \text{JoinTime}$ .

5 If operPointToPointMAC is FALSE, and there is no pending request, a transmit opportunity shall occur at a  
6 time value randomized between 0 and JoinTime seconds. These provisions shall apply even if a point-to-  
7 point subset Applicant has been implemented.

## 8 10.7.12 Operational reporting and statistics

### 9 10.7.12.1 Failure to register

10 Each MRP Participant maintains a count of the number of times that it has received a registration request,  
11 but has failed to register the attribute concerned due to lack of space in the FDB to record the registration.  
12 The value of this count may be examined by management (see 12.9.2.1.3).

13 NOTE—Further action to be taken on such events is a matter for implementation choice.

### 14 10.7.12.2 Peer tracking

15 An implementation may support the ability to record against each Registrar state machine the MAC address  
16 of the originator of the MRPDU that caused the most recent state change for that state machine (see  
17 12.9.3.1.3).

## 18 10.7.13 Interoperability considerations

19 Correct operation of MRP for a given MRP application requires that protocol exchanges among a given set  
20 of communicating MRP Participants maintain sequentiality; i.e., that Participant A cannot receive  
21 MRPDU B (generated as a consequence of Participant B receiving MRPDU A) before Participant A has  
22 received MRPDU A. In circumstances where the Participants concerned are all attached to the same LAN,  
23 such sequentiality is ensured. However, if a set of MRP Participants communicates via an intervening  
24 Bridge that does not implement that MRP application (or does not implement MRP at all), the sequentiality  
25 constraints expressed in 8.6.6, 8.6.7, and 8.6.8 are insufficient to guarantee the correct operation of MRP. In  
26 order for the correct sequencing of PDUs to be maintained through such a Bridge, the following constraint  
27 needs to be met:

28 If MRPDU A is received on Port X, and is due to be forwarded on Ports Y and Z, and subsequent to  
29 being forwarded on Y, MRPDU B is received on Port Y for forwarding on Port Z, then forwarding  
30 of B cannot precede A on Port Z.

31 NOTE—This expresses a stronger sequencing constraint for multicast frames than is stated in 8.6, but a weaker  
32 constraint than was required for conformance to IEEE Std 802.1D, 1993 Edition [B12].

33 The consequence of failure to meet this constraint is that the users of a given MRP application may  
34 experience an increased incidence of loss of registration. Therefore, it is inadvisable to construct LAN  
35 configurations involving forwarding of MRPDU through intervening Bridges if those Bridges do not meet  
36 the constraint expressed previously.

## 10.7.14 External control

The MRP External Control feature (12.32.4) specifies a managed object that the network manager uses to:

- a) Disable MRP attribute propagation (MAP) for the MRP Participant of a Bridge Port.
- b) Read MRP attribute registrations that the MRP Participant receives.
- c) Write MRP attribute values for the MRP Participant to declare.

There is one MRP External Control managed object for each MRP Participant (per Port per MRP application per MAP Context, as specified in 10.2 and 10.3.1).

Under default operation, the MRP External Control feature (externalControl attribute FALSE) is ignored by the operation of MRP and has no effect on MRP Attribute Propagation (MAP) specified in 10.3.

When the MRP External Control feature is enabled by network management (externalControl attribute TRUE), the operation of MAP in the Bridge performs as specified in 12.32.4, but all other aspects of MRP operation are performed as specified in Clause 10.

## 10.8 Structure and encoding of Multiple Registration Protocol Data Units (MRPDUs)

This subclause describes the generic structure and encoding of the MRPDUs exchanged between all MRP Participants. The structure and encoding of elements that are specific to the operation of the MRP applications are defined by the applications themselves.

Each MRPDU identifies the MRP application by which it was generated, and to which it is being transmitted. Bridges that receive MRPDUs identified as belonging to an MRP application that they do not support shall forward such PDUs on all other Ports with a Port State (8.4) of Forwarding.

NOTE 1—If MRP is used to support an application that can operate in any MAP Context other than 0 (the Base Spanning Tree Context), the application specification describes how that context is identified in protocol exchanges.

Each MRPDU carries one or more MRP messages, each of which identify one or more MRP events (e.g., Join, Leave, LeaveAll) and the attribute class(es) and value(s) to which each event applies. A given MRP Participant shall process MRPDUs in the order in which they are received, and shall process the MRP Messages in a PDU in the order in which they were put into the Data Link Service Data Unit (DLSDU).

NOTE 2—Any messages generated as a consequence of state machine responses to an sLA action and its associated LeaveAll events will be put into the DLSDU after the LeaveAll message(s), or into a later DLSDU.

### 10.8.1 Structure

#### 10.8.1.1 Transmission and representation of octets

All MRPDUs consist of an integral number of octets, numbered starting from 1 and increasing in the order that they are put into a DLSDU. The bits in each octet are numbered from 1 to 8, where 1 is the low-order bit.

When consecutive octets are used to represent a binary number, the lower octet number has the most significant value.

When the encoding of (an element of) an MRPDU is represented using a diagram in this clause, the following representations are used:

- a) Octet 1 is shown toward the top of the page, higher numbered octets being toward the bottom.
- b) Where more than one octet appears on a given line, octets are shown with the lowest numbered octet to the left, higher numbered octets being to the right.
- c) Within an octet, bits are shown with bit 8 to the left and bit 1 to the right.

## 10.8.1.2 Structure definition

MRP makes use of an EtherType value as the means of identifying the MRP application that has transmitted, and that will receive, a given MRPDU. Table 10-2 lists the set of MRP applications that are defined, and the EtherType values that correspond to them.

A protocol version field is included in the structure of the MRPDU, in order to provide the ability to identify enhancements to MRP applications.

MRPDUs exchanged according to the protocol specified in this clause shall have the following structure:

- a) The first octet contains the *ProtocolVersion*.
- b) Following the Protocol Version are one or more *Messages*. The last element in the PDU is an *EndMark*.
- c) Each Message consists of an *AttributeType*, an *AttributeLength*, and an *AttributeList*, in that order.
- d) An Attribute List consists of one or more *VectorAttributes*. The last element in the AttributeList is an *EndMark*.
- e) A VectorAttribute consists of a *VectorHeader*, a *FirstValue*, and a *Vector*, in that order. The VectorHeader is able to encode both a *LeaveAllEvent* and the number of attribute events encoded in the vector.
- f) If the end of an MRPDU is encountered before an EndMark is reached, then processing of the PDU is terminated as if an EndMark had been reached.

The following Backus-Naur Form (BNF) productions give the formal description of the MRPDU structure:

```
MRPDU ::= ProtocolVersion, Message {, Message}, EndMark
ProtocolVersion BYTE ::= Defined by the specific MRP application
Message ::= AttributeType, AttributeLength[, AttributeListLength], AttributeList
AttributeType BYTE ::= Nonzero integer defined by the specific MRP application
AttributeLength BYTE ::= Nonzero integer defined by the specific MRP application
AttributeListLength SHORT ::= Nonzero integer defined by the specific MRP application
AttributeList ::= VectorAttribute {, VectorAttribute}, EndMark
VectorAttribute ::= VectorHeader, FirstValue {, Vector}
VectorHeader SHORT ::= (LeaveAllEvent * 8192) + NumberOfValues
FirstValue ::= Defined by the specific MRP application
Vector ::= ThreePackedEvents {, ThreePackedEvents}
           [, FourPackedEvents {, FourPackedEvents}]
ThreePackedEvents BYTE ::= (((((AttributeEvent) * 6) + AttributeEvent) * 6) + AttributeEvent) * 6) + AttributeEvent
AttributeEvent BYTE ::= New | JoinIn | In | JoinMt | Mt | Lv
FourPackedEvents BYTE ::= ((FourPackedType * 64) + (FourPackedType * 16)
                           + (FourPackedType * 4) + FourPackedType)
FourPackedType BYTE ::= Integer defined by the specific MRP application
LeaveAllEvent BYTE ::= NullLeaveAllEvent | LeaveAll
NumberOfValues SHORT ::= Number of events encoded in the vector
EndMark SHORT ::= 0x0000 | End of PDU
NullLeaveAllEvent ::= 0
LeaveAll ::= 1
New ::= 0
JoinIn ::= 1
In ::= 2
JoinMt ::= 3
Mt ::= 4
Lv ::= 5
```

1 The parameters carried in MRPDUs, as identified in this structure definition, shall be encoded as specified in  
2 10.8.2.

3 Figure 10-5 illustrates the structure of the MRPDU and its components.

**Figure 10-5—Format of the major components of an MRPDU**

## 4 10.8.2 Encoding of MRPDU parameters

### 5 10.8.2.1 Encoding of ProtocolVersion

6 A ProtocolVersion shall be encoded in a single octet, taken to represent an unsigned binary number. It takes  
7 a value that is determined by the application concerned.

8 NOTE—The handling of protocol version information is defined in 10.8.3.5.

### 9 10.8.2.2 Encoding of AttributeType

10 An AttributeType shall be encoded as a single octet, taken to represent an unsigned binary number. The  
11 AttributeType identifies the type of Attribute to which the message applies. The range of values that can be  
12 taken by the AttributeType, and the meanings of those values, are defined by the application concerned. The  
13 value 0 is reserved, and shall not be used as an AttributeType by any MRP application. MRP applications  
14 may otherwise allocate meanings to any set of values of AttributeType in the range 1 through 255.

15 The definition of AttributeType values in the application associates the following with each AttributeType  
16 value defined:

- 17 a) The size, in octets, of attribute values, and how they are encoded.
- 18 b) Any restrictions that are placed upon the range of attribute values that the vector is permitted to  
19 represent.

### 20 10.8.2.3 Encoding of AttributeLength

21 An AttributeLength shall be encoded as a single octet, taken to represent an unsigned binary number. The  
22 AttributeLength indicates the length, in octets, of the FirstValue field (10.8.2.7) for the Attribute to which  
23 the message applies.

#### 1 10.8.2.4 Encoding of AttributeListLength

2 An AttributeListLength shall be encoded as two octets, taken to represent an unsigned binary number. The  
3 AttributeListLength indicates the length, in octets, of the AttributeList field for the Attribute to which the  
4 message applies. This field is not present in all MRPDUs. Specifically, Multiple MAC Registration Protocol  
5 Data Units (MMRPDUs) and Multiple VLAN Registration Protocol Data Units (MVRPDUs) do not use this  
6 field, whereas Multiple Stream Protocol Data Units (MSRPDUs) do use this field.

#### 7 10.8.2.5 Encoding of AttributeEvent

8 An AttributeEvent shall be encoded as an unsigned decimal number in the range 0 through 5. The permitted  
9 values and meanings of the AttributeEvent are as follows:

|    |    |                 |
|----|----|-----------------|
| 10 | 0: | New operator    |
| 11 | 1: | JoinIn operator |
| 12 | 2: | In operator     |
| 13 | 3: | JoinMt operator |
| 14 | 4: | Mt operator     |
| 15 | 5: | Lv operator     |

16 Further values of AttributeEvent are reserved.

17 The AttributeEvent is interpreted on receipt as a MAD event to be applied to the state machine for the  
18 Attribute defined by the AttributeType and AttributeValue to which the AttributeEvent relates.

#### 19 10.8.2.6 Encoding of LeaveAllEvent

20 A LeaveAllEvent shall be encoded as an unsigned binary number. The permitted values and meanings of  
21 LeaveAllEvent are as follows:

|    |    |                            |
|----|----|----------------------------|
| 22 | 0: | NullLeaveAllEvent operator |
| 23 | 1: | LeaveAll operator          |

24 Further values of LeaveAllEvent are reserved.

25 The LeaveAllEvent is interpreted on receipt as a MAD Leave All event to be applied to the state machines  
26 for all Attributes of the type defined by the AttributeType field.

27 The value NullLeaveAllEvent signifies that there is no Leave All event to process, and is included purely for  
28 encoding efficiency in the vector attribute structures. Receipt of this value does not cause any event to be  
29 applied to any state machine.

#### 30 10.8.2.7 Encoding of FirstValue

31 A FirstValue is encoded in N octets, taken to be an unsigned binary number, in accordance with the  
32 specification for the AttributeType defined by the MRP application concerned. The length, in octets, of the  
33 FirstValue field is specified by the value contained in the AttributeLength field (10.8.2.3). When  
34 NumberOfValues is greater than one (1) FirstValue is incremented in a way that is defined by each MRP  
35 application. For example MMRP simply increments FirstValue by adding the number one (1) to it, whereas  
36 MSRP adds one (1) to multiple fields within the FirstValue for each increment. Throughout this  
37 specification FirstValue incremented by one is denoted as FirstValue + 1, incrementing by two is denoted as  
38 FirstValue + 2, etc.

### 10.8.2.8 Encoding of VectorHeader

The VectorHeader is used to encode both the value of the LeaveAllEvent (10.8.2.6) and the NumberOfValues, the number of AttributeEvent values encoded in a Vector (10.8.2.10). The VectorHeader is taken to be an unsigned binary number, encoded in two octets, as follows:

- a) The value of the LeaveAllEvent is multiplied by 8192.
- b) The resulting number is added to NumberOfValues.

The range of values that NumberOfValues can take is restricted, such that the following are true:

- c) The size of the Vector that is defined by this number will fit in the available space in the PDU.
- d) Incrementing FirstValue the number of times specified in NumberOfValues does not exceed the permitted numeric range of FirstValue as defined for the application concerned.
- e) The number of AttributeEvent values does not exceed 8191.
- f) If the number of AttributeEvent values is zero, FirstValue is ignored and the value is skipped. However, FirstValue is still present, and of the correct length, in octets, as specified by the AttributeLength field (10.8.2.3) for the Attribute to which the message applies.
- g) If LeaveAllEvent is a NullLeaveAllEvent, the number of AttributeEvent values is nonzero.

### 10.8.2.9 Encoding of EndMark

An EndMark shall be encoded as two octets, taken to represent an unsigned binary number. It takes the numeric value 0.

Further values of EndMark are reserved and shall not be used.

NOTE—As defined by the MRPDU structure definition in 10.8.1, if the end of the MRPDU is encountered, this is taken to be an End Mark from the point of view of processing the PDU contents.

### 10.8.2.10 Encoding of Vector

#### 10.8.2.10.1 Encoding of Vector ThreePackedEvents

The Vector is encoded as zero or more 8-bit values, each containing a numeric value, ThreePackedEvents, derived from three packed numeric values, each of which represents an AttributeEvent, in the range 0 through 5.

As can be seen from the BNF definition of ThreePackedEvents, each 8-bit value is derived by successively adding an event value and multiplying the result by 6. In order to facilitate the subsequent description, the event values are numbered from *first* to *third*, as follows:

ThreePackedEvents BYTE ::=  
$$((((firstAttributeEvent) \times 6) + secondAttributeEvent) \times 6) + thirdAttributeEvent$$

The NumberOfValues field in the VectorHeader of the VectorAttribute determines the number of 8-bit ThreePackedEvents values, *E*, that will be present in the vector; hence *E* is determined by dividing NumberOfValues by 3 and rounding any noninteger answer up to the nearest larger integer.

The FirstValue field of the VectorAttribute determines which of the originator's state machines the *first* AttributeEvent value in the first ThreePackedEvents value relates to. The *second* AttributeEvent value in the first ThreePackedEvents value corresponds to the state machine identified by (FirstValue + 1), and the *third* AttributeEvent value in the first ThreePackedEvents value corresponds to the state machine identified by (FirstValue + 2), and so on, through subsequent packed values.

1 Where the NumberOfValues field carries a value that is not a multiple of 3, there will be either one or two  
2 AttributeEvent values packed in the final ThreePackedEvents that are ignored; these values are encoded as  
3 the numeric value 0 on transmission and are ignored on receipt.  
4 NOTE—If NumberOfValues is zero, there will be no ThreePackedEvents encoded in the vector.

## 5 10.8.2.10.2 Encoding of Vector FourPackedEvents

6 The Vector is encoded as zero or more 8-bit values, each containing a numeric value, FourPackedEvents,  
7 derived from four packed numeric values, each of which represent a FourPackedType, in the range 0 through  
8 3. The FourPackedTypes are defined by each MRP application that uses FourPackedEvents. Note that not all  
9 MRP applications use FourPackedEvents.

10 As can be seen from the BNF definition of FourPackedEvents, each 8-bit value is derived by successively  
11 adding a FourPackedType value and multiplying the result by 4. In order to facilitate the subsequent  
12 description, the event values are numbered from first to fourth, as follows:

13 FourPackedEvents BYTE ::= ((firstFourPackedType × 64) + (secondFourPackedType × 16) +  
14 (thirdFourPackedType × 4) + (fourthFourPackedType))

15 The NumberOfValues field in the VectorHeader of the VectorAttribute determines the number of 8-bit  
16 FourPackedEvents values, E, that will be present in the vector; hence E is determined by dividing  
17 NumberOfValues by 4 and rounding any noninteger answer up to the nearest larger integer.

18 The FirstValue field of the VectorAttribute determines which of the originator's state machines the first  
19 FourPackedType value in the first FourPackedEvents value relates to. The second FourPackedType value in  
20 the first FourPackedEvents value corresponds to the state machine identified by (FirstValue + 1). The third  
21 FourPackedType value in the first FourPackedEvents value corresponds to the state machine identified by  
22 (FirstValue + 2), and the fourth FourPackedType value in the first FourPackedEvents value corresponds to  
23 the state machine identified by (FirstValue + 3), and so on, through subsequent packed values.

24 Where the NumberOfValues field carries a value that is not a multiple of 4, there will be one, two, or three  
25 FourPackedType values packed in the final FourPackedEvent that are ignored; these values are encoded as  
26 the numeric value 0 on transmission and are ignored on receipt.

27 NOTE—If NumberOfValues is zero, there will be no FourPackedEvents encoded in the vector.

## 28 10.8.3 Packing and parsing MRPDUs

29 The use of the End Mark (10.8.2.9) to signal the end of an AttributeList and the end of an MRPDu, and the  
30 fact that the (physical) end of the PDU is interpreted as an End Mark, simplifies the requirements both for  
31 packing information into MRPDUs and for correctly interpreting that information on receipt.

### 32 10.8.3.1 Packing

33 Successive Messages are packed into the MRPDu, and within each Message, successive VectorAttributes  
34 are packed into each Message, until the end of the PDU is encountered or there are no more VectorAttributes  
35 to pack at that time. The following cases can occur:

- 36 a) The PDU has sufficient room for all the VectorAttributes that require to be transmitted at that time to  
37 be packed. In this case, the PDU is transmitted, and subsequent PDUs are transmitted when there are  
38 further VectorAttributes to transmit.
- 39 b) The PDU has enough room for the first N VectorAttributes that require to be transmitted at that time  
40 to be packed. In this case, the PDU is transmitted, and the next N VectorAttributes are encoded in a  
41 subsequent PDU.

### 10.8.3.2 Handling of received MRPDUs

Received MRPDUs, i.e., PDUs that are constructed in accordance with the MRPDU format defined in 10.8, that carry a destination MAC address and MRP EtherType value as specified for use by a defined MRP application, are processed as follows:

- a) In Bridges and end stations that support the operation of the MRP application concerned, all such PDUs shall be submitted to the MRP Participant associated with the reception Port for further processing.
- b) In Bridges that do not support the operation of the MRP application concerned, all such PDUs shall be submitted to the Forwarding Process.

### 10.8.3.3 Discarding badly formed MRPDUs

An MRP Participant that receives an MRPDU shall discard that PDU if the PDU is not formatted according to the MRPDU format defined in 10.8.

### 10.8.3.4 Parsing

Successive Messages, and within each Message, successive VectorAttributes, are unpacked from the PDU. If this process terminates because the end of the PDU is reached, then the end of the PDU is taken to signal termination both of the current AttributeList and the overall PDU. The following two cases can occur:

- a) The last VectorAttribute to be unpacked was complete. In this case, the VectorAttribute is processed normally, and processing of the PDU terminates.
- b) The last VectorAttribute to be unpacked was incomplete. In this case, the entire PDU is discarded, and processing of the PDU terminates.

### 10.8.3.5 Handling of protocol versions

In order to ensure compatibility with previous protocol versions, while allowing the protocol to be extended, the following requirements shall be met by the implementation:

- a) MRPDUs that carry a protocol version lower than the protocol version implemented shall be interpreted according to the definition corresponding to the protocol version carried in the PDU.
- b) MRPDUs that carry a protocol version equal to or higher than the protocol version implemented shall be interpreted according to the definition corresponding to the protocol version implemented.
- c) Where the MRPDU carries a higher protocol version than the version implemented, then:
  - 1) If a Message is encountered in which the AttributeType is not recognized, then that Message is discarded. This is achieved by discarding the successive VectorAttributes in the AttributeList until either an EndMark or the end of the PDU is reached. If an EndMark is reached, processing continues with the next Message.
  - 2) If a VectorAttribute is encountered in which the AttributeEvent is not recognized for the AttributeType concerned, then the VectorAttribute is discarded and processing continues with the next VectorAttribute, if the end of the PDU has not been reached.
  - 3) For the MSRP application (Clause 35), if a FirstValue is encountered in which a TLV is not recognized for the Type concerned, then the TLV is discarded and processing continues with the next TLV, if the end of the PDU has not been reached.

## 10.9 Multiple MAC Registration Protocol (MMRP)—Purpose

MMRP provides a mechanism that allows end stations and MAC Bridges to dynamically register (and subsequently, deregister) Group membership or individual MAC address information with the Bridges attached to the same LAN, and disseminates that information across all the Bridges that support Extended Filtering Services in the Bridged Network. The operation of MMRP relies upon the services provided by MRP.

The information registered, deregistered, and disseminated via MMRP can appear in any of the following forms:

- a) *Group membership information.* This indicates the presence of MMRP participants that are members of a particular Group (or Groups), and carries the group MAC address(es) associated with the Group(s). The exchange of specific Group membership information can result in the creation or updating of MAC Address Registration Entries in the FDB to indicate the Port(s) and VID(s) of the VLAN(s) on which members of the Group(s) have been registered. The structure of these entries is described in 8.8.4.
- b) *Group service requirement information.* This indicates that one or more MMRP participants require Forward All Groups or Forward Unregistered Groups to be the default Group filtering behavior (see 6.16.7 and 8.8.6).
- c) *Individual MAC address information.*

Registration of Group membership information makes Bridges aware that frames destined for the group MAC address concerned should only be forwarded in the direction of the registered members of the Group. Therefore, forwarding of frames destined for the address associated with that Group occurs only on Ports on which such membership registration has been received.

Registration of Group service requirement information makes the Bridges aware that Ports that can forward frames in the direction from which the information has been received should modify their default Group forwarding behavior in accordance with the service requirement expressed.

NOTE 1—Modification of default Group forwarding behavior allows Bridge Ports to accommodate MMRP-unaware devices in the Bridged Network by forwarding frames destined for unregistered group MAC addresses.

The operation of MMRP can result in:

- d) The propagation of Group membership information and Group service requirement information, and consequent creation, updating, or deletion of MAC Address Registration Entries in the FDBs of all Bridges in the network that support Extended Filtering Services.
- e) Consequent changes to the Group filtering behavior of such Bridges.

In VLAN Bridges, MMRP operates only when the Bridge Filtering Mode is set to Extended Filtering Mode. Bridges that are unable to operate in Extended Filtering Mode, or have been set to operate in Basic Filtering Mode, are transparent with respect to MMRP exchanges, and forward any MRPDUs destined for the MMRP application through all Ports that are in Forwarding.

NOTE 2—An MMRP user is not prevented from registering an individual MAC address associated with a location different from its actual location. Such registration could result in denial of service to the station associated with that MAC address and, possibly, the interception of associated traffic by an unintended recipient. Such consequences of the misuse of individual MAC address registration can be prevented by using MMRP individual MAC address registration only in secure network environments (i.e., only in networks providing perimeter security).

## 10.10 MMRP Model of operation

MMRP defines an *MRP application* that provides the extended filtering services defined in 6.16.5 and 6.16.7. To this end, MMRP makes use of:

- a) The declaration and propagation services offered by *MRP Attribute Declaration* (MAD; 10.2 and 10.3,) and *MRP Attribute Propagation* (MAP; 10.2 and 10.3) to declare and propagate Group membership, Group service requirement, and individual MAC address information within the Bridged Network.
- b) The registration services offered by MAD (10.2 and 10.3) to allow Group membership, Group service requirement, and individual MAC address information to control the frame filtering behavior of participating devices.

Figure 10-6 illustrates the architecture of MMRP in the case of a two-Port Bridge and an end station, for a given VLAN Context. Where MMRP is used in multiple VLAN Contexts, an instance of the MMRP Participant exists for each VLAN context.

**Figure 10-6—Operation of MMRP for a single VLAN Context**

As shown in the diagram, the MMRP Participant consists of the following components:

- c) The MMRP application, described in 10.12
- d) MRP Attribute Propagation (MAP), described in 10.3
- e) MRP Attribute Declaration (MAD), described in 10.2

### 10.10.1 Propagation of Group Membership information

2 The Forwarding Process uses the MAC Address Registration entries in the FDBs to ensure that frames are  
3 transmitted only through those Bridge Ports necessary to reach LANs to which Group members are attached.  
4 Figure 10-7 illustrates the MAC Address Registration Entries created by MMRP for a single Group.

### Figure 10-7—Example Directed Graph

5 By receiving frames from all Ports and forwarding only through Ports for which MMRP has created MAC  
6 Address Registration Entries, Bridges facilitate Group distribution mechanisms based on the concept of an  
7 Open Host Group. Any MMRP Participants (10.2) that wish to receive frames transmitted to a particular  
8 Group or Groups request membership of the Group(s) concerned. Any MAC Service user that wishes to  
9 send frames to a particular Group can do so from any point of attachment to the Bridged Network. These  
10 frames can be received on all LANs to which registered MMRP Participants are attached, but the filtering  
11 applied by Bridges ensures that frames are not transmitted on LANs that are not part of the active topology  
12 between the sources of the frames and the registered Group members. MMRP and the MAC Address  
13 Registration Entries thus restrict the frames to pruned subsets of the overall loop-free active topology.

14 NOTE—The term “Open Host Group” comes from the terminology introduced in the definition of the Internet Group  
15 Membership Protocol (IGMP) defined by the IETF.

16 MAC Service users that are sources of MAC frames destined for the Group do not have to register as  
17 members of the Group themselves unless they also wish to receive frames transmitted to the Group address  
18 by other sources.

## 10.10.2 Propagation of Group service requirement information

MMRP propagates Group service requirement information in the same manner as for Group registration information. If any Port in a given Bridge has a registered Group service requirement of All Groups or All Unregistered Groups (expressed in terms of the control information in Static Filtering Entries and/or MAC Address Registration Entries with a MAC address specification of All Groups or All Unregistered Groups), this fact is propagated on all other Ports of the Bridge, resulting in the registration of that information on Ports of adjacent Bridges. As a consequence of that registration, the default Group filtering behavior of those Ports can change in order to maintain compatibility with the service requirements expressed by the registered information, as defined in 8.8.6. This ensures that connectivity can be maintained in LANs where the service requirements of different regions of the Bridged Network differ.

NOTE—In a Bridged Network where the default Group filtering behavior is not the same for all “edge” Ports, service requirement propagation will tend to result in all “backbone” Ports switching to the highest precedence Group filtering behavior in use in the network. The precedence rules are defined in 8.8.6.

## 10.10.3 Source pruning

As described in 10.10.1, the operation of MMRP defines a subtree of the spanning tree as a result of the creation of MAC Address Registration Entries in the FDBs of the Bridges. End stations are also able to make use of the Group Membership information registered via MMRP to allow them to keep track of the set of Groups for which active members currently exist and the service requirements of upstream devices. This allows end stations that are sources of frames destined for a Group to suppress the transmission of such frames, if their registered Group membership and Group service requirement information indicates that there are no valid recipients of those frames reachable via the LANs to which they are attached.

NOTE—In effect, for the purposes of frame transmission, the end station can be viewed as if it operates as a single Port Bridge, with its own default Group filtering behavior and FDB entries updated via MMRP that tell it whether multicast frames that it has generated should be forwarded onto the attached LAN. In order to achieve this, it is necessary for the end station to implement both the Registrar and the Applicant functionality of MRP, as described in 10.6, 10.7.7, and 10.7.8. The Applicant-Only and Simple-Applicant Participants described in 10.6 do not contain the Registrar functionality that would be required for source pruning.

This end system behavior is known as *source pruning*. Source pruning allows MAC Service users that are sources of MAC frames destined for a number of Groups, such as server stations or routers, to avoid unnecessary flooding of traffic on their local LANs in circumstances where there are no current Group members in the network that wish to receive such traffic.

## 10.10.4 Use of Group service requirement registration by end stations

The ability to propagate Group service requirement information is described in this standard primarily as a means of propagating the requirements of the Bridges themselves. However, this mechanism can also be used by end stations that have requirements involving some aspect of promiscuous reception, such as Routers or network monitors. A MMRP-aware end station wishing to receive all multicast traffic can declare membership of All Groups on the LAN to which it is attached; similarly, an end station that wishes to receive unregistered multicast traffic can do so by declaring membership of All Unregistered Groups.

## 10.11 Default Group filtering behavior and MMRP propagation

The propagation of MMRP registrations within a VLAN Context has implications with respect to the choice of default Group filtering behavior within a Bridged Network. As MMRP frames are transmitted only on outbound Ports that are in the Member set (8.8.10) for the VID concerned, propagation of Group registrations by a given Bridge occurs only toward regions of the Bridged Network where that VID has been (statically or dynamically) registered. This is illustrated in Figure 10-8; dotted lines in the diagram show those regions of the Bridged Network where propagation of registrations for Group M for VID V does not occur. Consequently, the FDBs of the lower two Bridges will not contain any Dynamic MAC Address Registration Entry for Group M for VID V.

336

## 1 10.12 Definition of the MMRP application

### 2 10.12.1 Definition of MRP elements

#### 3 10.12.1.1 Use of MAP Contexts by MMRP

4 MMRP operates within a MAP Context, or set of MAP Contexts, that is determined by the type of Bridge  
5 component supporting the MMRP application. In a MAC Bridge component MMRP operates in the  
6 Base Spanning Tree Context. In a C-VLAN component or S-VLAN component MMRP operates in the set  
7 of C-VLAN Contexts or S-VLAN Contexts, respectively, that corresponds to the VIDs that are supported by  
8 the Virtual Bridged Network.

9 The MAP Context Identifier used to identify a VLAN Context shall be equal to the VID used to identify the  
10 corresponding VLAN.

11 The set of Ports of a Bridge defined to be part of the active topology for a given VLAN Context shall be  
12 equal to the set of Ports of a Bridge for which the following are true:

- 13 a) The Port is a member of the *Member set* (8.8.10) for that VID.
- 14 b) The Port is one of the Ports of the Bridge that are part of the active topology for the spanning tree  
15 that supports that VID.

16 NOTE—The above definition applies equally to SST and MST environments. It ensures that MMRP operates in either  
17 environment, without the MMRP implementations needing to be aware of whether the VLAN Contexts that apply are all  
18 supported by the same spanning tree, as in the SST environment, or are potentially distributed across two or more  
19 spanning trees, as in the MST environment.

20 VLAN Contexts can be hierarchical. For example, in a PBN that forwards C-VLAN-tagged frames between  
21 CBNs, there can be multiple C-VLAN Contexts within each S-VLAN context. Likewise, there can be  
22 multiple C-VLAN Contexts and/or S-VLAN Contexts within the Base Spanning Tree Context. While it is  
23 theoretically possible for an MMRP application to support hierarchical MAP Contexts by maintaining an  
24 MMRP Participant for each possible (or at least anticipated) combination of C-VLAN, S-VLAN and Base  
25 Spanning Tree MAP Contexts, an MMRP application is not required to support hierarchical MAP Contexts.  
26 The identification of MMRPDUs belonging to a hierarchical MAP Context, and the treatment of such  
27 MMRPDUs, is discussed in 10.12.1.2.

#### 28 10.12.1.2 Context identification in MMRP

29 In a MAC Bridge component, received MMRPDUs that are untagged are identified with the Base Spanning  
30 Tree Context and are directed to the MRP Participant for the Base Spanning Tree. Received MMRPDUs that  
31 are VLAN-tagged identify hierarchical MAP Contexts. If the MMRP application does not support  
32 hierarchical MAP Contexts (i.e., maintain an MRP Participant for each possible S-VLAN and/or C-VLAN  
33 Context within the Base Spanning Tree Context), then the received MMRPDUs are not directed to any MRP  
34 Participant and are transmitted, including the original VLAN tag(s), on each port in the Base Spanning Tree  
35 Context except the reception port.

36 Implementations of MMRP in VLAN Bridges apply the same ingress rules (8.6.2) to received MMRPDUs  
37 that are defined for the reception Port. Therefore,

- 38 a) MMRP frames with no VLAN classification (i.e., untagged or priority-tagged MMRPDUs) are  
39 discarded if the Acceptable Frame Types parameter (6.9) for the Port is set to *Admit Only VLAN-*  
40 *tagged frames*. Otherwise, they are classified either according to the PVID for the Port, or as  
41 determined by protocol-based VLAN classification (6.12) if that capability is implemented.
- 42 b) VLAN-tagged MMRP frames are classified according to the VID carried in the tag header,  
43 optionally translated using the VID translation table (6.9).
- 44 c) If Ingress Filtering (8.6.2) is enabled, and if the Port is not in the Member set (8.8.10) for the MMRP  
45 frame's VLAN classification, then the frame is discarded.

1 The VLAN classification thus associated with a received MMRP frame establishes the C-VLAN Context or  
2 S-VLAN Context for the received PDU, depending on whether the reception port is on a C-VLAN  
3 component or S-VLAN component, and identifies the MRP Participant instance to which the PDU is  
4 directed. MMRPDUs received at an S-VLAN component and containing a C-TAG, either alone or within an  
5 S-TAG, identify hierarchical MAP Contexts. If the MMRP application does not support hierarchical MAP  
6 Contexts (i.e., maintain an MRP Participant for each possible C-VLAN Context within each S-VLAN  
7 Context), then the received MMRPDUs are not directed to any MRP Participant and are transmitted,  
8 including the original C-TAG, on each port in the S-VLAN Context except the reception port.

9 MMRPDUs transmitted by MMRP Participants are VLAN classified according to the VLAN Context  
10 associated with that Participant. MMRP Participants in VLAN Bridges apply the same egress rules that are  
11 defined for the transmission Port (8.6.4). Therefore,

12 d) MMRPDUs are transmitted through a given Port only if the Member Set for the VID concerned  
13 indicates that the VID is registered on that Port.

14 e) MMRPDUs are transmitted through a given Port as VLAN-tagged frames or as untagged frames in  
15 accordance with the state of the Untagged Set (8.8.10) for that Port and for the VID concerned.

16 Where VLAN-tagged frames are transmitted, the VID field of the tag header carries the VLAN  
17 Context Identifier value, optionally translated using the VID translation table (6.9).

#### 18 **10.12.1.3 MMRP application address**

19 The group MAC address used as the destination address for MRPDUs destined for MMRP Participants shall  
20 be the group MAC address identified in Table 10-1 as “Customer and Provider Bridge MMRP address.”

#### 21 **10.12.1.4 MMRP application EtherType**

22 The EtherType used for MRPDUs destined for MMRP Participants shall be the MMRP EtherType identified  
23 in Table 10-2.

#### 24 **10.12.1.5 MMRP ProtocolVersion**

25 The ProtocolVersion for the version of MMRP defined in this standard takes the hexadecimal value 0x00.

#### 26 **10.12.1.6 MMRP AttributeType definitions**

27 MMRP defines two AttributeTypes (10.8.2.2) that are carried in MRP exchanges, as follows:

28 a) The Service Requirement Vector Attribute Type

29 b) The MAC Vector Attribute Type

30 Attributes identified by the Service Requirement Vector Attribute Type are instances of VectorAttributes  
31 (10.8.1), used to identify values of Group service requirements. The value of AttributeType used to identify  
32 the Service Requirement Vector Attribute Type in MRPDUs (10.8.2.2) shall be 1.

33 Attributes identified by the MAC Vector Attribute Type are instances of VectorAttributes (10.8.1), used to  
34 identify a sequence of values of MAC addresses. The value of AttributeType used to identify the MAC  
35 Vector Attribute Type in MRPDUs (10.8.2.2) shall be 2.

### 10.12.1.7 MMRP FirstValue definitions

The FirstValue field (10.8.2.7) in instances of the MAC Vector Attribute Type shall be encoded in MRPDUs as six octets, each taken to represent an unsigned binary number. The octets are derived from the Hexadecimal Representation of a MAC Address (defined in IEEE Std 802) as follows:

- a) Each two-digit hexadecimal numeral in the Hexadecimal Representation is taken to represent an unsigned hexadecimal value, in the normal way, i.e., the rightmost digit of each numeral represents the least significant digit of the value, the leftmost digit is the most significant.
- b) The first octet of the attribute value encoding is derived from the left-most hexadecimal value in the Hexadecimal Representation of the MAC address. The LSB of the octet (bit 1) is assigned the LSB of the hexadecimal value, the second significant bit is assigned the value of the second significant bit of the hexadecimal value, and so on.
- c) The second through sixth octets of the encoding are similarly assigned the value of the second through sixth hexadecimal values in the Hexadecimal Representation of the MAC address.

FirstValue + 1 is defined as adding 1 to FirstValue. There are no restrictions on the range of values that can be represented in this data type.

The FirstValue field in instances of the Service Requirement Attribute Type shall be encoded in MRPDUs (10.8.2.7) as a single octet, taken to represent an unsigned binary number. Only two values of this type are defined:

- d) All Groups shall be encoded as the value 0.
- e) All Unregistered Groups shall be encoded as the value 1.

The remaining possible values (2 through 255) are reserved.

### 10.12.1.8 MMRP AttributeLength definitions

The AttributeLength field (10.8.2.3) in instances of the MAC Vector Attribute Type shall be encoded in MRPDUs (10.8) as an unsigned binary number, equal to the value 0x06.

The AttributeLength field (10.8.2.3) in instances of the Service Requirement Vector Attribute Type shall be encoded in MRPDUs (10.8) as an unsigned binary number, equal to the value 0x01.

### 10.12.1.9 MMRP AttributeListLength definitions

The AttributeListLength field (10.8.2.4) is not present in the MMRPDUs.

### 10.12.1.10 MMRP Vector definitions

The ThreePackedEvent vectors are encoded as defined in 10.8.2.10.1.

The FourPackedEvent vectors (10.8.2.10.2) are not present in the MMRPDUs.

## 10.12.2 Provision and support of Extended Filtering Services

### 10.12.2.1 Initiating MMRP registration and deregistration

The MMRP application element of an MRP Participant provides the dynamic registration and deregistration services defined in 6.16.7.1, as follows:

On receipt of a REGISTER\_MAC\_ADDRESS service primitive, the MMRP Participant issues a MAD\_Join.request. The attribute\_type parameter of the request carries the value of the MAC Vector Attribute Type (10.12.1.6) and the attribute\_value parameter carries the value of the MAC\_ADDRESS parameter of the service primitive.

1 On receipt of a DEREGISTER\_MAC\_ADDRESS service primitive, the MMRP Participant issues a  
2 MAD\_Leave.request. The attribute\_type parameter of the request carries the value of the MAC Vector  
3 Attribute Type (10.12.1.6) and the attribute\_value parameter carries the value of the MAC\_ADDRESS  
4 parameter of the service primitive.

5 On receipt of a REGISTER\_SERVICE\_REQUIREMENT service primitive, the MMRP Participant issues a  
6 MAD\_Join.request. The attribute\_type parameter of the request carries the value of the Service Requirement  
7 Vector Attribute Type (10.12.1.6) and the attribute\_value parameter carries the value of the  
8 REQUIREMENT\_SPECIFICATION parameter of the service primitive.

9 On receipt of a DEREGISTER\_SERVICE\_REQUIREMENT service primitive, the MMRP Participant  
10 issues a MAD\_Leave.request. The attribute\_type parameter of the request carries the value of the Service  
11 Requirement Vector Attribute Type (10.12.1.6) and the attribute\_value parameter carries the value of the  
12 REQUIREMENT\_SPECIFICATION parameter of the service primitive.

13 NOTE—If the EISS is supported, the Extended Filtering service primitives issued by the MAC Service user should  
14 include a VID parameter in addition to the MAC\_ADDRESS or REQUIREMENT\_SPECIFICATION parameters, in  
15 order to identify the MMRP Participant associated with the primitive.

## 16 10.12.2.2 Registration and deregistration events

17 The MMRP application element of an MRP Participant responds to registration and deregistration events  
18 signaled by MAD as follows:

19 On receipt of a MAD\_Join.indication, the MMRP application element specifies the Port associated with the  
20 MMRP Participant as Forwarding in the Port Map field of the MAC Address Registration Entry (8.8.4) for  
21 the MAC address specification carried in the attribute\_value parameter and the VID associated with the  
22 MAP Context. If such a MAC Address Registration Entry does not exist in the FDB, a new MAC Address  
23 Registration Entry is created.

24 Creation of new MAC Address Registration Entries may be restricted by the  
25 Restricted\_MAC\_Address\_Registration control (10.12.2.3). If this control is TRUE, creation of a new  
26 dynamic entry is permitted only if there is a Static Filtering Entry for the MAC address with a Registrar  
27 Administrative Control value of Normal Registration.

28 NOTE—Group Membership and Group service requirement information can be recorded in the FDB by means of MAC  
29 Address Registration Entries (see 8.8.4). In the case of Group Membership Information, the MAC address specification  
30 in the MAC Address Registration Entry is a group MAC address. In the case of Group service requirement information,  
31 the MAC address specification is either “All Group Addresses” or “All Unregistered Group Addresses.”

32 On receipt of a MAD\_Leave.indication, the MMRP application element specifies the Port associated with  
33 the MMRP Participant as Filtering in the Port Map field of the MAC Address Registration Entry (8.8.4) for  
34 the MAC address specification carried in the attribute\_value parameter and the VID associated with the  
35 MAP Context. If such an FDB entry does not exist in the FDB, then the indication is ignored. If setting that  
36 Port to Filtering results in there being no Ports in the Port Map specified as Forwarding (i.e., all MMRP  
37 members are deregistered), then that MAC Address Registration Entry is removed from the FDB.

## 38 10.12.2.3 Administrative controls

39 The provision of static control over the registration state of the state machines associated with the MMRP  
40 application is achieved by means of the Registrar Administrative Control parameters associated with the  
41 operation of MRP (10.7.2). These parameters are represented in the FDB by the information held in Static  
42 Filtering Entries (8.8.1). If no Static Filtering Entry exists for a given MAC address specification, the value  
43 of the Registrar Administrative Control parameter for the corresponding attribute value is Normal  
44 Registration for all Ports of the Bridge.

1 The initial state of the Permanent Database (i.e., the state of the Permanent Database in a Bridge that has not  
2 been otherwise configured by management action) includes a Static Filtering Entry with a MAC address  
3 specification of All Groups, in which the Port Map indicates Registration Fixed (New ignored). This Static  
4 Filtering Entry will have the effect of determining the default Group filtering behavior of all Ports of the  
5 Bridge to be Forward All Groups. This Permanent Database entry may be deleted or updated by  
6 management action.

7 NOTE—This specification of an initial Static Filtering Entry means that operation using Forward Unregistered Groups  
8 or Filter Unregistered Groups requires a conscious action on the part of the network manager or administrator.

9 Where management capability is implemented, the Registrar Administrative Control parameters can be  
10 applied and modified by means of the management functionality defined in 12.7.

11 The provision of static control over the ability of Applicant state machines to participate in protocol  
12 exchanges is achieved by means of the Applicant Administrative Control parameters associated with the  
13 operation of MRP (10.7.3). Where management capability is implemented, the Applicant Administrative  
14 Control parameters can be applied and modified by means of the management functionality defined in  
15 Clause 12.

16 Further administrative control over dynamic MAC address registration may be achieved, if supported, by  
17 means of a per-Port Restricted\_MAC\_Address\_Registration control parameter. If the value of this control is  
18 TRUE for a given Port, the creation or modification of Dynamic MAC Address Registration Entries as a  
19 result of MMRP exchanges on that Port shall be restricted only to those MAC addresses for which Static  
20 Filtering Entries exist in which the Registrar Administrative Control value is Normal Registration. If the  
21 value of the Restricted\_MAC\_Address\_Registration control is FALSE, dynamic MAC address registration  
22 is not so restricted. Where management capability is implemented, the value of the  
23 Restricted\_MAC\_Address\_Registration control can be manipulated by means of the management  
24 functionality defined in Clause 12. If management of this parameter is not supported, the value of this  
25 parameter shall be FALSE for all Ports.

### 26 **10.12.3 Use of “new” declaration capability**

27 MMRP does not make use of the “new” declaration capability.

### 28 **10.12.4 Attribute value support requirements**

29 Implementations of MMRP shall maintain state information for all attribute values that support the Group  
30 service requirement registration (10.12.1.7).

31 Implementations of MMRP shall be capable of supporting any attribute value in the range of possible values  
32 that can be registered using Group membership and individual MAC address registration (10.12.1.7);  
33 however, the maximum number of attribute values for which the implementation is able to maintain current  
34 state information is an implementation decision. The number of values that the implementation can support  
35 shall be stated in the PICS.

### 36 **10.12.5 Registrar Administrative Controls**

37 MMRP supports the Registration Fixed (New ignored) value, but not the Registration Fixed (New  
38 propagated) value, of the Registrar Administrative Controls (10.7.2).

## 11. VLAN topology management

The egress rules (8.6.4) defined for the Forwarding Process in VLAN Bridges rely on the existence of configuration information for each VID that defines the set of Ports of the Bridge through which one or more members are reachable. This set of Ports is known as the Member Set (8.8.10), and its membership is determined by the presence or absence of configuration information in the FDB, in the form of Static and Dynamic VLAN Registration Entries (8.8.2, 8.8.5).

Reliable operation of the VLAN infrastructure requires VLAN membership information held in the FDB to be maintained in a consistent manner across all VLAN Bridges in the Virtual Bridged Network, in order to ensure that frames destined for end station(s) on a given VLAN can be correctly delivered, regardless of where in the Bridged Network the frame is generated. Maintenance of this information by end stations that are sources of VLAN-tagged frames can allow such stations to suppress transmission of such frames if no members exist for the VLAN concerned.

This standard defines the following mechanisms that allow VLAN membership information to be configured:

- a) Dynamic configuration and distribution of VLAN membership information by means of the MVRP, as described in 11.2.
- b) Static configuration of VLAN membership information via Management mechanisms, as described in Clause 12, which allow configuration of Static VLAN Registration Entries.

These mechanisms provide for the configuration of VLAN membership information as a result of the following:

- c) Dynamic registration actions taken by end stations or Bridges in the Bridged Network.
- d) Administrative actions.

### 11.1 Static and dynamic VLAN configuration

The combined functionality provided by the ability to configure Static VLAN Registration Entries in the FDB, coupled with the use of the Restricted\_VLAN\_Registration control (11.2.3.2.3) and the ability of MVRP to dynamically create and update Dynamic VLAN Registration Entries, offers the following possibilities with respect to how VIDs are configured on a given Port:

- a) *Static configuration only.* The management facilities described in Clause 12 are used to establish precisely which VIDs have this Port in their Member set, and the MVRP management controls are used to disable the operation of MVRP on that Port. Hence, any use of MVRP by devices reachable via that Port is ignored, and the Member set for all VIDs can therefore only be determined by means of static entries in the FDB.
- b) *Static configuration with topology changes.* The management facilities described in Clause 12 are used to establish precisely which VLANs have this Port in their Member set, and the MVRP or MIRP management controls are used to permit the signaling, via MVRP or MIRP, of network topology changes that require flushing learned address information from the FDB. MVRPDUs and MIRPDUs received from devices reachable via that Port are ignored for the purposes of creating or deleting Dynamic VLAN Registration Entries in the FDB on that Port, and the Member set for all VLANs can therefore only be determined by means of static entries in the FDB.
- c) *Dynamic configuration only.* The operation of MVRP is relied upon to establish Dynamic VLAN Registration Entries that will dynamically reflect which VIDs are registered on the Port, their contents changing as the configuration of the network changes. The MVRP management controls are set to enable the operation of MVRP on that Port.
- d) *Combined static and dynamic configuration.* The static configuration mechanisms are used in order to configure some VLAN membership information; for other VIDs, MVRP is relied upon to establish the configuration. The MVRP management controls are set to enable the operation of MVRP on that Port.

1 All of the previous approaches are supported by the mechanisms defined in this standard, and each approach  
2 is applicable in different circumstances. For example:

- 3 e) Use of static configuration may be appropriate on Ports where the configuration of the attached  
4 devices is fixed, or where the network administrator wishes to establish an administrative boundary  
5 outside of which any MVRP registration information is to be ignored. For example, it might be  
6 desirable for all Ports serving end user devices to be statically configured in order to ensure that  
7 particular end users have access only to VLANs identified by particular VIDs.
- 8 f) Use of static configuration with topology changes can be appropriate where the configuration of  
9 VLANs and ports is static in some part of the network, but dynamic in another part, so that changes  
10 in the topology of the dynamic part can necessitate the flushing of learned MAC address information  
11 in Bridges in the static part. For example, in a PBBN, a topology change in a customer network with  
12 dual attachments to the provider can require a provider's I-component to signal a MAC address flush  
13 across the backbone, even though the VLANs on the VIPs involved are statically configured.
- 14 g) Use of dynamic configuration may be appropriate on Ports where the VLAN configuration is  
15 inherently dynamic; where users of particular VIDs can connect to the network via different Ports on  
16 an ad hoc basis, or where it is desirable to allow dynamic reconfiguration in the face of spanning tree  
17 topology changes. In particular, if the "core" of the Virtual Bridged Network contains redundant  
18 paths that are pruned by the operation of the spanning tree protocol, then it is desirable for Bridge  
19 Ports that form the core network to be dynamically configured.
- 20 h) Use of both static and dynamic configuration can be appropriate on Ports where it is desirable to  
21 place restrictions on the configuration of some VIDs, while maintaining the flexibility of dynamic  
22 registration for others. For example, on Ports serving mobile end user devices, this would maintain  
23 the benefits of dynamic VLAN registration from the point of view of traffic reduction, while still  
24 allowing administrative control over some VIDs via that Port.

## 25 11.2 Multiple VLAN Registration Protocol (MVRP)

26 MVRP defines an *MRP application* that provides the VLAN registration service defined in 11.2.2. MVRP  
27 makes use of MRP Attribute Declaration (MAD) and MRP Attribute Propagation (MAP), which provide the  
28 common state machine descriptions and the common attribute propagation mechanisms defined for use in  
29 MRP-based applications. The MRP architecture, MAD, and MAP are defined in Clause 10.

30 MVRP provides a mechanism for dynamic maintenance of the contents of Dynamic VLAN Registration  
31 Entries for each VID, and for propagating the information they contain to other Bridges. This information  
32 allows MVRP-aware devices to dynamically establish and update their knowledge of the set of VIDs  
33 associated with VLANs that currently have active members, and through which Ports those members can be  
34 reached.

### 35 11.2.1 MVRP overview

36 The operation of MVRP is closely similar to the operation of MMRP (10.9), which is used for registering  
37 Group membership and individual MAC address information. The primary differences are as follows:

- 38 a) The attribute values carried by the protocol are 12-bit VID values, rather than Group service  
39 requirement information and MAC Addresses.
- 40 b) The act of registering/deregistering a VID affects the contents of Dynamic Registration Entries  
41 (8.8.5), rather than the contents of MAC Address Registration Entries (8.8.4).
- 42 c) In an SST environment, there is a single MVRP Participant per port, as opposed to one MMRP  
43 Participant per VID per port, and the MVRP Participants all operate in a single MAP Context.
- 44 d) In an MST environment, there is again a single MVRP Participant per port, but each MVRP  
45 Participant operates in multiple MAP Contexts.

1 MVRP allows both end stations and Bridges in a Bridged Network to issue and revoke declarations relating  
2 to membership of VLANs. The effect of issuing such a declaration is that each MVRP Participant that  
3 receives the declaration will create or update a Dynamic VLAN Registration Entry in the FDB to indicate  
4 that VID is registered on the reception Port. Subsequently, if all Participants on a LAN that had an interest in  
5 a given VID revoke their declarations, the Port attached to that LAN is set to Unregistered in the Dynamic  
6 VLAN Registration Entry for that VID by each MVRP Participant attached to that LAN.

7 Figure 11-1 illustrates the architecture of MVRP in the case of a two-Port Bridge and an end station.

**Figure 11-1—Operation of MVRP**

8 As shown in the diagram, the MVRP Participant consists of the following components:

- 9 e) The MVRP application, described in 11.2.3
- 10 f) MRP Attribute Propagation (MAP), described in 10.3
- 11 g) MRP Attribute Declaration (MAD), described in 10.2

#### 12 11.2.1.1 Behavior of end stations

13 VLAN-aware end stations participate in MVRP activity, as appropriate for the set of VIDs of VLANs of  
14 which they are currently members. MVRP provides a way for such an end station to ensure that the VIDs of  
15 VLAN(s) of which it is a member are registered for each Port on any LAN to which the end station is  
16 attached. MVRP also provides for that VID information to be propagated across the spanning tree to other  
17 VLAN-aware devices, as described in 11.2.1.2.

1 Incoming VLAN membership information (from all other devices on the same LAN) allows such end  
2 stations to “source prune” (i.e., discard at source; see 10.10.3) any traffic destined for VLANs that currently  
3 have no other members in the Bridged Network, thus avoiding the generation of unnecessary traffic on their  
4 local LANs. This is illustrated in Figure 11-1 by an FDB shown as being present in the end station.

5 NOTE—Non-VLAN-aware end stations have no need to register VLAN membership via MVRP; indeed, this would be  
6 impossible for them to achieve if truly VLAN-unaware, as they would have no knowledge of the set of VLANs in which  
7 they participate. Their VLAN registration requirements are taken care of by means of the configuration of PVIDs (and  
8 possibly other VLAN classification mechanisms) and the propagation of registered VIDs by the Bridges.

### 9 11.2.1.2 Behavior of Bridges

10 VLAN Bridges register and propagate VLAN memberships on all Bridge Ports that are part of the active  
11 topology of the underlying spanning tree(s). Incoming VID registration and deregistration information is  
12 used to update the Dynamic VLAN Registration Entries associated with each VID. Any changes in the state  
13 of registration of a given VID on a given Port are propagated on Ports that are part of the active topology of  
14 the underlying spanning tree, in order to ensure that other MVRP-aware devices in the Bridged Network  
15 update their FDBs appropriately. In Bridges that support multiple spanning tree instances, the MST  
16 Configuration Table (12.12, 13.8) is used to determine which spanning tree instance is to be used to  
17 propagate registration information for each supported VID.

18 The FDBs in all MVRP-aware devices are thus automatically configured such that the Port Map in the  
19 Dynamic VLAN Registration Entry for a given VID indicates that a given Port is registered if one or more  
20 members of the corresponding VLAN are reachable through the Port.

21 NOTE—The information that determines whether frames destined for each VID are transmitted VLAN-tagged or  
22 untagged is carried in Static VLAN Registration Entries (8.8.2); if no such entry exists for a VID, then it is assumed that  
23 frames for that VID are transmitted VLAN-tagged on all Ports. Therefore, if the configuration information held in the  
24 FDB for a given VID consists only of information configured by the operation of MVRP (i.e., only a Dynamic VLAN  
25 Registration Entry), then all traffic for that VID will be VLAN-tagged on transmission.

### 26 11.2.1.3 Use of the PVID and VID Set

27 The initial state of the Permanent Database contains a Static VLAN Registration Entry for the Default PVID,  
28 in which the Port Map indicates Registration Fixed (New ignored) on all Ports. This ensures that in the  
29 default state, where the value of every PVID of each Port is the Default PVID and where the VID Set of each  
30 Port is empty, membership of the Default PVID is propagated across the Bridged Network to all other  
31 MVRP-aware devices. Subsequent management action may change both the Permanent Database and the  
32 FDB in order to modify or remove this initial setting, and may change the PVID and/or VID Set value(s) on  
33 any Port of the Bridge.

34 NOTE—In the absence of any modification of these initial settings, this ensures that connectivity is established across  
35 the Bridged Network for the VLAN corresponding to the Default PVID.

### 36 11.2.2 VLAN registration service definition

37 The VLAN registration service allows MAC Service users to indicate to the MAC Service provider the set  
38 of VLANs in which they wish to participate; i.e., that the MAC Service user wishes to receive traffic  
39 destined for members of that set of VLANs. The service primitives allow the service user to:

- 40 a) Register membership of a VLAN.
- 41 b) Deregister membership of a VLAN.

42 Provision of these services is achieved by means of MVRP and its associated procedures, as described in  
43 11.2.3.

#### 44 ES\_REGISTER\_VLAN\_MEMBER (VID)

45 Indicates to the MAC Service provider that the MAC Service user wishes to receive frames destined for the  
46 VLAN identified by the VID parameter.

1 ES\_DEREGISTER\_VLAN\_MEMBER (VID)

2 Indicates to the MAC Service provider that the MAC Service user no longer wishes to receive frames  
3 destined for the VLAN identified by the VID parameter.

4 The use of these services can result in the propagation of VID information across the spanning tree, affecting  
5 the contents of Dynamic VLAN Registration Entries (8.8.5) in Bridges and end stations in the Bridged  
6 Network, and thereby affecting the frame forwarding behavior of those Bridges and end stations.

### 7 **11.2.3 Definition of the MVRP application**

#### 8 **11.2.3.1 Definition of MRP elements**

##### 9 **11.2.3.1.1 MAP Context for MVRP in SST environments**

10 In an SST environment, MVRP operates in the Base Spanning Tree Context (10.3.1); i.e., MVRP operates  
11 only on the CIST. Consequently, all MVRPDUs sent and received by MVRP Participants in SST Bridges are  
12 transmitted as untagged frames.

##### 13 **11.2.3.1.2 MAP Contexts for MVRP in MST environments**

14 In an MST environment, MVRP operates in multiple spanning tree contexts, one for each of the spanning  
15 trees. Each spanning tree context consists of the ports that are in the forwarding state for the corresponding  
16 spanning tree. The MVRP Participants associated with a given spanning tree operate in the MAP context  
17 identified by that spanning tree instance. MST Bridges can identify the MAP Contexts using the mappings  
18 of VID values to MSTID values (see 8.9.1). All MVRPDUs sent and received by MVRP Participants in  
19 MST Bridges are transmitted as untagged frames.

##### 20 **11.2.3.1.3 MVRP application address**

21 The group MAC address used as the destination address for MRPDUs destined for MVRP Participants shall  
22 be either:

- 23 a) The group MAC address identified in Table 10-1 as “Customer Bridge MVRP address” if the  
24 MVRP Participant is implemented in a C-VLAN component; or
- 25 b) The group MAC address identified in Table 8-1 as “Provider Bridge MVRP Address” if the MVRP  
26 Participant is implemented in an S-VLAN component.

##### 27 **11.2.3.1.4 MVRP application EtherType**

28 The EtherType used for MRPDUs destined for MVRP Participants shall be the MVRP EtherType identified  
29 in Table 10-2.

##### 30 **11.2.3.1.5 MVRP ProtocolVersion**

31 The ProtocolVersion for the version of MVRP defined in this standard takes the hexadecimal value 0x00.

##### 32 **11.2.3.1.6 MVRP AttributeType definitions**

33 MVRP defines a single Attribute Type (10.8.2.2) that is carried in MRP exchanges, as follows:

34 Attributes identified by the VID Vector Attribute Type are instances of VectorAttributes (10.8.1), used to  
35 identify a sequence of values of VIDs. The value of AttributeType used to identify the VID Vector Attribute  
36 Type in MRPDUs (10.8.2.2) shall be 1.

### 11.2.3.1.7 MVRP FirstValue definitions

The FirstValue field in instances of the VID Vector Attribute Type shall be encoded in MRPDUs (10.4) as two octets, taken to represent an unsigned binary number, and equal to the value of the VID that is to be encoded.

The range of permitted values that can be encoded in the FirstValue fields in MVRP is restricted to the range 0 through 4094. The value 0 represents the VID of the untagged frame on which the MRPDU is transmitted or received, and 1 through 4094 identify specific VIDs. If enabled by management [item e) in 12.9.2.2.2], and if there is only one VID whose untagged set includes the Port of an MVRP Participant, the Participant shall transmit the value 0 in place of that VID. All MVRP Participants shall translate the value 0 in a received message to the PVID of the receiving Port.

NOTE—Previous revisions of this Standard did not provide for transmission or reception of 0 as an MVRP Attribute value. No automatic means for determining whether the other MVRP Participants on a LAN are capable of receiving the value 0 are provided. Therefore, extreme care is in order when configuring an MVRP Participant to transmit Attribute value 0, as compliant implementations of previous revisions of this standard could drop such MRPDUs as badly formed.

### 11.2.3.1.8 MVRP AttributeLength definitions

The AttributeLength field (10.12.1.8) in instances of the VID Vector Attribute Type shall be encoded in MRPDUs (10.8) as an unsigned binary number, equal to the value 0x02.

### 11.2.3.1.9 MVRP AttributeListLength definitions

The AttributeListLength field (10.8.2.4) is not present in the MRPDUs.

### 11.2.3.1.10 MVRP Vector definitions

The ThreePackedEvent vectors are encoded as defined in 10.8.2.10.1.

The FourPackedEvent vectors (10.8.2.10.2) are not present in the MRPDUs.

## 11.2.3.2 Provision and support of the VLAN registration service

### 11.2.3.2.1 Initiating VLAN membership declaration

The MVRP application element of a MVRP Participant provides the dynamic registration and deregistration services defined in 11.2.2, as follows:

On receipt of an ES\_REGISTER\_VLAN\_MEMBER service primitive, the MVRP Participant issues a MAD\_Join.request service primitive (10.2, 10.3). The attribute\_type parameter of the request carries the value of the VID Vector Attribute Type (11.2.3.1.6) and the attribute\_value parameter carries the value of the VID parameter carried in the ES\_REGISTER\_VLAN\_MEMBER primitive.

On receipt of an ES\_DEREGISTER\_VLAN\_MEMBER service primitive, the MVRP Participant issues a MAD\_Leave.request service primitive (10.2, 10.3). The attribute\_type parameter of the request carries the value of the VID Vector Attribute Type (11.2.3.1.6) and the attribute\_value parameter carries the value of the VID parameter carried in the ES\_DEREGISTER\_VLAN\_MEMBER primitive.

### 11.2.3.2.2 VLAN membership registration

The MVRP application element of a MVRP Participant responds to registration and deregistration events signaled by MAD as follows:

On receipt of a MAD\_Join.indication whose attribute\_type is equal to the value of the VID Vector Attribute Type (11.2.3.1.6), the MVRP application element indicates the reception Port as Registered in the Port Map of the Dynamic VLAN Registration Entry for the VID indicated by the attribute\_value parameter. If no such entry exists, there is sufficient room in the FDB, and the VID is within the range of values supported by the implementation (see 9.6), then an entry is created. If not, then the indication is not propagated and the registration fails.

The creation of new Dynamic VLAN Registration Entries can be restricted by use of the Restricted\_VLAN\_Registration control (11.2.3.2.3). If the value of this control is TRUE, then creation of a new dynamic entry is permitted only if there is a Static VLAN Registration Entry for the VID concerned, in which the Registrar Administrative Control value is Normal Registration.

On receipt of a MAD\_Leave.indication whose attribute\_type is equal to the value of the VID Vector Attribute Type (11.2.3.1.6), the MVRP application element indicates the reception Port as not Registered in the Port Map of the Dynamic VLAN Registration Entry for the VID indicated by the attribute\_value parameter. If no such entry exists, the indication is ignored.

### 11.2.3.2.3 Administrative controls

The provision of static control over the declaration or registration state of the state machines associated with the MVRP application is achieved by means of the Registrar Administrative Control parameters provided by MRP (10.7.2). These parameters are represented as Static VLAN Registration Entries in the FDB (8.8.2). Where management capability is implemented, these parameters can be manipulated by means of the management functionality defined in 12.7.

The provision of static control over the ability of Applicant and Registrar state machines to participate in protocol exchanges is achieved by means of the Applicant Administrative Control parameters and Registrar Administrative Control parameters associated with the operation of MRP (10.7.2, 10.7.3). Where management capability is implemented, the Applicant and Registrar Administrative Control parameters can be applied and modified by means of the management functionality defined in 12.9. A separate managed variable [item c) in 12.9.2.1.3] controls whether the Applicant state machine transmits 0 or the VID as the Attribute for a VLAN on a Port in that VLAN's untagged set.

Further administrative control over dynamic VLAN registration can be achieved, if supported, by means of a per-Port Restricted\_VLAN\_Registration control parameter. If the value of this control is TRUE for a given Port, the creation or modification of Dynamic VLAN Registration Entries as a result of MVRP exchanges on that Port shall be restricted only to those VIDs for which Static VLAN Registration Entries exist in which the Registrar Administrative Control value is Normal Registration. If the value of the Restricted\_VLAN\_Registration control is FALSE, dynamic VLAN registration is not so restricted. The recommended default value of this parameter is FALSE. Where management capability is implemented, the value of the Restricted\_VLAN\_Registration control can be manipulated by means of the management functionality defined in 12.10. If management of this parameter is not supported, the value of this parameter shall be FALSE for all Ports.

#### 11.2.4 VID translation table

If a VID Translation Table (6.9) is in use for a Bridge Port, the VID values received in MVRP Attributes are translated on reception of MVRPDUs prior to MVRP processing as specified in this subclause (11.2), and translated after processing for encoding MVRP Attributes in transmitted MVRPDUs. The interpretation of the MVRP Attribute value 0 is not affected by the VID Translation Table in either direction.

NOTE—In the case that the Port on which an MVRPDU is transmitted is in the untagged set of the VID matching the PVID of the Port receiving the MVRPDU, the use of the value 0 in the FirstValue field effectively performs a VID translation.

#### 11.2.5 Use of “new” declaration capability

MVRP makes use of the “new” declaration capability in order to allow FDB entries to be removed or rapidly aged out on a per-VID basis following a topology change in the network connectivity supporting the VID concerned. The rules for propagation of “new” declarations as defined in Clause 10 ensure that all MADs that originate from, or are propagated through, a Bridge Port that has recently transitioned to Forwarding are marked as “new” declarations.

When any MVRP declaration marked as “new” is received on a given Port, either as a result of receiving an MVRPDU from the attached LAN (MAD\_Join.indication), or as a result of receiving a request from MAP or the MVRP Application (MAD\_Join.request), any Dynamic Filtering Entries in the FDB for that Port and for the VID corresponding to the attribute value in the MAD\_Join primitive are removed.

#### 11.2.6 New-Only Participant and Registrar Administrative Controls

A Bridge may support an MVRP New-Only Participant (10.6). This can be useful in an I-component that has statically configured S-VLAN registrations, but must still accommodate signaling the flushing of learned MAC address information. The choice of whether a given Port’s MVRP Participant operates as a Full Participant or a New-Only Participant is controlled by a managed object (12.9.2). This managed object is separate from the one controlling whether a given Port uses Registration Fixed (New ignored) or Registration Fixed (New propagated) Static VLAN Registration Entries [item d) in 12.7.7.3.3].

NOTE 1—Configuring an MVRP Participant as a New-Only Participant makes the assumption that all of the MVRP Participants on the LAN are configured completely via Static VLAN Registration Entries, and that no Dynamic VLAN Registration Entries are needed. If this assumption is violated, then the Bridged Network can fail to provide connectivity for the VLANs that need Dynamic VLAN Registration Entries. Therefore, extreme care is in order when configuring a New-Only MVRP Participant.

If a MAD\_Join.indication is received by the MVRP MAD with the *new* parameter set, e.g., because a “new” MVRP declaration is received on a Port configured for New propagated [item d) in 12.7.7.3.3] as a result of receiving an MVRPDU from the attached LAN, and that MAD\_Join.indication does not correspond to a Static VLAN Registration Entry of Registration Fixed (New propagated) in the FDB, that MAD\_Join.indication shall be discarded without being propagated.

NOTE 2—If only one S-VLAN is configured per VIP, then using a MVRP Participant (Clause 39) can provide bandwidth and processing savings over using an MVRP New-Only Participant on a VIP. See 39.2.1.1 and 39.2.1.6.

#### 11.2.7 Attribute value support requirements

Implementations of MVRP shall be capable of supporting all attribute values in the range of possible values that can be registered using MVRP, and shall be capable of maintaining current state information for all attributes in the range of possible values.

## 12. Bridge management

This clause defines the set of managed objects, and their functionality, that allow administrative configuration of VLANs.

This clause:

- a) Introduces the functions of management to assist in the identification of the requirements placed on Bridges for the support of management facilities.
- b) Establishes the correspondence between the Processes used to model the operation of the Bridge (8.3) and the managed objects of the Bridge.
- c) Specifies the management operations supported by each managed object.

### 12.1 Management functions

Management functions relate to the users' needs for facilities that support the planning, organization, supervision, control, protection, and security of communications resources, and account for their use. These facilities may be categorized as supporting the functional areas of Configuration, Fault, Performance, Security, and Accounting Management. Each functional area is summarized in 12.1.1 through 12.1.5, together with the facilities commonly required for the management of communication resources, and the particular facilities provided in that functional area by Bridge Management.

It can be necessary, particularly in PBNs, for multiple organizations to manage a single Bridge, with each organization having different abilities to manage, or even detect the existence of, Bridge Ports, Bridges, or entire networks. Access to all of the managed objects in Clause 12 for reading, writing, or detection can be restricted. Access by certain organizations can be limited to only a small number of managed objects, particularly to those specified in 12.14.

#### 12.1.1 Configuration Management

Configuration Management provides for the identification of communications resources, initialization, reset and close-down, the supply of operational parameters, and the establishment and discovery of the relationship between resources. The facilities provided by Bridge Management in this functional area are:

- a) The identification of all Bridges that together make up the network and their respective locations and, as a consequence of that identification, the location of specific end stations to particular individual LANs.
- b) The ability to remotely reset, i.e., reinitialize, specified Bridges.
- c) The ability to control the priority with which a Bridge Port transmits frames.
- d) The ability to force a specific configuration of a spanning tree.
- e) The ability to control the propagation of frames with specific group MAC addresses to certain parts of the configured network.
- f) The ability to identify the VIDs in use, and through which Ports of the Bridge and for which protocols frames destined for a given VID may be received and/or forwarded.
- g) The ability to create and delete the functional elements of CFM and to control their operation.
- h) The ability to create and delete the functional elements of DDCFM and to control their operations.
- i) The ability to create and delete the functional elements of congestion notification and to control their operation.
- j) The ability to control the operation of MIRP.
- k) The ability to control the operation of SPB.
- l) The ability to configure the functional elements of EVB and to control their operation.

- 1 m) The ability to create and delete the functional elements of congestion isolation and to control their  
2 operation.

### 3 **12.1.2 Fault Management**

4 Fault Management provides for fault prevention, detection, diagnosis, and correction. The facilities provided  
5 by Bridge Management in this functional area are:

- 6 a) The ability to identify and correct Bridge malfunctions, including error logging and reporting.  
7 b) Within the context of multiple management organizations, the ability to:  
8 1) Actively monitor the connectivity of a set of managed endpoints on individual VLANs,  
9 simultaneously over multiple physical extents.  
10 2) Actively monitor and ensure the segregation of data among different VLANs.  
11 3) Issue trains of point-to-point query-response messages to selected network components in a  
12 VLAN.  
13 4) Issue multicast query-relay-response messages to determine the path taken by frames addressed  
14 to specific individual MAC addresses through a VLAN.  
15 5) Determine whether a flow of specified data frames (e.g., frames associated with a service  
16 instance or selected data frames with certain destination address) can reach a particular  
17 destination.  
18 6) Determine whether a flow of data frames can be sent without error from a specific location  
19 within a network to a station or stations specified by the DA field of each frame.

### 20 **12.1.3 Performance Management**

21 Performance Management provides for evaluation of the behavior of communications resources and of the  
22 effectiveness of communication activities. The facilities provided by Bridge Management in this functional  
23 area are as follows:

- 24 a) The ability to gather statistics relating to performance and traffic analysis. Specific metrics include  
25 network utilization, frame forward, and frame discard counts for individual Ports within a Bridge.

### 26 **12.1.4 Security Management**

27 Security Management provides for the protection of resources. Bridge Management does not provide any  
28 specific facilities in this functional area.

### 29 **12.1.5 Accounting Management**

30 Accounting Management provides for the identification and distribution of costs and the setting of charges.  
31 Bridge Management does not provide any specific facilities in this functional area.

## 32 **12.2 VLAN Bridge objects**

33 Managed objects model the semantics of management operations. Operations on an object supply  
34 information concerning, or facilitate control over, the process or entity associated with that object.

35 The managed resources of a VLAN Bridge or Bridge Component are those of the processes and entities in  
36 8.3. Specifically,

- 37 a) The Bridge Management Entity (12.4 and 8.12)  
38 b) The individual MAC Entities associated with each Bridge Port (12.5, 8.2, and 8.5)  
39 c) The Forwarding Process of the MAC Relay Entity (12.6, 8.2, and 8.6)

- 1 d) The FDB of the MAC Relay Entity (12.7 and 8.8)
- 2 e) The Bridge Protocol Entity (12.8 and 8.10)
- 3 f) MRP participants (Clause 10)
- 4 g) MVRP participants (12.10, Clause 11)
- 5 h) MMRP participants (12.11, Clause 10)
- 6 i) The MST Configuration Table (12.12)
- 7 j) Additional objects to support Provider Bridge management (12.13)
- 8 k) The CFM Entities (12.14)
- 9 l) The DDCFM Entities (12.17)
- 10 m) The PBB-TE protection switching Entities (12.18)
- 11 n) The TPMR Entities (12.19)
- 12 o) The management entities for FQTSS (12.20)
- 13 p) The congestion notification entities (12.20.4)
- 14 q) The Shortest Path Bridging managed objects
- 15 r) The EVB entities (12.26)
- 16 s) The congestion isolation entities (12.33)

17 The management of each of these resources is described in terms of managed objects and operations in 12.4  
18 through 12.12.

19 NOTE—The values specified in this clause, as inputs and outputs of management operations, are abstract information  
20 elements. Questions of formats or encodings are a matter for particular protocols that convey or otherwise represent this  
21 information.

22 Some data elements that are represented by the managed objects specified in this clause are required to be  
23 persistent across reinitializations or rebooting of the system within which the objects are implemented. For  
24 example, it may be desirable for changes in configuration parameters to persist across such events. Where  
25 such a requirement exists, this is indicated in the specification by marking the object concerned with the  
26 keyword “*Persistent*.”

## 27 12.3 Data types

28 This subclause specifies the semantics of operations independent of their encoding in management protocol.  
29 The data types of the parameters of operations are defined only as required for that specification.

30 The following data types are used:

- 31 a) Boolean.
- 32 b) Enumerated, for a collection of named values.
- 33 c) Unsigned, for all parameters specified as “the number of” some quantity, and for spanning tree  
34 priority values that are numerically compared. When comparing spanning tree priority values, the  
35 lower number represents the higher priority value.
- 36 d) MAC address.
- 37 e) Latin1 String, as defined by ANSI X3.159, for all text strings.
- 38 f) Time Interval, an Unsigned value representing a positive integral number of seconds, for all  
39 spanning tree protocol timeout parameters.
- 40 g) Counter, for all parameters specified as a “count” of some quantity. A counter increments and wraps  
41 with a modulus of 2 to the power of 64.
- 42 h) MRP Time Interval, an Unsigned value representing a positive integral number of centiseconds, for  
43 all MRP timeout parameters.

- 1 i) Port Number, an Unsigned value assigned to a Port as part of a Port Identifier. Valid Port Numbers  
2 are in the range 1 through 4095.
- 3 j) Port Priority, an Unsigned value used to represent the priority component of a Port Identifier. Valid  
4 Port Priorities are in the range 0 through 240, in steps of 16.
- 5 k) Bridge Priority, an Unsigned value used to represent the priority component of a Bridge Identifier.  
6 Valid Bridge Priorities are in the range 0 through 61440, in steps of 4096.
- 7 l) ComponentID, an unsigned value used to uniquely identify the management objects for a particular  
8 VLAN Bridge Component (12.2, Clause 8, 5.4) within a system (such as a BEB) comprising  
9 multiple such components. ComponentIDs start at 1 and go through 4294967295. If the system has a  
10 single component it will have a ComponentID equal to 1.
- 11 m) ComponentType, an enumerated list used to classify a particular VLAN Bridge Component within a  
12 system comprising multiple components.
- 13 n) Port Index, a handle, unique within a system, that identifies a port.
- 14 o) PIP Index, a Port Index for a PIP.
- 15 p) Percentage.
- 16 q) ECT-ALGORITHM. A 4-byte unsigned identifier. Used as a worldwide unique definition of an  
17 Equal Cost Tree (ECT) Algorithm, the first 3 bytes are expected to be taken from the OUI or CID  
18 space for the organization that has defined the algorithm. The last byte is allocated by that  
19 organization.
- 20 r) SPSourceID. A 20-bit Unsigned identifier. Used to represent a node uniquely within an SPT Domain  
21 (27.10).
- 22 s) Timer exp, an unsigned value from 0–31 representing a positive integer for the exponent of 2, which  
23 forms the multiplier of 10  $\mu$ s, used for EVB protocol timeout parameters.  
24 NOTE—For example, a value of 4 represents  $2^4 \times 10 \mu$ s, or 160  $\mu$ s.
- 25 t) Boolean array, an array of Boolean values.
- 26 u) IP Address, an IPv4 address, IPv6 address, or null for no IP address.

## 27 12.4 Bridge Management Entity

28 The Bridge Management Entity is described in 8.12.

29 This managed resource comprises the following objects:

- 30 a) The Bridge Configuration (12.4.1)
- 31 b) The Port Configuration for each Port (12.4.2)

### 32 12.4.1 Bridge Configuration

33 The Bridge Configuration object models the operations that modify, or inquire about, the configuration of  
34 the Bridge's resources. There is a single Bridge Configuration object per Bridge.

35 The management operations that can be performed on the Bridge Configuration are as follows:

- 36 a) Discover Bridge (12.4.1.1)
- 37 b) Read Bridge (12.4.1.2)
- 38 c) Set Bridge Name (12.4.1.3)
- 39 d) Reset Bridge (12.4.1.4)
- 40 e) Read component table entry (12.4.1.5)
- 41 f) Update component table entry (12.4.1.5)

## 1 12.4.1.1 Discover Bridge

### 2 12.4.1.1.1 Purpose

3 To solicit configuration information regarding the Bridge(s) in the network.

### 4 12.4.1.1.2 Inputs

5 a) Inclusion Range, a set of ordered pairs of specific MAC addresses. Each pair specifies a range of  
6 MAC addresses. A Bridge shall respond if and only if:

7 1) For one of the pairs, the numerical comparison of its Bridge Address with each MAC address  
8 of the pair shows it to be greater than or equal to the first, and

9 2) Less than or equal to the second, and

10 3) Its Bridge Address does not appear in the Exclusion List parameter below.

11 The numerical comparison of one MAC address with another, for the purpose of this operation, is  
12 achieved by deriving a number from the MAC address according to the following procedure. The  
13 consecutive octets of the MAC address are taken to represent a binary number; the first octet that  
14 would be transmitted on a LAN medium when the MAC address is used in the source or destination  
15 fields of a MAC frame has the most significant value, the next octet the next most significant value.  
16 Within each octet, the first bit of each octet is the LSB.

17 b) Exclusion List, a list of specific MAC addresses.

### 18 12.4.1.1.3 Outputs

19 a) Bridge Address—the MAC address for the Bridge from which the Bridge Identifiers used by STP,  
20 RSTP, and MSTP are derived (8.13.8, 13.26).

21 b) Bridge Name—a text string of up to 32 characters, of locally determined significance.

22 c) Number of Ports—the number of Bridge Ports (MAC Entities).

23 d) Port Addresses—a list specifying the following for each Port:

24 1) Port Number—the number of the Bridge Port (13.27).

25 2) Port Address—the specific MAC address of the individual MAC Entity associated with the  
26 Port (8.13.2).

27 e) Uptime—count in seconds of the time elapsed since the Bridge was last reset or initialized.

28 NOTE—Events that are considered to reset or initialize the Bridge include changing the MCID.

## 29 12.4.1.2 Read Bridge

### 30 12.4.1.2.1 Purpose

31 To obtain general information regarding the Bridge.

### 32 12.4.1.2.2 Inputs

33 None.

### 34 12.4.1.2.3 Outputs

35 a) Bridge Address—the MAC address for the Bridge from which the Bridge Identifiers used by RSTP  
36 and MSTP are derived (8.13.8, 13.26).

37 b) Bridge Name—a text string of up to 32 characters, of locally determined significance.

38 c) Number of Ports—the number of Bridge Ports (MAC Entities).

39 d) Port Addresses—a list specifying the following for each Port:

40 1) Port Number (13.27).

- 1        2) Port Address—the specific MAC address of the individual MAC Entity associated with the  
2        Port (8.13.2).  
3        e) Uptime—count in seconds of the time elapsed since the Bridge was last reset or initialized.

#### 4 **12.4.1.3 Set Bridge Name**

##### 5 **12.4.1.3.1 Purpose**

6 To associate a text string, readable by the Read Bridge operation, with a Bridge.

##### 7 **12.4.1.3.2 Inputs**

- 8        a) Bridge Name—a text string of up to 32 characters.

##### 9 **12.4.1.3.3 Outputs**

10 None.

#### 11 **12.4.1.4 Reset Bridge**

##### 12 **12.4.1.4.1 Purpose**

13 To reset the specified Bridge. The FDB is cleared and initialized with the entries specified in the Permanent  
14 Database, and the Bridge Protocol Entity is initialized.

##### 15 **12.4.1.4.2 Inputs**

16 None.

##### 17 **12.4.1.4.3 Outputs**

18 None.

#### 19 **12.4.1.5 Bridge Component configuration**

20 There is a single Bridge Component table per system. Each entry in the component table represents a  
21 component of the system (Table 12-1). The entries hold the parameters for each component including the  
22 component type and capabilities.

**Table 12-1—Component table entry managed object**

| Name                      | Data type            | Operations supported <sup>a</sup> | References     |
|---------------------------|----------------------|-----------------------------------|----------------|
| compComponentId           | ComponentID          | R                                 | 12.3 l)        |
| compMACAddress            | MAC address          | R                                 | 8.13.8, 13.24  |
| compNumberPorts           | unsigned (1..4095)   | R                                 | 12.4.1.1.3 c)  |
| compComponentType         | ComponentType        | R                                 | 12.3 m)        |
| compDeviceCapabilities    | Boolean array (0..7) | R                                 | 12.10.1.1.3 b) |
| compTrafficClassesEnabled | Boolean              | RW                                | —              |
| compMmrpEnabledStatus     | Boolean              | RW                                | —              |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

1 The operations that can be implemented on component table entries are as follows:

- 2 a) Read component table entry
- 3 b) Update component table entry

4 NOTE—The Bridge Component table is implemented in Clause 17 as the BridgeBaseTable (see Table 17-3).

#### 5 **12.4.1.5.1 Component type enumeration**

6 The compComponentType parameter can be assigned the following values:

- 7 a) iComponent—An I-Component (5.7)
- 8 b) bComponent—A B-Component (5.8)
- 9 c) cVlanComponent—A C-VLAN Component (5.5)
- 10 d) sVlanComponent—An S-VLAN Component (5.6)
- 11 e) dBridgeComponent—A MAC Bridge Component (5.13)
- 12 f) edgeRelay—An EVB station ER (5.24.1)

#### 13 **12.4.1.5.2 Component device capabilities**

14 The compDeviceCapabilities parameter contains an array of Boolean values for the following:

- 15 a) ExtendedFilteringServices
- 16 b) TrafficClasses
- 17 c) StaticEntryIndividualPort
- 18 d) IVLCapable
- 19 e) SVLCapable
- 20 f) HybridCapable
- 21 g) ConfigurablePvidTagging
- 22 h) LocalVlanCapable

#### 23 **12.4.2 Port configuration**

24 The Port Configuration object models the operations that modify, or inquire about, the configuration of the  
25 Ports of a Bridge. Unless the system explicitly supports the ability to dynamically create and/or delete ports,  
26 there is a fixed set of Bridge Ports per Bridge (one for each MAC interface), and each is identified by a  
27 permanently allocated Port Number.

28 The allocated Port Numbers are not required to be consecutive. Also, some Port Numbers may be dummy  
29 entries, with no actual LAN Port (for example, to allow for expansion of the Bridge by addition of further  
30 MAC interfaces). Such dummy Ports shall support the Port Configuration management operations and other  
31 Port-related management operations in a manner consistent with the Port being permanently disabled.

32 The information provided by the Port Configuration consists of summary data indicating its name and type.  
33 Specific counter information pertaining to the number of frames forwarded, filtered, and in error is  
34 maintained by the Forwarding Process resource. The management operations supported by the Bridge  
35 Protocol Entity allow for controlling the states of each Port.

36 A port table entry can be implemented by a Bridge for each Port of each component (Table 12-2). It  
37 comprises the parameters for each Port including the port type, capabilities, and statistics.

**Table 12-2—Port table entry**

| Name                       | Data type                   | Operations supported <sup>a</sup> | References       |
|----------------------------|-----------------------------|-----------------------------------|------------------|
| portComponentId            | ComponentID                 | R                                 | 12.4.1.5         |
| portPortNumber             | Port Number                 | R                                 | 13.25            |
| portMACAddress             | MAC address                 | R                                 | 12.4.1.1.3 a)    |
| portDelayExceededDiscards  | counter                     | R                                 | —                |
| portMtuExceededDiscards    | counter                     | R                                 | —                |
| portCapabilities           | unsigned                    | R                                 | —                |
| portTypeCapabilities       | unsigned                    | R                                 | —                |
| portType                   | enumerated                  | R                                 | 12.4.2.1         |
| portExternal               | Boolean                     | R                                 | —                |
| portAdminPointToPoint      | unsigned                    | RW                                | IEEE Std 802.1AC |
| portOperPointToPoint       | Boolean                     | R                                 | IEEE Std 802.1AC |
| portName                   | Latin1 String (SIZE(0..32)) | RW                                | —                |
| portMediaDependentOverhead | unsigned                    | R                                 | 12.4.2.2         |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

1 The management operations that can be performed on the port table are as follows:

- 2 a) Read port table entry (12.4.2.1)
- 3 b) Update port table entry (12.4.2.1)

#### 4 **12.4.2.1 Port type capabilities and enumeration**

5 The portTypeCapabilities array has a bit for each port type the Port can take, while the portType is an  
6 enumeration. The portTypeCapabilities can take any combination of port types while the portType can take  
7 exactly one of the following values:

- 8 a) C-VLAN Bridge Port
- 9 b) Provider Network Port (PNP)
- 10 c) Customer Network Port (CNP)
- 11 d) Customer Edge Port (CEP)
- 12 e) Customer Backbone Port (CBP)
- 13 f) Virtual Instance Port (VIP)
- 14 g) D-Bridge Port
- 15 h) Remote Customer Access Port (RCAP) (12.13.3)
- 16 i) Station-facing Bridge Port (SBP) (12.26.2)
- 17 j) Uplink Access Port (UAP) (12.26.4)
- 18 k) Uplink relay port (URP) (12.26.5)

19 NOTE—A portType is not required for a downlink relay port (DRP) or an S-channel Access Port (CAP) as no special  
20 EVB objects are necessary. A DRP is type C-VLAN Bridge Port while a CAP is type CNP.

## 12.4.2.2 Media-dependent overhead

The portMediaDependentOverhead parameter provides the number of additional octets for media-dependent framing. The overhead includes:

- a) All octets prior to the first octet of the Destination Address field and
- b) The minimum number of octets after the last octet of the frame check sequence before a subsequent frame, including its media-dependent overhead, can be transmitted.

NOTE—An example of media-dependent overhead is 20 octets to account preamble, start of frame delimiter, and a minimal inter-frame gap (IFG) of 12 octets for IEEE 802.3 point-to-point media.

## 12.5 MAC entities

The Management Operations and Facilities provided by the MAC Entities are those specified in the Layer Management standards of the individual MACs. A MAC Entity is associated with each Bridge Port.

### 12.5.1 ISS Port Number table managed object (optional)

An instance of the ISS Port Number table can be implemented by a Bridge system to identify the ISS interfaces that can be assigned to Bridge Ports. The ISS table is required when the Bridge Port assigned to an ISS and the ISS itself are referenced using different Port Numbers. The ISS table is keyed on the ISS Port Number. Each ISS table entry identifies a mapping from the ISS Port Number to a Bridge Port's ComponentID and Port Number. An issToComponentID value of 0 indicates the ISS is not bound to a Bridge Port. The issToComponentID and issToPortNumber parameters are updated indirectly as a result of creating or updating other system-specific Port objects.

The operation that can be implemented on an ISS Port Number table is as follows:

- a) Read ISS Port Number table entry (see Table 12-3)

**Table 12-3—ISS Port Number table entry**

| Name             | Data type      | Operations supported <sup>a</sup> | References |
|------------------|----------------|-----------------------------------|------------|
| issPortNumber    | Port Number    | R                                 | 12.3 i)    |
| issMACAddress    | MAC address    | R                                 | 8.13.2     |
| issToComponentID | ComponentID, 0 | R                                 | 12.4.2     |
| issToPortNumber  | Port Number, 0 | R                                 | 12.4.2     |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

## 12.6 Forwarding process

The Forwarding Process contains information relating to the forwarding of frames. Counters are maintained that provide information on the number of frames forwarded, filtered, and dropped due to error. Configuration data, defining how frame priority is handled, is maintained by the Forwarding Process.

This managed resource comprises the following objects:

- a) The Port Counters (12.6.1)
- b) The Priority Handling objects for each Port (12.6.2)
- c) The Traffic Class Table for each Port (12.6.3)

### 12.6.1 The Port Counters

The Port Counters object models the operations that can be performed on the Port counters of the Forwarding Process resource. There are multiple instances (one for each VID for each MAC Entity) of the Port Counters object per Bridge.

The management operation that can be performed on the Port Counters is Read Forwarding Port Counters (12.6.1.1).

#### 12.6.1.1 Read forwarding port counters

##### 12.6.1.1.1 Purpose

To read the forwarding counters associated with a specific Bridge Port.

##### 12.6.1.1.2 Inputs

- a) Port Number (13.27)
- b) Optionally, VID (9.6)

If the VID parameter is supported, then the forwarding Port counters are maintained per VID per Port. If the parameter is not supported, then the forwarding Port counters are maintained per Port only.

##### 12.6.1.1.3 Outputs

- a) Frames Received—count of all valid frames received (including BPDUs, frames addressed to the Bridge as an end station, and frames that were submitted to the Forwarding Process, 8.5).
- b) Optionally, Octets Received—count of the total number of octets in all valid frames received (including BPDUs, frames addressed to the Bridge as an end station, and frames that were submitted to the Forwarding Process).
- c) Discard Inbound—count of valid frames received that were discarded by the Forwarding Process (8.6).
- d) Forward Outbound—count of frames forwarded to the associated MAC Entity (8.5).
- e) Discard Lack of Buffers—count of frames that were to be transmitted through the associated Port but were discarded due to lack of buffers (8.6.6).
- f) Discard Transit Delay Exceeded—count of frames that were to be transmitted but were discarded due to the maximum Bridge transit delay being exceeded (buffering may have been available, 8.6.6).
- g) Discard on Error—count of frames that were to be forwarded on the associated MAC but could not be transmitted (e.g., frame would be too large, 6.5.8).
- h) If Ingress Filtering is supported (8.6.2), Discard on Ingress Filtering—count of frames that were discarded as a result of Ingress Filtering being enabled.
- i) If flow filtering is supported (44.2), Discard TTL Expired—count of frames discarded because they were received with the TTL field expired.

## 12.6.2 Priority handling

The Priority Handling object models the operations that can be performed on, or inquire about, the Default Priority parameter, the Priority Regeneration Table parameter, the Outbound Access Priority Table parameter, the Priority Code Point parameters, and the Service Access Priority parameters for each Port. The operations that can be performed on this object are as follows:

- a) Read Port Default Priority (12.6.2.1)
- b) Set Port Default Priority (12.6.2.2)
- c) Read Port Priority Regeneration Table (12.6.2.3)
- d) Set Port Priority Regeneration Table (12.6.2.4)
- e) Read Port Priority Code Point Selection (12.6.2.5)
- f) Set Port Priority Code Point Selection (12.6.2.6)
- g) Read Port Priority Code Point Decoding Table (12.6.2.7)
- h) Optionally, Set Port Priority Code Point Decoding Table (12.6.2.8)
- i) Read Port Priority Code Point Encoding Table (12.6.2.9)
- j) Optionally, Set Port Priority Code Point Encoding Table (12.6.2.10)
- k) Read Use\_DEI parameter (12.6.2.11)
- l) Optionally, Set Use\_DEI parameter (12.6.2.12)
- m) Read Require Drop Encoding parameter (12.6.2.13)
- n) Optionally, Set Require Drop Encoding parameter (12.6.2.14)
- o) Read Service Access Priority Selection (12.6.2.15)
- p) Optionally, Set Service Access Priority Selection (12.6.2.16)
- q) Read Service Access Priority Table (12.6.2.17)
- r) Optionally, Set Service Access Priority Table (12.6.2.18)

### 12.6.2.1 Read Port Default Priority

#### 12.6.2.1.1 Purpose

To read the current state of the Default Priority parameter (IEEE Std 802.1AC) for a specific Bridge Port.

#### 12.6.2.1.2 Inputs

- a) Port number.

#### 12.6.2.1.3 Outputs

- a) Default Priority value—Integer in range 0–7.

### 12.6.2.2 Set Port Default Priority

#### 12.6.2.2.1 Purpose

To set the current state of the Default Priority parameter (IEEE Std 802.1AC) for a specific Bridge Port.

#### 12.6.2.2.2 Inputs

- a) Port number.
- b) Default Priority value—Integer in range 0–7.

#### 12.6.2.2.3 Outputs

None.

### 12.6.2.3 Read Port Priority Regeneration Table

#### 12.6.2.3.1 Purpose

To read the current state of the Priority Regeneration Table parameter (6.9.4) for a specific Bridge Port.

#### 12.6.2.3.2 Inputs

- a) Port number.

#### 12.6.2.3.3 Outputs

- a) Regenerated Priority value for Received Priority 0—Integer in range 0–7.
- b) Regenerated Priority value for Received Priority 1—Integer in range 0–7.
- c) Regenerated Priority value for Received Priority 2—Integer in range 0–7.
- d) Regenerated Priority value for Received Priority 3—Integer in range 0–7.
- e) Regenerated Priority value for Received Priority 4—Integer in range 0–7.
- f) Regenerated Priority value for Received Priority 5—Integer in range 0–7.
- g) Regenerated Priority value for Received Priority 6—Integer in range 0–7.
- h) Regenerated Priority value for Received Priority 7—Integer in range 0–7.

### 12.6.2.4 Set Port Priority Regeneration Table

#### 12.6.2.4.1 Purpose

To set the current state of the Priority Regeneration Table parameter (6.9.4) for a specific Bridge Port.

#### 12.6.2.4.2 Inputs

- a) Port number.
- b) Regenerated Priority value for Received Priority 0—Integer in range 0–7.
- c) Regenerated Priority value for Received Priority 1—Integer in range 0–7.
- d) Regenerated Priority value for Received Priority 2—Integer in range 0–7.
- e) Regenerated Priority value for Received Priority 3—Integer in range 0–7.
- f) Regenerated Priority value for Received Priority 4—Integer in range 0–7.
- g) Regenerated Priority value for Received Priority 5—Integer in range 0–7.
- h) Regenerated Priority value for Received Priority 6—Integer in range 0–7.
- i) Regenerated Priority value for Received Priority 7—Integer in range 0–7.

#### 12.6.2.4.3 Outputs

None.

### 12.6.2.5 Read Port Priority Code Point Selection

#### 12.6.2.5.1 Purpose

To read which row of the Priority Code Point Encoding Table and Priority Code Point Decoding Table (6.9.3) is currently selected for use on this Port.

#### 1 12.6.2.5.2 Inputs

- 2 a) Port Number: the number of the Bridge Port.

#### 3 12.6.2.5.3 Outputs

- 4 a) Priority Code Point Selection. This takes one of the following values:

- 5 1) 8P0D  
6 2) 7P1D  
7 3) 6P2D  
8 4) 5P3D

#### 9 12.6.2.6 Set Port Priority Code Point Selection

##### 10 12.6.2.6.1 Purpose

11 To set which row of the Priority Code Point Encoding Table and Priority Code Point Decoding Table (6.9.3)  
12 will be selected for use on this Port.

##### 13 12.6.2.6.2 Inputs

- 14 a) Port Number: the number of the Bridge Port.  
15 b) Priority Code Point Selection. This takes one of the following values:  
16 1) 8P0D  
17 2) 7P1D  
18 3) 6P2D  
19 4) 5P3D

##### 20 12.6.2.6.3 Outputs

21 None.

#### 22 12.6.2.7 Read Priority Code Point Decoding Table

##### 23 12.6.2.7.1 Purpose

24 To read the current contents of a row in the Priority Code Point Decoding Table (6.9.3) for a Port.

##### 25 12.6.2.7.2 Inputs

- 26 a) Port Number: the number of the Bridge Port.  
27 b) Priority Code Point Row. This takes one of the following values:  
28 1) 8P0D  
29 2) 7P1D  
30 3) 6P2D  
31 4) 5P3D

##### 32 12.6.2.7.3 Outputs

- 33 a) Priority value for Priority Code Point 0: Integer in range 0–7.  
34 b) Drop\_eligible value for Priority Code Point 0: Boolean.  
35 c) Priority value for Priority Code Point 1: Integer in range 0–7.  
36 d) Drop\_eligible value for Priority Code Point 1: Boolean.  
37 e) Priority value for Priority Code Point 2: Integer in range 0–7.  
38 f) Drop\_eligible value for Priority Code Point 2: Boolean.  
39 g) Priority value for Priority Code Point 3: Integer in range 0–7.

- 1 h) Drop\_eligible value for Priority Code Point 3: Boolean.
- 2 i) Priority value for Priority Code Point 4: Integer in range 0–7.
- 3 j) Drop\_eligible value for Priority Code Point 4: Boolean.
- 4 k) Priority value for Priority Code Point 5: Integer in range 0–7.
- 5 l) Drop\_eligible value for Priority Code Point 5: Boolean.
- 6 m) Priority value for Priority Code Point 6: Integer in range 0–7.
- 7 n) Drop\_eligible value for Priority Code Point 6: Boolean.
- 8 o) Priority value for Priority Code Point 7: Integer in range 0–7.
- 9 p) Drop\_eligible value for Priority Code Point 7: Boolean.

#### 10 **12.6.2.8 Set Priority Code Point Decoding Table**

##### 11 **12.6.2.8.1 Purpose**

12 To modify the contents of a row in the Priority Code Point Decoding Table (6.9.3) for a Port.

##### 13 **12.6.2.8.2 Inputs**

- 14 a) Port Number: the number of the Bridge Port.
- 15 b) Priority Code Point Row. This takes one of the following values:
  - 16 1) 8P0D
  - 17 2) 7P1D
  - 18 3) 6P2D
  - 19 4) 5P3D
- 20 c) Priority value for Priority Code Point 0: Integer in range 0–7.
- 21 d) Drop\_eligible value for Priority Code Point 0: Boolean.
- 22 e) Priority value for Priority Code Point 1: Integer in range 0–7.
- 23 f) Drop\_eligible value for Priority Code Point 1: Boolean.
- 24 g) Priority value for Priority Code Point 2: Integer in range 0–7.
- 25 h) Drop\_eligible value for Priority Code Point 2: Boolean.
- 26 i) Priority value for Priority Code Point 3: Integer in range 0–7.
- 27 j) Drop\_eligible value for Priority Code Point 3: Boolean.
- 28 k) Priority value for Priority Code Point 4: Integer in range 0–7.
- 29 l) Drop\_eligible value for Priority Code Point 4: Boolean.
- 30 m) Priority value for Priority Code Point 5: Integer in range 0–7.
- 31 n) Drop\_eligible value for Priority Code Point 5: Boolean.
- 32 o) Priority value for Priority Code Point 6: Integer in range 0–7.
- 33 p) Drop\_eligible value for Priority Code Point 6: Boolean.
- 34 q) Priority value for Priority Code Point 7: Integer in range 0–7.
- 35 r) Drop\_eligible value for Priority Code Point 7: Boolean.

##### 36 **12.6.2.8.3 Outputs**

37 None.

## 1 12.6.2.9 Read Priority Code Point Encoding Table

### 2 12.6.2.9.1 Purpose

3 To read the current contents of a row in the Priority Code Point Encoding Table (6.9.3) for a Port.

### 4 12.6.2.9.2 Inputs

- 5 a) Port Number: the number of the Bridge Port.
- 6 b) Priority Code Point Row. This takes one of the following values:
  - 7 1) 8P0D
  - 8 2) 7P1D
  - 9 3) 6P2D
  - 10 4) 5P3D

### 11 12.6.2.9.3 Outputs

- 12 a) Priority Code Point value for priority 0 with drop\_eligible False: Integer in range 0–7.
- 13 b) Priority Code Point value for priority 0 with drop\_eligible True: Integer in range 0–7.
- 14 c) Priority Code Point value for priority 1 with drop\_eligible False: Integer in range 0–7.
- 15 d) Priority Code Point value for priority 1 with drop\_eligible True: Integer in range 0–7.
- 16 e) Priority Code Point value for priority 2 with drop\_eligible False: Integer in range 0–7.
- 17 f) Priority Code Point value for priority 2 with drop\_eligible True: Integer in range 0–7.
- 18 g) Priority Code Point value for priority 3 with drop\_eligible False: Integer in range 0–7.
- 19 h) Priority Code Point value for priority 3 with drop\_eligible True: Integer in range 0–7.
- 20 i) Priority Code Point value for priority 4 with drop\_eligible False: Integer in range 0–7.
- 21 j) Priority Code Point value for priority 4 with drop\_eligible True: Integer in range 0–7.
- 22 k) Priority Code Point value for priority 5 with drop\_eligible False: Integer in range 0–7.
- 23 l) Priority Code Point value for priority 5 with drop\_eligible True: Integer in range 0–7.
- 24 m) Priority Code Point value for priority 6 with drop\_eligible False: Integer in range 0–7.
- 25 n) Priority Code Point value for priority 6 with drop\_eligible True: Integer in range 0–7.
- 26 o) Priority Code Point value for priority 7 with drop\_eligible False: Integer in range 0–7.
- 27 p) Priority Code Point value for priority 7 with drop\_eligible True: Integer in range 0–7.

## 28 12.6.2.10 Set Priority Code Point Encoding Table

### 29 12.6.2.10.1 Purpose

30 To modify the contents of a row in the Priority Code Point Encoding Table (6.9.3) for a Port.

### 31 12.6.2.10.2 Inputs

- 32 a) Port Number: the number of the Bridge Port.
- 33 b) Priority Code Point Row. This takes one of the following values:
  - 34 1) 8P0D
  - 35 2) 7P1D
  - 36 3) 6P2D
  - 37 4) 5P3D
- 38 c) Priority Code Point value for priority 0 with drop\_eligible False: Integer in range 0–7.
- 39 d) Priority Code Point value for priority 0 with drop\_eligible True: Integer in range 0–7.
- 40 e) Priority Code Point value for priority 1 with drop\_eligible False: Integer in range 0–7.
- 41 f) Priority Code Point value for priority 1 with drop\_eligible True: Integer in range 0–7.
- 42 g) Priority Code Point value for priority 2 with drop\_eligible False: Integer in range 0–7.
- 43 h) Priority Code Point value for priority 2 with drop\_eligible True: Integer in range 0–7.
- 44 i) Priority Code Point value for priority 3 with drop\_eligible False: Integer in range 0–7.

- 1 j) Priority Code Point value for priority 3 with drop\_eligible True: Integer in range 0–7.
- 2 k) Priority Code Point value for priority 4 with drop\_eligible False: Integer in range 0–7.
- 3 l) Priority Code Point value for priority 4 with drop\_eligible True: Integer in range 0–7.
- 4 m) Priority Code Point value for priority 5 with drop\_eligible False: Integer in range 0–7.
- 5 n) Priority Code Point value for priority 5 with drop\_eligible True: Integer in range 0–7.
- 6 o) Priority Code Point value for priority 6 with drop\_eligible False: Integer in range 0–7.
- 7 p) Priority Code Point value for priority 6 with drop\_eligible True: Integer in range 0–7.
- 8 q) Priority Code Point value for priority 7 with drop\_eligible False: Integer in range 0–7.
- 9 r) Priority Code Point value for priority 7 with drop\_eligible True: Integer in range 0–7.

### 10 **12.6.2.10.3 Outputs**

11 None.

### 12 **12.6.2.11 Read Use\_DEI Parameter**

#### 13 **12.6.2.11.1 Purpose**

14 To read the current state of the Use\_DEI parameter (6.9.3) for the Port.

#### 15 **12.6.2.11.2 Inputs**

- 16 a) Port Number: the number of the Bridge Port.

#### 17 **12.6.2.11.3 Outputs**

- 18 a) Use\_DEI parameter: Boolean.

### 19 **12.6.2.12 Set Use\_DEI Parameter**

#### 20 **12.6.2.12.1 Purpose**

21 To set the current state of the Use\_DEI parameter (6.9.3) for the Port.

#### 22 **12.6.2.12.2 Inputs**

- 23 a) Port Number: the number of the Bridge Port.
- 24 b) Use\_DEI parameter: Boolean.

#### 25 **12.6.2.12.3 Outputs**

26 None.

### 27 **12.6.2.13 Read Require Drop Encoding Parameter**

#### 28 **12.6.2.13.1 Purpose**

29 To read the current state of the Require Drop Encoding parameter (8.6.6) for the Port.

#### 30 **12.6.2.13.2 Inputs**

- 31 a) Port Number: the number of the Bridge Port.

#### 32 **12.6.2.13.3 Outputs**

- 33 a) Require Drop Encoding parameter: Boolean.

#### 1 **12.6.2.14 Set Require Drop Encoding Parameter**

##### 2 **12.6.2.14.1 Purpose**

3 To set the current state of the Require Drop Encoding parameter (8.6.6) for the Port.

##### 4 **12.6.2.14.2 Inputs**

- 5 a) Port Number: the number of the Bridge Port.
- 6 b) Require Drop Encoding parameter: Boolean.

##### 7 **12.6.2.14.3 Outputs**

8 None.

#### 9 **12.6.2.15 Read Service Access Priority Selection**

##### 10 **12.6.2.15.1 Purpose**

11 To read the current state of whether Service Access Priority Selection is enabled (6.13) for the Port.

##### 12 **12.6.2.15.2 Inputs**

- 13 a) Port Number: the number of the Bridge Port.

##### 14 **12.6.2.15.3 Outputs**

- 15 a) Enable Service Access Priority Selection: the permissible values are as follows:
  - 16 1) Enabled
  - 17 2) Disabled

#### 18 **12.6.2.16 Set Service Access Priority Selection**

##### 19 **12.6.2.16.1 Purpose**

20 To enable or disable Service Access Priority Selection (6.13) for the Port.

##### 21 **12.6.2.16.2 Inputs**

- 22 a) Port Number: the number of the Bridge Port.
- 23 b) Service Access Priority Selection: the permissible values are as follows:
  - 24 1) Enabled
  - 25 2) Disabled

##### 26 **12.6.2.16.3 Outputs**

27 None.

#### 28 **12.6.2.17 Read Service Access Priority Table**

##### 29 **12.6.2.17.1 Purpose**

30 To read the current contents of the Service Access Priority Table (6.13.1) for the Port.

## 1 12.6.2.17.2 Inputs

- 2 a) Port Number: the number of the Bridge Port.

## 3 12.6.2.17.3 Outputs

- 4 a) Service Access Priority value for Received Priority 0: Integer in range 0–7.  
5 b) Service Access Priority value for Received Priority 1: Integer in range 0–7.  
6 c) Service Access Priority value for Received Priority 2: Integer in range 0–7.  
7 d) Service Access Priority value for Received Priority 3: Integer in range 0–7.  
8 e) Service Access Priority value for Received Priority 4: Integer in range 0–7.  
9 f) Service Access Priority value for Received Priority 5: Integer in range 0–7.  
10 g) Service Access Priority value for Received Priority 6: Integer in range 0–7.  
11 h) Service Access Priority value for Received Priority 7: Integer in range 0–7.

## 12 12.6.2.18 Set Service Access Priority Table

### 13 12.6.2.18.1 Purpose

14 To modify the contents of the Service Access Priority Table (6.13.1) for the Port.

### 15 12.6.2.18.2 Inputs

- 16 a) Port Number: the number of the Bridge Port.  
17 b) Service Access Priority value for Received Priority 0: Integer in range 0–7.  
18 c) Service Access Priority value for Received Priority 1: Integer in range 0–7.  
19 d) Service Access Priority value for Received Priority 2: Integer in range 0–7.  
20 e) Service Access Priority value for Received Priority 3: Integer in range 0–7.  
21 f) Service Access Priority value for Received Priority 4: Integer in range 0–7.  
22 g) Service Access Priority value for Received Priority 5: Integer in range 0–7.  
23 h) Service Access Priority value for Received Priority 6: Integer in range 0–7.  
24 i) Service Access Priority value for Received Priority 7: Integer in range 0–7.

### 25 12.6.2.18.3 Outputs

26 None.

## 27 12.6.3 Traffic Class Table

28 The Traffic Class Table object models the operations that can be performed on, or inquire about, the current  
29 contents of the Traffic Class Table (8.6.6) for a given Port. The operations that can be performed on this  
30 object are Read Port Traffic Class Table and Set Port Traffic Class Table.

### 31 12.6.3.1 Read Port Traffic Class Table

#### 32 12.6.3.1.1 Purpose

33 To read the contents of the Traffic Class Table (8.6.6) for a given Port.

#### 34 12.6.3.1.2 Inputs

- 35 a) Port Number.

#### 36 12.6.3.1.3 Outputs

- 37 a) The number of traffic classes, in the range 1 through 8, supported on the Port.  
38 b) For each value of traffic class supported on the Port, the value of the traffic class in the range 0  
39 through 7, and the set of priority values assigned to that traffic class.

## 1 12.6.3.2 Set Port Traffic Class Table

### 2 12.6.3.2.1 Purpose

3 To set the contents of the Traffic Class Table (8.6.6) for a given Port.

### 4 12.6.3.2.2 Inputs

- 5 a) Port number.
- 6 b) For each value of traffic class supported on the Port, the value of the traffic class in the range 0  
7 through 7, and the set of priority values assigned to that traffic class.

8 NOTE—If a traffic class value greater than the largest traffic class available on the Port is specified, then the value  
9 applied to the Traffic Class Table is the largest available traffic class.

### 10 12.6.3.2.3 Outputs

11 None.

## 12 12.7 Filtering Database (FDB)

13 The FDB is described in 8.8. It contains filtering information used by the Forwarding Process (8.6) in  
14 deciding through which Ports of the Bridge frames should be forwarded.

15 This managed resource comprises the following objects:

- 16 a) The Filtering Database (12.7.1)
- 17 b) The Static Filtering Entries (12.7.2)
- 18 c) The Dynamic Filtering Entries (12.7.3)
- 19 d) The MAC Address Registration Entries (12.7.4)
- 20 e) The Static VLAN Registration Entries (12.7.5)
- 21 f) The Dynamic VLAN Registration Entries (12.7.5)
- 22 g) The Permanent Database (12.7.6)

### 23 12.7.1 The Filtering Database object

24 The Filtering Database object models the operations that can be performed on, or affect, the FDB as a whole.

25 There is a single Filtering Database object per Bridge.

26 The management operations that can be performed on the Database are as follows:

- 27 a) Read Filtering Database (12.7.1.1)
- 28 b) Set Filtering Database Ageing Time (12.7.1.2)
- 29 c) Read Permanent Database (12.7.6.1)
- 30 d) Create Filtering Entry (12.7.7.1)
- 31 e) Delete Filtering Entry (12.7.7.2)
- 32 f) Read Filtering Entry (12.7.7.3)
- 33 g) Read Filtering Entry Range (12.7.7.4)

#### 34 12.7.1.1 Read Filtering Database

##### 35 12.7.1.1.1 Purpose

36 To obtain general information regarding the Bridge's FDB.

##### 37 12.7.1.1.2 Inputs

38 None.

### 12.7.1.1.3 Outputs

- a) Filtering Database Size—the maximum number of entries that can be held in the FDB.
- b) Number of Static Filtering Entries—the number of Static Filtering Entries (8.8.1) currently in the FDB.
- c) Number of Dynamic Filtering Entries—the number of Dynamic Filtering Entries (8.8.3) currently in the FDB.
- d) Number of Static VLAN Registration Entries—the number of Static VLAN Registration Entries (8.8.2) currently in the FDB.
- e) Number of Dynamic VLAN Registration Entries—the number of Dynamic VLAN Registration Entries (8.8.5) currently in the FDB.
- f) Ageing Time—for ageing out Dynamic Filtering Entries when the Port associated with the entry is in the Forwarding state (8.8.3).
- g) If Extended Filtering Services are supported, Number of MAC Address Registration Entries—the number of MAC Address Registration Entries (8.8.4) currently in the FDB.

### 12.7.1.2 Set Filtering Database Ageing Time

#### 12.7.1.2.1 Purpose

To set the ageing time for Dynamic Filtering Entries (8.8.3).

#### 12.7.1.2.2 Inputs

- a) Ageing Time.

#### 12.7.1.2.3 Outputs

None.

### 12.7.2 A Static Filtering Entry object

A Static Filtering Entry object models the operations that can be performed on a single Static Filtering Entry in the FDB. The set of Static Filtering Entry objects within the FDB changes only under management control.

A Static Filtering Entry object supports the following operations:

- a) Create Filtering Entry (12.7.7.1)
- b) Delete Filtering Entry (12.7.7.2)
- c) Read Filtering Entry (12.7.7.3)
- d) Read Filtering Entry Range (12.7.7.4)

### 12.7.3 A Dynamic Filtering Entry object

A Dynamic Filtering Entry object models the operations that can be performed on a single Dynamic Filtering Entry (i.e., one that is created by the Learning Process as a result of the observation of network traffic) in the FDB.

A Dynamic Filtering Entry object supports the following operations:

- a) Delete Filtering Entry (12.7.7.2)
- b) Read Filtering Entry (12.7.7.3)
- c) Read Filtering Entry Range (12.7.7.4)

#### 1 **12.7.4 A MAC Address Registration Entry object**

2 A MAC Address Registration Entry object models the operations that can be performed on a single MAC  
3 Address Registration Entry in the FDB. The set of MAC Address Registration Entry objects within the FDB  
4 changes only as a result of MMRP exchanges.

5 A MAC Address Registration Entry object supports the following operations:

- 6 a) Read Filtering Entry (12.7.7.3)
- 7 b) Read Filtering Entry Range (12.7.7.4)

#### 8 **12.7.5 A VLAN Registration Entry object**

9 A VLAN Registration Entry object models the operations that can be performed on a single VLAN  
10 Registration Entry in the FDB. The set of VLAN Registration Entry objects within the FDB changes under  
11 management control and also as a result of MVRP exchanges.

##### 12 **12.7.5.1 Static VLAN Registration Entry object**

13 A Static VLAN Registration Entry object supports the following operations:

- 14 a) Create Filtering Entry (12.7.7.1)
- 15 b) Delete Filtering Entry (12.7.7.2)
- 16 c) Read Filtering Entry (12.7.7.3)
- 17 d) Read Filtering Entry Range (12.7.7.4)

##### 18 **12.7.5.2 Dynamic VLAN Registration Entry object**

19 A Dynamic VLAN Registration Entry object supports the following operations:

- 20 a) Read Filtering Entry (12.7.7.3)
- 21 b) Read Filtering Entry Range (12.7.7.4)

#### 22 **12.7.6 Permanent Database object**

23 The Permanent Database object models the operations that can be performed on, or affect, the Permanent  
24 Database. There is a single Permanent Database per FDB.

25 The management operations that can be performed on the Permanent Database are as follows:

- 26 a) Read Permanent Database (12.7.6.1)
- 27 b) Create Filtering Entry (12.7.7.1)
- 28 c) Delete Filtering Entry (12.7.7.2)
- 29 d) Read Filtering Entry (12.7.7.3)
- 30 e) Read Filtering Entry Range (12.7.7.4)

##### 31 **12.7.6.1 Read Permanent Database**

###### 32 **12.7.6.1.1 Purpose**

33 To obtain general information regarding the Permanent Database (8.8.11).

###### 34 **12.7.6.1.2 Inputs**

35 None.

### 12.7.6.1.3 Outputs

- a) Permanent Database Size—maximum number of entries that can be held in the Permanent Database.
- b) Number of Static Filtering Entries—number of Static Filtering Entries (8.8.1) currently in the Permanent Database.
- c) Number of Static VLAN Registration Entries—number of Static VLAN Registration Entries (8.8.2) currently in the Permanent Database.

## 12.7.7 General FDB operations

In these operations on the FDB, the operation parameters make use of VID values, even when operating on a Dynamic Filtering Entry (8.8.3) whose structure carries an FID rather than a VID. In this case, the value used in the VID parameter can be any VID that has been allocated to the FID concerned (8.8.8).

### 12.7.7.1 Create Filtering Entry

#### 12.7.7.1.1 Purpose

To create or update a Static Filtering Entry (8.8.1) or Static VLAN Registration Entry (8.8.2) in the FDB or Permanent Database. Only static entries may be created in the FDB or Permanent Database.

#### 12.7.7.1.2 Inputs

- a) Identifier—FDB or Permanent Database.
- b) Address—MAC address of the entry (not present in VLAN Registration Entries).
- c) VID—VLAN Identifier of the entry.
- d) Port Map—a set of control indicators, one for each Port, as specified in 8.8.1 and 8.8.2.

#### 12.7.7.1.3 Outputs

- a) Operation rejected because a Port identified by the Port Map includes a port already in the member set of a VID of a different type than the currently registered VID.
- b) Operation rejected because the specified Static Filtering Entry is associated with an Infrastructure Protection Group (IPG) and is administered by IPS Control.
- c) Operation rejected because the VID identifies an SPVID.
- d) Operation accepted.

### 12.7.7.2 Delete Filtering Entry

#### 12.7.7.2.1 Purpose

To delete a Filtering Entry or VLAN Registration Entry from the FDB or Permanent Database.

#### 12.7.7.2.2 Inputs

- a) Identifier—FDB or Permanent Database.
- b) Address—MAC address of the desired entry (not present in VLAN Registration Entries).
- c) VID—VLAN Identifier of the entry.

#### 12.7.7.2.3 Outputs

None.

### 12.7.7.3 Read Filtering Entry

#### 12.7.7.3.1 Purpose

To read a Filtering Entry, MAC Address Registration Entry, or VLAN Registration Entry from the Filtering or Permanent Databases.

#### 12.7.7.3.2 Inputs

- a) Identifier—FDB or Permanent Database.
- b) Address—MAC address of the desired entry (not present in VLAN Registration Entries).
- c) VID—VLAN Identifier of the entry.
- d) Type—Static or Dynamic entry.

#### 12.7.7.3.3 Outputs

- a) Address—MAC address of the desired entry (not present in VLAN Registration Entries).
- b) VID—VLAN Identifier of the entry.
- c) Type—Static or Dynamic entry.
- d) Port Map—a set of control indicators as appropriate for the entry (that may include a Connection Identifier), as specified in 8.8.1 through 8.8.5.

### 12.7.7.4 Read Filtering Entry range

#### 12.7.7.4.1 Purpose

To read a range of FDB entries (of any type) from the Filtering or Permanent Databases.

Since the number of values to be returned in the requested range may have exceeded the capacity of the SDU conveying the management response, the returned entry range is identified. The indices that define the range take on values from zero up to Filtering Database Size minus one.

#### 12.7.7.4.2 Inputs

- a) Identifier—FDB or Permanent Database.
- b) Start Index—inclusive starting index of the desired entry range.
- c) Stop Index—inclusive ending index of the desired range.

#### 12.7.7.4.3 Outputs

- a) Start Index—inclusive starting index of the returned entry range.
- b) Stop Index—inclusive ending index of the returned entry range.
- c) For each index returned:
  - 1) Address—MAC address of the desired entry (not present in VLAN Registration Entries).
  - 2) VID—VLAN Identifier of the entry.
  - 3) Type—Static or Dynamic entry.
  - 4) Port Map—a set of control indicators as appropriate for the entry (that may include a Connection Identifier), as specified in 8.8.1 through 8.8.5.

## 12.8 Bridge Protocol Entity

The Bridge Protocol Entity is described in 8.10 and Clause 13.

This managed resource comprises the following objects:

- a) The Protocol Entity
- b) The Ports under its control

### 12.8.1 The Protocol Entity

The Protocol Entity object models the operations that can be performed on, or inquire about, the operation of STP. There is a single Protocol Entity per Bridge; it can therefore be identified as a single fixed component of the Protocol Entity resource.

The management operations that can be performed on the Protocol Entity are as follows:

- a) Read CIST Bridge Protocol Parameters (12.8.1.1)
- b) Read MSTI Bridge Protocol Parameters (12.8.1.2)
- c) Set CIST Bridge Protocol Parameters (12.8.1.3)
- d) Set MSTI Bridge Protocol Parameters (12.8.1.4)

#### 12.8.1.1 Read CIST Bridge Protocol Parameters

##### 12.8.1.1.1 Purpose

To obtain information regarding the Bridge's Bridge Protocol Entity for the CIST.

##### 12.8.1.1.2 Inputs

None.

##### 12.8.1.1.3 Outputs

- a) Bridge Identifier—as defined in 13.26.2. The Bridge Identifier for the CIST.
- b) Time Since Topology Change—in an STP Bridge, the count in seconds of the time elapsed since the Topology Change flag parameter for the Bridge (8.5.3.12 of IEEE Std 802.1D, 1998 Edition [B13]) was last True, or in an RSTP or MSTP Bridge, the count in seconds since tcWhile timer (13.25) for any Port was nonzero.
- c) Topology Change Count—in an STP Bridge, the count of the times the Topology Change flag parameter for the Bridge has been set (i.e., transitioned from False to True) since the Bridge was powered on or initialized, or in an RSTP or MSTP Bridge, the count of times that there has been at least one nonzero tcWhile timer (13.25).
- d) CIST Root Identifier (13.26.10).
- e) CIST External Root Path Cost (13.26.10).
- f) Root Port (13.26.9).
- g) Max Age (13.26.11).
- h) Forward Delay (13.26.11).
- i) Bridge Max Age (13.26.4).
- j) Bridge Hello Time (13.25). This parameter is present only if the Bridge supports STP or RSTP.
- k) Bridge Forward Delay (13.26.4).
- l) Hold Time (8.5.3.14 of IEEE Std 802.1D, 1998 Edition [B13]) or Transmission Limit (TxHoldCount in 13.26.12).

1 The following parameter is present only if the Bridge supports RSTP or MSTP:

- 2 m) forceVersion—the value of the Force Protocol Version parameter for the Bridge (13.7.2).

3 The following additional parameters are present only if the Bridge supports MSTP:

- 4 n) CIST Regional Root Identifier (13.26.10). The Bridge Identifier of the current CIST Regional Root.  
5 o) CIST Path Cost (CIST Internal Root Path Cost, in 13.26.10). The CIST path cost from the  
6 transmitting Bridge to the CIST Regional Root.  
7 p) MaxHops (13.26.4).

## 8 12.8.1.2 Read MSTI Bridge Protocol Parameters

### 9 12.8.1.2.1 Purpose

10 In an MST Bridge, to obtain information regarding the Bridge's Bridge Protocol Entity for the specified  
11 spanning tree instance.

### 12 12.8.1.2.2 Inputs

- 13 a) MSTID—Identifies the set of parameters that will be returned. For Bridges that support MSTP, this  
14 parameter is the identifier of the spanning tree for which the operation is being performed. This  
15 parameter takes a value in the range 1 through 4094.

### 16 12.8.1.2.3 Outputs

- 17 a) MSTID—identifies the set of parameters that are being returned. This parameter is the identifier of  
18 the MST Instance for which the operation is being performed.  
19 b) Bridge Identifier—as defined in 13.26.2. The Bridge Identifier for the spanning tree instance  
20 identified by the MSTID.  
21 c) Time Since Topology Change—count in seconds of the time elapsed since tcWhile (13.25) was last  
22 nonzero for any Port for the given MSTI.  
23 d) Topology Change Count—count of the times tcWhile has been nonzero for any Port for the given  
24 MSTI since the Bridge was powered on or initialized.  
25 e) Topology Change (tcWhile, 13.25). True if tcWhile is nonzero for any Port for the given MST.  
26 f) Designated Root (MSTI Regional Root Identifier, 13.26.10). The Bridge Identifier of the Root  
27 Bridge for the spanning tree instance identified by the MSTID.  
28 g) Root Path Cost (MSTI Internal Root Path Cost, 13.26.10). The path cost from the transmitting  
29 Bridge to the Root Bridge for the spanning tree instance identified by the MSTID.  
30 h) Root Port (13.26.9). The Root Port for the spanning tree instance identified by the MSTID.

## 31 12.8.1.3 Set CIST Bridge Protocol Parameters

### 32 12.8.1.3.1 Purpose

33 To modify parameters in the Bridge's Bridge Protocol Entity for the CIST, in order to force a configuration  
34 of the spanning tree and/or tune the reconfiguration time to suit a specific topology. In RSTP and MSTP  
35 implementations, this operation causes these values to be set for all Ports of the Bridge.

### 36 12.8.1.3.2 Inputs

- 37 a) Bridge Max Age—the new value (13.26.4).  
38 b) Bridge Hello Time—the new value (13.25) This parameter is present only if the Bridge supports  
39 STP or RSTP.  
40 c) Bridge Forward Delay—the new value (13.26.4).  
41 d) Bridge Priority—the new value of the priority part of the Bridge Identifier (13.26.2) for the CIST.

1 The following parameters are present only if the Bridge supports RSTP or MSTP:

- 2 e) forceVersion—the new value of the Force Protocol Version parameter for the Bridge (13.7.2).
- 3 f) TxHoldCount—the new value of TxHoldCount (13.26.12).

4 The following parameter is present only if the Bridge supports MSTP:

- 5 g) MaxHops—the new value of MaxHops (13.26.4).

### 6 **12.8.1.3.3 Outputs**

7 a) Operation status. This takes one of the following values:

- 8 1) Operation rejected due to invalid Bridge Priority value (12.3).
- 9 2) Operation rejected due to the specified Max Age, Hello Time, or Forward Delay values being
- 10 outside the range specified for the parameter (see 12.8.1.3.4).
- 11 3) Operation rejected due to the specified Max Age, Hello Time, or Forward Delay values not
- 12 being in compliance with the requirements of this standard (see 12.8.1.3.4).
- 13 4) Operation rejected due to the specified MaxHops value not being within the permitted range
- 14 specified in Table 13-5.
- 15 5) Operation accepted.

### 16 **12.8.1.3.4 Procedure**

17 In the following description, the references to Bridge Hello Time apply only to Bridges that support STP or  
18 RSTP.

19 The input parameter values are checked for compliance with their definitions in Clause 13. If they do not  
20 comply, or the value of Bridge Max Age or Bridge Forward Delay is less than the lower limit of the  
21 range specified in Table 13-5, then no action shall be taken for any of the supplied parameters. If the value of  
22 any of Bridge Max Age, Bridge Forward Delay, or Bridge Hello Time is outside the range specified in  
23 Table 13-5, then the Bridge need not take action.

24 Otherwise,

- 25 a) The Bridge's Bridge Max Age, Bridge Hello Time, and Bridge Forward Delay parameters are set to
- 26 the supplied values.
- 27 b) In STP Bridges, the Set Bridge Priority procedure (8.8.4 of IEEE Std 802.1D, 1998 Edition [B13]) is
- 28 used to set the priority part of the Bridge Identifier to the supplied value.
- 29 c) In RSTP and MSTP Bridges, the priority component of the Bridge Identifier (13.26.2) is updated
- 30 using the supplied value. For all Ports of the Bridge, the reselect for the CIST parameter (13.27) is
- 31 set TRUE, and the selected parameter for the CIST is set FALSE.

### 32 **12.8.1.4 Set MSTI Bridge Protocol Parameters**

#### 33 **12.8.1.4.1 Purpose**

34 To modify parameters in the Bridge's Bridge Protocol Entity for the specified spanning tree instance, in  
35 order to force a configuration of the spanning tree and/or tune the reconfiguration time to suit a specific  
36 topology.

#### 37 **12.8.1.4.2 Inputs**

- 38 a) MSTID—identifies the set of parameters upon which the operation will be performed.
- 39 b) Bridge Priority—the new value of the priority part of the Bridge Identifier (13.26.2) for the spanning
- 40 tree instance identified by the MSTID.

#### 12.8.1.4.3 Outputs

- a) Operation status. This takes one of the following values:
- 1) Operation rejected due to invalid Bridge Priority value (12.3).
  - 2) Operation rejected due to invalid MSTID (i.e, there is currently no MST Instance with that value of MSTID supported by the Bridge).
  - 3) Operation accepted.

#### 12.8.1.4.4 Procedure

The Bridge Priority parameter value is checked for compliance with its definition in Clause 13. If it does not comply, then no action shall be taken.

Otherwise, the priority part of the Bridge Identifier is set to the supplied value for the specified spanning tree instance.

### 12.8.2 Bridge Port

A Bridge Port object models the operations related to an individual Bridge Port in relation to the operation of STP. There are a fixed set of Bridge Ports per Bridge; each can therefore be identified by a permanently allocated Port Number, as a fixed component of the Protocol Entity resource.

The management operations that can be performed on a Bridge Port are as follows:

- a) Read CIST Port Parameters (12.8.2.1)
- b) Read MSTI Port Parameters (12.8.2.2)
- c) Set CIST Port Parameters (12.8.2.3)
- d) Set MSTI Port Parameters (12.8.2.4)
- e) Force BPDU Migration Check (12.8.2.5)

#### 12.8.2.1 Read CIST Port Parameters

##### 12.8.2.1.1 Purpose

To obtain information regarding a specific Port within the Bridge's Bridge Protocol Entity, for the CIST.

##### 12.8.2.1.2 Inputs

- a) Port Number—the number of the Bridge Port.

##### 12.8.2.1.3 Outputs

- a) Uptime—count in seconds of the time elapsed since the Port was last reset or initialized (BEGIN, 13.26).
- b) Port State—Discarding, Listening, Learning, or Forwarding (8.4).
- c) Port Identifier—the unique Port identifier comprising two parts, the Port Number and the Port Priority field (13.27.46).
- d) Path Cost (ExternalPortPathCost, 13.27.25).
- e) Designated Root (CIST Root Identifier, 13.27.20).
- f) Designated Cost (External Root Path Cost, 13.27.20).
- g) Designated Bridge (13.27.20).
- h) Designated Port (13.27.20).
- i) Topology Change Acknowledge (13.27.72).

- 1 j) Hello Time (13.27.48).
- 2 k) adminEdgePort (13.27.1). Present in implementations that support the identification of edge ports.
- 3 l) operEdgePort (13.27.44). Present in implementations that support the identification of edge ports.
- 4 m) autoEdgePort (13.27.6). Optional and provided only in implementations that support the automatic  
5 identification of edge ports.
- 6 n) autoIsolatePort (13.27.19). Present in implementations that support detection of fragile Bridges.
- 7 o) isolatePort (13.27.27). Present in implementations that support detection of fragile Bridges.
- 8 p) MAC Enabled—the current state of the MAC Enabled parameter (IEEE Std 802.1AC). Present if  
9 the implementation supports the MAC Enabled parameter.
- 10 q) MAC Operational—the current state of the MAC Operational parameter (IEEE Std 802.1AC).  
11 Present if the implementation supports the MAC Operational parameter.
- 12 r) adminPointToPointMAC—the current state of the adminPointToPointMAC parameter  
13 (IEEE Std 802.1AC). Present if the implementation supports the adminPointToPointMAC  
14 parameter.
- 15 s) operPointToPointMAC—the current state of the operPointToPointMAC parameter  
16 (IEEE Std 802.1AC). Present if the implementation supports the operPointToPointMAC parameter.
- 17 t) restrictedRole—the current state of the restrictedRole parameter for the Port (13.27.63).
- 18 u) restrictedTcn—the current state of the restrictedTcn parameter for the Port (13.27.65).
- 19 v) Port Role—the current Port Role for the Port (i.e., Root, Alternate, Designated, or Backup)
- 20 w) Disputed—the current value of the disputed variable for the CIST for the Port (13.27.22).
- 21 x) enableBPDURx—the value of enableBPDURx (13.27.23).
- 22 y) enableBPDUTx—the value of enableBPDUTx (13.27.24).
- 23 z) pseudoRootId—the value of Bridge Identifier used by the L2 gateway protocol (13.27.51).
- 24 aa) isL2gp—the value of isL2gp (13.27.26).

25 The following additional parameters are present only if the Bridge supports MSTP:

- 26 ab) CIST Regional Root Identifier (13.26.10). The Bridge Identifier of the current CIST Regional Root.
- 27 ac) CIST Path Cost (CIST Internal Root Path Cost, in 13.26.10). The CIST path cost from the  
28 transmitting Bridge to the CIST Regional Root.
- 29 ad) Port Hello Time. The administrative value of Hello Time for the Port (13.27.48).

## 30 12.8.2.2 Read MSTI Port Parameters

### 31 12.8.2.2.1 Purpose

32 To obtain information regarding a specific Port within the Bridge's Bridge Protocol Entity, for a given  
33 MSTI.

### 34 12.8.2.2.2 Inputs

- 35 a) Port Number—the number of the Bridge Port.
- 36 b) MSTID—identifies the set of parameters that will be returned, in the range 1 through 4094.

### 37 12.8.2.2.3 Outputs

- 38 a) MSTID—identifies the set of parameters that are being returned. This parameter is the identifier of  
39 the spanning tree for which the operation is being performed.
- 40 b) Uptime—count in seconds of the time elapsed since the Port was last reset or initialized (BEGIN).
- 41 c) State—the current state of the Port (i.e., Disabled, Listening, Learning, Forwarding, or Blocking)  
42 (8.4, 13.38).

- 1 d) Port Identifier—the unique Port identifier comprising two parts, the Port Number and the Port  
2 Priority field (13.27.46).
- 3 e) Path Cost (13.27.20).
- 4 f) Designated Root (13.27.20).
- 5 g) Designated Cost (13.27.20).
- 6 h) Designated Bridge (13.27.20).
- 7 i) Designated Port (13.27.20).
- 8 j) Port Role—the current Port Role for the Port (i.e., Root, Alternate, Designated, or Backup,  
9 13.27.66).
- 10 k) Disputed—the current value of the disputed variable (13.27.22).
- 11 l) pseudoRootId—the new value of Bridge Identifier used by the L2 gateway protocol (13.27.51).

### 12 12.8.2.3 Set CIST port parameters

#### 13 12.8.2.3.1 Purpose

14 To modify parameters for a Port in the Bridge's Bridge Protocol Entity in order to force a configuration of  
15 the spanning tree for the CIST.

#### 16 12.8.2.3.2 Inputs

- 17 a) Port Number—the number of the Bridge Port.
- 18 b) Path Cost—the new ExternalPortPathCost (13.27.25).
- 19 c) Port Priority—the new value of the priority field for the Port Identifier (13.27.46).
- 20 d) adminEdgePort—the new value of the adminEdgePort parameter (13.27.1). Present in  
21 implementations that support the identification of edge ports.
- 22 e) autoEdgePort—the new value of the autoEdgePort parameter (13.27.6). Optional and provided only  
23 in implementations that support the automatic identification of edge ports.
- 24 f) autoIsolatePort—the new value of the autoIsolatePort parameter (13.27.19). Present in  
25 implementations that support detection of fragile Bridges.
- 26 g) MAC Enabled—the new value of the MAC Enabled parameter (IEEE Std 802.1AC). May be  
27 present if the implementation supports the MAC Enabled parameter.
- 28 h) adminPointToPointMAC—the new value of the adminPointToPointMAC parameter  
29 (IEEE Std 802.1AC). May be present if the implementation supports the adminPointToPointMAC  
30 parameter.
- 31 i) restrictedRole—the new value of the restrictedRole parameter for the Port (13.27.63).
- 32 j) restrictedTcn—the new value of the restrictedTcn parameter for the Port (13.27.65).
- 33 k) enableBPDURx—the new value of enableBPDURx (13.27.23).
- 34 l) enableBPDUTx—the new value of enableBPDUTx (13.27.24).
- 35 m) pseudoRootId—the new value of Bridge Identifier used by the L2 gateway protocol (13.27.51).
- 36 n) isL2gp—the new value of isL2gp (13.27.26).

#### 37 12.8.2.3.3 Outputs

- 38 a) Operation status. This takes one of the following values:
  - 39 1) Operation rejected due to invalid Port Priority value (12.3)
  - 40 2) Operation accepted

#### 12.8.2.3.4 Procedure

In STP Bridges, the Set Path Cost procedure (8.8.6 of IEEE Std 802.1D, 1998 Edition [B13]) is used to set the Path Cost parameter for the specified Port for the specified spanning tree instance. The Set Port Priority procedure (8.8.5 of IEEE Std 802.1D, 1998 Edition [B13]) is used to set the priority part of the Port Identifier (8.5.5.1 of IEEE Std 802.1D, 1998 Edition [B13]) for the CIST to the supplied value.

In RSTP and MSTP Bridges, the Path Cost (13.27.25) and Port Priority (13.27.47) parameters for the Port are updated using the supplied values. The reselect parameter value for the CIST for the Port (13.27.62) is set TRUE, and the selected parameter for the CIST for the Port (13.27.67) is set FALSE.

#### 12.8.2.4 Set MSTI port parameters

##### 12.8.2.4.1 Purpose

To modify parameters for a Port in the Bridge's Bridge Protocol Entity in order to force a configuration of the spanning tree for the specified spanning tree instance.

##### 12.8.2.4.2 Inputs

- a) MSTID—identifies the set of parameters upon which the operation will be performed. This parameter is the identifier of the spanning tree for which the operation is being performed.
- b) Port Number—the number of the Bridge Port.
- c) Path Cost—the new value (13.27.25).
- d) Port Priority—the new value of the priority field for the Port Identifier (13.27.46).
- e) pseudoRootId—the new value of Bridge Identifier used by the L2 gateway protocol (13.27.51).

##### 12.8.2.4.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to invalid Port Priority value (12.3).
  - 2) Operation rejected due to invalid MSTID (i.e., there is currently no spanning tree instance with that value of MSTID supported by the Bridge).
  - 3) Operation accepted.

##### 12.8.2.4.4 Procedure

The Path Cost (13.27.25) and Port Priority (13.27.47) parameters for the specified MSTI and Port are updated using the supplied values. The reselect parameter value for the MSTI for the Port (13.27.62) is set TRUE, and the selected parameter for the MSTI for the Port (13.27.67) is set FALSE.

#### 12.8.2.5 Force BPDU Migration Check

This operation is available only in Bridges that support RSTP or MSTP, as specified in Clause 13.

##### 12.8.2.5.1 Purpose

To force the specified Port to transmit Rapid Spanning Tree (RST) or MST BPDUs (see 13.32).

##### 12.8.2.5.2 Inputs

- a) Port Number—the number of the Bridge Port.

##### 12.8.2.5.3 Outputs

None.

#### 1 12.8.2.5.4 Procedure

2 The mcheck variable (13.27.38) for the specified Port is set to the value TRUE if the value of the  
3 forceVersion variable (13.7.2) is greater than or equal to 2.

### 4 12.9 MRP Entities

5 The operation of MRP is described in Clause 10.

6 This managed resource comprises the following objects:

- 7 a) The MRP Timer objects (12.9.1)
- 8 b) The MRP Attribute Type objects (12.9.2)
- 9 c) The Periodic State Machine objects (12.9.3)

#### 10 12.9.1 The MRP Timer object

11 The MRP Timer object models the operations that can be performed on, or inquire about, the current settings  
12 of the timers used by MRP on a given Port. The management operations that can be performed on the MRP  
13 Participant are as follows:

- 14 a) Read MRP Timers (12.9.1.1)
- 15 b) Set MRP Timers (12.9.1.2)

16 NOTE—The MRP timer values modeled by this object are the values used to initialize timer instances that are used  
17 within the MRP state machines, not the timer instances themselves. Hence, there is a single MRP Timer object per Port,  
18 regardless of whether the Bridge supports single or multiple spanning trees.

##### 19 12.9.1.1 Read MRP Timers

###### 20 12.9.1.1.1 Purpose

21 To read the current MRP Timers for a given Port.

###### 22 12.9.1.1.2 Inputs

- 23 a) The Port identifier.

###### 24 12.9.1.1.3 Outputs

- 25 a) Current value of JoinTime—Centiseconds, *Persistent*. (10.7.4.1 and 10.7.11).
- 26 b) Current value of LeaveTime—Centiseconds, *Persistent*. (10.7.4.2 and 10.7.11).
- 27 c) Current value of LeaveAllTime—Centiseconds, *Persistent*. (10.7.4.3 and 10.7.11).

##### 28 12.9.1.2 Set MRP Timers

###### 29 12.9.1.2.1 Purpose

30 To set new values for the MRP Timers for a given Port.

###### 31 12.9.1.2.2 Inputs

- 32 a) The Port identifier.
- 33 b) New value of JoinTime—Centiseconds (10.7.4.1 and 10.7.11).
- 34 c) New value of LeaveTime—Centiseconds (10.7.4.2 and 10.7.11).
- 35 d) New value of LeaveAllTime—Centiseconds (10.7.4.3 and 10.7.11).

### 1 12.9.1.2.3 Outputs

2 None.

## 3 12.9.2 The MRP Attribute Type object

4 The MRP Attribute Type object models the operations that can be performed on, or inquire about, the  
5 operation of MRP for a given Attribute Type (10.8.2.2). The management operations that can be performed  
6 on an MRP Attribute Type are as follows:

- 7 a) Read MRP Applicant Controls (12.9.2.1)
- 8 b) Set MRP Applicant Controls (12.9.2.2)

### 9 12.9.2.1 Read MRP Applicant Controls

#### 10 12.9.2.1.1 Purpose

11 To read the current values of the MRP Applicant Administrative control parameters (10.7.3) and Transmit  
12 Zero parameters (11.2.3.1.7) associated with all MRP Participants for a given Port, MRP Application, and  
13 Attribute Type.

#### 14 12.9.2.1.2 Inputs

- 15 a) The Port identifier.
- 16 b) The MRP Application.
- 17 c) The Attribute Type (10.8.2.2).

#### 18 12.9.2.1.3 Outputs

- 19 a) The current Applicant Administrative Control Value, *Persistent*. (10.7.3);
- 20 b) Failed Registrations—count of the number of times that this MRP Application has failed to register  
21 an attribute of this type due to lack of space in the FDB, *Persistent*. (12.10.1.6).
- 22 c) Transmit zero enable—whether the transmission of 0 as an Attribute value is currently enabled  
23 (MVRP only). (11.2.3.1.7).

### 24 12.9.2.2 Set MRP Applicant Controls

#### 25 12.9.2.2.1 Purpose

26 To set new values for the MRP Applicant Administrative control parameters (10.7.3) and Transmit Zero  
27 parameters (11.2.3.1.7) associated with all MRP Participants for a given Port, MRP Application, and  
28 Attribute Type.

#### 29 12.9.2.2.2 Inputs

- 30 a) The Port identifier
- 31 b) The MRP Application
- 32 c) The Attribute Type (10.8.2.2) associated with the state machine
- 33 d) The desired Applicant Administrative Control Value (10.7.3)
- 34 e) The desired Transmit zero enable value (MVRP only) (11.2.3.1.7)

#### 35 12.9.2.2.3 Outputs

36 None.

#### 1 **12.9.2.2.4 Procedures**

2 A Bridge shall not allow both MIRP and MVRP to be enabled on the same VIP.

#### 3 **12.9.3 Periodic state machine objects**

4 The Periodic state machine object models the operations that can be performed upon, or inquire about, the  
5 operation of the Periodic state machine for a given Port.

6 The management operations that can be performed on a Periodic state machine are Read Periodic state  
7 machine state and Set Periodic state machine state.

#### 8 **12.9.3.1 Read Periodic state machine state**

##### 9 **12.9.3.1.1 Purpose**

10 To inquire whether a particular Periodic state machine is enabled or disabled.

##### 11 **12.9.3.1.2 Inputs**

12 a) The Port identifier.

##### 13 **12.9.3.1.3 Outputs**

14 a) The Port identifier.

15 b) The state of the Periodic state machine. This can take either of the values “enabled” or “disabled.”

#### 16 **12.9.3.2 Set Periodic state machine state**

##### 17 **12.9.3.2.1 Purpose**

18 To enable or disable a particular Periodic state machine.

##### 19 **12.9.3.2.2 Inputs**

20 a) The Port identifier.

21 b) The desired state of the Periodic state machine. This can take either of the values “enabled” or  
22 “disabled.”

##### 23 **12.9.3.2.3 Outputs**

24 None.

#### 25 **12.10 Bridge VLAN managed objects**

26 The following managed objects define the semantics of the management operations that can be performed  
27 on the VLAN aspects of a Bridge:

28 a) The Bridge VLAN Configuration managed object (12.10.1)

29 b) The VLAN Configuration managed object (12.10.2)

30 c) The VID to FID allocation managed object (12.10.3)

## 12.10.1 Bridge VLAN Configuration managed object

The Bridge VLAN Configuration managed object models operations that modify, or inquire about, the overall configuration of the Bridge's VLAN resources. There is a single Bridge VLAN Configuration managed object per Bridge Component.

The management operations that can be performed on the Bridge VLAN Configuration managed object are as follows:

- a) Read Bridge VLAN Configuration (12.10.1.1)
- b) Configure PVID and VID Set values (12.10.1.2)
- c) Configure Acceptable Frame Types parameters (12.10.1.3)
- d) Configure Enable Ingress Filtering parameters (12.10.1.4)
- e) Reset Bridge (12.10.1.5)
- f) Configure Restricted\_VLAN\_Registration parameters (12.10.1.6)
- g) Configure Protocol Group Database (12.10.1.7)
- h) Configure VID to FID allocation (12.10.3)
- i) Configure VID Translation Table (12.10.1.8)
- j) Configure Egress VID Translation Table (12.10.1.9)

### 12.10.1.1 Read Bridge VLAN Configuration

#### 12.10.1.1.1 Purpose

To obtain general VLAN information from a Bridge.

#### 12.10.1.1.2 Inputs

None.

#### 12.10.1.1.3 Outputs

- a) The IEEE 802.1Q VLAN Version number. Reported as "1" by Bridges that support only SST operation, and reported as "2" by Bridges that support MST operation.

NOTE—No IEEE 802.1Q VLAN version numbers other than 1 and 2 are specified.

- b) The optional VLAN features supported by the implementation:
  - 1) The maximum number of VIDs supported.
  - 2) Whether the implementation supports the ability to override the default PVID setting, and its egress status (VLAN-tagged or untagged) on each Port.
  - 3) For a Bridge that supports Port-and-Protocol-based VLAN classification, which of the Protocol Template formats (6.12.1) are supported by the implementation.
  - 4) For MST Bridges, the maximum number of MSTIs supported within an MST Region (i.e., the number of spanning tree instances that can be supported in addition to the CIST). For SST Bridges, this parameter may be either omitted or reported as "0."
- c) For each Port:
  - 1) The Port number.
  - 2) The PVID value (6.9) currently assigned to that Port.
  - 3) For a Bridge that supports Port-and-Protocol-based VLAN classification, whether the implementation supports Port-and-Protocol-based VLAN classification on that Port.
  - 4) For a Bridge that supports Port-and-Protocol-based VLAN classification on that Port, the maximum number of entries supported in the VID Set on that Port; the VID value and Protocol Group Identifier currently assigned to each entry in the VID Set (8.6.2) on that Port.

- 1 5) The state of the Acceptable Frame Types parameter (6.9). The permissible values for this  
2 parameter are as follows:
  - 3 i) *Admit Only VLAN-tagged frames*
  - 4 ii) *Admit Only Untagged and Priority Tagged frames*
  - 5 iii) *Admit All frames*
- 6 6) The state of the Enable Ingress Filtering parameter (6.9); Enabled or Disabled;
- 7 7) The state of the Restricted\_VLAN\_Registration parameter (11.2.3.2.3), TRUE or FALSE.
- 8 8) Whether the Bridge supports a VID Translation Table on that Port; whether the Bridge supports  
9 an Egress VID Translation Table on that Port;
- 10 9) For a Bridge that supports a VID Translation Table on that Port, a set of (Local VID, Relay  
11 VID) bindings (6.9);
- 12 10) For a Bridge that supports an Egress VID Translation Table on that Port, a set of (Relay VID,  
13 Local VID) bindings (6.9).
- 14 d) For a Bridge that supports Port-and-Protocol-based VLAN classification: the contents of the  
15 Protocol Group Database comprising a set of {Protocol Template, Protocol Group Identifier}  
16 bindings (6.12.1, 6.12.2, and 6.12.3); the maximum number of entries supported in the Protocol  
17 Group Database.

## 18 12.10.1.2 Configure PVID and VID Set values

### 19 12.10.1.2.1 Purpose

20 To configure the PVID and VID Set value(s) (6.9) associated with one or more Ports.

### 21 12.10.1.2.2 Inputs

- 22 a) For each Port to be configured, a Port number and the PVID value to be associated with that Port.
- 23 b) In addition, for a Bridge that supports Port-and-Protocol-based VLAN classification: for each Port  
24 to be configured, a Port number, a Protocol Group Identifier, and a VID value for the member of the  
25 Port's VID Set that is to be configured.

### 26 12.10.1.2.3 Outputs

- 27 a) Operation status for each Port to be configured. This takes one of the following values:
  - 28 1) Operation rejected due to there being no spare VID Set entries on this Port
  - 29 2) Operation rejected due to the PVID or VID being out of the supported range for this Port
  - 30 3) Operation accepted

## 31 12.10.1.3 Configure Acceptable Frame Types parameters

### 32 12.10.1.3.1 Purpose

33 To configure the Acceptable Frame Types parameter (6.9) associated with one or more Ports.

### 34 12.10.1.3.2 Inputs

- 35 a) For each Port to be configured, a Port number and the value of the Acceptable Frame Types  
36 parameter to be associated with that Port. The permissible values of this parameter are (as defined in  
37 6.9) as follows:
  - 38 1) *Admit Only VLAN-tagged frames*
  - 39 2) *Admit Only Untagged and Priority Tagged frames*
  - 40 3) *Admit All frames*

### 1 **12.10.1.3.3 Outputs**

2 None.

### 3 **12.10.1.4 Configure Enable Ingress Filtering parameters**

#### 4 **12.10.1.4.1 Purpose**

5 To configure the Enable Ingress Filtering parameter(s) (8.6.2) associated with one or more Ports.

#### 6 **12.10.1.4.2 Inputs**

7 a) For each Port to be configured, a Port number and the value of the Enable Ingress Filtering  
8 parameter to be associated with that Port. The permissible values for the parameter are as follows:

- 9 1) Enabled
- 10 2) Disabled

#### 11 **12.10.1.4.3 Outputs**

12 None.

### 13 **12.10.1.5 Reset Bridge**

#### 14 **12.10.1.5.1 Purpose**

15 To reset all statically configured VLAN-related information in the Bridge to its default state. This operation:

- 16 a) Deletes all VLAN Configuration managed objects.
- 17 b) Resets the PVID associated with each Bridge Port to the Default PVID value (Table 9-2).
- 18 c) Removes all entries in the Protocol Group Database and removes all members of the VID Set on  
19 each port, for a Bridge that supports Port-and-Protocol-based VLAN classification.
- 20 d) Resets the Acceptable Frame Types parameter value associated with each Port to the default value  
21 (6.9).

#### 22 **12.10.1.5.2 Inputs**

23 None.

#### 24 **12.10.1.5.3 Outputs**

25 None.

### 26 **12.10.1.6 Configure Restricted\_VLAN\_Registration parameters**

#### 27 **12.10.1.6.1 Purpose**

28 To configure the Restricted\_VLAN\_Registration parameter (11.2.3.2.3) associated with one or more Ports.

#### 29 **12.10.1.6.2 Inputs**

30 a) For each Port to be configured, a Port number and the value of the Restricted\_VLAN\_Registration  
31 parameter. The permissible values of this parameter are (as defined in 11.2.3.2.3) as follows:

- 32 1) TRUE
- 33 2) FALSE

#### 34 **12.10.1.6.3 Outputs**

35 None.

### 1 **12.10.1.7 Configure Protocol Group Database**

2 To configure a Protocol Group Database (6.12.3) entry. This operation is not applicable to a Bridge that does  
3 not support Port-and-Protocol-based VLAN classification.

4 NOTE—Implementation of the Configure Protocol Group Database operation is not mandatory; conformant  
5 implementations may implement a fixed set of Protocol Group Database entries.

#### 6 **12.10.1.7.1 Inputs**

- 7 a) A value representing the frame format to be matched: Ethernet, RFC\_1042, SNAP\_8021H,  
8 SNAP\_Other, or LLC\_Other (6.12.1).
- 9 b) One of:
  - 10 1) An IEEE 802.3 EtherType value, for matching frame formats of Ethernet, RFC\_1042, or
  - 11 SNAP\_8021H.
  - 12 2) A 40-bit Protocol Identifier (PID), for matching frame formats of SNAP\_Other.
  - 13 3) A pair of ISO/IEC 8802-2 DSAP and SSAP address field values, for matching frame formats of
  - 14 LLC\_Other.
- 15 c) A Protocol Group Identifier (6.12.2).

16 NOTE—While the intent is to identify VID traffic, an ID of 0 may be used to indicate untagged traffic that needs  
17 prioritization.

#### 18 **12.10.1.7.2 Outputs**

- 19 a) Operation status. This takes one of the following values:
  - 20 1) Operation rejected due to there being no spare Protocol Group Database entries.
  - 21 2) Operation rejected due to an unsupported frame format.
  - 22 3) Operation rejected due to an unsupported value for an IEEE 802.3 EtherType value, PID,
  - 23 DSAP, or SSAP.
  - 24 4) Operation accepted.

### 25 **12.10.1.8 VID Translation Configuration managed object**

26 To configure the VID Translation Table (6.9) associated with a Port. This object is not applicable to Ports  
27 that do not support a VID Translation Table. The default configuration of the table has the value of the Relay  
28 VID equal to the value of the Local VID for all Local VID values. If the port supports an Egress VID  
29 translation table, the VID Translation Configuration object configures the Local VID to Relay VID mapping  
30 on ingress only. If an Egress VID translation is not supported, the VID Translation Configuration object  
31 defines a single bidirectional mapping.

32 The management operations that can be performed are as follows:

- 33 a) Read VID Translation Table Entry (12.10.1.8.1)
- 34 b) Configure VID Translation Table Entry (12.10.1.8.2)

#### 35 **12.10.1.8.1 Read VID Translation Table Entry**

##### 36 **12.10.1.8.1.1 Purpose**

37 To read the relay VID associated with the local VID.

##### 38 **12.10.1.8.1.2 Inputs**

- 39 a) Port Number: the number of the port that is capable of performing VID translation.
- 40 b) Local VLAN Identifier: a 12-bit VID.

### 1 **12.10.1.8.1.3 Outputs**

- 2 a) Relay VLAN Identifier: a 12-bit VID.

### 3 **12.10.1.8.2 Configure VID Translation Table Entry**

#### 4 **12.10.1.8.2.1 Purpose**

5 To modify an entry in the VID Translation Table.

#### 6 **12.10.1.8.2.2 Inputs**

- 7 a) Port Number: the number of the port that is capable of performing VID translation. This port should  
8 be at the edge of an administrative or a control protocol domain (6.9).  
9 b) Local VLAN Identifier: a 12-bit VID.  
10 c) Relay VLAN Identifier: a 12-bit VID.

#### 11 **12.10.1.8.2.3 Outputs**

- 12 a) Operation status. This takes one of the following values:  
13 1) Operation rejected because the port does not have Egress VID translation capabilities  
14 2) Operation accepted

### 15 **12.10.1.9 Egress VID Translation Configuration managed object**

16 To configure the Egress VID Translation Table (6.9) associated with a Port. This object is not applicable to  
17 Ports that do not support an Egress VID Translation Table. The default configuration of the table has the  
18 value of the Local VID equal to the value of the Relay VID for all Relay VID values.

19 The management operations that can be performed are as follows:

- 20 a) Read Egress VID Translation Table Entry (12.10.1.9.1)  
21 b) Configure Egress VID Translation Table Entry (12.10.1.9.2)

### 22 **12.10.1.9.1 Read Egress VID Translation Table Entry**

#### 23 **12.10.1.9.1.1 Purpose**

24 To read the local VID associated with the relay VID.

#### 25 **12.10.1.9.1.2 Inputs**

- 26 a) Port Number: the number of the port that is capable of performing Egress VID translation.  
27 b) Relay VLAN Identifier: a 12-bit VID.

#### 28 **12.10.1.9.1.3 Outputs**

- 29 a) Local VLAN Identifier: a 12-bit VID.

### 30 **12.10.1.9.2 Configure Egress VID Translation Table Entry**

#### 31 **12.10.1.9.2.1 Purpose**

32 To modify an entry in the Egress VID Translation Table.

#### 33 **12.10.1.9.2.2 Inputs**

- 34 a) Port Number: the number of the port that is capable of performing Egress VID translation. This port  
35 should be at the edge of an administrative or a control protocol domain (6.9).  
36 b) Relay VLAN Identifier: a 12-bit VID.  
37 c) Local VLAN Identifier: a 12-bit VID.

### 1 **12.10.1.9.2.3 Outputs**

- 2 a) Operation rejected because the port does not have Egress VID translation capabilities.
- 3 b) Operation accepted.

## 4 **12.10.2 VLAN Configuration managed object**

5 The VLAN Configuration object models operations that modify, or inquire about, the configuration of a  
6 particular VID within a Bridge. There are multiple VLAN Configuration objects per Bridge; only one such  
7 object can exist for a given VID.

8 The management operations that can be performed on the VLAN Configuration are as follows:

- 9 a) Read VLAN Configuration (12.10.2.1)
- 10 b) Create VLAN Configuration (12.10.2.2)
- 11 c) Delete VLAN Configuration (12.10.2.3)

### 12 **12.10.2.1 Read VLAN Configuration**

#### 13 **12.10.2.1.1 Purpose**

14 To obtain general information regarding a specific VLAN Configuration.

#### 15 **12.10.2.1.2 Inputs**

- 16 a) VLAN Identifier: a 12-bit VID.

#### 17 **12.10.2.1.3 Outputs**

- 18 a) VLAN Name: A text string of up to 32 characters of locally determined significance.
- 19 b) List of Untagged Ports: The set of Port numbers in the untagged set (8.8.2) for this VID.
- 20 c) List of Egress Ports: The set of Port numbers in the member set (8.8.10) for this VID.

21 NOTE—The values of the member set and the untagged set are determined by the values held in VLAN Registration  
22 Entries in the FDB (8.8.2, 8.8.5, and 8.8.10).

### 23 **12.10.2.2 Create VLAN Configuration**

#### 24 **12.10.2.2.1 Purpose**

25 To create or update a VLAN Configuration managed object.

#### 26 **12.10.2.2.2 Inputs**

- 27 a) VLAN Identifier: a 12-bit VID.
- 28 b) VLAN Name: a text string of up to 32 characters of locally determined significance.

29 NOTE—Static configuration of the member set and the Untagged set is achieved by means of the management  
30 operations for manipulation of VLAN Registration Entries (12.7.5).

#### 31 **12.10.2.2.3 Outputs**

32 None.

### 33 **12.10.2.3 Delete VLAN Configuration**

#### 34 **12.10.2.3.1 Purpose**

35 To delete a VLAN Configuration managed object.

### 1 **12.10.2.3.2 Inputs**

- 2 a) VLAN Identifier: a 12-bit VID.

### 3 **12.10.2.3.3 Outputs**

- 4 None.

## 5 **12.10.3 The VID to FID allocation managed object**

6 The VID to FID allocations managed object models operations that modify, or inquire about VID to FID  
7 allocations (8.8.8) that apply to the operation of the Learning Process and the FDB. The object is modeled as  
8 a fixed-length table, as follows:

- 9 a) A VID to FID allocation table (8.8.8) with an entry per VID supported by the implementation. Each  
10 table entry indicates, for that VID, that there is currently:  
11 1) No allocation defined or  
12 2) A fixed allocation to FID X or  
13 3) A dynamic allocation to FID X.

14 The management operations that can be performed on the VID to FID allocations managed object are as  
15 follows:

- 16 b) Read VID to FID allocations (12.10.3.1)  
17 c) Read FID allocation for VID (12.10.3.2)  
18 d) Read VIDs allocated to FID (12.10.3.3)  
19 e) Set VID to FID allocation (12.10.3.4)  
20 f) Delete VID to FID allocation (12.10.3.5)

## 21 **12.10.3.1 Read VID to FID allocations**

### 22 **12.10.3.1.1 Purpose**

23 To read the contents of a range of one or more entries in the VID to FID allocation table.

### 24 **12.10.3.1.2 Inputs**

- 25 a) First Entry—VID of first entry to be read.  
26 b) Last Entry—VID of last entry to be read.

### 27 **12.10.3.1.3 Outputs**

- 28 a) List of Entries—For each entry that was read:  
29 1) VID—the VLAN Identifier for this entry.  
30 2) Allocation Type—the type of the allocation: Undefined, Fixed, or Dynamic.  
31 3) FID—the FID to which the VID is allocated (if not of type Undefined).

32 NOTE 1—Where this operation is implemented using a remote management protocol, PDU size constraints may restrict  
33 the number of entries that are actually read to fewer than was requested in the input parameters. In such cases, retrieving  
34 the remainder of the desired entry range can be achieved by repeating the operation with a modified entry range  
35 specification.

36 NOTE 2—The Allocation Type of Dynamic is applicable only for SPT Bridges and VIDs that have been reserved for use  
37 as SPVIDs.

## 38 **12.10.3.2 Read FID allocation for VID**

### 39 **12.10.3.2.1 Purpose**

40 To read the FID to which a specified VID is currently allocated.

## 1 12.10.3.2.2 Inputs

- 2 a) VID—the VLAN Identifier to which the read operation applies.

## 3 12.10.3.2.3 Outputs

- 4 a) VID—the VLAN Identifier to which the read operation applies.  
5 b) Allocation Type—the type of the allocation: Undefined, Fixed, or Dynamic.  
6 c) FID—the FID to which the VID is allocated (if not of type Undefined).

7 NOTE—The Allocation Type of Dynamic is applicable only for SPT Bridges and VIDs that have been reserved for use  
8 as SPVIDs.

## 9 12.10.3.3 Read VIDs allocated to FID

### 10 12.10.3.3.1 Purpose

11 To read all VIDs currently allocated to a given FID.

### 12 12.10.3.3.2 Inputs

- 13 a) FID—the Filtering Identifier to which the read operation applies.

### 14 12.10.3.3.3 Outputs

- 15 a) FID—the Filtering Identifier to which the read operation applies.  
16 b) Allocation List—a list of allocations for this FID. For each element in the list:  
17 1) Allocation Type—the type of the allocation: Fixed or Dynamic.  
18 2) VID—the VID that is allocated.

19 NOTE—The Allocation Type of Dynamic is applicable only for SPT Bridges and VIDs that have been reserved for use  
20 as SPVIDs.

## 21 12.10.3.4 Set VID to FID allocation

### 22 12.10.3.4.1 Purpose

23 To establish a fixed allocation of a VID to an FID.

### 24 12.10.3.4.2 Inputs

- 25 a) VID—the VID of the entry to be set.  
26 b) FID—the FID to which the VID is to be allocated.

### 27 12.10.3.4.3 Outputs

- 28 a) Operation status. This takes one of the following values:  
29 1) Operation rejected due to VID exceeding the maximum VID supported by the allocation table  
30 2) Operation rejected due to FID exceeding the maximum ID supported by the implementation  
31 3) Operation accepted

### 32 12.10.3.4.4 Procedure

33 In MST Bridges, the Configuration Digest element of the MCID is recalculated, in accordance with the  
34 definition in 13.8, following any change in the allocation of VIDs to FIDs that results in a change in the  
35 allocation of VIDs to spanning trees.

### 1 **12.10.3.5 Delete VID to FID allocation**

#### 2 **12.10.3.5.1 Purpose**

3 To remove a fixed VID to FID allocation from the VID to FID allocation table. This operation has the effect  
4 of setting the value of the specified table entry to “Undefined.”

5 NOTE—If the VID concerned represents a currently active VID, then removal of a fixed allocation may result in the  
6 “Undefined” value in the table immediately being replaced by a dynamic allocation to an FID.

#### 7 **12.10.3.5.2 Inputs**

- 8 a) VID—VID of the allocation to be deleted.

#### 9 **12.10.3.5.3 Outputs**

- 10 a) Operation status. This takes one of the following values:  
11 1) Operation rejected due to VID exceeding the maximum value supported by the allocation table  
12 2) Operation accepted

#### 13 **12.10.3.5.4 Procedure**

14 In MST Bridges, the Configuration Digest element of the MCID is recalculated, in accordance with the  
15 definition in 13.8, and the MSTP state machine variables are reinitialized by asserting BEGIN, following  
16 any change in the allocation of VIDs to FIDs that results in a change in the allocation of VIDs to spanning  
17 trees.

### 18 **12.11 MMRP entities**

19 The following managed object defines the semantics of the management operations that can be performed  
20 on the operation of MMRP in a Bridge:

- 21 a) The MMRP Configuration managed object (12.11.1)

#### 22 **12.11.1 MMRP Configuration managed object**

23 The MMRP Configuration managed object models operations that modify, or inquire about, the overall  
24 configuration of the operation of MMRP. There is a single MMRP Configuration managed object per  
25 Bridge.

26 The management operations that can be performed on the MMRP Configuration managed object are as  
27 follows:

- 28 a) Read MMRP Configuration (12.11.1.1)  
29 b) Notify MAC address registration failure (12.11.1.2)  
30 c) Configure Restricted\_MAC\_Address\_Registration parameters (12.11.1.3)

##### 31 **12.11.1.1 Read MMRP Configuration**

###### 32 **12.11.1.1.1 Purpose**

33 To obtain general MMRP configuration information from a Bridge.

###### 34 **12.11.1.1.2 Inputs**

35 None.

### 1 12.11.1.1.3 Outputs

- 2 a) For each Port:
  - 3 1) The Port number.
  - 4 2) The state of the Restricted\_MAC\_Address\_Registration parameter, *Persistent*. (10.12.2.3),
  - 5 TRUE or FALSE.

### 6 12.11.1.2 Notify MAC address registration failure

#### 7 12.11.1.2.1 Purpose

8 To notify a manager that MMRP has failed to register a given MAC address owing to lack of  
9 resources in the FDB for the creation of a MAC Address Registration Entry (8.8.4) or to the  
10 Restricted\_MAC\_Address\_Registration parameter.

#### 11 12.11.1.2.2 Inputs

12 None.

#### 13 12.11.1.2.3 Outputs

- 14 a) The MAC address that MMRP failed to register
- 15 b) The Port number of the Port on which the registration request was received
- 16 c) The reason for the failure:
  - 17 1) Lack of Resources or
  - 18 2) Registration Restricted

### 19 12.11.1.3 Configure Restricted\_MAC\_Address\_Registration parameters

#### 20 12.11.1.3.1 Purpose

21 To configure the Restricted\_MAC\_Address\_Registration parameter (10.12.2.3) associated with one or more  
22 Ports.

#### 23 12.11.1.3.2 Inputs

- 24 a) For each Port to be configured, a Port number and the value of the  
25 Restricted\_MAC\_Address\_Registration parameter. The permissible values of this parameter are as  
26 follows (as defined in 10.12.2.3):
  - 27 1) TRUE
  - 28 2) FALSE

#### 29 12.11.1.3.3 Outputs

30 None.

## 31 12.12 MST configuration entities

32 The following managed objects define the semantics of the management operations that can be performed  
33 on the MST configuration in a Bridge:

- 34 a) The MSTI List object (12.12.1)
- 35 b) The FID to MSTID Allocation Table object (12.12.2)
- 36 c) The MST Configuration Table object (12.12.3)

## 12.12.1 The MSTI List

For MST Bridges, the MSTI List object models the operations that modify, or inquire about, the list of MST spanning tree instances supported by the Bridge. The object is modeled as a list of MSTIDs corresponding to the MSTIs supported by the Bridge.

The MSTID List object supports the following operations:

- a) Read MSTI List (12.12.1.1)
- b) Create MSTI (12.12.1.2)
- c) Delete MSTI (12.12.1.3)

### 12.12.1.1 Read MSTI List

#### 12.12.1.1.1 Purpose

To read the list of MSTIDs that are currently supported by the Bridge.

#### 12.12.1.1.2 Inputs

None.

#### 12.12.1.1.3 Outputs

- a) MSTID list. The list of MSTID values that are currently supported by the Bridge.

### 12.12.1.2 Create MSTI

#### 12.12.1.2.1 Purpose

To create a new MSTI and its associated state machines and parameters, and to add its MSTID to the MSTI List.

#### 12.12.1.2.2 Inputs

- a) The MSTID of the MSTI to be created.

#### 12.12.1.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to the number of MSTIs currently supported by the Bridge being equal to the maximum number of MSTIs that the Bridge is able to support.
  - 2) Operation rejected as the MSTID value supplied in the input parameters is already present in the MSTI List.
  - 3) Operation rejected as the MSTID value supplied in the input parameters is one of the reserved MSTID values (8.9.3).
  - 4) Operation accepted.

### 12.12.1.3 Delete MSTI

#### 12.12.1.3.1 Purpose

To delete an existing MSTI and its associated state machines and parameters, and to remove its MSTID from the MSTI List.

### 1 12.12.1.3.2 Inputs

- 2 a) The MSTID of the MSTI to be deleted.

### 3 12.12.1.3.3 Outputs

- 4 a) Operation status. This takes one of the following values:
- 5 1) Operation rejected as the MSTID value supplied in the input parameters is not present in the
- 6 MSTI List.
- 7 2) Operation rejected as the MSTID value supplied in the input parameter currently has one or
- 8 more FIDs allocated to it in the FID to MSTID Allocation Table.
- 9 3) Operation accepted.

## 10 12.12.2 The FID to MSTID Allocation Table

11 For MST Bridges, the FID to MSTID Allocation Table object models the operations that modify, or inquire  
12 about, the assignment of FIDs to spanning tree instances currently supported by the Bridge (8.9.3). The  
13 object is modeled as a fixed-length table in which each entry in the table corresponds to a FID, and the value  
14 of the entry specifies the MSTID of the spanning tree to which the set of VIDs supported by that FID are  
15 assigned. A value of zero in an entry specifies that the set of VIDs supported by that FID are assigned to the  
16 CST.

17 The MSTID Allocation Table object supports the following operations:

- 18 a) Read FID to MSTID allocations (12.12.2.1).
- 19 b) Set FID to MSTID allocation (12.12.2.2).

### 20 12.12.2.1 Read FID to MSTID allocations

#### 21 12.12.2.1.1 Purpose

22 To read a range of one or more entries in the FID to MSTID Allocation Table.

#### 23 12.12.2.1.2 Inputs

- 24 a) First FID—the FID of the first entry to be read.
- 25 b) Last FID—the FID of the last entry to be read.

26 If the value of Last FID is numerically equal to, or smaller than, the value of First FID, then a single table  
27 entry is read, corresponding to the value of First FID.

#### 28 12.12.2.1.3 Outputs

- 29 a) List of entries—for each entry that was read:
- 30 1) The FID of the entry
- 31 2) The MSTID to which that FID is allocated

### 32 12.12.2.2 Set FID to MSTID allocation

#### 33 12.12.2.2.1 Purpose

34 To change the contents of an entry in the FID to MSTID Allocation Table.

#### 35 12.12.2.2.2 Inputs

- 36 a) FID—the FID of the entry to be changed.
- 37 b) MSTID—the MSTID to which the FID is to be allocated.

### 12.12.2.2.3 Outputs

- a) Operation status. This takes one of the following values:
- 1) Operation rejected as the MSTID value supplied in the input parameters is not present in the MSTI List.
  - 2) Operation rejected as the FID value supplied in the input parameters is invalid or is not supported.
  - 3) Operation accepted.

### 12.12.2.2.4 Procedure

The Configuration Digest element of the MCID is recalculated, in accordance with the definition in 13.8, following any change in the allocations of FIDs to MSTIDs.

## 12.12.3 The MST Configuration Table

The MST Configuration Table managed object models the operations that can be performed on the MST Configuration Table for the Bridge (3.173, 8.9.1, and 13.8). Associated with the table is the MCID for the Bridge (8.9.2, 13.8).

The MST Configuration Table is a read-only table, its elements derived from other configuration information held by the Bridge; specifically, the current state of the VID to FID allocation table (8.8.8, 12.10.3), and the FID to MSTID allocation table (8.9.3, 12.12.2). Hence, changes made to either of these tables can in turn affect the contents of the MST Configuration Table, and also affect the value of the “digest” element of the MCID. The MST Configuration Table is modeled as a fixed table of 4096 elements, as described in 13.8.

The MST Configuration Table managed object supports the following operations:

- a) Read MST Configuration Table Element (12.12.3.1).
- b) Read VIDs assigned to MSTID (12.12.3.2).
- c) Read MST Configuration Identifier (12.12.3.3).
- d) Set MST Configuration Identifier Elements (12.12.3.4).

### 12.12.3.1 Read MST Configuration Table Element

#### 12.12.3.1.1 Purpose

To read a single element of the current MST Configuration Table for the Bridge (13.8).

#### 12.12.3.1.2 Inputs

- a) A VID value, in the range 0 through 4094.

#### 12.12.3.1.3 Outputs

- a) A VID value, in the range 0 through 4094.
- b) The MSTID value corresponding to that VID.

### 12.12.3.2 Read VIDs assigned to MSTID

#### 12.12.3.2.1 Purpose

To read the list of VIDs that are currently assigned to a given MSTID in the MST Configuration Table for the Bridge (13.8).

1 **12.12.3.2.2 Inputs**

- 2 a) An MSTID value, in the range 0 through 4095.

3 **12.12.3.2.3 Outputs**

- 4 a) A MSTID value, in the range 0 through 4095.  
5 b) A 4096-bit vector in which bit N is set TRUE if VID N is assigned to the given MSTID and is  
6 otherwise set FALSE.

7 **12.12.3.3 Read MST Configuration Identifier**

8 **12.12.3.3.1 Purpose**

9 To read the current value of the MCID for the Bridge (13.8).

10 **12.12.3.3.2 Inputs**

11 None.

12 **12.12.3.3.3 Outputs**

- 13 a) The MCID (13.8), consisting of:  
14 1) The Configuration Identifier Format Selector in use by the Bridge. This has a value of 0 to  
15 indicate the format specified in this standard.  
16 2) The Configuration Name.  
17 3) The Revision Level.  
18 4) The Configuration Digest.

19 **12.12.3.4 Set MST Configuration Identifier Elements**

20 **12.12.3.4.1 Purpose**

21 To change the current values of the modifiable elements of the MCID for the Bridge (13.8).

22 NOTE—The Configuration Digest element of the MCID is read-only; its value is recalculated whenever configuration  
23 changes occur that result in a change in the allocation of VIDs to MSTIs.

24 **12.12.3.4.2 Inputs**

- 25 a) The MCID (13.8) Format Selector in use by the Bridge. This has a value of 0 to indicate the format  
26 specified in this standard.  
27 b) The Configuration Name.  
28 c) The Revision Level.

29 **12.12.3.4.3 Outputs**

- 30 a) Operation Status. This can take the following values:  
31 1) Operation rejected due to unsupported Configuration Identifier Format Selector value  
32 2) Operation accepted

## 12.13 Provider Bridge management

The conformance requirements of Provider Bridges are specified in 5.10. The S-VLAN Component and the externally accessible ports of all Provider Bridges, including Provider Edge Bridges, are managed using the managed objects defined in 12.4 through 12.12. This subclause defines additional managed objects specific to the operation of Provider Bridges.

The internal ports, LANs, C-VLAN Components, and Port-mapping S-VLAN Components of a Provider Edge Bridge are not managed directly using the managed objects defined in 12.4 through 12.12. Their operation is controlled and monitored through managed objects defined in this subclause.

Each externally accessible Bridge Port on a Provider Bridge is designated as a PNP, CNP, CEP, or RCAP. Designating a port as a CEP implies Provider Edge Bridge functionality and, specifically, the existence of a C-VLAN Component associated with that port. This C-VLAN Component is uniquely identified within the Bridge by the port number of the associated CEP. The management of the forwarding process, filtering data base, and C-VLANs of the C-VLAN Component and the internal connections are achieved through the Customer Edge Port Configuration managed object defined here (12.13.2).

Designating a port as a RCAP implies the existence of a Port-mapping S-VLAN Component associated with that port. The Port-mapping S-VLAN Component is uniquely identified within the Bridge by the port number of the associated RCAP. Designating an internal port on the Port-mapping S-VLAN Component as a C-tagged RCSI implies a C-VLAN Component with a CEP connected via an internal LAN to that internal port (PAP). This C-VLAN Component and internal connection are uniquely identified by the port number of the RCAP and the S-VID associated with the PAP or by the port number of the internal CEP. Designating an internal port on the Port-mapping S-VLAN Component as a Port-based RCSI or a PNP implies an internal LAN connecting this port with a CNP or PNP, respectively. These ports and internal connections are uniquely identified by the port number of the RCAP and the S-VID associated with the PAP or by the port number of the CNP or PNP. The management of the forwarding process, filtering data base, and S-VLANs of Port-mapping S-VLAN Components and their internal connections are achieved through the Remote Customer Access Port Configuration managed object defined here (12.13.3).

An internal connection between a CNP on the S-VLAN Component and a PEP on the C-VLAN Component is instantiated for each service instance. The CNP is identified by the CEP identifier and the S-VID value used for the PVID of the CNP. The PEP is identified by the CEP identifier and the C-VLAN Identifier (C-VID) value used for the PVID of the PEP. These PVID values and the connection between the CNP and PEP are established by reciprocal entries in the C-VID Registration Table (12.13.2.2) and the PEP Configuration Table (12.13.2.4) as follows:

- a) An entry in the C-VID Registration Table is created for each C-VLAN supported in the C-VLAN Component associated with a CEP. The CEP identifier and C-VID combination identify a PEP. The entry contains (among other parameters) an S-VID value corresponding to the PVID of the CNP, which associates the PEP with a specific CNP. Note that the CEP/C-VID combination identifies a single PEP; however, multiple CEP/C-VID combinations can identify the same PEP if the entries for those CEP/C-VID combinations contain the same S-VID value. This many-to-one mapping of CEP/C-VID to PEP permits “bundling”, i.e., mapping multiple C-VLANs to the same service instance.
- b) An entry in the PEP Configuration Table is created for each S-VID corresponding to a service instance accessed by the C-VLAN Component. The CEP identifier and S-VID combination identify a CNP. The entry contains (among other parameters) a C-VID value corresponding to the PVID of the PEP, which associates the CNP with a specific PEP. Note that the CEP/S-VID combination identifies a single CNP; however, multiple CEP/S-VID combinations can identify the same CNP if the entries for those CEP/S-VID combinations contain the same C-VID value. This many-to-one mapping of CEP/S-VID to CNP permits configuration of asymmetric VLANs and can be used to establish rooted-multipoint connectivity (F.1.3.2).

1 Management control of the member sets and untagged sets for C-VIDs in the C-VLAN Component is  
2 provided in C-VID Registration Table entries rather than through Static VLAN Registration Entries (thus  
3 eliminating the need for Filtering Database managed objects for the C-VLAN Component). Management  
4 control of the member sets and untagged sets for S-VIDs in the S-VLAN Component is provided through  
5 Static VLAN Registration Entries in the FDB. Creating an entry for an S-VID in the PEP Configuration  
6 Table does not automatically modify the Static VLAN Registration Entries for the corresponding S-VLAN.  
7 A CNP is added to the member set and untagged set of an S-VLAN by including the CEP identifier (since  
8 the CEP identifier and S-VID combination identifies the CNP) in the Port Map of a Static VLAN  
9 Registration Entry for that S-VLAN (12.7.7.1, 8.8.2).

10 A C-VLAN Component with more than one PEP (i.e., supporting more than one service instance)  
11 participates in the customer network spanning tree protocol by running an instance of RSTP with the  
12 enhancements specified in 13.41. This protocol instance is managed using the managed objects defined in  
13 12.8 and 12.12. All BPDUs generated by this protocol instance use the MAC address of the CEP as a source  
14 address and as the Bridge address portion of Bridge Identifier. For each PEP, the protocol uses the S-VID  
15 value that is the PVID of the associated CNP as the port number. For the CEP, the protocol uses the value  
16 0xFFFF as the port number.

17 The following managed objects define the semantics of the management operations specific to Provider  
18 Bridges:

- 19 c) The Provider Bridge Port Type managed object (12.13.1)
- 20 d) The Customer Edge Port Configuration managed object (12.13.2)
- 21 e) The Remote Customer Access Port Configuration managed object (12.13.3)

## 22 12.13.1 Provider Bridge Port Type managed object

23 The management operations that can be performed on the Provider Bridge Port Type managed object are as  
24 follows:

- 25 a) Read Provider Bridge Port Type (12.13.1.1)
- 26 b) Configure Provider Bridge Port Type (12.13.1.2)

### 27 12.13.1.1 Read Provider Bridge Port Type

#### 28 12.13.1.1.1 Purpose

29 To obtain information regarding the designated type of an externally accessible port on a Provider Bridge.

#### 30 12.13.1.1.2 Inputs

- 31 a) Port Number: the number of the Bridge Port.

#### 32 12.13.1.1.3 Outputs

- 33 a) Port Type. This takes one of the following values:
  - 34 1) PNP
  - 35 2) CNP
  - 36 3) CEP
  - 37 4) RCAP

### 38 12.13.1.2 Configure Provider Bridge Port Type

#### 39 12.13.1.2.1 Purpose

40 To designate the type of an externally accessible port on a Provider Bridge.

### 1 12.13.1.2.2 Inputs

- 2 a) Port Number: the number of the Bridge Port.
- 3 b) Port Type. This takes one of the following values:
  - 4 1) PNP
  - 5 2) CNP
  - 6 3) CEP
  - 7 4) RCAP

### 8 12.13.1.2.3 Outputs

9 None.

## 10 12.13.2 Customer Edge Port Configuration managed object

11 The Customer Edge Port Configuration managed object applies to each externally accessible CEP on a  
12 Provider Edge Bridge. It includes:

- 13 a) The C-VID Registration Table, which provides a mapping between a C-VID and the service instance  
14 represented by an S-VID selected for that C-VLAN. This table provides the equivalent functionality  
15 of :
  - 16 1) configuring the PVID of the internal CNP on the S-VLAN Component;
  - 17 2) adding the corresponding PEP on the C-VLAN Component to the member set of the C-VLAN;
  - 18 3) adding the PEP and/or CEP to the untagged set of the C-VLAN (if it is desired that frames  
19 forwarded to that port are transmitted untagged for this C-VLAN).
- 20 b) The PEP configuration parameters, which provide the subset of the Bridge VLAN Configuration  
21 managed object (12.10.1) that is relevant for the internal ports of the C-VLAN Component  
22 associated with the CEP.
- 23 c) The Service Priority Regeneration Table, which provides the Priority Regeneration Table (12.6.2)  
24 for each internal CNP connected to the C-VLAN Component associated with the CEP.

25 The management operations that can be performed are as follows:

- 26 d) Read C-VID Registration Table Entry (12.13.2.1)
- 27 e) Configure C-VID Registration Table Entry (12.13.2.2)
- 28 f) Read Provider Edge Port Configuration (12.13.2.3)
- 29 g) Set Provider Edge Port Configuration (12.13.2.4)
- 30 h) Read Service Priority Regeneration Table (12.13.2.5)
- 31 i) Set Service Priority Regeneration Table (12.13.2.6)

### 32 12.13.2.1 Read C-VID Registration Table Entry

#### 33 12.13.2.1.1 Purpose

34 To read the VID of the service associated with a specific Customer VLAN in the C-VLAN Component of a  
35 Provider Edge Bridge.

#### 36 12.13.2.1.2 Inputs

- 37 a) Port Number: the number of the CEP.
- 38 b) Customer VLAN Identifier: a 12-bit C-VID.

### 12.13.2.1.3 Outputs

- a) Service VLAN Identifier: a 12-bit S-VID.
- b) Untagged PEP: a boolean indicating frames for this C-VLAN should be forwarded untagged through the Provider Edge Port.
- c) Untagged CEP: a boolean indicating frames for this C-VLAN should be forwarded untagged through the Customer Edge Port.

### 12.13.2.2 Configure C-VID Registration Table Entry

#### 12.13.2.2.1 Purpose

To modify an entry in the C-VID Registration Table.

#### 12.13.2.2.2 Inputs

- a) Port Number: the number of the CEP.
- b) Customer VLAN Identifier: a 12-bit C-VID.
- c) Service VLAN Identifier: a 12-bit S-VID.
- d) Untagged PEP: a boolean indicating frames for this C-VLAN should be forwarded untagged through the Provider Edge Port.
- e) Untagged CEP: a boolean indicating frames for this C-VLAN should be forwarded untagged through the Customer Edge Port.

#### 12.13.2.2.3 Outputs

None.

### 12.13.2.3 Read Provider Edge Port Configuration

#### 12.13.2.3.1 Purpose

To read the current configuration of an internal PEP in the C-VLAN Component of a Provider Edge Bridge.

#### 12.13.2.3.2 Inputs

- a) Port Number: the number of the CEP.
- b) Service VLAN Identifier: a 12-bit S-VID.

#### 12.13.2.3.3 Outputs

- a) PVID: a 12-bit C-VID to be used for untagged frames received at the PEP.
- b) Default priority: an integer range 0–7 to be used for untagged frames received at the PEP.
- c) Acceptable Frame Types: the Acceptable Frame Types (8.6.2) for frames received at the PEP. The permissible values for the parameter are as follows:
  - 1) *Admit only VLAN-tagged frames*
  - 2) *Admit only Untagged and Priority-tagged frames*
  - 3) *Admit all frames*
- d) Enable Ingress Filtering: the Enable Ingress Filtering parameter for frames received at the PEP. The permissible values for the parameter are as follows:
  - 1) Enabled
  - 2) Disabled

## 1 12.13.2.4 Set Provider Edge Port Configuration

### 2 12.13.2.4.1 Purpose

3 To modify the configuration of a PEP in the C-VLAN Component of a Provider Edge Bridge.

### 4 12.13.2.4.2 Inputs

- 5 a) Port Number: the number of the CEP.
- 6 b) Service VLAN Identifier: a 12-bit S-VID.
- 7 c) PVID: a 12-bit C-VID to be used for untagged frames received at the PEP.
- 8 d) Default priority: an integer range 0–7 to be used for untagged frames received at the PEP.
- 9 e) Acceptable Frame Types: the Acceptable Frame Types (8.6.2) for frames received at the PEP. The  
10 permissible values for the parameter are as follows:
  - 11 1) *Admit only VLAN-tagged frames*
  - 12 2) *Admit only Untagged and Priority-tagged frames*
  - 13 3) *Admit all frames*
- 14 f) Enable Ingress Filtering: the Enable Ingress Filtering parameter for frames received at the PEP. The  
15 permissible values for the parameter are as follows:
  - 16 1) Enabled
  - 17 2) Disabled

### 18 12.13.2.4.3 Outputs

19 None.

## 20 12.13.2.5 Read Service Priority Regeneration Table

### 21 12.13.2.5.1 Purpose

22 To read the current contents of the Priority Regeneration Table (6.9.3) for an internal CNP connected to the  
23 C-VLAN Component associated with a CEP.

### 24 12.13.2.5.2 Inputs

- 25 a) Port Number: the number of the CEP.
- 26 b) Service VLAN Identifier: a 12-bit S-VID.

### 27 12.13.2.5.3 Outputs

- 28 a) Regenerated Priority value for Received Priority 0: Integer in range 0–7.
- 29 b) Regenerated Priority value for Received Priority 1: Integer in range 0–7.
- 30 c) Regenerated Priority value for Received Priority 2: Integer in range 0–7.
- 31 d) Regenerated Priority value for Received Priority 3: Integer in range 0–7.
- 32 e) Regenerated Priority value for Received Priority 4: Integer in range 0–7.
- 33 f) Regenerated Priority value for Received Priority 5: Integer in range 0–7.
- 34 g) Regenerated Priority value for Received Priority 6: Integer in range 0–7.
- 35 h) Regenerated Priority value for Received Priority 7: Integer in range 0–7.

## 36 12.13.2.6 Set Service Priority Regeneration Table

### 37 12.13.2.6.1 Purpose

38 To modify the contents of the Priority Regeneration Table (6.9.3) for an internal CNP connected to the  
39 C-VLAN Component associated with a CEP.

## 1 12.13.2.6.2 Inputs

- 2 a) Port Number: the number of the CEP.
- 3 b) Service VLAN Identifier: a 12-bit S-VID.
- 4 c) Regenerated Priority value for Received Priority 0: Integer in range 0–7.
- 5 d) Regenerated Priority value for Received Priority 1: Integer in range 0–7.
- 6 e) Regenerated Priority value for Received Priority 2: Integer in range 0–7.
- 7 f) Regenerated Priority value for Received Priority 3: Integer in range 0–7.
- 8 g) Regenerated Priority value for Received Priority 4: Integer in range 0–7.
- 9 h) Regenerated Priority value for Received Priority 5: Integer in range 0–7.
- 10 i) Regenerated Priority value for Received Priority 6: Integer in range 0–7.
- 11 j) Regenerated Priority value for Received Priority 7: Integer in range 0–7.

## 12 12.13.2.6.3 Outputs

13 None.

## 14 12.13.3 Remote Customer Access managed object

15 Designating an external port as a RCAP automatically creates a Port-mapping S-VLAN Component  
16 associated with that port. This Port-mapping S-VLAN Component includes one internal PNP.

17 The Remote Customer Access managed object applies to each externally accessible RCAP on a Provider  
18 Edge Bridge. It includes the following:

- 19 a) The Internal Interface Table, which configures the internal interfaces between the Port-mapping  
20 S-VLAN Component and the S-VLAN or C-VLAN Components. This table provides the following  
21 equivalent functionality:
  - 22 1) For an RCSI supporting a Port-based service interface:
    - 23 i) Creating an internal PAP connected to a CNP on the S-VLAN Component.
    - 24 ii) Configuring both the PAP and CNP to accept only untagged frames.
    - 25 iii) Setting the member set for the external S-VID to include the PAP and RCAP.
    - 26 iv) Setting the PAP's PVID to the external S-VID and adding that port to that S-VID's  
27 untagged set.
    - 28 v) Setting the CNP's PVID to the internal S-VID for the Port-based service instance and add-  
29 ing the port to that S-VID's untagged set.
  - 30 2) For an RCSI supporting a C-tagged service interface:
    - 31 i) Creating a PAP connected to a CEP on a C-VLAN Component.
    - 32 ii) Setting the member set for the external S-VID to include the PAP and RCAP.
    - 33 iii) Configuring the PAP's PVID to the external S-VID and adding the port to that S-VID's  
34 untagged set.
  - 35 3) For a PNP:
    - 36 i) Setting the member set for the external S-VID to include the PNP and RCAP.
    - 37 ii) Adding the associated primary S-VLAN Component PNP to the member set of the inter-  
38 nal S-VLAN.
    - 39 iii) Configuring the associated primary S-VLAN Component PNP's VID translation table to  
40 translate between the external S-VID and the internal S-VID for the selected service  
41 instance.

42 Note that in the case of an RCSI supporting a C-tagged service interface the C-VLAN Component can be  
43 further configured using the Customer Edge managed object. This configuration includes the following:

- 44 — The parameters to set the C-VID Registration Table entries (12.13.2.2)
- 45 — The PEP configuration parameters (12.13.2.4)
- 46 — The Service Priority Regeneration Table entries (12.13.2.6)

all associated with the configuration of the internal CEP, which is directly connected to the internal PAP identified by the external S-VID and the RCAP.

The management operations that can be performed on the Remote Customer Access managed object are as follows:

- b) Read Internal Interface Table Entry (12.13.3.1)
- c) Configure Internal Interface Table Entry (12.13.3.2)

Further configuration related to a C-VLAN Component associated with an RCSI supporting a C-tagged service interface is accomplished using the Customer Edge managed object (12.13.2).

### 12.13.3.1 Read Internal Interface Table Entry

#### 12.13.3.1.1 Purpose

To read the Internal Interface Table entry associated with a specific external S-VID in a Port-mapping S-VLAN Component of a RCAP.

#### 12.13.3.1.2 Inputs

- a) External Port Number: the number of the RCAP.
- b) External S-VLAN Identifier: a 12-bit S-VID.

#### 12.13.3.1.3 Outputs

- a) Internal Port Number: the port number used to reference the internal interface.
- b) A value indicating the type of internal interface associated with the external S-VID, one of the following:
  - 1) Port-based RCSI
  - 2) C-tagged RCSI
  - 3) PNP
  - 4) Discard (external S-VID is not associated with an internal port)
- c) Internal S-VLAN Identifier: a 12-bit S-VID (not applicable for a C-tagged RCSI).

### 12.13.3.2 Configure Internal Interface Table Entry

#### 12.13.3.2.1 Purpose

To add or delete an entry in the Internal Interface Table.

#### 12.13.3.2.2 Inputs

- a) External Port Number: the number of the RCAP.
- b) External S-VLAN Identifier: a 12-bit S-VID.
- c) Internal Port Number (optional): the port number used to reference the internal interface;
- d) A value indicating the type of internal interface associated with the external S-VID, one of the following:
  - 1) Port-based RCSI
  - 2) C-tagged RCSI
  - 3) PNP
  - 4) Discard (delete entry for the external S-VID)
- e) Internal S-VLAN Identifier: a 12-bit S-VID (not applicable for a C-tagged RCSI).

### 1 12.13.3.2.3 Outputs

2 None

## 3 12.14 CFM entities

4 The CFM managed objects model operations that modify, or inquire about, the configuration and the  
5 operation of CFM. Figure 12-1 illustrates the simple hierarchical relationships among the various CFM  
6 managed objects, including the control of access to those objects. See 17.4.7 for an explanation of methods  
7 available to distinguish between an Owner and a Maintenance Domain administrator. See Clause 18 for an  
8 explanation of the use of Maintenance Domains and Maintenance Associations (MAs). The following are  
9 the CFM managed objects in a Bridge:

- 10 a) Maintenance Domain list managed object (12.14.1)
- 11 b) CFM Stack managed object (12.14.2)
- 12 c) Default MD Level managed object (12.14.3)
- 13 d) Configuration Error List managed object (12.14.4)
- 14 e) Maintenance Domain managed objects (12.14.5)
- 15 f) Maintenance Association managed objects (12.14.6)
- 16 g) Maintenance association Endpoint managed objects (12.14.7)

### 17 12.14.1 Maintenance Domain list managed object

18 There is one Maintenance Domain list managed object per Bridge. It contains a list of the Maintenance  
19 Domains that have been configured on the Bridge.

20 The management operations that can be performed on the Maintenance Domain list managed object are as  
21 follows:

- 22 a) Read Maintenance Domain list (12.14.1.1)
- 23 b) Create Maintenance Domain managed object (12.14.1.2)
- 24 c) Delete Maintenance Domain managed object (12.14.1.3)

25 NOTE—In Provider Bridge applications, each Maintenance Domain, and thus each Maintenance Domain managed  
26 object, can be controlled by a different administrative organization. Some or all of these administrative organizations can  
27 be different from that which controls the Maintenance Domain list managed object or the managed objects in Clause 12  
28 other than those in 12.14. See 17.3.7 for a discussion of the means by which control of and access to different instances  
29 of the Maintenance Domain managed object are allocated to these different administrative organizations.

#### 30 12.14.1.1 Read Maintenance Domain list

##### 31 12.14.1.1.1 Purpose

32 To obtain information about all of the Maintenance Domains in a Bridge.

##### 33 12.14.1.1.2 Inputs

34 None.

##### 35 12.14.1.1.3 Outputs

- 36 a) A list, perhaps empty, of the Maintenance Domain managed objects configured on the Bridge. For  
37 each item in the list, the Read Maintenance Domain list command returns the following:
  - 38 1) A Maintenance Domain Name, including the format specifier from Table 21-18 (21.6.5.1)
  - 39 2) A reference to that Maintenance Domain's Maintenance Domain managed object (12.14.5)

Figure 12-1—Relationships among CFM managed objects

#### 12.14.1.2 Create Maintenance Domain managed object

##### 12.14.1.2.1 Purpose

To create a new Maintenance Domain managed object in a Bridge, and add it to the Bridge's Maintenance Domain list managed object.

##### 12.14.1.2.2 Inputs

- a) A Maintenance Domain Name, including the format specifier from Table 21-18 (21.6.5.1); default value is the character string (format 4) "DEFAULT."
- b) The MD Level at which the Maintenance Domain is to be created; default value is 0.

##### 12.14.1.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to invalid Maintenance Domain Name (21.6.5.1)
  - 2) Operation rejected because Maintenance Domain Name already exists

- 1        3) Operation rejected due to invalid MD Level
- 2        4) Operation accepted

### 3 **12.14.1.3 Delete Maintenance Domain managed object**

#### 4 **12.14.1.3.1 Purpose**

5 To delete a specific Maintenance Domain managed object from a Bridge and from the Bridge's Maintenance  
6 Domain list managed object.

#### 7 **12.14.1.3.2 Inputs**

- 8        a) A reference to a particular Maintenance Domain managed object (12.14.5).

#### 9 **12.14.1.3.3 Outputs**

- 10       a) Operation status. This takes one of the following values:
  - 11           1) Operation rejected due to invalid or nonexistent Maintenance Domain
  - 12           2) Operation accepted

### 13 **12.14.2 CFM Stack managed object**

14 There is one CFM Stack managed object per Bridge. It permits retrieval of information about the  
15 MPs configured on a particular Bridge Port or aggregated port. The management operation that can be  
16 performed is as follows:

- 17       a) Read CFM Stack managed object (12.14.2.1)

#### 18 **12.14.2.1 Read CFM Stack managed object**

##### 19 **12.14.2.1.1 Purpose**

20 To obtain the contents of the CFM Stack managed object, which allows a network administrator to discover  
21 the relationships among MEPs and MHFs configured on a particular Bridge Port or aggregated port.

##### 22 **12.14.2.1.2 Inputs**

- 23       a) An interface, either a Bridge Port, or an aggregated IEEE 802.3 port within a Bridge Port, on which  
24           MPs might be configured.
- 25       b) An MD Level.
- 26       c) A value indicating the direction in which any reported MP faces, either:
  - 27           1) Down (Active SAP is further away from the Frame filtering entity) or
  - 28           2) Up (Active SAP is closer to the Frame filtering entity).
- 29       d) A specific VID, I-SID, Traffic Engineering service instance Identifier (TE-SID), or Segment  
30           Identifier (SEG-ID) associated with an MP, or 0, in the case that the MP is associated with no VID,  
31           I-SID, TE-SID, or SEG-ID.

##### 32 **12.14.2.1.3 Outputs**

- 33       a) Operation status. This takes one of the following values:
  - 34           1) Operation rejected due to illegal inputs.
  - 35           2) No MP is configured on the indicated Bridge Port or aggregated port at the indicated MD Level  
36           and direction.
  - 37           3) A MEP is configured.
  - 38           4) An MHF is configured.

- 1 b) Either the Maintenance Domain managed object (12.14.5) to which the MP's MA is associated, or
- 2 an indication that there is no Maintenance Domain associated with the MP.
- 3 c) Either the Maintenance Association managed object (12.14.6) to which the MP is associated, or an
- 4 indication that there is no MA associated with the MP.
- 5 d) If a MEP is configured, its MA Endpoint Identifier (MEPID), else 0.
- 6 e) The MAC address of the MP.

### 7 **12.14.3 Default MD Level managed object**

8 There is a single Default MD Level managed object per Bridge Component. It controls MIP Half Function  
9 (MHF) creation for VIDs or I-SIDs of I- or B-Components that are not contained in the list of VIDs attached  
10 to any specific Maintenance Association managed object [item c) in 12.14.5.3.2], and the transmission of the  
11 Sender ID TLV (21.5.3) by those MHFs.

12 The management commands that can be performed on the Default MD Level managed object are as follows:

- 13 a) Read Default MD Level managed object (12.14.3.1).
- 14 b) Write Default MD Level managed object (12.14.3.2).

#### 15 **12.14.3.1 Read Default MD Level managed object**

##### 16 **12.14.3.1.1 Purpose**

17 To read the table of default parameters for controlling MHFs not associated with any MA configured on the  
18 Bridge Component.

##### 19 **12.14.3.1.2 Input**

- 20 a) A VID or I-SID in an I- or B-Component.

##### 21 **12.14.3.1.3 Output**

- 22 a) A list of VIDs associated with any MHF on the VID named in item a) in 12.14.3.1.2, always
- 23 including that VID, or the Backbone-SID of the B-Component or VIP-SID of the I-Component
- 24 associated with any MHF on the I-SID named in item a) in 12.14.3.1.2. The first VID is the MAs'  
25 Primary VID. List is empty if no VID specified in 12.14.3.1.2.
- 26 b) A Boolean value indicating whether this entry is in effect or has been overridden by the existence of
- 27 a Maintenance Association managed object associated with the same VID or I-SID of I- or
- 28 B-Components and MD Level, and on which is configured an Up MEP. True if this Maintenance  
29 Domain managed object is in effect.
- 30 c) (writable) The MD Level at which MHFs are to be created.
- 31 d) (writable) An enumerated value indicating whether the management entity can create MHFs for this
- 32 VID(s) or I-SID(s) of I- or B-Components: defMHFnone: [item n) in 22.2.3, the default],
- 33 defMHFdefault [item o)], or defMHFexplicit [item q)].
- 34 e) (writable) An enumerated value indicating what, if anything, is to be included in the Sender ID TLV
- 35 (21.5.3) transmitted by MPs configured in the Default Maintenance Domain: sendIdNone (1, the  
36 default value), sendIdChassis (2), sendIdManage (3), or sendIdChassisManage (4).

#### 37 **12.14.3.2 Write Default MD Level managed object**

##### 38 **12.14.3.2.1 Purpose**

39 To write entries in the table of default parameters for controlling MHFs on VIDs or on I-SIDs used in an I-  
40 or B-Component not associated with any MA.

#### 1 12.14.3.2.2 Inputs

- 2 a) A list of VIDs or the VIP-SIDs used in the I-Component or Backbone-SID used in the
- 3 B-Component, or 0, indicating no VID or I-SID. The first VID in the list is the Primary VID.
- 4 b) One of the writable managed object in 12.14.3.1.3.

#### 5 12.14.3.2.3 Outputs

- 6 a) Operation status. This takes one of the following values:
  - 7 1) Operation rejected because creating or assigning these VIDs or I-SIDs to this MD Level would
  - 8 exceed the number of MD Levels supported by some Bridge Port [item c) in 22.2.4].
  - 9 2) Operation rejected because the VID list provided [item a) in 12.14.3.2.2] specifies a different
  - 10 Primary VID, or contains one or more but not all of the VIDs, in the definition of an MA or
  - 11 some other entry in the Default MD Level managed object.
  - 12 3) Operation accepted.

#### 13 12.14.4 Configuration Error List managed object

14 The Configuration Error List managed object is a list of {identifier, port} pairs configured in error together  
15 with the identity of the configuration error. The identifier is a VID, I-SID, TE-SID, or SEG-ID and the port  
16 is a simple Bridge Port or aggregated Bridge Port.

#### 17 12.14.4.1 Read Configuration Error List managed object

##### 18 12.14.4.1.1 Purpose

19 To list the entries in the Configuration Error List where each entry describes the identifier and port pair that  
20 identifies the entry, together with a description of the particular configuration error.

##### 21 12.14.4.1.2 Inputs

- 22 a) A VID, I-SID, or TE-SID, specifying which service instance to check for ports in error or a SEG-ID
- 23 specifying which Infrastructure Segment to check for ports in error.
- 24 b) An interface, either a Bridge Port or an aggregated IEEE 802.3 port within a Bridge Port.

##### 25 12.14.4.1.3 Outputs

- 26 a) An indication of the result of the operation:
  - 27 1) Operation rejected due to illegal vlan\_identifier
  - 28 2) Operation rejected due to illegal or nonexistent Bridge Port or aggregated port
  - 29 3) Operation accepted
- 30 b) If the operation was accepted, a vector of Boolean error conditions from 22.2.4, any of which may  
31 be true:
  - 32 1) CFMleak
  - 33 2) ConflictingVIDs
  - 34 3) ExcessiveLevels and/or
  - 35 4) OverlappedLevels

#### 36 12.14.5 Maintenance Domain managed object

37 There can be any number of Maintenance Domain managed objects per Bridge. A Maintenance Domain  
38 managed object is required in order to create an MA with a Maintenance Association Identifier (MAID) that  
39 includes that Maintenance Domain's Name. From this Maintenance Domain managed object, all  
40 Maintenance Association managed objects associated with that Maintenance Domain managed object can be  
41 accessed, and thus controlled.

1 The management operations that can be performed on the Maintenance Domain managed object are as  
2 follows:

- 3 a) Read Maintenance Domain managed object (12.14.5.1)
- 4 b) Write Maintenance Domain managed object (12.14.5.2)
- 5 c) Create Maintenance Association managed object (12.14.5.3)
- 6 d) Delete Maintenance Association managed object (12.14.5.4)

7 NOTE 1—The Maintenance Domain managed object is defined in such a manner that it can be configured identically in  
8 all of the Bridges in that Bridged Network. All of the information local to a particular MA or a particular Bridge is  
9 contained in other managed objects, e.g., the Maintenance Association managed object (12.14.6) or the Maintenance  
10 association Endpoint managed object (12.14.7).

11 NOTE 2—A single Maintenance Domain managed object can be used to manage any number of separate Maintenance  
12 Domains, as Maintenance Domains are defined in 18.1. For example, the Maintenance Association managed object for  
13 all of the physical links in a Bridged Network that are protected by MAs can be grouped together under a single  
14 Maintenance Domain managed object for the convenience of the network administrator.

15 NOTE 3—Multiple Maintenance Domain managed objects can be used to manage a single Maintenance Domain, as  
16 Maintenance Domains are defined in 18.1. For example, a PBN's Domain Service Access Points (DoSAPs) could be  
17 split among two Maintenance Domain managed objects, one for point-to-point services and one for multipoint services.

## 18 **12.14.5.1 Read Maintenance Domain managed object**

### 19 **12.14.5.1.1 Purpose**

20 To obtain information from a Bridge about a specific Maintenance Domain managed object.

### 21 **12.14.5.1.2 Inputs**

- 22 a) A reference to a particular Maintenance Domain managed object (12.14.5).

### 23 **12.14.5.1.3 Outputs**

- 24 a) Operation status. This takes one of the following values:
  - 25 1) Operation rejected due to nonexistent Maintenance Domain
  - 26 2) Operation accepted
- 27 b) The MD Level of the specific Maintenance Domain identified by the Input.
- 28 c) (writable) An enumerated value indicating whether the management entity can create MHFs for this  
29 Maintenance Domain: defMHFnone: [item n) in 22.2.3, the default], defMHFdefault [item o)], or  
30 defMHFexplicit [item p)].
- 31 d) (writable) An enumerated value indicating what, if anything, is to be included in the Sender ID TLV  
32 (21.5.3) transmitted by MPs configured in this Maintenance Domain: sendIdNone (1, the default  
33 value), sendIdChassis (2), sendIdManage (3), or sendIdChassisManage (4) [item d) in 12.14.6.1.3].
- 34 e) (writable) The network address to which Fault Alarms (12.14.7.7) are to be transmitted, or a value  
35 indicating "Fault Alarms are not to be transmitted." Default value is "not transmitted."

36 NOTE—The variables item c) through item e) could be writable by the organization operating the Maintenance Domain.

- 37 f) A list of references to the Maintenance Association managed objects (12.14.6) attached to the  
38 indicated Maintenance Domain managed object.

## 39 **12.14.5.2 Write Maintenance Domain managed object**

### 40 **12.14.5.2.1 Purpose**

41 To alter a value of a specific Maintenance Domain managed object.

### 1 12.14.5.2.2 Inputs

- 2 a) A reference to a particular Maintenance Domain managed object (12.14.5).
- 3 b) A reference to a writable managed object in 12.14.5.1.3 to be altered.
- 4 c) A new value for the managed object.

### 5 12.14.5.2.3 Outputs

- 6 a) Operation status. This takes one of the following values:
  - 7 1) Operation rejected due to nonexistent Maintenance Domain
  - 8 2) Operation rejected due to the selected managed object being Read-Only
  - 9 3) Operation rejected due to invalid value for the selected managed object
  - 10 4) Operation accepted

## 11 12.14.5.3 Create Maintenance Association managed object

### 12 12.14.5.3.1 Purpose

13 To create a new Maintenance Association managed object within a Maintenance Domain managed object.

### 14 12.14.5.3.2 Inputs

- 15 a) A reference to a particular Maintenance Domain managed object (12.14.5).
- 16 b) The Short MA Name of an MA within that Maintenance Domain, including the format specifier  
17 from Table 21-19 (21.6.5.4). In the case of a PBB-TE, VID-based, or Infrastructure Segment MA,  
18 the default value is a 2-octet integer (format 3) containing the primary VID, or 0, if the MA is not  
19 attached to a VID.
- 20 c) The list of VIDs, the I-SID, the TE-SID, or the SEG-ID monitored by this MA, or 0, if the MA is not  
21 attached to any VID, I-SID, TE-SID, or SEG-ID. In the case that a list of VIDs is specified, the first  
22 VID in the list is the MA's Primary VID (default none). The specification of I-SID is allowed only in  
23 the case of I- or B-Components. The TE-SID is allowed only in the case that PBB-TE or SPBM is  
24 supported. The SEG-ID is allowed only in the case that IPS is supported.

### 25 12.14.5.3.3 Outputs

- 26 a) Operation status. This takes one of the following values:
  - 27 1) Operation rejected due to nonexistent Maintenance Domain.
  - 28 2) Operation rejected due to invalid Short MA Name (21.6.5.4).
  - 29 3) Operation rejected due to the existence of another MA in the same Maintenance Domain with  
30 the same Short MA Name.
  - 31 4) Operation rejected because creation of this MA would exceed the number of MD Levels  
32 supported by some Bridge Port [item c) in 22.2.4].
  - 33 5) Operation rejected because the VID list provided [item c) in 12.14.5.3.2] specifies a different  
34 Primary VID, or contains one or more, but not all, of the VIDs, in the definition of another MA  
35 or an entry in the Default MD Level managed object.
  - 36 6) Operation rejected because the I-SID value specified does not correspond to a valid backbone  
37 service instance.
  - 38 7) Operation rejected because the TE-SID value specified does not correspond to a valid TESI or  
39 set of SPBM path endpoints.
  - 40 8) Operation rejected because the SEG-ID value specified does not correspond to a valid  
41 Infrastructure Segment.
  - 42 9) Operation accepted.

#### 1 **12.14.5.4 Delete Maintenance Association managed object**

##### 2 **12.14.5.4.1 Purpose**

3 To delete a specific Maintenance Association managed object from a Maintenance Domain managed object.

##### 4 **12.14.5.4.2 Inputs**

- 5 a) A reference to a particular Maintenance Association managed object (12.14.6).

##### 6 **12.14.5.4.3 Outputs**

- 7 a) Operation status. This takes one of the following values:

- 8 1) Operation rejected due to nonexistent MA  
9 2) Operation accepted

#### 10 **12.14.6 Maintenance Association managed object**

11 There can be any number of Maintenance Association managed objects per Bridge, one for each service  
12 instance for which an MP is defined on that Bridge. From this Maintenance Association managed object, all  
13 Maintenance association Endpoint managed objects associated with that Maintenance Association managed  
14 object can be accessed, and thus controlled.

15 The management operations that can be performed on the Maintenance Association managed object are as  
16 follows:

- 17 a) Read Maintenance Association managed object (12.14.6.1)  
18 b) Write Maintenance Association managed object (12.14.6.2)  
19 c) Create Maintenance association Endpoint managed object (12.14.6.3)  
20 d) Delete Maintenance association Endpoint managed object (12.14.6.4)

21 NOTE 1—The Maintenance Association managed object is defined in such a manner that it can be configured  
22 identically in all of the Bridges in its Maintenance Domain. All information local to a particular Bridge is contained in  
23 other managed objects, e.g., the Maintenance association Endpoint managed object (12.14.7).

24 NOTE 2—Although MHFs are created via the Maintenance Domain managed object, the Default MD Level managed  
25 object, and the Maintenance Association managed object, and although there is a Maintenance association Endpoint  
26 managed object, there is no “MIP Half Function managed object.” One reason for this omission is that no controls over  
27 the behavior of the MHF beyond its existence is required. Another is that the burden of implementing, providing access  
28 to, and providing the maintenance capabilities to access the counters and similar managed objects appropriate to an MHF  
29 Managed Object seemed to the developers of this standard to outweigh the benefits of having that information available.

#### 30 **12.14.6.1 Read Maintenance Association managed object**

##### 31 **12.14.6.1.1 Purpose**

32 To obtain information from a Bridge about a specific Maintenance Association managed object.

##### 33 **12.14.6.1.2 Inputs**

- 34 a) A reference to a particular Maintenance Association managed object (12.14.6).

##### 35 **12.14.6.1.3 Outputs**

- 36 a) Operation status. This takes one of the following values:

- 37 1) Operation rejected due to nonexistent MA  
38 2) Operation accepted

- 1 b) The VID(s), I-SID, TE-SID, or SEG-ID monitored by this MA, or 0, if the MA is not attached to any  
2 VID, I-SID, TE-SID, or SEG-ID. In the case of a list of VIDs, the first VID returned is the MA's  
3 Primary VID.
- 4 c) (writable) An enumerated value indicating whether the management entity can create MHFs for this  
5 MA: defMHFnone: [item n) in 22.2.3], defMHFdefault [item o)], or defMHFexplicit [item p)] or  
6 defMHFdefer [item q)], default value is defMHFdefer.
- 7 d) (writable) An enumerated value indicating what, if anything, is to be included in the Sender ID TLV  
8 (21.5.3) transmitted by MPs configured in this MA:
- 9 1) **sendIdNone**: The Sender ID TLV is not to be sent.
- 11 2) **sendIdChassis**: The Chassis ID Length, Chassis ID Subtype, and Chassis ID fields of the  
13 Sender ID TLV are to be sent, but not the Management Address Length or Management  
14 Address fields.
- 15 3) **sendIdManage**: The Management Address Length and Management Address of the Sender ID  
17 TLV are to be sent, but the Chassis ID Length is to be transmitted with a 0 value, and the  
18 Chassis ID Subtype and Chassis ID fields not sent.
- 19 4) **sendIdChassisManage**: The Chassis ID Length, Chassis ID Subtype, Chassis ID,  
21 Management Address Length, and Management Address fields are all to be sent.
- 22 5) **sendIdDefer**: (the default value) The contents of the Sender ID TLV are determined by the  
24 Maintenance Domain managed object, item d) in 12.14.5.1.3.
- 25 e) (writable) An enumerated value, other than 0, indicating the interval between CCM transmissions to  
26 be used by all MEPs in the MA (20.8.1, 21.6.1.3) (default 1 s).
- 27 f) (writable) The network address to which Fault Alarms (12.14.7.7) are to be transmitted, a value  
28 indicating "not specified," or a value indicating "Fault Alarms are not to be transmitted." If "not  
29 specified," the address used is that from the Maintenance Domain managed object [item e) in  
30 12.14.5.1.3].
- 31 g) (writable) A list of the MEPIDs of the MEPs in the MA.

## 32 12.14.6.2 Write Maintenance Association managed object

### 33 12.14.6.2.1 Purpose

34 To alter a value of a specific Maintenance Association managed object.

### 35 12.14.6.2.2 Inputs

- 36 a) A reference to a particular Maintenance Association managed object (12.14.6).
- 37 b) A reference to one of the writable managed objects in 12.14.6.1.3 is to be altered.
- 38 c) A new value for the managed object.

### 39 12.14.6.2.3 Outputs

- 40 a) Operation status. This takes one of the following values:
- 41 1) Operation rejected due to nonexistent MA
- 42 2) Operation rejected due to the selected managed object being Read-Only
- 43 3) Operation rejected due to lack of authority to set this variable
- 44 4) Operation rejected due to invalid value for the selected managed object
- 45 5) Operation accepted

## 46 12.14.6.3 Create Maintenance association Endpoint managed object

### 47 12.14.6.3.1 Purpose

48 To create a new Maintenance association Endpoint managed object within a Maintenance Association  
49 managed object on a specific Bridge Port or aggregated port.

### 12.14.6.3.2 Inputs

- a) A reference to a particular Maintenance Association managed object (12.14.6).
- b) A MEPID for the created MEP.
- c) A value indicating the direction in which the MEP faces on the Bridge Port or aggregated port, either:
  - 1) Down (Active SAP is further away from the Frame filtering entity) (the default) or
  - 2) Up (Active SAP is closer to the Frame filtering entity).
- d) An interface, either a Bridge Port or an aggregated IEEE 802.3 port within a Bridge Port.

### 12.14.6.3.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to nonexistent MA.
  - 2) Operation rejected because the specified MEPID already exists in this MA in this Bridge.
  - 3) Operation rejected because MEPID is not in the MA's list of MEPIDs [item g) in 12.14.6.1.3].
  - 4) Operation rejected due to the existence of a MEP in the same direction (Up or Down) at that same MD Level, for the same VID(s), I-SID, TE-SID, or SEG-ID as this MEP (or for no VID, I-SID, TE-SID, or SEG-ID, if this MEP's MA has no VID, I-SID, TE-SID, or SEG-ID), on that Bridge Port or aggregated port.
  - 5) Operation failed because one or more of the listed VIDs, I-SID, or TE-SID in this MA are assigned to some other MA on which Up MEPs are configured on any Bridge Port.
  - 6) Operation rejected because the Bridge is incapable of instantiating a MEP on that Bridge Port or aggregated IEEE 802.3 port.
  - 7) Operation rejected because an Up MEP cannot be configured for an MA that has no VID, I-SID, or TE-SID.
  - 8) Operation rejected because a MEP exists on this MA that has a different value for its Up/Down parameter [item c) in 12.14.6.3.2].
  - 9) Operation accepted.

## 12.14.6.4 Delete Maintenance association Endpoint managed object

### 12.14.6.4.1 Purpose

To delete an existing Maintenance association Endpoint managed object from a Maintenance Association managed object.

### 12.14.6.4.2 Inputs

- a) A reference to a particular Maintenance association Endpoint managed object (12.14.7).

### 12.14.6.4.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to nonexistent MEP
  - 2) Operation accepted

## 12.14.7 Maintenance association Endpoint managed object

There can be any number of Maintenance association Endpoint managed objects per Bridge, one for each MEP defined within that Bridge. From this Maintenance association Endpoint managed object, all management objects related to that MEP can be controlled.

1 The management operations that can be performed on the Maintenance association Endpoint managed  
2 object are as follows:

- 3 a) Read Maintenance association Endpoint managed object (12.14.7.1)
- 4 b) Write Maintenance association Endpoint managed object (12.14.7.2)
- 5 c) Transmit Loopback Messages (12.14.7.3)
- 6 d) Transmit Linktrace Message (12.14.7.4)
- 7 e) Read Linktrace Reply (12.14.7.5)
- 8 f) Read MEP Database (12.14.7.6)
- 9 g) Transmit MEP Fault Alarm (12.14.7.7)

## 10 **12.14.7.1 Read Maintenance association Endpoint managed object**

### 11 **12.14.7.1.1 Purpose**

12 To obtain information from a Bridge about a specific Maintenance association Endpoint managed object.

### 13 **12.14.7.1.2 Inputs**

- 14 a) A reference to a particular Maintenance association Endpoint managed object (12.14.7).

### 15 **12.14.7.1.3 Outputs**

- 16 a) Operation status. This takes one of the following values:
  - 17 1) Operation rejected due to nonexistent MEP
  - 18 2) Operation accepted
- 19 b) An interface, either a Bridge Port or an aggregated IEEE 802.3 port within a Bridge Port, to which  
20 the MEP is attached.
- 21 c) A value indicating the direction in which the MEP faces on the interface, either:
  - 22 1) Down (Active SAP is further away from Frame filtering entity) or
  - 23 2) Up (Active SAP is closer to the Frame filtering entity).
- 24 d) (writable) An integer indicating the Primary VID of the MEP, always one of the VIDs assigned to  
25 the MEP's MA. The value 0 indicates either that the Primary VID is that of the MEP's MA or that  
26 the MEP's MA is associated with no VID. In the case of a PBB-TE associated MEP, the Primary  
27 VID is not writable but is always associated with the value of the ESP-VID parameter identifying  
28 the MA's ESP that has the MEP's MAC address in its ESP-SA field (MEPprimaryVID, 20.9.7). In  
29 the case of an Infrastructure Segment associated MEP, the Primary VID (MEPprimaryVID, 20.9.7)  
30 is not writable but is always associated with the value of the SMP-VID parameter identifying the  
31 MA's SMP that has the MEP's MAC address in its SMP-SA field. In the case of an SPB associated  
32 MEP, the Primary VID is not writable but is always associated with the value of the SPVID for the  
33 node on which the MEP is configured (for SPBV) or the Base VID (for SPBM).
- 34 e) (writable) A Boolean flag indicating the administrative state of the MEP (20.9.1) (default FALSE).
- 35 f) A value indicating the current state of the MEP Fault Notification Generator state machine (20.37).
- 36 g) (writable) A Boolean flag indicating whether the MEP is or is not to generate CCMs (CCIenabled,  
37 20.10.1) (default FALSE, no CCMs).
- 38 h) (writable) The priority parameter for CCMs and LTMs transmitted by the MEP (default value: the  
39 highest priority, i.e., that with the highest numerical value, allowed to pass through the Bridge Port  
40 for any of this MEP's VIDs, I-SID, TE-SID, or SEG-ID).

41 NOTE—The management entity can obtain the default value for this variable from the Priority regeneration  
42 table in 6.9.3 by extracting the highest priority value in the table on this MEP's Bridge Port (1 is lowest, then 2,  
43 then 0, then 3–7), appropriate to the direction in which frames are emitted from the MEP's Active SAP.

- 1 i) The MAC address of the MEP (19.4). In the case of a MEP that is associated with a TESI, the MAC  
2 address of the CBP upon which the MEP is operating. In the case of a MEP that is associated with an  
3 Infrastructure Segment, the MAC address of the PNP upon which the MEP is operating.
- 4 j) (writable) The network address to which Fault Alarms (12.14.7.7) are to be transmitted, a value  
5 indicating “not specified,” or a value indicating “Fault Alarms are not to be transmitted.” If “not  
6 specified,” the address used is that from the Maintenance Association managed object [item f)  
7 in 12.14.6.1.3].
- 8 k) (writable) An integer value specifying the lowest priority defect that is allowed to generate a Fault  
9 Alarm (20.9.5):
  - 10 1) All defects: DefRDICCM, DefMACstatus, DefRemoteCCM, DefErrorCCM, and  
11 DefXconCCM.
  - 12 2) Only DefMACstatus, DefRemoteCCM, DefErrorCCM, and DefXconCCM (the default).
  - 13 3) Only DefRemoteCCM, DefErrorCCM, and DefXconCCM.
  - 14 4) Only DefErrorCCM and DefXconCCM.
  - 15 5) Only DefXconCCM.
  - 16 6) No defects are to be reported.
- 17 l) (writable) The time that defects must be present before a Fault Alarm is issued (20.35.3)  
18 (default 2.5 s).
- 19 m) (writable) The time that defects must be absent before resetting a Fault Alarm (20.35.4)  
20 (default 10 s).
- 21 n) An enumerated value indicating the highest priority defect that has been present since the MEP Fault  
22 Notification Generator state machine was last in the FNG\_RESET state (20.35.9):
  - 23 1) **DefNone**: No defect has been present since the last FNG\_RESET state.
  - 24 2) **DefRDICCM**: The last CCM received by this MEP from some remote MEP contained the RDI  
25 bit, so variable item o) in 12.14.7.1.3 is set.
  - 26 3) **DefMACstatus**: The last CCM received by this MEP from some remote MEP indicated that  
27 the transmitting MEP’s associated MAC is reporting an error status via the Port Status TLV  
28 (21.5.4) or Interface Status TLV (21.5.5), so variable item p) in 12.14.7.1.3 is set.
  - 29 4) **DefRemoteCCM**: This MEP is not receiving CCMs from some other MEP in its configured  
30 list [item g) in 12.14.6.1.3], so variable item q) in 12.14.7.1.3 is set.
  - 31 5) **DefErrorCCM**: This MEP is receiving invalid CCMs, so variable item r) in 12.14.7.1.3, is set.
  - 32 6) **DefXconCCM**: This MEP is receiving CCMs that could be from some other MA, so variable  
33 item s) in 12.14.7.1.3 is set.
- 34 o) A Boolean flag (20.35.7) indicating that some other MEP in this MEP’s MA is transmitting the RDI  
35 bit (can trigger DefRDICCM).
- 36 p) A Boolean flag (20.35.6) indicating that a Port Status TLV (21.5.4) or Interface Status TLV (21.5.5)  
37 is indicating an error condition (can trigger DefMACstatus).
- 38 q) A Boolean flag (20.35.5) indicating that CCMs are not being received from at least one of the  
39 configured remote MEPs (can trigger DefRemoteCCM).
- 40 r) A Boolean flag (20.21.3) indicating that erroneous CCMs are being received from some MEP in this  
41 MEP’s MA (can trigger DefErrorCCM).
- 42 s) A Boolean flag (20.23.3) indicating that CCMs are being received from a MEP that could be in  
43 some other MA (can trigger DefXconCCM).
- 44 t) The last-received CCM (20.21.2) that triggered a DefErrorCCM fault (20.21.3).
- 45 u) The last-received CCM (20.23.2) that triggered a DefXconCCM fault (20.23.3).
- 46 v) (optional) The total number of out-of-sequence CCMs received (20.16.12).
- 47 w) The total number of CCMs transmitted (20.10.2).
- 48 x) The next Loopback Transaction Identifier to be sent in an LBM (20.30.2).
- 49 y) The total number of valid, in-order LBRs received (20.33.1).
- 50 z) The total number of valid, out-of-order LBRs received (20.33.1).

- 1 aa) (optional) The total number of LBRs received whose mac\_service\_data\_unit did not match (except  
2 for the OpCode) that of the corresponding LBM (20.2.3).
- 3 ab) The next LTM Transaction Identifier to be sent in an LTM (20.41.1).
- 4 ac) The total number of unexpected LTRs received (20.44.1).
- 5 ad) The total number of LBRs transmitted (20.28.2).
- 6 ae) (writable) A list indicating which of the remote MEPs in the same MA are active. The Remote MEP  
7 state machines (20.20) are instantiated only for the active remote MEPs. By default, all configured  
8 remote MEPs in the same MA are active.
- 9 af) (writable) Only applicable for PBB-TE MEPs supporting the Traffic field (21.6.1.4), a Boolean flag  
10 indicating that the capability to report the presence of traffic is enabled. The default value is FALSE.
- 11 ag) (writable) Only applicable for PBB-TE MEPs supporting the Traffic field (21.6.1.4), a Boolean flag  
12 indicating that the mismatch defect is allowed to generate a Fault Alarm. The default value is  
13 FALSE.
- 14 ah) Only applicable for PBB-TE MEPs supporting the Traffic field (21.6.1.4), a Boolean flag indicating  
15 the presence of a traffic field mismatch defect (20.25.2) (can trigger DefMmCCM).
- 16 ai) Only applicable for PBB-TE MEPs supporting the Traffic field (21.6.1.4), a Boolean flag indicating  
17 the presence of a local mismatch defect (20.25.5) (can trigger DefMmCCM).
- 18 aj) Only applicable for PBB-TE MEPs supporting the Traffic field (21.6.1.4), an enumerated value  
19 indicating if the mismatch defect that has been present since the MEP Mismatch Fault Notification  
20 Generator state machine (20.40) was last in the MFNG\_RESET state, either:
  - 21 1) **DefNone**: No defect has been present since the last MFNG\_RESET state; or
  - 22 2) **DefMmCCM**: This MEP is receiving CCMs that have different value in their Traffic field than  
23 the CCMs transmitted by this MEP or is transmitting CCMs with both the RDI and the Traffic  
24 field bit set to 1 and the disableLocdefect (20.25.4) variable is cleared, so variable item ah) in  
25 12.14.7.1.3 is set.
- 26 ak) Only applicable for PBB-TE MEPs supporting the Traffic field (21.6.1.4), a value indicating the  
27 current state of the MEP Mismatch Fault Notification Generator state machine (20.40).
- 28 al) (writable) Only applicable for ECMP path MEPs, a list of flow hash values to be used in a path  
29 testing cycle (20.10.5).

## 30 12.14.7.2 Write Maintenance association Endpoint managed object

### 31 12.14.7.2.1 Purpose

32 To alter a value in a specific managed object within a specific Maintenance association Endpoint managed  
33 object.

### 34 12.14.7.2.2 Inputs

- 35 a) A reference to a particular Maintenance association Endpoint managed object (12.14.7).
- 36 b) A reference to one of the writable managed objects in 12.14.7.1.3 is to be altered.
- 37 c) A new value for the managed object.

### 38 12.14.7.2.3 Outputs

- 39 a) Operation status. This takes one of the following values:
  - 40 1) Operation rejected due to nonexistent MEP
  - 41 2) Operation rejected due to the selected managed object being Read-Only
  - 42 3) Operation rejected due to invalid value for the selected managed object
  - 43 4) Operation accepted

### 12.14.7.3 Transmit Loopback Messages

#### 12.14.7.3.1 Purpose

To signal to the MEP to transmit some number of LBMs.

NOTE—The Maintenance association Endpoint managed object (12.14.7) can be examined to determine whether the corresponding LBRs have been received by the MEP.

#### 12.14.7.3.2 Inputs

- a) A reference to a particular Maintenance association Endpoint managed object (12.14.7).
- b) An indication of the target MAC address for LBMs transmitted by the MEP (20.31.1):
  - 1) The MEPID of a MEP in that MA or
  - 2) An Individual destination MAC address or
  - 3) For PBB-TE and SPBM VID MEPs, an individual MAC address to be used as the MIP MAC address in a PBB-TE MIP TLV.
- c) The number of LBMs to be transmitted (default 1).
- d) An arbitrary amount of data to be included in a Data TLV, along with an indication whether the Data TLV is to be included (20.31.1) (default no Data TLV).
- e) The priority and drop\_eligible parameters to be used in the transmitted LBMs [default is CCM priority item h) in 12.14.7.1.3, drop\_eligible FALSE].
- f) In the case of a PBB-TE MEP, the Reverse VID to be used in the associated PBB-TE MIP TLV 21.7.5. The parameter is not required in the case of PBB-TE MEPs associated with point-to-point TESIs or if the b3) entry is a MAC address corresponding to an entry in the ESP-DA field of any of the MA's ESPs.
- g) In the case of an SPBM VID MEP, an individual or group MAC address to be used as the destination\_address for the LBM primitive. If no value is provided the group MAC address for the SPBM default I-SID (Table 9-3, Figure 27-3) is used.
- h) In the case of ECMP with flow filtering, a flow hash value if the destination address is an individual address.

#### 12.14.7.3.3 Outputs

- a) An indication of whether the command was accepted by the MEP:
  - 1) Operation rejected due to nonexistent MEP;
  - 2) Operation rejected due to invalid number of LBMs to be transmitted;
  - 3) Operation rejected due to too much data to be transmitted;
  - 4) Operation rejected due to invalid priority or drop\_eligible parameters to be transmitted;
  - 5) Operation rejected due to invalid ESP-VID;
  - 6) The LBM(s) will be (or have been) sent; or
  - 7) The LBM(s) will not be sent (e.g., because the Bridge is busy with another LBM transmit operation).
- b) The Loopback Transaction Identifier (20.30.2) of the first LBM (to be) sent. The value returned is undefined if the Transmit Loopback Messages command was not accepted.

### 12.14.7.4 Transmit Linktrace Message

#### 12.14.7.4.1 Purpose

To signal to the MEP to transmit an LTM and to create an LTM entry in the MEP's Linktrace Database.

NOTE—The Maintenance association Endpoint managed object (12.14.7) can be examined to determine whether the corresponding LTRs have been received by the MEP.

#### 12.14.7.4.2 Inputs

- a) A reference to a particular Maintenance association Endpoint managed object (12.14.7).
- b) The Flags field for LTMs transmitted by the MEP (20.42.1).
- c) An indication of the Target MAC Address field to be transmitted, either:
  - 1) The MEPID of another MEP in the same MA or
  - 2) An individual MAC address.
- d) An initial value for the LTM TTL field (21.8.4). Default value, if not specified, is 64.
- e) In the case of a PBB-TE MEP, the Reverse VID to be used in the associated PBB-TE MIP TLV (21.7.5). The parameter is not required in the case of PBB-TE MEPs associated with point-to-point TESI.
- f) In the case of an SPBM VID MEP, an individual or group MAC address to be used as the destination\_address for the LTM primitive. If no value is provided the group MAC address for the SPBM default I-SID (Table 9-3, Figure 27-3) is used.
- g) In the case of ECMP with flow filtering, a flow hash value if the destination address is an Individual address.

#### 12.14.7.4.3 Outputs

- a) An indication of whether the command was accepted by the MEP:
  - 1) Operation rejected due to nonexistent MEP;
  - 2) Operation rejected due to invalid Flags field to be transmitted;
  - 3) Operation rejected due to invalid Target MAC Address to be transmitted;
  - 4) Operation rejected due to invalid LTM TTL field to be transmitted;
  - 5) Operation rejected due to invalid ESP-VID;
  - 6) The command was accepted and the LTM has (or will be) transmitted; or
  - 7) The command was rejected and no LTM will be sent (e.g., because the Bridge is busy with another LTM transmit operation).
- b) The LTM Transaction Identifier (20.41.1) of the LTM sent. The value returned is undefined if the Transmit Linktrace Message command was not accepted.
- c) The LTM Egress Identifier TLV value transmitted in the LTM. The value returned is undefined if the Transmit Linktrace Message command was not accepted.

#### 12.14.7.5 Read Linktrace Reply

##### 12.14.7.5.1 Purpose

To obtain from the MEP's Linktrace database (20.41.2) the LTM entry for a previously transmitted LTM with a specific LTM Transaction Identifier. An LTM entry consists of a list of LTR entries, each corresponding to a Linktrace Reply (LTR) PDU received in response to that LTM. The LTM Transaction Identifier returned by successful Transmit Linktrace Message command [item b) in 12.14.7.5.2] is used in the Read Linktrace Reply command [item b) in 12.14.7.5.2] to select the LTM entry.

See J.5 for a discussion of how to interpret the output from the Read Linktrace Reply command.

##### 12.14.7.5.2 Inputs

- a) A reference to a particular Maintenance association Endpoint managed object (12.14.7).
- b) The LTM Transaction Identifier returned from a previous Transmit Linktrace Message command, indicating the LTM entry to which the LTR entries will be attached.
- c) An index to distinguish among multiple LTRs with the same LTR Transaction Identifier field value.

### 12.14.7.5.3 Outputs

A list of LTR entries returned corresponding to the selected LTM Transaction Identifier (20.41.2). Each LTR entry in the list returns:

- a) An indication of whether the command was accepted by the MEP:
  - 1) Operation rejected due to nonexistent MEP;
  - 2) Operation rejected due to LTM Transaction Identifier not found;
  - 3) Operation rejected due to LTR entry has been discarded because too many LTRs have been returned corresponding to that LTM Transaction Identifier;
  - 4) Operation rejected due to LTR entry with that index has not yet been returned; or
  - 5) Operation accepted.
- b) The integer Reply TTL field value returned in the LTR (20.41.2.2).
- c) A Boolean value stating whether an LTM was forwarded by the responding MP, as returned in the FwdYes flag of the Flags field (20.41.2.1).
- d) A Boolean value stating whether the forwarded LTM reached a MEP enclosing its MA, as returned in the TerminalMEP flag of the Flags field (20.41.2.1).
- e) An octet string holding the Last Egress Identifier field returned in the LTR Egress Identifier TLV of the LTR (20.41.2.3).
- f) An octet string holding the Next Egress Identifier field returned in the LTR Egress Identifier TLV of the LTR (20.41.2.4).
- g) An enumerated value indicating the value returned in the Relay Action field (20.41.2.5): RlyHit, RlyFDB, or RlyMPDB.
- h) (if returned in the LTR) An enumerated value indicating the format of the Chassis ID (21.5.3.2).
- i) (if returned in the LTR) The Chassis ID (21.5.3.3).
- j) (if returned in the LTR) The Management Address information of the Bridge transmitting the LTR (21.5.3.7).
- k) (if returned in the LTR) An enumerated value indicating the value returned in the Ingress Action field (20.41.2.6) of the LTR: IngOK, IngDown, IngBlocked, or IngVID.
- l) (if returned in the LTR) The MAC address returned in the Ingress MAC Address field (20.41.2.7).
- m) (if returned in the LTR) An enumerated value indicating the format of the Ingress Port ID field (20.41.2.8).
- n) (if returned in the LTR) The Ingress Port ID (20.41.2.9).
- o) (if returned in the LTR) An enumerated value indicating the value returned in the Egress Action field (20.41.2.10) of the LTR: EgrOK, EgrDown, EgrBlocked, or EgrVID.
- p) (if returned in the LTR) The MAC address returned in the Egress MAC Address field (20.41.2.11).
- q) (if returned in the LTR) An enumerated value indicating the format of the Egress Port ID (20.41.2.12).
- r) (if returned in the LTR) The Egress Port ID (20.41.2.13).
- s) (if returned in the LTR) The OUI or CID and contents of any Organization-Specific TLVs (21.5.2) returned in the LTR.

### 12.14.7.6 Read MEP Database

#### 12.14.7.6.1 Purpose

To obtain from the MEP the contents of one element in the MEP CCM Database.

## 1 12.14.7.6.2 Inputs

- 2 a) A reference to a particular Maintenance association Endpoint managed object (12.14.7).
- 3 b) The MEPID of a remote MEP whose information from the selected database is to be returned.

## 4 12.14.7.6.3 Outputs

- 5 a) An indication of whether the command was accepted by the MEP:
  - 6 1) Operation rejected due to nonexistent MEP;
  - 7 2) Operation rejected due remote MEPID not configured in MA; or
  - 8 3) Operation accepted.
- 9 b) An enumerated value indicating the operational state of the Remote MEP state machine (20.20) for  
10 this remote MEP:
  - 11 1) RMEP\_IDLE;
  - 12 2) RMEP\_START;
  - 13 3) RMEP\_FAILED; or
  - 14 4) RMEP\_OK.
- 15 c) The time (SysUpTime, IETF RFC 3418) at which the Remote MEP state machine last entered either  
16 the RMEP\_FAILED or RMEP\_OK state, or 0 if it has not yet entered either of those states.
- 17 d) The MAC address of the remote MEP (the source\_address of the last received CCM) or 0 if no CCM  
18 has been received (20.19.7).
- 19 e) A Boolean value indicating the state of the RDI bit in the last received CCM (TRUE for RDI = 1), or  
20 FALSE, if none has been received (20.19.2). In the case of an ECMP path MEP, an array of Boolean  
21 values indicating the value of rMEPlastRDI[i] for i=0..(Npaths – 1) indicating the RDI values in the  
22 last CCMs received in each path test cycle period. These values are true for any RDI = 1 or false if  
23 all RDI = 0 or if no CCM has ever been received (20.19.2).
- 24 f) (optional) The enumerated value from the Port Status TLV (20.19.3) from the last CCM received  
25 from the remote MEP, or the default value:
  - 26 1) **psNoPortStateTLV**: Indicates either that no CCM has been received, or that no Port Status  
27 TLV was present in the last CCM received.
- 28 g) (optional) The enumerated value from the Interface Status TLV (20.19.4) from the last CCM  
29 received from the remote MEP, or the default value:
  - 30 1) **isNoInterfaceStatusTLV**: Indicates either that no CCM has been received or that no Interface  
31 Status TLV was present in the last CCM received.
- 32 h) (optional) The Sender ID TLV (20.19.5) from the last CCM received from the remote MEP or the  
33 default value:
  - 34 1) **isNoSenderIdTLV**: Indicates either that no CCM has been received, or that no Sender ID TLV  
35 was present in the last CCM received.

## 36 12.14.7.7 Transmit MEP Fault Alarm

### 37 12.14.7.7.1 Purpose

38 To alert the Manager to the existence of a fault in a monitored MA by issuing a Fault Alarm. Transmit MEP  
39 Fault Alarm is not a command; it is an unsolicited notification from the xmitFaultAlarm() procedure, issued  
40 upon detection of the Fault Alarm condition by the MEP Fault Notification Generator state machine (20.37),  
41 or by the MEP Mismatch Fault Notification Generator state machine (20.40). The Fault Alarm is sent to the  
42 address specified in item j) in 12.14.7.1.3.

#### 1 12.14.7.7.2 Outputs

- 2 a) An indication of which Bridge is reporting the Fault Alarm.
- 3 b) A reference, in a suitable format for the method of delivering the Fault Alarm, to the reporting MEP.
- 4 c) An enumerated value, equal to the contents of the variable highestDefect (20.35.9), and to the
- 5 corresponding MEP managed object [item n) in 12.14.7.1.3] or indicating the presence of a
- 6 mismatch defect [item aj) in 12.14.7.1.3].

#### 7 12.15 Backbone Core Bridge (BCB) management

8 Each BCB is a conformant S-VLAN Bridge (5.10.1) that is managed by the managed objects summarized in  
9 12.2 and specified in detail in 12.4 through 12.14.

#### 10 12.16 Backbone Edge Bridge (BEB) management

11 The conformance requirements for BEBs are specified in 5.12. Each of the I-Components and (or) the  
12 B-Component of a BEB are managed using the managed objects defined in 12.2, while this subclause adds  
13 managed objects used in conjunction with those of 12.2 to manage the overall configuration and the VIPs,  
14 PIPs, and CBPs of a BEB. This subclause specifies the additional managed objects specific to the operation  
15 of BEBs, which:

- 16 a) Support a BEB configuration managed object identifying all the BEB Components (12.16.1).
- 17 b) Identify BEB port types (12.16.2).
- 18 c) Provide additional managed objects for management of the VIPs, PIPs, and CBPs (12.16.3, 12.16.4,
- 19 12.16.5).

20 Only a single view of the BEB managed objects exists. This view may only contain the objects needed for  
21 the type of BEB under management. If the BEB contains only a single I-Component then the view will have  
22 only the BEB configuration, BEB, VIP configuration, and PIP configuration managed objects. If the BEB  
23 has only a B-Component, then the view will have only the BEB configuration, BEB, and CBP configuration  
24 managed objects.

25 An instance of a managed object associated with a BEB is referenced by a unique identifier. Rules  
26 associated with the selection of this identifier are specified within this subclause. Each BEB has a single  
27 BEB configuration managed object, which is described in this subclause and illustrated in Figure 12-2. This  
28 managed object is accessed at only one of the components within a given BEB, the B-Component if that is  
29 present, and the single I-Component otherwise, and is referenced by that component's MAC address.

1

**Figure 12-2—Relationship among BEB managed objects**

2 Each VLAN Bridge Component relays frames between Bridge Ports. In a BEB, these Bridge Ports can  
3 provide external connectivity directly, or can connect to other Bridge Components through internal LANs.  
4 Each component contained within a BEB is associated with the BEB configuration managed object  
5 representing that BEB. The component is uniquely identified within the PBBN by the combination of a  
6 componentID unique within the BEB and by the MAC address of the BEB within that the component is  
7 contained. Each component may also be identified by the MAC address of the component that is unique  
8 within the PBBN. Within a BEB, a B-Component uses two types of Bridge Ports—PNPs and CBPs—and an  
9 I-Component uses two types of Bridge Ports—VIPs and CNPs. Each Bridge Port is represented by a Bridge  
10 Port managed object (12.4.2), a Provider Bridge Port Type managed object (12.13.1), and a BEB port  
11 configuration managed object (12.16.2). Each such managed object is uniquely identified, within the BEB,  
12 by the combination of the ComponentID and Port Number (12.3) of the associated Bridge Port.

13 Each VIP associated with an I-Component is mapped to a PIP associated with that I-Component. In general,  
14 multiple VIPs are associated with a single PIP. PIPs are not Bridge Ports, though they are ports on BEBs, as  
15 they are not used directly by the MAC Relay Entity (see Clause 8) of a Bridge Component. Each VIP is  
16 supported by one and only one PIP. Each PIP is therefore identified uniquely by the ComponentID and Port  
17 Number of any of the VIPs that it supports and by convention is referenced by the smallest Port Number  
18 supported by the PIP. Each PIP is managed using the PIP configuration managed object (12.16.4), and each  
19 VIP is managed using the VIP configuration managed object of (12.16.3).

20 PIPs and CBPs of a BEB may be internal or external. Each externally accessible port on a BEB is designated  
21 as a PNP, CBP, PIP, or CNP.

22 The following managed objects define the semantics of the management operations specific to BEBs:

- 23 d) The BEB configuration managed object (12.16.1)
- 24 e) The BEB/PB/VLAN Bridge Port configuration managed object (12.16.2)
- 25 f) The VIP configuration managed object (12.16.3)
- 26 g) The PIP configuration managed object (12.16.4)

1 h) The CBP configuration managed object (12.16.5)

2 NOTE—All objects specified in 12.16 are persistent over power-up/down and system reboot unless otherwise specified.

### 3 **12.16.1 BEB configuration managed object**

4 The BEB configuration managed object identifies a BEB and all the managed objects that manage the BEB.

5 The management operations that can be performed on the BEB configuration managed object are as follows:

- 6 a) Read BEB configuration (12.16.1.1)
- 7 b) Set BEB configuration (12.16.1.2)
- 8 c) Create BEB Component (12.16.1.3)
- 9 d) Delete BEB Component (12.16.1.4)
- 10 e) Create BEB Bridge Port (12.16.1.5)
- 11 f) Create BEB PIP (12.16.1.6)
- 12 g) Delete BEB Bridge Port (12.16.1.7)
- 13 h) Delete BEB PIP (12.16.1.8)

14 Items marked “(MIRP only)” shall be supported if the B-Component supports the Multiple I-SID  
15 Registration Protocol (MIRP) (Clause 39).

#### 16 **12.16.1.1 Read BEB configuration**

##### 17 **12.16.1.1.1 Purpose**

18 All BEBs shall implement the read BEB configuration function to obtain information regarding the type of  
19 components and ports within a BEB. Items marked “(MIRP only)” shall be supported if the B-Component  
20 supports the Multiple I-SID Registration Protocol (MIRP) (Clause 39).

##### 21 **12.16.1.1.2 Inputs**

22 None.

##### 23 **12.16.1.1.3 Outputs**

- 24 a) BEB address—the MAC address for the BEB used to access the BEB configuration managed object  
25 (8.13.8). Each BEB has a single BEB address even if the BEB has many components.
- 26 b) BEB name—a text string of up to 32 characters, of locally determined significance.
- 27 c) Number of I-Components—in the BEB, which may range from 0 to many.
- 28 d) I-Component addresses—a list specifying the following for each I-Component or a NULL list value  
29 for no I-Components:
  - 30 1) ComponentID—the number of the I-Component.
  - 31 2) A Bridge address that is the MAC address for the I-Component (8.13.8).
- 32 e) Number of B-Components—in the BEB, which may be 0 or 1.
- 33 f) B-Component address—a list specifying the following for the B-Component or a NULL list value  
34 for no B-Component:
  - 35 1) ComponentID—the number of the B-Component.
  - 36 2) A Bridge address that is the MAC address for the B-Component (8.13.8).
- 37 g) Number of BEB ports (MAC Entities).
- 38 h) Port addresses—a list specifying the following for each port:
  - 39 1) ComponentID—the number identifying the Bridge Component associated with this port.
  - 40 2) An interface—either that component’s Port Number for the Bridge Port, or in the case of a PIP,  
41 the PIP Index.

- 1 3) Port address—the specific MAC address associated with the port (8.13.2).  
2 4) External port—a Boolean indicating that the port is an external port.
- 3 i) (MIRP only) A Boolean value specifying whether MIRP is (TRUE) or is not (FALSE) enabled in  
4 this B-Component (Clause 39).
- 5 j) (MIRP only) The MIRP B-VID to which MIRPDUs transmitted from a PNP are to be assigned if  
6 item k) contains the value cbpMirpGroup (1). The value 0 (the default value) indicates that the CBP  
7 PVID is to be used (39.2.1.6).
- 8 k) (MIRP only) An enumerated value specifying what destination\_address and vlan\_identifier are to be  
9 used when the MIRP Participant transmits an MIRPDU from a PNP:
- 10 1) cbpMirpGroup: Use the Nearest Customer Bridge group address from Table 8-1 with the MIRP  
12 B-VID (this is the default value) [item a) in 39.2.1.6];
- 13 2) cbpMirpVlan: Use the Nearest Customer Bridge group address from Table 8-1 with the B-VID  
15 field from the Backbone Service Instance table [item b) in 39.2.1.6]; or
- 16 3) cbpMirpTable: Use the Default Backbone Destination and B-VID fields from the Backbone  
18 Service Instance table [item c) in 39.2.1.6].
- 19 l) (MIRP only) A Boolean value specifying the administrative status requested by management for  
20 attaching a MIRP Participant to a PNP or management Port. If TRUE, the BEB is to attach a MIRP  
21 Participant to exactly one PNP or management Port, and if FALSE, no MIRP Participant is to be  
22 present on any PNP or management Port. Default value is TRUE (39.1.2).
- 23 m) (MIRP only) The read-only Bridge Port Number (or 0, if none) of the PNP to which the MIRP  
24 Participant is attached (39.1.2).

## 25 12.16.1.2 Set BEB configuration

### 26 12.16.1.2.1 Purpose

27 All BEBs shall implement the set BEB configuration function to set the BEB Name. Items marked “(MIRP  
28 only)” shall be supported if the B-Component supports the Multiple I-SID Registration Protocol (MIRP)  
29 (Clause 39). All items are persistent over power up or reboot.

### 30 12.16.1.2.2 Inputs

- 31 a) BEB Name—a text string of up to 32 characters, of locally determined significance.
- 32 b) (MIRP only) A Boolean value specifying whether MIRP is (TRUE) or is not (FALSE) enabled in  
33 this B-Component (Clause 39).
- 34 c) (MIRP only) The MIRP B-VID to which received MIRPDUs are to be assigned if item d) contains  
35 the value cbpMirpGroup (1). The value 0 (the default) indicates that the CBP PVID is to be used  
36 (39.2.1.6).
- 37 d) (MIRP only) An enumerated value specifying what destination\_address and vlan\_identifier are to be  
38 used when the MIRP Participant transmits an MIRPDU towards the MAC relay entity, either  
39 cbpMirpGroup (1), cbpMirpVlan (2), or cbpMirpTable (3) (39.2.1.6).
- 40 e) (MIRP only) A Boolean value specifying the administrative status requested by management for  
41 attaching a MIRP Participant to a PNP or management Port. If TRUE, the BEB is to attach a MIRP  
42 Participant to exactly one PNP or management Port, and if FALSE, no MIRP Participant is to be  
43 present on any PNP or management Port (39.1.2).

### 44 12.16.1.2.3 Outputs

45 None.

### 1 **12.16.1.3 Create BEB component (optional)**

#### 2 **12.16.1.3.1 Purpose**

3 A BEB may implement the create BEB component function to allow the dynamic creation of new  
4 components. Components created by this command are persistent over power-up or reboot.

#### 5 **12.16.1.3.2 Inputs**

6 a) ComponentType. This takes one of the following values:

7 1) I-Comp

8 2) B-Comp

#### 9 **12.16.1.3.3 Outputs**

10 None.

### 11 **12.16.1.4 Delete BEB component (optional)**

#### 12 **12.16.1.4.1 Purpose**

13 A BEB may implement the delete BEB component function to allow deletion of components. Component  
14 deletion using this command is persistent over power-up or reboot.

#### 15 **12.16.1.4.2 Inputs**

16 a) ComponentID—indicates the component being deleted.

#### 17 **12.16.1.4.3 Outputs**

18 None.

### 19 **12.16.1.5 Create BEB Bridge Port (optional)**

#### 20 **12.16.1.5.1 Purpose**

21 A BEB may implement the create BEB Bridge Port function to allow dynamic creation of Bridge Ports.  
22 Bridge Ports created by this command are persistent over power-up or reboot.

#### 23 **12.16.1.5.2 Inputs**

24 a) Port Index—indicates the port where the new Bridge Port will be created.

25 b) ComponentID—indicates the component where the new Bridge Port will be created.

26 c) Port type. This takes one of the following values:

27 1) CNP

28 2) PNP

29 3) CBP

30 4) VIP

#### 31 **12.16.1.5.3 Outputs**

32 None.

1 **12.16.1.6 Create BEB PIP (optional)**

2 **12.16.1.6.1 Purpose**

3 A BEB may implement the create BEB PIP function to allow dynamic creation of PIPs. PIPs created by this  
4 command are persistent over power-up or reboot.

5 **12.16.1.6.2 Inputs**

- 6 a) Port Index—indicates the port where the new PIP will be created.
- 7 b) ComponentID—indicates the component where the new PIP will be created.

8 **12.16.1.6.3 Outputs**

9 None.

10 **12.16.1.7 Delete BEB Bridge Port (optional)**

11 **12.16.1.7.1 Purpose**

12 A BEB may implement the delete BEB Bridge Port function to allow deletion of Bridge Ports. Bridge Port  
13 deletion using this command is persistent over power-up or reboot.

14 **12.16.1.7.2 Inputs**

- 15 a) ComponentID—the component for the Bridge Port.
- 16 b) Port Number—the Port Number for the Bridge Port.

17 **12.16.1.7.3 Outputs**

18 None.

19 **12.16.1.8 Delete BEB PIP (optional)**

20 **12.16.1.8.1 Purpose**

21 A BEB may implement the delete BEB PIP function to allow deletion of PIPs. PIP deletion using this  
22 command is persistent over power-up or reboot.

23 **12.16.1.8.2 Inputs**

- 24 a) PIP Index—identifies the PIP within the BEB.

25 **12.16.1.8.3 Outputs**

26 None.

## 12.16.2 BEB/PB/VLAN Bridge Port configuration managed object

The management operation that can be performed on the BEB/PB/VLAN Bridge Port configuration managed object is as follows:

- a) Read BEB/PB/VLAN Bridge Port configuration (12.16.2.1)

### 12.16.2.1 Read BEB/PB/VLAN Bridge Port configuration

#### 12.16.2.1.1 Purpose

All BEBs shall implement the read BEB/PB/VLAN Bridge Port configuration function to obtain information regarding the port type of a Bridge Port on the BEB.

#### 12.16.2.1.2 Inputs

- a) ComponentID—the number identifying the Bridge Component associated with this port.
- b) Port Number—that component's Port Number for the Bridge Port.

#### 12.16.2.1.3 Outputs

- a) Port Type. This takes one of the following values:
  - 1) C-VLAN Port
  - 2) PNP (identical to the PNP Bridge Port type specified by 12.13.1)
  - 3) CNP (identical to the CNP Bridge Port type specified by 12.13.1)
  - 4) CEP (identical to the CEP Bridge Port type specified by 12.13.1)
  - 5) CBP (5.12, 6.11, 12.13.1 will indicate PNP)
  - 6) VIP (5.12, 6.10, 12.13.1 will indicate PNP)

NOTE—Support for C-VLAN ports requires equipment with VLAN Bridge (5.9) functions in addition to BEB (5.12) functions. Support for CEP ports requires equipment with Provider Bridge (5.10) functions in addition to BEB functions.

## 12.16.3 VIP configuration managed object

The VIP configuration managed object applies to each VIP (6.10) on a BEB whether its associated PIP is externally or internally accessible.

It includes:

- a) The VIP configuration parameters, which provide the subset of the Bridge VLAN Configuration managed object (12.10.1) that is relevant for the configuration of the backbone service instance.

The management operations that can be performed are as follows:

- b) Read VIP configuration (12.16.3.1)
- c) Set VIP configuration (12.16.3.2)

### 12.16.3.1 Read VIP configuration

#### 12.16.3.1.1 Purpose

All BEBs with I-Components shall implement the read VIP configuration function to allow reading the current configuration of the VIPs (6.10) in an I-Component of a BEB. Each VIP is configured by 12.8, 12.10, 12.16.3.2. The adminPointToPointMAC parameter is configured by 12.8.2.3.2 while the PVID and Acceptable Frame Types parameters are supplied by the Bridge Port configuration of 12.10.1.2 and 12.10.1.3.

### 1 12.16.3.1.2 Inputs

- 2 a) ComponentID—the number identifying the Bridge Component associated with this port.
- 3 b) Port Number—that component's Port Number for the Bridge Port.

### 4 12.16.3.1.3 Outputs

- 5 a) ComponentID—the number identifying the Bridge Component associated with this port.
- 6 b) Port Number—that component's Port Number for the Bridge Port.
- 7 c) PIP Name—a text string of up to 32 characters that identifies the PIP within a BEB with which this
- 8 VIP is associated.
- 9 d) VIP-ISID—the I-SID associated with this VIP (6.10).
- 10 e) Default Backbone Destination—an EUI-48 DA (6.10.2).
- 11 f) enableConnectionIdentifier—A Boolean to indicate if the connection\_identifier parameter is
- 12 allowed to learn associations between a B-MAC address and a C-MAC address (6.10).

## 13 12.16.3.2 Set VIP configuration

### 14 12.16.3.2.1 Purpose

15 All BEBs with I-Components shall implement the set VIP configuration function to allow setting the  
16 configuration of the internal VIP in the I-Component of a BEB.

### 17 12.16.3.2.2 Inputs

- 18 a) ComponentID—the number identifying the Bridge Component associated with this port.
- 19 b) Port Number—that component's Port Number for the Bridge Port.
- 20 c) VIP-ISID—the I-SID associated with this VIP (6.10).
- 21 d) enableConnectionIdentifier—A Boolean that determines if the connection\_identifier parameter is
- 22 allowed to learn associations between a B-MAC address and a C-MAC address (6.10). The default
- 23 value is TRUE. This parameter should be configured to FALSE at the root node of a
- 24 point-to-multipoint TESI.

### 25 12.16.3.2.3 Outputs

- 26 a) Operation status. This takes one of the following values:
  - 27 1) Operation rejected because the Bridge Port identified by the ComponentID and Port Number is
  - 28 not a VIP.
  - 29 2) Operation accepted.

## 30 12.16.4 PIP configuration managed object

31 The PIP Configuration managed object applies to each PIP (6.10) on a BEB.

32 It includes the following:

- 33 a) The VIP mapping, which provides the set of VIPs multiplexed on this PIP
- 34 b) The PIP MAC address, which is used as the B-SA for all encapsulated frames

35 The management operations that can be performed are as follows:

- 36 c) Read PIP Configuration (12.16.4.1)
- 37 d) Optionally, Set PIP Configuration (12.16.4.2)
- 38 e) Read VIP to PIP mapping (12.16.4.3)
- 39 f) Optionally, Set VIP to PIP mapping (12.16.4.4)

- 1 g) Read PIP Priority Code Point Selection (12.16.4.5)
- 2 h) Set PIP Priority Code Point Selection (12.16.4.6)
- 3 i) Read PIP Priority Code Point Decoding Table (12.16.4.7)
- 4 j) Optionally, Set PIP Priority Code Point Decoding Table (12.16.4.8)
- 5 k) Read PIP Priority Code Point Encoding Table (12.16.4.9)
- 6 l) Optionally, Set PIP Priority Code Point Encoding Table (12.16.4.10)
- 7 m) Read PIP Use\_DEI parameter (12.16.4.11)
- 8 n) Optionally, Set PIP Use\_DEI parameter (12.16.4.12)
- 9 o) Read PIP Require Drop Encoding parameter (12.16.4.13)
- 10 p) Optionally, Set PIP Require Drop Encoding parameter (12.16.4.14)

#### 11 **12.16.4.1 Read PIP configuration**

##### 12 **12.16.4.1.1 Purpose**

13 All BEBs with I-Components shall implement the read PIP configuration function to allow reading the  
14 current configuration of the PIP in the I-Component of a BEB.

##### 15 **12.16.4.1.2 Inputs**

- 16 a) PIP Index—an identifier for the PIP within this BEB.

##### 17 **12.16.4.1.3 Outputs**

- 18 a) PIP B-MAC address—identifies the PIP (6.10.2).
- 19 b) PIP Name—a text string of up to 32 characters used to identify a PIP within a BEB.
- 20 c) ComponentID—the number identifying the I-Component with this PIP.
- 21 d) VIP map—a bit array of 4094 bits indicating all the VIPs associated with this port.

#### 22 **12.16.4.2 Set PIP configuration (optional)**

##### 23 **12.16.4.2.1 Purpose**

24 All BEBs with I-Components may implement the set PIP configuration function to set the current  
25 configuration of the PIP in the I-Component of a BEB.

##### 26 **12.16.4.2.2 Inputs**

- 27 a) PIP Index—an identifier for the PIP within this BEB.
- 28 b) PIP B-MAC address—the B-MAC address used by this PIP in the B-SA field of transmitted frames.
- 29 c) PIP Name—a text string of up to 32 characters used to identify the PIP within a BEB.
- 30 d) VIP map—a bit array of 4094 bits indicating all the VIPs associated with this PIP.

##### 31 **12.16.4.2.3 Outputs**

- 32 a) Operation status. This takes one of the following values:
  - 33 1) Operation rejected because the PIP Index is invalid
  - 34 2) Operation rejected because the VIP map identifies a port that is not a VIP
  - 35 3) Operation accepted

### 12.16.4.3 Read VIP to PIP mapping

#### 12.16.4.3.1 Purpose

All BEBs with I-Components shall implement the read VIP to PIP mapping function to allow reading the VIP to PIP map information from the PIP configuration managed object.

#### 12.16.4.3.2 Inputs

- a) ComponentID—the number identifying a Bridge Component with a VIP.
- b) Port Number—that component's Port Number for this VIP.

#### 12.16.4.3.3 Outputs

- a) ComponentID—the number identifying a Bridge Component with a VIP.
- b) Port Number—that component's Port Number for this VIP.
- c) PIP Index—identifies the PIP supporting this VIP.
- d) PIP B-MAC address—the B-MAC address used by this PIP supporting this VIP (6.10.2).
- e) PIP Name—a text string of up to 32 characters identifying the PIP supporting this VIP.

### 12.16.4.4 Set VIP to PIP mapping (optional)

#### 12.16.4.4.1 Purpose

All BEBs with I-Components may implement the set VIP to PIP mapping function to allow binding individual VIPs to PIPs. The set VIP to PIP mapping function allows setting map entries for individual VIPs while the set PIP configuration function sets the entire VIP to PIP map.

#### 12.16.4.4.2 Inputs

- a) ComponentID—the number identifying a Bridge Component with a VIP.
- b) Port Number—that component's Port Number for this VIP.
- c) PIP Index—an identifier for this PIP within this component of the BEB.

#### 12.16.4.4.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because the ComponentID and Port Number do not identify a VIP.
  - 2) Operation rejected because the PIP Index does not identify a PIP within the specified component.
  - 3) Operation accepted.

### 12.16.4.5 Read PIP Priority Code Point Selection

#### 12.16.4.5.1 Purpose

To read which row of the Priority Code Point Encoding Table and Priority Code Point Decoding Table (6.10.3) is currently selected for use on this PIP.

1 **12.16.4.5.2 Inputs**

- 2 a) PIP Index—an identifier for this PIP within this component of the BEB.

3 **12.16.4.5.3 Outputs**

- 4 a) Priority Code Point Selection. This takes one of the following values:

- 5 1) 8P0D  
6 2) 7P1D  
7 3) 6P2D  
8 4) 5P3D

9 **12.16.4.6 Set PIP Priority Code Point Selection**

10 **12.16.4.6.1 Purpose**

11 To set which row of the Priority Code Point Encoding Table and Priority Code Point Decoding Table  
12 (6.10.3) will be selected for use on this PIP.

13 **12.16.4.6.2 Inputs**

- 14 a) PIP Index—an identifier for this PIP within this component of the BEB.

- 15 b) Priority Code Point Selection. This takes one of the following values:

- 16 1) 8P0D  
17 2) 7P1D  
18 3) 6P2D  
19 4) 5P3D

20 **12.16.4.6.3 Outputs**

21 None.

22 **12.16.4.7 Read PIP Priority Code Point Decoding Table**

23 **12.16.4.7.1 Purpose**

24 To read the current contents of a row in the Priority Code Point Decoding Table (6.10.3) for a PIP.

25 **12.16.4.7.2 Inputs**

- 26 a) PIP Index—an identifier for this PIP.

- 27 b) Priority Code Point Row. This takes one of the following values:

- 28 1) 8P0D  
29 2) 7P1D  
30 3) 6P2D  
31 4) 5P3D

32 **12.16.4.7.3 Outputs**

- 33 a) Priority value for Priority Code Point 0: Integer in range 0–7.  
34 b) Drop\_eligible value for Priority Code Point 0: Boolean.  
35 c) Priority value for Priority Code Point 1: Integer in range 0–7.  
36 d) Drop\_eligible value for Priority Code Point 1: Boolean.  
37 e) Priority value for Priority Code Point 2: Integer in range 0–7.  
38 f) Drop\_eligible value for Priority Code Point 2: Boolean.

- 1 g) Priority value for Priority Code Point 3: Integer in range 0–7.
- 2 h) Drop\_eligible value for Priority Code Point 3: Boolean.
- 3 i) Priority value for Priority Code Point 4: Integer in range 0–7.
- 4 j) Drop\_eligible value for Priority Code Point 4: Boolean.
- 5 k) Priority value for Priority Code Point 5: Integer in range 0–7.
- 6 l) Drop\_eligible value for Priority Code Point 5: Boolean.
- 7 m) Priority value for Priority Code Point 6: Integer in range 0–7.
- 8 n) Drop\_eligible value for Priority Code Point 6: Boolean.
- 9 o) Priority value for Priority Code Point 7: Integer in range 0–7.
- 10 p) Drop\_eligible value for Priority Code Point 7: Boolean.

#### 11 **12.16.4.8 Set PIP Priority Code Point Decoding Table (optional)**

##### 12 **12.16.4.8.1 Purpose**

13 To modify the contents of a row in the Priority Code Point Decoding Table (6.10.3) for a PIP.

##### 14 **12.16.4.8.2 Inputs**

- 15 a) PIP Index—an identifier for this PIP.
- 16 b) b) Priority Code Point Row. This takes one of the following values:
  - 17 1) 8P0D
  - 18 2) 7P1D
  - 19 3) 6P2D
  - 20 4) 5P3D
- 21 c) Priority value for Priority Code Point 0: Integer in range 0–7.
- 22 d) Drop\_eligible value for Priority Code Point 0: Boolean.
- 23 e) Priority value for Priority Code Point 1: Integer in range 0–7.
- 24 f) Drop\_eligible value for Priority Code Point 1: Boolean.
- 25 g) Priority value for Priority Code Point 2: Integer in range 0–7.
- 26 h) Drop\_eligible value for Priority Code Point 2: Boolean.
- 27 i) Priority value for Priority Code Point 3: Integer in range 0–7.
- 28 j) Drop\_eligible value for Priority Code Point 3: Boolean.
- 29 k) Priority value for Priority Code Point 4: Integer in range 0–7.
- 30 l) Drop\_eligible value for Priority Code Point 4: Boolean.
- 31 m) Priority value for Priority Code Point 5: Integer in range 0–7.
- 32 n) Drop\_eligible value for Priority Code Point 5: Boolean.
- 33 o) Priority value for Priority Code Point 6: Integer in range 0–7.
- 34 p) Drop\_eligible value for Priority Code Point 6: Boolean.
- 35 q) Priority value for Priority Code Point 7: Integer in range 0–7.
- 36 r) Drop\_eligible value for Priority Code Point 7: Boolean.

##### 37 **12.16.4.8.3 Outputs**

38 None.

#### 39 **12.16.4.9 Read PIP Priority Code Point Encoding Table**

##### 40 **12.16.4.9.1 Purpose**

41 To read the current contents of a row in the Priority Code Point Encoding Table (6.10.3) for a Port.

## 1 12.16.4.9.2 Inputs

- 2 a) PIP Index—an identifier for this PIP.
- 3 b) Priority Code Point Row. This takes one of the following values:
  - 4 1) 8P0D
  - 5 2) 7P1D
  - 6 3) 6P2D
  - 7 4) 5P3D

## 8 12.16.4.9.3 Outputs

- 9 a) Priority Code Point value for priority 0 with drop\_eligible False: Integer in range 0–7.
- 10 b) Priority Code Point value for priority 0 with drop\_eligible True: Integer in range 0–7.
- 11 c) Priority Code Point value for priority 1 with drop\_eligible False: Integer in range 0–7.
- 12 d) Priority Code Point value for priority 1 with drop\_eligible True: Integer in range 0–7.
- 13 e) Priority Code Point value for priority 2 with drop\_eligible False: Integer in range 0–7.
- 14 f) Priority Code Point value for priority 2 with drop\_eligible True: Integer in range 0–7.
- 15 g) Priority Code Point value for priority 3 with drop\_eligible False: Integer in range 0–7.
- 16 h) Priority Code Point value for priority 3 with drop\_eligible True: Integer in range 0–7.
- 17 i) Priority Code Point value for priority 4 with drop\_eligible False: Integer in range 0–7.
- 18 j) Priority Code Point value for priority 4 with drop\_eligible True: Integer in range 0–7.
- 19 k) Priority Code Point value for priority 5 with drop\_eligible False: Integer in range 0–7.
- 20 l) Priority Code Point value for priority 5 with drop\_eligible True: Integer in range 0–7.
- 21 m) Priority Code Point value for priority 6 with drop\_eligible False: Integer in range 0–7.
- 22 n) Priority Code Point value for priority 6 with drop\_eligible True: Integer in range 0–7.
- 23 o) Priority Code Point value for priority 7 with drop\_eligible False: Integer in range 0–7.
- 24 p) Priority Code Point value for priority 7 with drop\_eligible True: Integer in range 0–7.

## 25 12.16.4.10 Set PIP Priority Code Point Encoding Table (optional)

### 26 12.16.4.10.1 Purpose

27 To modify the contents of a row in the Priority Code Point Encoding Table (6.10.3) for a PIP.

### 28 12.16.4.10.2 Inputs

- 29 a) PIP Index—an identifier for this PIP.
- 30 b) Priority Code Point Row. This takes one of the following values:
  - 31 1) 8P0D
  - 32 2) 7P1D
  - 33 3) 6P2D
  - 34 4) 5P3D
- 35 c) Priority Code Point value for priority 0 with drop\_eligible False: Integer in range 0–7.
- 36 d) Priority Code Point value for priority 0 with drop\_eligible True: Integer in range 0–7.
- 37 e) Priority Code Point value for priority 1 with drop\_eligible False: Integer in range 0–7.
- 38 f) Priority Code Point value for priority 1 with drop\_eligible True: Integer in range 0–7.
- 39 g) Priority Code Point value for priority 2 with drop\_eligible False: Integer in range 0–7.
- 40 h) Priority Code Point value for priority 2 with drop\_eligible True: Integer in range 0–7.
- 41 i) Priority Code Point value for priority 3 with drop\_eligible False: Integer in range 0–7.
- 42 j) Priority Code Point value for priority 3 with drop\_eligible True: Integer in range 0–7.
- 43 k) Priority Code Point value for priority 4 with drop\_eligible False: Integer in range 0–7.
- 44 l) Priority Code Point value for priority 4 with drop\_eligible True: Integer in range 0–7.
- 45 m) Priority Code Point value for priority 5 with drop\_eligible False: Integer in range 0–7.
- 46 n) Priority Code Point value for priority 5 with drop\_eligible True: Integer in range 0–7.

- 1 o) Priority Code Point value for priority 6 with drop\_eligible False: Integer in range 0–7.
- 2 p) Priority Code Point value for priority 6 with drop\_eligible True: Integer in range 0–7.
- 3 q) Priority Code Point value for priority 7 with drop\_eligible False: Integer in range 0–7.
- 4 r) Priority Code Point value for priority 7 with drop\_eligible True: Integer in range 0–7.

#### 5 **12.16.4.10.3 Outputs**

6 None.

#### 7 **12.16.4.11 Read PIP Use\_DEI parameter**

##### 8 **12.16.4.11.1 Purpose**

9 To read the current state of the Use\_DEI parameter (6.10.3) for the PIP.

##### 10 **12.16.4.11.2 Inputs**

- 11 a) PIP Index—an identifier for this PIP.

##### 12 **12.16.4.11.3 Outputs**

- 13 a) Use\_DEI parameter: Boolean.

#### 14 **12.16.4.12 Set PIP Use\_DEI parameter (optional)**

##### 15 **12.16.4.12.1 Purpose**

16 To set the current state of the Use\_DEI parameter (6.10.3) for the PIP.

##### 17 **12.16.4.12.2 Inputs**

- 18 a) PIP Index: an identifier for this PIP.
- 19 b) Use\_DEI parameter: Boolean.

##### 20 **12.16.4.12.3 Outputs**

21 None.

#### 22 **12.16.4.13 Read PIP Require Drop Encoding parameter**

##### 23 **12.16.4.13.1 Purpose**

24 To read the current state of the Require Drop Encoding parameter (8.6.6) for the PIP.

##### 25 **12.16.4.13.2 Inputs**

- 26 a) PIP Index—an identifier for this PIP.

##### 27 **12.16.4.13.3 Outputs**

- 28 a) Require Drop Encoding parameter—Boolean.

#### 29 **12.16.4.14 Set PIP Require Drop Encoding parameter (optional)**

##### 30 **12.16.4.14.1 Purpose**

31 To set the current state of the Require Drop Encoding parameter (8.6.6) for the PIP.

#### 1 **12.16.4.14.2 Inputs**

- 2 a) PIP Index—an identifier for this PIP.
- 3 b) Require Drop Encoding parameter—Boolean.

#### 4 **12.16.4.14.3 Outputs**

5 None.

#### 6 **12.16.5 CBP Configuration managed object**

7 The CBP Configuration managed object includes the following:

- 8 a) A Backbone Service Instance table (6.11)
- 9 b) A Flow Filtering Control Table (44.2.2)

10 Item b) is applicable only on BEBs supporting ECMP with flow filtering.

11 The management operations that can be performed are as follows:

- 12 c) Read Backbone Service Instance table entry (12.16.5.1)
- 13 d) Set Backbone Service Instance table entry (12.16.5.2)
- 14 e) TESI assignment managed object (12.16.5.3)
- 15 f) Read Flow Filtering Control Table entry (12.16.5.4)
- 16 g) Set Flow Filtering Control Table entry (12.16.5.5)

#### 17 **12.16.5.1 Read Backbone Service Instance table entry**

##### 18 **12.16.5.1.1 Purpose**

19 All BEBs shall implement the read Backbone Service Instance table entry function to allow reading the  
20 Backbone Service Instance table entries in the CBP configuration managed object.

##### 21 **12.16.5.1.2 Inputs**

- 22 a) ComponentID—the number identifying the Bridge Component associated with this port.
- 23 b) Port Number—that component's Port Number for the Bridge Port.
- 24 c) Backbone-SID—identifying the backbone service instance (6.11).

##### 25 **12.16.5.1.3 Outputs**

- 26 a) ComponentID—the number identifying the Bridge Component associated with this port.
- 27 b) Port Number—that component's Port Number for the Bridge Port.
- 28 c) Backbone-SID—the identifier used in the PBBN for the backbone service instance (6.11).
- 29 d) B-VID (optional)—12-bit VID (6.11).
- 30 e) Default Backbone Destination (optional)—EUI-48 DA (6.11).
- 31 f) Local-SID (optional)—24-bit I-SID value (6.11).

## 12.16.5.2 Set Backbone Service Instance table entry

### 12.16.5.2.1 Purpose

All BEBs shall implement the set Backbone Service Instance table entry function to allow configuration of the backbone service instances available on each CBP. This information is persistent over power-up or reboot.

### 12.16.5.2.2 Inputs

- a) ComponentID—the number identifying the Bridge Component associated with this port.
- b) Port Number—that component's Port Number for the Bridge Port.
- c) Backbone-SID—24-bit I-SID value (6.11).
- d) B-VID (optional)—12-bit VID (6.11).
- e) Default Backbone Destination (optional)—EUI-48 DA (6.11).
- f) Local-SID (optional)—24-bit I-SID value (6.11).

### 12.16.5.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because the ComponentID and Port Number do not identify a valid CBP.
  - 2) Operation rejected because the B-VID is assigned to ECMP with flow filtering (12.25.4.1, Table 44-1) and the Bridge does not support flow filtering.
  - 3) Operation accepted.

## 12.16.5.3 TESI assignment managed object

### 12.16.5.3.1 Purpose

All CBPs providing TESI shall implement the TESI assignment managed object to assign a particular TESI on this CBP.

### 12.16.5.3.2 Inputs

- a) ComponentID—the number identifying the Bridge Component associated with this port.
- b) Port Number—that component's Port Number for the Bridge Port.
- c) A series of ordered 3-tuples of the form <ESP-DA, ESP-SA, ESP-VID>.

### 12.16.5.3.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because the ComponentID and Port Number do not identify a valid CBP.
  - 2) Operation rejected because a 3-tuple in the provided series has a VID value in its ESP-VID field that is not allocated to TE-MSTID.
  - 3) Operation rejected because no 3-tuple in the provided series has the CBP's MAC address in its ESP-SA field.
  - 4) Operation rejected because there are only two 3-tuples provided and the values in their ESP-DA and ESP-SA fields are not reversed.
  - 5) Operation rejected because there are more than two different values specified in the ESP-DA fields of the provided series of 3-tuples.
  - 6) Operation accepted.

## 1 12.16.5.4 Read Flow Filtering Control Table entry

### 2 12.16.5.4.1 Purpose

3 BEBs supporting ECMP with flow filtering shall implement the read Flow Filtering Control Table entry  
4 function to allow reading the Flow Filtering Control Table entries in the CBP configuration managed object.

### 5 12.16.5.4.2 Inputs

- 6 a) ComponentID—the number identifying the Bridge Component associated with this port.
- 7 b) Port Number—that component's Port Number for the Bridge Port.
- 8 c) VID—identifying a B-VID.

### 9 12.16.5.4.3 Outputs

- 10 a) Operation status. This takes one of the following values:
  - 11 1) Operation rejected because the ComponentID and Port Number do not identify a valid CBP
  - 12 2) Operation rejected because the CBP does not support F-TAG processing
  - 13 3) Operation accepted
- 14 b) ComponentID—the number identifying the Bridge Component associated with this port.
- 15 c) Port Number—that component's Port Number for the Bridge Port.
- 16 d) VID—the identifier of a B-VLAN.
- 17 e) Flow Filtering—indicates whether flow filtering behavior is enabled on the port for the VID  
18 (enabled/disabled).
- 19 f) Flow Hash Generation—indicates whether flow hash generation is enabled on the port for the VID  
20 (enabled/disabled).
- 21 g) TTL Value—the initial TTL value for frames entering the flow filtering SPT Domain (1..63).

## 22 12.16.5.5 Set Flow Filtering Control Table entry

### 23 12.16.5.5.1 Purpose

24 BEBs supporting ECMP with flow filtering shall implement the set Flow Filtering Control Table entry  
25 function to allow configuration of the initial TTL value for frames entering an SPT Domain. This  
26 information is persistent over power-up or reboot.

### 27 12.16.5.5.2 Inputs

- 28 a) ComponentID—the number identifying the Bridge Component associated with this port.
- 29 b) Port Number—that component's Port Number for the Bridge Port.
- 30 c) VID—12-bit VID.
- 31 d) TTL Value—the initial TTL value for frames entering the SPT Domain, Integer in range 1–63. The  
32 default value is 8.

33 NOTE—The Flow Filtering and Flow Hash Generation fields in the Flow Filtering Control Table are controlled by  
34 ISIS-SPB (28.8) and therefore are not settable by management.

### 35 12.16.5.5.3 Outputs

- 36 a) Operation status. This takes one of the following values:
  - 37 1) Operation rejected because the ComponentID and Port Number do not identify a valid CBP
  - 38 2) Operation rejected because the CBP does not support F-TAG processing
  - 39 3) Operation accepted

## 12.17 DDCFM entities

The following are the DDCFM managed objects in a Bridge:

- a) DDCFM Stack managed object (12.17.1)
- b) Reflection Responder managed object (12.17.2)
- c) RFM Receiver managed object (12.17.3)
- d) Decapsulator Responder managed object (12.17.4)
- e) SFM Originator managed object (12.17.5)

### 12.17.1 DDCFM Stack managed object

There is one DDCFM Stack managed object per Bridge. It allows the network administrator to retrieve DDCFM entities configured on a particular Bridge Port or an aggregated port within a Bridge Port. The management operation that can be performed is as follows:

- a) Read DDCFM Stack managed object (12.17.1.1)

#### 12.17.1.1 Read DDCFM Stack managed object

##### 12.17.1.1.1 Purpose

To retrieve DDCFM entities configured on a particular Bridge Port or an aggregated port within a Bridge Port.

##### 12.17.1.1.2 Input

- a) An interface, either a Bridge Port, or an aggregated port within a Bridge Port.

##### 12.17.1.1.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because of invalid reference to an interface;
  - 2) Operation accepted, but there is no DDCFM entity configured on the specified interface; or
  - 3) Operation accepted, there are (is a) DDCFM entities (entity) configured on the specified interface, and
- b) If there are DDCFM entities configured on the specified interface, the following attributes should be returned:
  - 1) An RR is configured, its associated maintenance domain, and the value indicating its direction; and/or
  - 2) An RFM Receiver is configured, its associated maintenance domain; and/or
  - 3) A DR is configured, its associated maintenance domain, and its associated MA; and/or
  - 4) An SFM Originator is configured, its associated maintenance domain, its associated MA, and the value indicating its direction.

### 12.17.2 Reflection Responder managed object

The management operations that can be performed on the Reflection Responder managed object are as follows:

- a) Create Reflection Responder managed object (12.17.2.1)
- b) Write Reflection Responder managed object's attributes (12.17.2.2)
- c) Read Reflection Responder managed object's attributes (12.17.2.3)
- d) Delete Reflection Responder managed object (12.17.2.4)

- 1 e) Activate Reflection Responder (12.17.2.5)
- 2 f) Deactivate Reflection Responder (12.17.2.6)

### 3 **12.17.2.1 Create Reflection Responder managed object**

#### 4 **12.17.2.1.1 Purpose**

5 To create a Reflection Responder (RR). After the creation, all the writable attributes have their default  
6 values unless being configured differently by the Write Reflection Responder managed object operation  
7 (12.17.2.2). The RR is in the inactive state after the creation and remains so until activated by a subsequent  
8 Activate Reflection Responder operation (12.17.2.5).

#### 9 **12.17.2.1.2 Inputs**

- 10 a) A reference to a particular Reflection Responder managed object, which includes the following:
  - 11 1) An interface (either a Bridge Port or an aggregated port within a Bridge Port) on which the RR
  - 12 is defined. The interface identifier could be MAC address or port identifier.
  - 13 2) A reference to a particular Maintenance Domain managed object (12.14.5).
  - 14 3) A value indicating the direction in which the RR faces, which can be either Down [Active SAP
  - 15 is further away from the Frame filtering entity (default)], or Up (Active SAP is closer to the
  - 16 Frame filtering entity).

#### 17 **12.17.2.1.3 Outputs**

- 18 a) Operation status. This takes one of the following values:
  - 19 1) Operation rejected because of invalid interface reference or invalid Maintenance Domain level
  - 20 2) Operation accepted

### 21 **12.17.2.2 Write Reflection Responder managed object's attributes**

#### 22 **12.17.2.2.1 Purpose**

23 To configure and alter the value of one or more writable attribute(s) of an Reflection Responder managed  
24 object. The attributes of an Reflection Responder managed object cannot be modified when the RR is active.

#### 25 **12.17.2.2.2 Inputs**

- 26 a) Reference to a Reflection Responder managed object [item a) in 12.17.2.1.2].
- 27 b) Writable attributes are as follows:
  - 28 1) Reference to a Maintenance Association managed object (12.14.6) within the RR's
  - 29 Maintenance Domain. If set to 0, the MA associated with the filtered frame shall be used for the
  - 30 Reflected Frame Message (RFM) emitted by the RR.
  - 31 2) Reflection Filter definition(s), which is to specify what data frames are selected to be reflected.
  - 32 Multiple filters can be combined together by "&& (and)", "|| (or)", or "!(negation)" operations
  - 33 with precedence association being determined by "()." DDCFM-capable Bridges shall support
  - 34 each of the following filter primitives. Implementers may support additional filters, such as
  - 35 length of data frame being equal, larger, or smaller than a particular value.
  - 36 —All.
  - 37 —VID== vid; This primitive uses SVID if the RR is defined on a S Component, and CVID if
  - 38 the RR is defined on a C Component. Untagged frame shall not be selected by this filter
  - 39 primitive.
  - 40 —DA == xx.xx.xx.xx.xx.xx.
  - 41 —SA == xx.xx.xx.xx.xx.xx.
  - 42 —The first 2 bytes of the EtherType field ==xx.

- 1 3) Sampling Interval (29.2.3.4).
- 2 4) Reflection Target Address, which is a MAC address to which the reflected frames are targeted.
- 3 Only individual address is allowed for the Reflection Target Address. The default is the
- 4 source\_address of the selected data frame being used for Reflection Target Address.
- 5 5) Continue option, indicating whether the selected data frames are to be continued toward the
- 6 destination\_address specified in the data frame. The default is TRUE to allow data frames to be
- 7 forwarded to their destinations.
- 8 6) Boolean variable indicating if the duration is in seconds or in number of data frames.
- 9 7) Duration in seconds for the RR to remain active after being activated. Minimum 1 and
- 10 maximum is implementation dependent.
- 11 8) The number data frames for the RR to reflect after being activated. Once this frame count is
- 12 reached, the RR shall be deactivated automatically. Default is 0, which means the duration is
- 13 limited by RR's timer.
- 14 9) The priority and drop\_eligible parameters to be used in the transmitted encapsulated frames
- 15 (default value: the highest priority, i.e., that with the highest numerical value, allowed to pass
- 16 through the Bridge Port for any of the VID. Default value for drop\_eligible is FALSE).
- 17 10) FloodingEnabled Flag indicating whether flooding is allowed if Egress port cannot be
- 18 identified for RFM by the FDB.
- 19 11) Truncation flag indicating if the received data frame should be truncated to keep the length of
- 20 RFM encapsulated frame not exceeding the Maximum Service Data Unit Size (6.5.8). If the
- 21 Truncation flag is not set and the RFM encapsulated frame exceeds the Maximum Service Data
- 22 Unit Size, the filtered data frame is fragmented to two smaller frames and encapsulated in two
- 23 separate RFMs.

#### 24 **12.17.2.2.3 Outputs**

- 25 a) Operation status. This takes one of the following values:
- 26 1) Operation rejected because the referenced Reflection Responder managed object does not exist
- 27 2) Operation rejected because of one or more invalid writable attribute(s)
- 28 3) Operation rejected because the referenced RR is active
- 29 4) Operation accepted

#### 30 **12.17.2.3 Read Reflection Responder managed object's attributes**

##### 31 **12.17.2.3.1 Purpose**

32 To retrieve values of attributes in a Reflection Responder managed object.

##### 33 **12.17.2.3.2 Input**

- 34 a) Reference to a particular Reflection Responder managed object [item a) in 12.17.2.1.2].

##### 35 **12.17.2.3.3 Outputs**

- 36 a) Operation status. This takes one of the following values:
- 37 1) Operation rejected because of invalid reference to the Reflection Responder managed object
- 38 2) Operation rejected because there is no RR with the given reference
- 39 3) Operation accepted
- 40 b) If the operation is accepted, the following attributes for the RR should be returned:
- 41 1) Reference to the Reflection Responder managed object.
- 42 2) Reference to a Maintenance Association managed object (12.14.6) for the RFMs generated by
- 43 the RR (writable).
- 44 3) Reflection Filter definition(s) (writable).
- 45 4) Sampling Interval (writable).

- 1        5) The Reflection Target Address (writable).
- 2        6) Continue option (writable).
- 3        7) Duration for RR to stay active after being activated (writable).
- 4        8) DurationInTimeFlag (writable).
- 5        9) The priority and drop\_eligible parameters to be used in the transmitted RFMs (writable).
- 6        10) FloodingFlag (writable).
- 7        11) Truncation flag (writable).
- 8        12) Activation status (TRUE or FALSE).
- 9        13) Remaining time or count left for the RR to be active.
- 10       14) nextRFMtransID (29.3.1.16) value.

## 11 **12.17.2.4 Delete Reflection Responder managed object**

### 12 **12.17.2.4.1 Purpose**

13 To delete a Reflection Responder managed object. If the corresponding RR is still active, the deletion will  
14 deactivate the RR and then delete the corresponding managed object.

### 15 **12.17.2.4.2 Input**

- 16    a) Reference to a Reflection Responder managed object [item a) in 12.17.2.1.2].

### 17 **12.17.2.4.3 Outputs**

- 18    a) Operation status. This takes one of the following values:
- 19        1) Operation rejected because of invalid reference to RR
  - 20        2) Operation rejected because the referenced RR managed does not exist
  - 21        3) Operation accepted

## 22 **12.17.2.5 Activate Reflection Responder**

### 23 **12.17.2.5.1 Purpose**

24 To activate an RR.

25 Depending on the filter conditions specified for each RR, some RRs can potentially reflect large amount of  
26 data frames into the network, which could cause excessive extra traffic injected into the network and impact  
27 network performance. For those RRs, it is recommended that no more than one instance of the Reflection  
28 Responder managed object be activated per MD for an RR associated with an MP and that no more than one  
29 instance of the Reflection Responder managed object be activated per VID for an RR not associated with an  
30 MP (e.g., for an RR created on a Bridge Port).

### 31 **12.17.2.5.2 Inputs**

- 32    a) Reference to a Reflection Responder managed object [item a) in 12.17.2.1.2].

### 33 **12.17.2.5.3 Outputs**

- 34    a) Operation status. This takes one of the following values:
- 35        1) Operation rejected because invalid reference or the referenced RR does not exist
  - 36        2) Operation rejected because of the referenced RR already being activated
  - 37        3) Operation accepted

## 1 **12.17.2.6 Deactivate Reflection Responder**

### 2 **12.17.2.6.1 Purpose**

3 To deactivate an active RR before its duration expires.

### 4 **12.17.2.6.2 Input**

- 5 a) Reference to a Reflection Responder managed object [item a) in 12.17.2.1.2].

### 6 **12.17.2.6.3 Outputs**

- 7 a) Operation status. This takes one of the following values:
- 8 1) Operation rejected because invalid reference or the referenced RR does not exist
  - 9 2) Operation rejected because of the referenced RR not being activated
  - 10 3) Operation accepted

## 11 **12.17.3 RFM Receiver managed object**

12 The management operations that can be performed on the RFM Receiver managed object are as follows:

- 13 a) Create RFM Receiver managed object (12.17.3.1)
- 14 b) Delete RFM Receiver managed object (12.17.3.2)

15 An RFM Receiver is active when the corresponding RFM Receiver managed object is created. Therefore,  
16 there is no “Activate and Deactivate” operations for the RFM Receiver managed object.

## 17 **12.17.3.1 Create RFM Receiver managed object**

### 18 **12.17.3.1.1 Purpose**

19 To create an RFM Receiver managed object. Once an RFM Receiver managed object is created, the  
20 corresponding RFM Receiver is able to receive RFMs.

### 21 **12.17.3.1.2 Inputs**

- 22 a) Reference to an RFM Receiver managed object, which could be either:
- 23 1) Reference to an MP or
  - 24 2) An interface (either a Bridge Port or an aggregated port within a Bridge Port) on which RFM  
25 Receiver is created and a reference to the corresponding RR’s Maintenance Domain managed  
26 object.

### 27 **12.17.3.1.3 Outputs**

- 28 a) Operation status. This takes one of the following values:
- 29 1) Operation rejected because of invalid reference to the RFM Receiver managed object
  - 30 2) Operation rejected because the referenced RFM Receiver managed object already exists
  - 31 3) Operation accepted

## 32 **12.17.3.2 Delete RFM Receiver managed object**

### 33 **12.17.3.2.1 Purpose**

34 To delete an RFM Receiver managed object.

### 1 12.17.3.2.2 Input

- 2 a) Reference to an RFM Receiver managed object [item a) in 12.17.3.1.2].

### 3 12.17.3.2.3 Outputs

- 4 a) Operation status. This takes one of the following values:
- 5 1) Operation rejected because of invalid reference to the RFM Receiver managed object
  - 6 2) Operation rejected because the referenced RFM Receiver managed object does not exist
  - 7 3) Operation accepted

## 8 12.17.4 Decapsulator Responder managed object

9 The management operations that can be performed on the Decapsulator Responder managed object are as  
10 follows:

- 11 a) Create Decapsulator Responder managed object (12.17.4.1)
- 12 b) Read Decapsulator Responder managed object (12.17.4.2)
- 13 c) Write Decapsulator Responder managed object's attributes (12.17.4.3)
- 14 d) Delete Decapsulator Responder managed object (12.17.4.4)
- 15 e) Activate Decapsulator Responder (12.17.4.5)
- 16 f) Deactivate Decapsulator Responder (12.17.4.6)

### 17 12.17.4.1 Create Decapsulator Responder managed object

#### 18 12.17.4.1.1 Purpose

19 To create a Decapsulator Responder managed object and corresponding Decapsulator Responder (DR).

#### 20 12.17.4.1.2 Inputs

- 21 a) Reference to a DR, which could be either:
- 22 1) Reference to an MP or
  - 23 2) A triple consisting of an interface (either a Bridge Port or an aggregated port within a Bridge
  - 24 Port), a reference to a Maintenance Domain managed object, and a reference to a Maintenance
  - 25 Association managed object.

#### 26 12.17.4.1.3 Outputs

- 27 a) Operation status. This takes one of the following values:
- 28 1) Operation rejected because of invalid reference to a Decapsulator Responder managed object.
  - 29 2) Operation rejected because the referenced Decapsulator Responder managed object already
  - 30 exists.
  - 31 3) Operation accepted.

### 32 12.17.4.2 Read Decapsulator Responder managed object

#### 33 12.17.4.2.1 Purpose

34 To retrieve the attributes of a Decapsulator Responder managed object.

#### 35 12.17.4.2.2 Input

- 36 a) Reference to a Decapsulator Responder managed object [item a) in 12.17.4.1.2].

### 12.17.4.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because of invalid reference to a Decapsulator Responder managed object.
  - 2) Operation rejected because the referenced Decapsulator Responder managed object does not exist.
  - 3) Operation accepted.
- b) If the operation is accepted, the following attributes for the DR should be returned:
  - 1) Reference to the Decapsulator Responder managed object.
  - 2) MAC address of the SFM Originator (writable).
  - 3) The value of SourceAddressStayFlag (writable).
  - 4) The value of FloodingEnabled flag (writable).
  - 5) The specified duration in seconds, for DR to remain active once activated (writable).
  - 6) Activation status.
  - 7) Remaining time left for DR to be active.
  - 8) The total number of out-of-sequence SFMs received (29.3.8.7).

### 12.17.4.3 Write Decapsulator Responder managed object's attributes

#### 12.17.4.3.1 Purpose

To alter the value of one or more attributes of a Decapsulator Responder managed object when the corresponding DR is not active.

#### 12.17.4.3.2 Inputs

- a) Reference to a Decapsulator Responder managed object [item a) in 12.17.4.1.2].
- b) Reference to the attribute whose value is to be changed:
  - 1) Boolean flag, SourceAddressStayFlag, to enforce the DR not to replace the source\_address field of the decapsulated frame with the DR's own MAC address. Default is FALSE.
  - 2) MAC address of the SFM Originator, which is optional.
  - 3) Boolean FloodingEnabled flag indicating if flooding is allowed (TRUE) or not (FALSE) if the Egress port cannot be identified by the FDB.
  - 4) Duration in seconds, for DR to remain active once activated.

#### 12.17.4.3.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because of invalid reference to a Decapsulator Responder managed object.
  - 2) Operation rejected because the referenced Decapsulator Responder managed object does not exist.
  - 3) Operation rejected because of invalid attribute reference or invalid value.
  - 4) Operation rejected because the referenced DR is active.
  - 5) Operation accepted.

### 12.17.4.4 Delete Decapsulator Responder managed object

#### 12.17.4.4.1 Purpose

To delete a Decapsulator Responder managed object. If the DR is still active, the deletion will deactivate the DR first and then delete the corresponding managed object.

1 **12.17.4.4.2 Input**

- 2 a) Reference to a Decapsulator Responder managed object [item a) in 12.17.4.1.2].

3 **12.17.4.4.3 Outputs**

- 4 a) Operation status. This takes one of the following values:
- 5 1) Operation rejected because of invalid reference to a Decapsulator Responder managed object.
  - 6 2) Operation rejected because the referenced Decapsulator Responder managed object does not
  - 7 exist.
  - 8 3) Operation accepted.

9 **12.17.4.5 Activate Decapsulator Responder**

10 **12.17.4.5.1 Purpose**

11 To activate a DR.

12 **12.17.4.5.2 Input**

- 13 a) Reference to the Decapsulator Responder managed object [item a) in 12.17.4.1.2].

14 **12.17.4.5.3 Outputs**

- 15 a) Operation status. This takes one of the following values:
- 16 1) Operation rejected because of invalid reference.
  - 17 2) Operation rejected because the referenced Decapsulator Responder managed object does not
  - 18 exist.
  - 19 3) Operation rejected because the referenced DR has already been activated.
  - 20 4) Operation accepted.

21 **12.17.4.6 Deactivate Decapsulator Responder**

22 **12.17.4.6.1 Purpose**

23 To deactivate a DR.

24 **12.17.4.6.2 Input**

- 25 a) Reference to the Decapsulator Responder managed object [item a) in 12.17.4.1.2].

26 **12.17.4.6.3 Outputs**

- 27 a) Operation status. This takes one of the following values:
- 28 1) Operation rejected because of invalid reference.
  - 29 2) Operation rejected because the referenced Decapsulator Responder managed object does not
  - 30 exist.
  - 31 3) Operation rejected because the referenced DR is not active.
  - 32 4) Operation accepted.

33 **12.17.5 SFM Originator managed object**

34 The management operations that can be performed on the SFM Originator managed object are as follows:

- 35 a) Create SFM Originator managed object (12.17.5.1)
- 36 b) Read SFM Originator managed object (12.17.5.2)
- 37 c) Delete SFM Originator managed object (12.17.5.3)

- 1 d) Write SFM Originator managed object's attributes (12.17.5.4)
- 2 e) Activate SFM Originator (12.17.5.5)
- 3 f) Deactivate SFM Originator (12.17.5.6)

#### 4 **12.17.5.1 Create SFM Originator managed object**

##### 5 **12.17.5.1.1 Purpose**

6 To create a SFM Originator managed object.

##### 7 **12.17.5.1.2 Inputs**

- 8 a) Reference to a SFM Originator managed object, which could be either:
  - 9 1) Reference to an MP or
  - 10 2) An interface (either a Bridge Port, or an aggregated port within a Bridge Port), a reference to a
  - 11 Maintenance Domain managed object, a reference to a Maintenance Association managed
  - 12 object, and a value indicating the direction in which the SFM Originator faces on the interface.

##### 13 **12.17.5.1.3 Outputs**

- 14 a) Operation status. This takes one of the following values:
  - 15 1) Operation rejected because of invalid reference
  - 16 2) Operation rejected because the referenced SFM Originator managed object already exists
  - 17 3) Operation accepted

#### 18 **12.17.5.2 Read SFM Originator managed object**

##### 19 **12.17.5.2.1 Purpose**

20 To retrieve attributes of SFM Originator managed object.

##### 21 **12.17.5.2.2 Inputs**

- 22 a) Reference to a SFM Originator managed object [item a) in 12.17.5.1.2].

##### 23 **12.17.5.2.3 Outputs**

- 24 a) Operation status. This takes one of the following values:
  - 25 1) Operation rejected because of invalid reference
  - 26 2) Operation rejected because the referenced SFM Originator managed object does not exist
  - 27 3) Operation accepted
- 28 b) If the operation is accepted, following attributes for the SFM Originator should be returned:
  - 29 1) MAC address of the SFM Originator
  - 30 2) MAC address of the corresponding DR (writable)
  - 31 3) Duration (writable)
  - 32 4) Activation status: TRUE/FALSE
  - 33 5) The remaining time left for the SFM Originator to remain active

#### 34 **12.17.5.3 Delete SFM Originator managed object**

##### 35 **12.17.5.3.1 Purpose**

36 To delete a SFM Originator managed object, and the corresponding SFM Originator.

1 **12.17.5.3.2 Inputs**

- 2 a) The reference to a SFM Originator managed object [item a) in 12.17.5.1.2].

3 **12.17.5.3.3 Outputs**

- 4 a) Operation status. This takes one of the following values:  
5 1) Operation rejected because of invalid reference  
6 2) Operation rejected because the referenced SFM Originator managed object does not exist  
7 3) Operation accepted

8 **12.17.5.4 Write SFM Originator managed object's attribute**

9 **12.17.5.4.1 Purpose**

10 To change an attribute of a SFM Originator managed object.

11 **12.17.5.4.2 Inputs**

- 12 a) Reference to a SFM Originator managed object [item a) in 12.17.5.1.2].  
13 b) MAC address of the corresponding DR.  
14 c) Duration in seconds, for SFM Originator to stay active once activated.

15 **12.17.5.4.3 Outputs**

- 16 a) Operation status. This takes one of the following values:  
17 1) Operation rejected because of invalid reference of SFM Originator managed object or the  
18 attributes.  
19 2) Operation rejected because the referenced SFM Originator managed object does not exist.  
20 3) Operation accepted.

21 **12.17.5.5 Activate SFM Originator**

22 **12.17.5.5.1 Purpose**

23 To activate a SFM Originator.

24 **12.17.5.5.2 Input**

- 25 a) Reference to the SFM Originator managed object [item a) in 12.17.5.1.2].

26 **12.17.5.5.3 Outputs**

- 27 a) Operation status. This takes one of the following values:  
28 1) Operation rejected because of invalid reference  
29 2) Operation rejected because the referenced SFM Originator managed object does not exist  
30 3) Operation rejected because the referenced SFM Originator has already been activated  
31 4) Operation accepted

32 **12.17.5.6 Deactivate SFM Originator**

33 **12.17.5.6.1 Purpose**

34 To deactivate a SFM Originator.

### 12.17.5.6.2 Input

- a) Reference to a SFM Originator managed object [item a) in 12.17.5.1.2].

### 12.17.5.6.3 Output

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because of invalid reference
  - 2) Operation rejected because the referenced SFM Originator managed object does not exist
  - 3) Operation rejected because the referenced SFM Originator is not active
  - 4) Operation accepted

## 12.18 PBB-TE Protection Switching managed objects

The PBB-TE Protection Switching managed objects model operations that create, modify, delete, or inquire about, the configuration and the operation of protection switching. The following are the PBB-TE Protection Switching managed objects in a B-Component of an IB-BEB capable of supporting TESIs:

- a) The TE protection group list managed object
- b) The TE protection group managed object

### 12.18.1 TE protection group list managed object

There is one TE protection group list managed object per IB-BEB. It contains a list of the TE protection groups that have been configured on the IB-BEB.

The management operations that can be performed on the TE protection group list managed object are as follows:

- a) Read TE protection group list
- b) Create TE protection group managed object
- c) Delete TE protection group managed object

#### 12.18.1.1 Read TE protection group list

##### 12.18.1.1.1 Purpose

To obtain information about all of the TE protection groups in an IB-BEB.

##### 12.18.1.1.2 Inputs

None.

##### 12.18.1.1.3 Outputs

A list, perhaps empty, of the TE protection group managed objects configured on the IB-BEB. For each item in the list, the Read TE protection group list command returns:

- a) A reference to a particular Maintenance Association managed object (12.14.6) identifying a PBB-TE MA that corresponds to the group's working entity.
- b) A reference to a particular Maintenance Association managed object (12.14.6) identifying a PBB-TE MA with the same endpoints as the one provided in item b) that corresponds to the group's protection entity.
- c) A reference to all TE protection group managed objects (12.18.2) that share a working or protection entity with the TE protection group in the list.

## 1 12.18.1.2 Create TE protection group managed object

### 2 12.18.1.2.1 Purpose

3 To create a new TE protection group managed object in an IB-BEB and add it to the IB-BEB's TE protection  
4 group list managed object.

### 5 12.18.1.2.2 Inputs

- 6 a) A reference to a particular Maintenance Association managed object (12.14.6) identifying a  
7 PBB-TE MA that corresponds to the working entity.
- 8 b) A reference to a particular Maintenance Association managed object identifying a PBB-TE MA  
9 with the same endpoints as the one provided in item a) that will monitor the protection entity.

### 10 12.18.1.2.3 Outputs

- 11 a) Operation status. This takes one of the following values:
  - 12 1) Operation rejected due to nonexistent Maintenance Domain.
  - 13 2) Operation rejected due to nonexistent MAs.
  - 14 3) Operation rejected because the referred MAs do not correspond to PBB-TE services.
  - 15 4) Operation rejected because the two referred MAs do not have the same endpoints.
  - 16 5) Operation rejected because the two referred MAs do not belong to the same MD.
  - 17 6) Operation rejected due to duplicate MAs.
  - 18 7) Operation accepted. In addition, the list, perhaps empty, of the TE protection group managed  
19 objects (12.18.2) that share a working or protection entity with the created TE protection group  
20 is provided.

## 21 12.18.1.3 Delete TE protection group managed object

### 22 12.18.1.3.1 Purpose

23 To delete a specific TE protection group managed object from an IB-BEB and from the IB-BEB's TE  
24 protection group list managed object.

### 25 12.18.1.3.2 Inputs

- 26 a) A reference to a particular TE protection group managed object (12.18.2).

### 27 12.18.1.3.3 Outputs

- 28 a) Operation status. This takes one of the following values:
  - 29 1) Operation rejected due to nonexistent TE protection group
  - 30 2) Operation rejected because the TE protection group is enabled
  - 31 3) Operation accepted

## 32 12.18.2 TE protection group managed object

33 There can be any number of TE protection group managed objects per IB-BEB, one for each working and  
34 protection pair of TESIs with common endpoints.

35 The management operations that can be performed on the TE protection group managed object are as  
36 follows:

- 37 a) Read TE protection group managed object
- 38 b) Write TE protection group managed object
- 39 c) TE protection group administrative commands managed object

## 1 12.18.2.1 Read TE protection group managed object

### 2 12.18.2.1.1 Purpose

3 To obtain information from an IB-BEB about a specific TE protection group managed object.

### 4 12.18.2.1.2 Inputs

- 5 a) A reference to a particular TE protection group managed object.

### 6 12.18.2.1.3 Outputs

- 7 a) Operation status. This takes one of the following values:
- 8 1) Operation rejected due to nonexistent TE protection group
- 9 2) Operation accepted
- 10 b) (writable) A list of Backbone-SIDs, identifying the protected backbone service instances, or NULL
- 11 indicating that no backbone service instances are assigned to the TE protection group and that the
- 12 TE protection group is disabled.
- 13 c) An enumerated value indicating the operational state of the Service Mapping state machine
- 14 (Figure 26-17) for each TE protection group:
- 15 1) WORKING\_PATH
- 16 2) PROTECTION\_PATH
- 17 3) WTR
- 18 4) PROT\_ADMIN
- 19 d) An enumerated value indicating the status of active requests within the TE protection group:
- 20 1) NoRequest: No administrative command is in effect.
- 22 2) LoP: Set if LoP (26.10.3.3.4) is TRUE, indicating that an administrative command to prohibit
- 24 the use of the protection entity is in effect.
- 25 3) FS: Set if FS (26.10.3.3.5) is TRUE, indicating that an administrative command to perform
- 27 forced switching to the protection path(s) is in effect.
- 28 4) p.SFH: Set if SFH (26.10.3.3.3) is TRUE on the protection entity.
- 30 5) w.SFH: Set if SFH is TRUE on the working entity.
- 32 6) MStoProtection: Set if MStoProtection (26.10.3.3.6) is TRUE, indicating that an administrative
- 34 command to perform manual switching to the protection path(s) is in effect.
- 35 7) MStoWorking: Set if MStoWorking (26.10.3.3.7) is TRUE, indicating that an administrative
- 37 command to perform manual switching to the working path is in effect.
- 38 e) (writable) (optional) The Wait-to-restore (WTR) period (26.10.3.3.8). In revertive operation it may
- 39 be configured in steps of 1 min between 5 min and 12 min; the default value is 5 min. The value 0
- 40 indicates nonrevertive operation.
- 41 f) (writable) (optional) The Hold-Off period (26.10.3.3.9). The range of the Hold-Off period is 0 s to
- 42 10 s in steps of 100 ms; the default value is 0.

## 43 12.18.2.2 Write TE protection group managed object

### 44 12.18.2.2.1 Purpose

45 To alter a value of a specific TE protection group managed object.

### 46 12.18.2.2.2 Inputs

- 47 a) A reference to a particular TE protection group managed object.
- 48 b) A reference to one of the writable managed objects in 12.18.2.1.3 that is to be altered.
- 49 c) A new value for the managed object.

### 12.18.2.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to nonexistent TE protection group
  - 2) Operation rejected due to the selected managed object being Read-Only
  - 3) Operation rejected due to lack of authority to set this variable
  - 4) Operation rejected due to invalid value for the selected managed object
  - 5) Operation accepted

### 12.18.2.3 TE protection group administrative commands managed object

#### 12.18.2.3.1 Purpose

To set an administrative command on a TE protection group managed object.

#### 12.18.2.3.2 Inputs

- a) A reference to a particular TE protection group managed object.
- b) An enumerated value indicating the exercised administrative command:
  - 1) Clear: An indication to clear all other administrative commands.
  - 2) Lockout of Protection: An administrative command to prohibit the use of the protection entity.
  - 3) Forced Switch: An administrative command to perform forced switching to the protection path(s).
  - 4) Manual Switch To Protection: An administrative command to perform manual switching to the protection path(s) if it is operational.
  - 5) Manual Switch To Working: An administrative command to perform manual switching to the working path if it is operational.

#### 12.18.2.3.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to nonexistent TE protection group
  - 2) Operation rejected due to lack of authority to set this variable
  - 3) Operation rejected due to an active higher priority request
  - 4) Operation accepted

### 12.19 TPMR managed objects

The managed resources of a TPMR, accessed via the TPMR management entity, are those of the processes and entities defined in this clause, and listed as follows:

- a) The TPMR management entity (12.19.1)
- b) The individual MAC and PHY entities associated with each TPMR Port
- c) The Forwarding Process of the MAC Relay Entity (8.6, 12.19.3)
- d) The MAC Status Propagation Entity (MSPE) (23.3, 12.19.4)

The management of each of these resources is described in terms of managed objects and operations in the following subclauses.

## 1 **12.19.1 TPMR management entity**

2 This managed resource comprises the following objects:

- 3 a) The TPMR Configuration (12.19.1.1)
- 4 b) The Port Configuration for each Port (12.19.1.2)

### 5 **12.19.1.1 TPMR configuration**

6 The TPMR configuration object models the operations that modify, or inquire about, the configuration of the  
7 TPMR's resources. There is a single TPMR configuration object per TPMR.

8 The management operations that can be performed on the TPMR configuration are as follows:

- 9 a) Read TPMR (12.19.1.1.1)
- 10 b) Set TPMR Name (12.19.1.1.2)

#### 11 **12.19.1.1.1 Read TPMR**

##### 12 **12.19.1.1.1.1 Purpose**

13 To obtain general information regarding the TPMR.

##### 14 **12.19.1.1.1.2 Inputs**

15 None.

##### 16 **12.19.1.1.1.3 Outputs**

- 17 a) TPMR Name—a text string of up to 32 characters, of locally determined significance.
- 18 b) TPMR MAC addresses—the MAC addresses of the two externally accessible TPMR Ports. The  
19 following information is returned for each Port:
  - 20 1) The Port number.
  - 21 2) The MAC address of the Port.
  - 22 3) A Boolean value, which is TRUE if the MAC address is the management address for the  
23 TPMR, and is otherwise FALSE.

24 NOTE 1—The TPMR management entity may make use of one or both Ports of a TPMR to transmit and receive  
25 management frames. However, the MAC address used by the TPMR management entity as the source MAC address in  
26 transmitted management frames (the management MAC address) is the individual MAC address associated with one of  
27 the Ports of the TPMR (a management Port, see 8.3, 8.5).

28 NOTE 2—As the transmission and reception rules for a TPMR (8.5.2) mean that frames forwarded by a TPMR are not  
29 received by higher layer entities on the forwarding Port, by receiving management frames on either Port the TPMR  
30 management entity can determine which LAN incoming management frames were transmitted on, as incoming frames  
31 are only presented to higher layer entities attached to the reception Port.

- 32 c) Uptime—count in seconds of the time elapsed since the TPMR was last reset or initialized.

#### 33 **12.19.1.1.2 Set TPMR Name**

##### 34 **12.19.1.1.2.1 Purpose**

35 To associate a text string, readable by the Read TPMR operation, with a TPMR.

##### 36 **12.19.1.1.2.2 Inputs**

- 37 a) TPMR Name—a text string of up to 32 characters.

##### 38 **12.19.1.1.2.3 Outputs**

39 None.

## 1 **12.19.1.2 Port configuration**

2 The Port Configuration object models the operations that modify, or inquire about, the configuration of the  
3 Ports of a TPMR. By definition there are two Ports per TPMR (one for each MAC interface), and each is  
4 identified by a permanently allocated Port number.

5 The management operations that can be performed on the Port Configuration are as follows:

- 6 a) Read Port (12.19.1.2.1)
- 7 b) Set Port Name (12.19.1.2.2)

### 8 **12.19.1.2.1 Read Port**

#### 9 **12.19.1.2.1.1 Purpose**

10 To obtain general information regarding a specific TPMR Port.

#### 11 **12.19.1.2.1.2 Inputs**

- 12 a) Port Number—the number of the Port. This parameter can take the integer values 1 and 2 only.

#### 13 **12.19.1.2.1.3 Outputs**

- 14 a) Port Name—a text string of up to 32 characters, of locally determined significance.
- 15 b) Port Type—the MAC Entity type of the Port (IEEE Std 802.3; ISO/IEC 8802-11; ISO 9314; other).
- 16 c) Management address forwarding status. This takes the value TRUE if forwarding is enabled for the  
17 management address on the Port or FALSE if forwarding is disabled for the management address on  
18 the Port (see 5.15).

### 19 **12.19.1.2.2 Set Port Name**

#### 20 **12.19.1.2.2.1 Purpose**

21 To associate a text string, readable by the Read Port operation, with a TPMR Port.

#### 22 **12.19.1.2.2.2 Inputs**

- 23 a) Port Number—the number of the Port. This parameter can take the integer values 1 and 2 only.
- 24 b) Port Name—a text string of up to 32 characters.

#### 25 **12.19.1.2.2.3 Outputs**

26 None.

## 27 **12.19.2 MAC and PHY entities**

28 The management operations and facilities provided by the MAC and PHY entities are those specified in the  
29 layer management standards of the individual MACs and PHYs. A MAC entity, and its underlying PHY  
30 entity, is associated with each TPMR Port.

## 31 **12.19.3 Forwarding Process**

32 The Forwarding Process contains information relating to the forwarding of frames. Counters are maintained  
33 that provide information on the number of frames forwarded, filtered, and dropped due to error.

34 This managed resource comprises the following objects:

- 35 a) The Port Counters (12.19.3.1)
- 36 b) Optionally, the Priority Handling objects for each Port (12.19.3.2)

- 1 c) Optionally, The Traffic Class Table for each Port (12.6.3)

### 2 **12.19.3.1 The Port Counters**

3 The Port Counters object models the operations that can be performed on the Port counters of the  
4 Forwarding Process resource. There is one instance of the Port Counters object for each MAC Entity per  
5 TPMR (i.e., two instances total).

6 The management operation that can be performed on the Port Counters is as follows:

- 7 a) Read Forwarding Port Counters (12.19.3.1.1)

#### 8 **12.19.3.1.1 Read forwarding port counters**

##### 9 **12.19.3.1.1.1 Purpose**

10 To read the forwarding counters associated with a specific TPMR Port.

##### 11 **12.19.3.1.1.2 Inputs**

- 12 a) Port Number—the number of the Port. This parameter can take the integer values 1 and 2 only.

##### 13 **12.19.3.1.1.3 Outputs**

- 14 a) Frames Received—count of all valid frames received on this Port (including BPDUs, frames  
15 addressed to the TPMR as an end station, and frames that were submitted to the Forwarding Process,  
16 8.6).
- 17 b) Octets Received—count of the total number of octets in all valid frames received on this Port  
18 (including BPDUs, frames addressed to the TPMR as an end station, and frames that were submitted  
19 to the Forwarding Process).
- 20 c) Frames Discarded by Forwarding Process—count of all frames that were received on this Port but  
21 were discarded by the Forwarding Process for any reason.
- 22 d) Frames Forwarded to Transmission Port—count of all frames that were received on this Port and  
23 were forwarded to the transmission Port (8.6.8).
- 24 e) Frames Discarded due to Queue Full—count of all frames received on this Port that were to be  
25 transmitted through the transmission Port but were discarded due to lack of available queue space  
26 (8.6.6, 8.6.7).
- 27 f) Frames Discarded Lifetime Exceeded—count of all frames received on this Port that were to be  
28 transmitted through the transmission Port but were discarded due to their frame lifetime having been  
29 exceeded (8.6.7).
- 30 g) Frames Discarded on Error—count of all frames received on this Port that were to be transmitted  
31 through the transmission Port but could not be transmitted (e.g., frame would be too large, 6.5.8).
- 32 h) Frame Discard on Error Details—a list of 16 elements, each containing the source address of a frame  
33 and the reason why the frame was discarded (e.g., frame too large). The list is maintained as a  
34 circular buffer. The reason for discard on error, at present, is as follows:
- 35 1) Transmissible SDU size exceeded

### 36 **12.19.3.2 Priority handling**

37 The Priority Handling object models the operations that can be performed on, or inquire about, the Default  
38 Priority parameter, the Priority Regeneration Table parameter, the Outbound Access Priority Table  
39 parameter, the Priority Code Point parameters, and the Service Access Priority parameters for each Port. The  
40 operations that can be performed on this object are as follows:

- 41 a) Read Port Default Priority (12.6.2.1)  
42 b) Set Port Default Priority (12.6.2.2)

- 1 c) Read Port Priority Regeneration Table (12.6.2.3)
- 2 d) Set Port Priority Regeneration Table (12.6.2.4)
- 3 e) Read Port Priority Code Point Selection (12.6.2.5)
- 4 f) Set Port Priority Code Point Selection (12.6.2.6)
- 5 g) Optionally, Read Port Priority Code Point Decoding Table (12.6.2.7)
- 6 h) Read Use\_DEI parameter (12.6.2.11)
- 7 i) Optionally, Set Use\_DEI parameter (12.6.2.12)

#### 8 **12.19.3.2.1 Read Port Default Priority**

##### 9 **12.19.3.2.1.1 Purpose**

10 To read the current state of the Default Priority parameter (IEEE Std 802.1ACI) for a specific TPMR Port.

##### 11 **12.19.3.2.1.2 Inputs**

- 12 a) Port number.

##### 13 **12.19.3.2.1.3 Outputs**

- 14 a) Default Priority value—Integer in range 0–7.

#### 15 **12.19.3.2.2 Set Port Default Priority**

##### 16 **12.19.3.2.2.1 Purpose**

17 To set the current state of the Default Priority parameter (IEEE Std 802.1AC) for a specific TPMR Port.

##### 18 **12.19.3.2.2.2 Inputs**

- 19 a) Port number.
- 20 b) Default Priority value—Integer in range 0–7.

##### 21 **12.19.3.2.2.3 Outputs**

22 None.

#### 23 **12.19.3.2.3 Read Port Priority Regeneration Table**

##### 24 **12.19.3.2.3.1 Purpose**

25 To read the current state of the Priority Regeneration Table parameter (6.9.4) for a specific TPMR Port.

##### 26 **12.19.3.2.3.2 Inputs**

- 27 a) Port number.

##### 28 **12.19.3.2.3.3 Outputs**

- 29 a) Regenerated Priority value for Received Priority 0—Integer in range 0–7.
- 30 b) Regenerated Priority value for Received Priority 1—Integer in range 0–7.
- 31 c) Regenerated Priority value for Received Priority 2—Integer in range 0–7.
- 32 d) Regenerated Priority value for Received Priority 3—Integer in range 0–7.
- 33 e) Regenerated Priority value for Received Priority 4—Integer in range 0–7.
- 34 f) Regenerated Priority value for Received Priority 5—Integer in range 0–7.
- 35 g) Regenerated Priority value for Received Priority 6—Integer in range 0–7.
- 36 h) Regenerated Priority value for Received Priority 7—Integer in range 0–7.

#### 37 **12.19.3.2.4 Set Port Priority Regeneration Table**

##### 38 **12.19.3.2.4.1 Purpose**

39 To set the current state of the Priority Regeneration Table parameter (6.9.4) for a specific TPMR Port.

#### 1 **12.19.3.2.4.2 Inputs**

- 2 a) Port number;
- 3 b) Regenerated Priority value for Received Priority 0—Integer in range 0–7.
- 4 c) Regenerated Priority value for Received Priority 1—Integer in range 0–7.
- 5 d) Regenerated Priority value for Received Priority 2—Integer in range 0–7.
- 6 e) Regenerated Priority value for Received Priority 3—Integer in range 0–7.
- 7 f) Regenerated Priority value for Received Priority 4—Integer in range 0–7.
- 8 g) Regenerated Priority value for Received Priority 5—Integer in range 0–7.
- 9 h) Regenerated Priority value for Received Priority 6—Integer in range 0–7.
- 10 i) Regenerated Priority value for Received Priority 7—Integer in range 0–7.

#### 11 **12.19.3.2.4.3 Outputs**

12 None.

### 13 **12.19.3.2.5 Read Port Priority Code Point Selection**

#### 14 **12.19.3.2.5.1 Purpose**

15 To read which row of the Priority Code Point Decoding Table (6.9.3) is currently selected for use on this  
16 Port.

#### 17 **12.19.3.2.5.2 Inputs**

- 18 a) Port Number: the number of the TPMR Port.

#### 19 **12.19.3.2.5.3 Outputs**

- 20 a) Priority Code Point Selection. This takes one of the following values:
  - 21 1) 8P0D
  - 22 2) 7P1D
  - 23 3) 6P2D
  - 24 4) 5P3D

### 25 **12.19.3.2.6 Set Port Priority Code Point Selection**

#### 26 **12.19.3.2.6.1 Purpose**

27 To set which row of the Priority Code Point Decoding Table (6.9.3) will be selected for use on this Port.

#### 28 **12.19.3.2.6.2 Inputs**

- 29 a) Port Number: the number of the TPMR Port.
- 30 b) Priority Code Point Selection. This takes one of the following values:
  - 31 1) 8P0D
  - 32 2) 7P1D
  - 33 3) 6P2D
  - 34 4) 5P3D

#### 35 **12.19.3.2.6.3 Outputs**

36 None.

### 37 **12.19.3.2.7 Read Priority Code Point Decoding Table**

#### 38 **12.19.3.2.7.1 Purpose**

39 To read the current contents of a row in the Priority Code Point Decoding Table (6.9.3) for a Port.

1 **12.19.3.2.7.2 Inputs**

- 2 a) Port Number: the number of the Bridge Port.
- 3 b) Priority Code Point Row. This takes one of the following values:
  - 4 1) 8P0D
  - 5 2) 7P1D
  - 6 3) 6P2D
  - 7 4) 5P3D

8 **12.19.3.2.7.3 Outputs**

- 9 a) Priority value for Priority Code Point 0: Integer in range 0–7.
- 10 b) Drop\_eligible value for Priority Code Point 0: Boolean.
- 11 c) Priority value for Priority Code Point 1: Integer in range 0–7.
- 12 d) Drop\_eligible value for Priority Code Point 1: Boolean.
- 13 e) Priority value for Priority Code Point 2: Integer in range 0–7.
- 14 f) Drop\_eligible value for Priority Code Point 2: Boolean.
- 15 g) Priority value for Priority Code Point 3: Integer in range 0–7.
- 16 h) Drop\_eligible value for Priority Code Point 3: Boolean.
- 17 i) Priority value for Priority Code Point 4: Integer in range 0–7.
- 18 j) Drop\_eligible value for Priority Code Point 4: Boolean.
- 19 k) Priority value for Priority Code Point 5: Integer in range 0–7.
- 20 l) Drop\_eligible value for Priority Code Point 5: Boolean.
- 21 m) Priority value for Priority Code Point 6: Integer in range 0–7.
- 22 n) Drop\_eligible value for Priority Code Point 6: Boolean.
- 23 o) Priority value for Priority Code Point 7: Integer in range 0–7.
- 24 p) Drop\_eligible value for Priority Code Point 7: Boolean.

25 **12.19.3.2.8 Read Use\_DEI Parameter**

26 **12.19.3.2.8.1 Purpose**

27 To read the current state of the Use\_DEI parameter (6.9.3) for the Port.

28 **12.19.3.2.8.2 Inputs**

- 29 a) Port Number: the number of the TPMR Port.

30 **12.19.3.2.8.3 Outputs**

- 31 a) Use\_DEI parameter: Boolean.

32 **12.19.3.2.9 Set Use\_DEI Parameter**

33 **12.19.3.2.9.1 Purpose**

34 To set the current state of the Use\_DEI parameter (6.9.3) for the Port.

35 **12.19.3.2.9.2 Inputs**

- 36 a) Port Number: the number of the TPMR Port.
- 37 b) Use\_DEI parameter: Boolean.

38 **12.19.3.2.9.3 Outputs**

39 None.

### 1 **12.19.3.3 Traffic Class Table**

2 The Traffic Class Table object models the operations that can be performed on, or inquire about, the current  
3 contents of the Traffic Class Table (8.6.6) for a given Port. The operations that can be performed on this  
4 object are Read Port Traffic Class Table and Set Port Traffic Class Table.

#### 5 **12.19.3.3.1 Read Port Traffic Class Table**

##### 6 **12.19.3.3.1.1 Purpose**

7 To read the contents of the Traffic Class Table (8.6.6) for a given Port.

##### 8 **12.19.3.3.1.2 Inputs**

- 9 a) Port Number.

##### 10 **12.19.3.3.1.3 Outputs**

- 11 a) The number of traffic classes, in the range 1 through 8, supported on the Port.  
12 b) For each value of traffic class supported on the Port, the value of the traffic class in the range 0  
13 through 7, and the set of priority values assigned to that traffic class.

#### 14 **12.19.3.3.2 Set Port Traffic Class Table**

##### 15 **12.19.3.3.2.1 Purpose**

16 To set the contents of the Traffic Class Table (8.6.6) for a given Port.

##### 17 **12.19.3.3.2.2 Inputs**

- 18 a) Port number.  
19 b) For each value of traffic class supported on the Port, the value of the traffic class in the range 0  
20 through 7, and the set of priority values assigned to that traffic class.

21 NOTE—If a traffic class value greater than the largest traffic class available on the Port is specified, then the value  
22 applied to the traffic class Table is the largest available traffic class.

##### 23 **12.19.3.3.2.3 Outputs**

24 None.

### 25 **12.19.4 MAC Status Propagation Entity (MSPE)**

26 This managed resource comprises the following object:

- 27 a) The MAC status propagation configuration for each Port of the TPMR (12.19.4.1)

#### 28 **12.19.4.1 MAC status propagation (MSP)**

29 The MAC status propagation object models the operations that modify, or inquire about, the configuration  
30 and statistics of the MSPE for a particular Port of the TPMR.

31 The management operations that can be performed on the MAC status propagation configuration are as  
32 follows:

- 33 a) Read MSP performance parameters (12.19.4.1.1)  
34 b) Set MSP performance parameters (12.19.4.1.2)  
35 c) Read MSP statistics (12.19.4.1.3)

## 1 **12.19.4.1.1 Read MSP performance parameters**

### 2 **12.19.4.1.1.1 Purpose**

3 To solicit information regarding the current configuration of the MSP performance parameters with respect  
4 to a particular Port of the TPMR.

### 5 **12.19.4.1.1.2 Inputs**

6 a) Port number. The number of the Port of the TPMR. This can take the values 1 or 2 only.

### 7 **12.19.4.1.1.3 Outputs**

8 a) LinkNotify. The current value (Boolean) of LinkNotify (23.5.1) being used by the MSP state  
9 machines.

10 b) LinkNotifyWait. The current value, in centiseconds, of LinkNotifyWait (23.5.2) being used by the  
11 MSP state machines.

12 c) LinkNotifyRetry. The current value, in centiseconds, of LinkNotifyRetry (23.5.3) being used by the  
13 MSP state machines.

14 d) MACNotify. The current value (Boolean) of MACNotify (23.5.4) being used by the MSP state  
15 machines.

16 e) MACNotifyTime. The current value, in centiseconds, of MACNotifyTime (23.5.5) being used by  
17 the MSP state machines.

18 f) MACRecoverTime. The current value, in centiseconds, of MACRecoverTime (23.5.6) being used  
19 by the MSP state machines.

## 20 **12.19.4.1.2 Set MSP performance parameters**

### 21 **12.19.4.1.2.1 Purpose**

22 To change the MSP performance parameters to be used for a particular Port of the TPMR.

### 23 **12.19.4.1.2.2 Inputs**

24 a) Port number. The number of the Port of the TPMR. This can take the values 1 or 2 only.

25 b) LinkNotify. The desired value (Boolean) of LinkNotify (23.5.1) to be used by the MSP state  
26 machines.

27 c) LinkNotifyWait. The desired value, in centiseconds, of LinkNotifyWait (23.5.2) to be used by the  
28 MSP state machines.

29 d) LinkNotifyRetry. The desired value, in centiseconds, of LinkNotifyRetry (23.5.3) to be used by the  
30 MSP state machines.

31 e) MACNotify. The desired value (Boolean) of MACNotify (23.5.4) to be used by the MSP state  
32 machines.

33 f) MACNotifyTime. The desired value, in centiseconds, of MACNotifyTime (23.5.5) to be used by the  
34 MSP state machines.

35 g) MACRecoverTime. The desired value, in centiseconds, of MACRecoverTime (23.5.6) to be used by  
36 the MSP state machines.

### 37 **12.19.4.1.2.3 Outputs**

38 None.

## 39 **12.19.4.1.3 Read MSP statistics**

### 40 **12.19.4.1.3.1 Purpose**

41 To read the MSP statistics (23.12) for a particular Port of the TPMR.

### 1 12.19.4.1.3.2 Inputs

- 2 a) Port number. The number of the Port of the TPMR. This can take the values 1 or 2 only.

### 3 12.19.4.1.3.3 Outputs

- 4 a) `acksTransmitted`: The number of *acks* transmitted (23.6.15) by the Port's Transmit Process as a  
5 consequence of `txAck` being set.
- 6 b) `addNotificationsTransmitted`: The number of *adds* transmitted (23.6.16) by the Port's Transmit  
7 Process as a consequence of `txAdd` being set.
- 8 c) `addConfirmationsTransmitted`: The number of *add confirms* transmitted (23.6.17) by the Port's  
9 Transmit Process as a consequence of `txAddConfirm` being set.
- 10 d) `lossNotificationsTransmitted`: The number of *losses* transmitted (23.6.18) by the Port's Transmit  
11 Process as a consequence of `txLoss` being set.
- 12 e) `lossConfirmationsTransmitted`: The number of *loss confirms* transmitted (23.6.19) by the Port's  
13 Transmit Process as a consequence of `txLossConfirm` being set.
- 14 f) `acksReceived`: The number of *acks* received (23.6.10) by the Port's Receive Process.
- 15 g) `addNotificationsReceived`: The number of *adds* received (23.6.11) by the Port's Receive Process.
- 16 h) `addConfirmationsReceived`: The number of *add confirms* received (23.6.12) by the Port's Receive  
17 Process.
- 18 i) `lossNotificationsReceived`: The number of *losses* received (23.6.13) by the Port's Receive Process.
- 19 j) `lossConfirmationsReceived`: The number of *loss confirms* received (23.6.14) by the Port's Receive  
20 Process.
- 21 k) `addEvents`: The number of transitions to `STM:ADD` directly from `STM:DOWN` or `STM:LOSS`  
22 (23.8).
- 23 l) `lossEvents`: The number of transitions to `STM:LOSS` directly from `STM:UP` or `STM:ADD` (23.8).
- 24 m) `macStatusNotifications`: The number of transitions to `SNM:MAC_NOTIFICATION` (23.9).

## 25 12.20 Management entities for FQTSS

26 The Bridge enhancements for support of FQTSS are defined in Clause 34.

27 This managed resource comprises the following objects:

- 28 a) The Bandwidth Availability Parameter Table (12.20.1)
- 29 b) The Transmission Selection Algorithm Table (12.20.2)
- 30 c) The Priority Regeneration Override Table (12.20.3)
- 31 d) The SR Class to Priority Mapping Table (12.20.4)

### 32 12.20.1 The Bandwidth Availability Parameter Table

33 There is one Bandwidth Availability Parameter Table per Port of a Bridge Component. Each table row  
34 contains a set of parameters for each traffic class configured for use with time-sensitive streams, as detailed  
35 in Table 12-4. Rows in the table can be created or removed dynamically in implementations that support  
36 dynamic configuration of Ports and components.

**Table 12-4—Bandwidth Availability Parameter Table row elements**

| Name                      | Data type               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References       |
|---------------------------|-------------------------|-----------------------------------|--------------------------|------------------|
| trafficClass <sup>c</sup> | unsigned integer [0..7] | R                                 | BE                       | 3.280, 8.6.8     |
| deltaBandwidth            | percentage              | RW                                | BE                       | 34.3             |
| adminIdleSlope            | unsigned integer        | RW                                | BEC                      | 34.3             |
| operIdleSlope             | unsigned integer        | R                                 | BE                       | 34.3             |
| classMeasurementInterval  | unsigned integer        | RW                                | be                       | 34.3, 34.4, 34.6 |
| lockClassBandwidth        | Boolean                 | RW                                | be                       | 34.3             |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of FQTSS; E = Required for end station support of FQTSS; b = Optional for Bridge or Bridge Component support of FQTSS; e = Optional for end station support of FQTSS; C = Required for Bridge or Bridge Component support of Stream reservation remote management,

<sup>c</sup> The term “trafficClass” in this table is the same as the “traffic class” definition of this standard.

The classMeasurementInterval attribute provides management control of the classMeasurementInterval parameter specified in 34.3. The classMeasurementInterval attribute uses units of nanoseconds, converted to/from units of seconds for use in 34.3. If management of classMeasurementInterval is not supported, the default values (34.5) are used as the fixed Port configuration.

If management of lockClassBandwidth is not supported, the default value of false is used as the fixed Port configuration.

## 1 12.20.2 The Transmission Selection Algorithm Table

2 There is one Transmission Selection Algorithm Table per Port of a Bridge Component. Each table row  
3 contains a set of parameters for each traffic class that the Port supports, as detailed in Table 12-5.

4 NOTE—To manage the mapping of traffic class to priority, refer to the Traffic Class Table managed object (12.6.3).

**Table 12-5—Transmission Selection Algorithm Table row elements**

| Name                             | Data type                     | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References          |
|----------------------------------|-------------------------------|-----------------------------------|--------------------------|---------------------|
| Traffic class                    | unsigned integer [0..7]       | R                                 | B                        | 8.6.8               |
| Transmission selection algorithm | enumerated<br>(see Table 8-6) | RW                                | B                        | 8.6.8,<br>Table 8-6 |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of FQTSS.

## 5 12.20.3 The Priority Regeneration Override Table

6 There is one Priority Regeneration Override Table per Port of a Bridge Component. This is in addition to the  
7 Priority Handling managed object (12.6.2) that would also exist per Port of a Bridge Component. Each table  
8 row contains a set of parameters for each received priority value that is associated with an SR class (3.271,  
9 6.9.4), as detailed in Table 12-6.

**Table 12-6—Priority Regeneration Override Table row elements**

| Name                  | Data type      | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|-----------------------|----------------|-----------------------------------|--------------------------|------------|
| Received priority     | integer [0..7] | R                                 | B                        | 6.9.4      |
| Regenerated priority  | integer [0..7] | RW                                | B                        | 6.9.4      |
| SRPdomainBoundaryPort | boolean        | R                                 | B                        | 35.1.4     |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of FQTSS.

#### 12.20.4 SR Class to Priority Mapping Table

There is one SR Class to Priority Mapping Table per Bridge Component. Each table row corresponds to an SR class, as detailed in Table 12-7. Rows in the table can be created or removed dynamically in implementations that support dynamic configuration of Ports and components, using Priority to specify the row to create/delete.

**Table 12-7—SR Class to Priority Mapping Table row elements**

| Name      | Data type               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|-----------|-------------------------|-----------------------------------|--------------------------|------------|
| Priority  | unsigned integer [0..7] | R                                 | b                        | 6.9.3      |
| SRclassID | unsigned integer [0..6] | RW                                | b                        | 35.2.2.9.2 |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> b = Optional for Bridge or Bridge Component support of FQTSS.

The SRclassID attribute specifies the SR class ID from Table 35-6 of 35.2.2.9.2, mapped to the associated Priority (SRclassPriority of 35.2.2.9.3). The default values for this managed object use the default values specified in 34.5 (i.e., Priority 3 for SRclassID 6 and Priority 2 for SRclassID 5).

If this managed object is not supported, the default values specified in 34.5 are used as the fixed configuration.

NOTE 1—This managed object is not needed for an end station, since according to the requirements of 35.2.2.9.3, an end station uses the SR class to priority mapping that the neighboring Bridge provides in SRP's Domain attribute.

NOTE 2—To manage the mapping of traffic class to priority, refer to the Traffic Class Table managed object (12.6.3).

NOTE 3—The maximum number of rows supported for this table is provided in the maxSRclasses parameter of 12.22.1.

#### 12.21 Congestion Notification managed objects

A number of the variables that implement congestion notification, including Congestion Points (CPs), Reaction Points (RPs), and Congestion Notification Domain (CND) defense, are manageable objects. There are a number of managed objects, each including a number of variables. The managed objects are as follows:

- CN component managed object (12.21.1)
- CN component priority managed object (12.21.2)
- CN Port priority managed object (12.21.3)
- Congestion Point managed object (12.21.4)

1 e) Reaction Point port priority managed object (12.21.5)

2 f) Reaction Point group managed object (12.21.6)

3 NOTE—If multiple managed objects are altered over a period of time, then between the time the first and last object has  
4 been altered, operation of the state machines could produce unexpected results. This standard assumes that any number  
5 of managed objects can be altered as an atomic operation, so that no inconsistent intermediate states can occur. See  
6 17.7.13 for one mechanism to ensure consistency.

## 7 12.21.1 CN component managed object

8 A single instance of the CN component managed object shall be implemented by a Bridge Component or  
9 end station that is congestion aware. It comprises all of the variables included in the CN component  
10 variables (32.2), as illustrated in Table 12-8. An end station may omit the managed objects noted “C” in the  
11 Conformance column of Table 12-8 if it does not support CPs, and may in any case omit the managed object  
12 marked “e.”

**Table 12-8—CN component managed object row elements**

| Name                   | Data type               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|------------------------|-------------------------|-----------------------------------|--------------------------|------------|
| cngMasterEnable        | Boolean                 | RW                                | BE                       | 32.2.1     |
| cngCnmTransmitPriority | unsigned integer [0..7] | R                                 | BC                       | 32.2.2     |
| cngDiscardedFrames     | counter                 | R                                 | BC                       | 32.2.3     |
| cngErroredPortList     | list                    | R                                 | Be                       | 32.2.4     |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for a Bridge or Bridge Component that is congestion aware; C = Required for an end station that implements one or more CPs; E = Required for an end station that is congestion aware; e = Optional for an end station that is congestion aware.

## 13 12.21.2 CN component priority managed object

14 The CN component priority managed object contains the managed objects that control a single CNPV for all  
15 Ports in an end station or Bridge Component. It comprises all of the variables included in the congestion  
16 notification per-CNPV variables (32.3), as illustrated in Table 12-9. In one common use case for congestion  
17 notification, every Port of a Bridge or end station has the same number of CPs, each configured for the same  
18 set of priority values. This managed object facilitates configuring that case. These objects can override, and  
19 can be overridden by, the CN Port priority managed objects (12.21.3) as described in 32.1.3.

20 A CN component priority managed object shall be implemented by a Bridge Component or end station that  
21 is congestion aware for each priority value that can be a CNPV. An end station may omit the managed  
22 objects noted “C” in the Conformance column in Table 12-9 if it does not support CPs. The operations that  
23 can be performed on a congestion-aware system’s CN component priority managed object are as follows:

24 a) Create CN component priority managed object (12.21.2.1)

25 b) Delete CN component priority managed object (12.21.2.2)

**Table 12-9—CN component priority managed object row elements**

| Name                     | Data type                                                  | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|--------------------------|------------------------------------------------------------|-----------------------------------|--------------------------|------------|
| cncpDefModeChoice        | enum {cpcAdmin, cpcAuto}                                   | RW                                | BE                       | 32.3.1     |
| cncpAlternatePriority    | integer [0..7]                                             | RW                                | BC                       | 32.3.2     |
| cncpAutoAltPri           | integer [0..7]                                             | R                                 | BC                       | 32.3.3     |
| cncpAdminDefenseMode     | enum {cptDisabled, cptInterior, cptInteriorReady, cptEdge} | RW                                | BE                       | 32.3.4     |
| cncpCreation             | enum {cncpAutoEnable, cncpAutoDisable}                     | RW                                | BE                       | 32.3.5     |
| cncpLldpInstanceChoice   | enum {cnlNone, cnlAdmin}                                   | RW                                | BE                       | 32.3.6     |
| cncpLldpInstanceSelector | IEEE 802.1AB™ LLDP instance selector                       | RW                                | BE                       | 32.3.7     |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for a Bridge or Bridge Component that is congestion aware; C = Required for an end station that implements one or more CPs; E = Required for an end station that is congestion aware.

### 12.21.2.1 Create CN component priority managed object

Creating a CN component priority managed object creates an instance of each of the congestion notification per-CNPV variables (32.3), and also creates the corresponding CN Port priority managed objects (12.21.3) and all their dependent managed objects and variables, on every Port in the Bridge Component or end station, as illustrated in CN Port priority managed object. Depending on the value of cncpCreation (32.3.5), creating a CN component priority managed object can make the selected priority a CNPV throughout the Bridge Component or end station.

### 12.21.2.2 Delete CN component priority managed object

Deleting a CN component priority managed object deletes all of the CN component variables (32.2), and also deletes the corresponding CN Port priority managed objects (12.21.3) and all their dependent managed objects and variables, on all Ports in the Bridge Component or end station, thus making the priority not a CNPV throughout the Bridge Component or end station.

### 12.21.3 CN Port priority managed object

There is one CN Port priority managed object per Port per priority in a congestion-aware end station or Bridge Component. It comprises some of the variables included in the CND defense per-Port per-CNPV variables (32.4), as illustrated in Table 12-10. These objects can override, and can be overridden by, the CN component managed objects (12.21.1) and CN component priority managed objects (12.21.2) as described in 32.1.3.

A CN Port priority managed object is created or deleted when the corresponding Port or CN component priority managed object is created or deleted, and its initial state on creation is determined by cncpCreation (32.3.5).

**Table 12-10—CN Port priority managed object row elements**

| Name                    | Data type                                                 | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|-------------------------|-----------------------------------------------------------|-----------------------------------|--------------------------|------------|
| cnpdDefModeChoice       | enum{cpcAdmin, cpcAuto, cpcComp}                          | RW                                | BE                       | 32.4.1     |
| cnpdAdminDefenseMode    | enum{cptDisabled, cptInterior, cptInteriorReady, cptEdge} | RW                                | BE                       | 32.4.2     |
| cnpdAutoDefenseMode     | enum{cptDisabled, cptInterior, cptInteriorReady, cptEdge} | R                                 | BE                       | 32.4.3     |
| cnpdLdpInstanceChoice   | enum{cnlNone, cnlAdmin}                                   | RW                                | BE                       | 32.4.4     |
| cnpdLdpInstanceSelector | IEEE 802.1AB LLDP instance selector                       | RW                                | BE                       | 32.4.5     |
| cnpdAlternatePriority   | integer [0..7]                                            | RW                                | BC                       | 32.4.6     |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for a Bridge or Bridge Component that is congestion aware; C = Required for an end station that implements one or more CPs; E = Required for an end station that is congestion aware.

<sup>1</sup> The CN Port priority managed object shall be implemented by a Bridge Component or end station that is  
<sup>2</sup> congestion aware. An end station may omit the managed objects noted “C” in the Conformance column in  
<sup>3</sup> Table 12-10 if it does not support CPs.

#### <sup>4</sup> 12.21.4 Congestion Point managed object

<sup>5</sup> There is one Congestion Point managed object for each CP in a Bridge Component or end station. It  
<sup>6</sup> comprises some of the variables included in the CP variables (32.8), as illustrated in Table 12-11.

**Table 12-11—Congestion Point managed object row elements**

| Name                | Data type               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|---------------------|-------------------------|-----------------------------------|--------------------------|------------|
| cpMacAddress        | MAC address             | R                                 | BC                       | 32.8.1     |
| cpId                | octet string (size = 8) | R                                 | BC                       | 32.8.2     |
| cpQSp               | unsigned integer        | R                                 | BC                       | 32.8.3     |
| cpW                 | real number             | RW                                | BC                       | 32.8.6     |
| cpSampleBase        | unsigned integer        | RW                                | BC                       | 32.8.11    |
| cpDiscardedFrames   | counter                 | R                                 | BC                       | 32.8.12    |
| cpTransmittedFrames | counter                 | R                                 | BC                       | 32.8.13    |
| cpTransmittedCnms   | counter                 | R                                 | BC                       | 32.8.14    |
| cpMinHeaderOctets   | unsigned integer        | RW                                | BC                       | 32.8.15    |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for a Bridge or Bridge Component that is congestion aware; C = Required for an end station that implements one or more CPs.

<sup>1</sup> The Congestion Point managed object shall be implemented by a congestion-aware Bridge Component. It  
<sup>2</sup> shall be implemented by an end station that supports CPs.

<sup>3</sup> NOTE—The Recommended priority to traffic class mappings in Table 8-5 can assign more than one CNPV to the same  
<sup>4</sup> traffic class, the same queue, and hence the same CP. There can be only one CP controlling a given queue, and that CP  
<sup>5</sup> has one set of controlling managed objects, not one set per CNPV. That set of managed objects can be accessed using  
<sup>6</sup> any of the CNPV values assigned to the CP's queue. Thus, changing a managed object for one CNPV changes the  
<sup>7</sup> managed object for all CNPVs assigned to the same queue.

## <sup>8</sup> 12.21.5 Reaction Point port priority managed object

<sup>9</sup> A congestion-aware end station shall implement one Reaction Point port priority managed object for each  
<sup>10</sup> CNPV on each port. The Reaction Point port priority managed object controls the creation of RPs on the  
<sup>11</sup> port and CNPV, as illustrated in Table 12-12.

**Table 12-12—Reaction Point port priority managed object row elements**

| Name               | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|--------------------|------------------|-----------------------------------|--------------------------|------------|
| rpppMaxRps         | unsigned integer | RW                                | E                        | 32.10.1    |
| rpppCreatedRps     | counter          | R                                 | E                        | 32.10.2    |
| rpppRpCentiseconds | unsigned integer | R                                 | E                        | 32.10.3    |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> E = Required for an end station that is congestion aware.

## <sup>12</sup> 12.21.6 Reaction Point group managed object

<sup>13</sup> There is one Reaction Point group managed object for each set of RP group variables (32.11), as illustrated  
<sup>14</sup> in Table 12-13. The Reaction Point group managed object shall be implemented by an end station that is  
<sup>15</sup> congestion aware.

**Table 12-13—Reaction Point group managed object row elements**

| Name         | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|--------------|------------------|-----------------------------------|--------------------------|------------|
| rpgEnable    | Boolean          | RW                                | E                        | 32.11.1    |
| rpgTimeReset | unsigned integer | RW                                | E                        | 32.11.2    |
| rpgByteReset | unsigned integer | RW                                | E                        | 32.11.3    |
| rpgThreshold | unsigned integer | RW                                | E                        | 32.11.4    |
| rpgMaxRate   | unsigned integer | RW                                | E                        | 32.11.5    |
| rpgAiRate    | unsigned integer | RW                                | E                        | 32.11.6    |
| rpgHaiRate   | unsigned integer | RW                                | E                        | 32.11.7    |

**Table 12-13—Reaction Point group managed object row elements (*continued*)**

| Name         | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|--------------|------------------|-----------------------------------|--------------------------|------------|
| rpgGd        | real number      | RW                                | E                        | 32.11.8    |
| rpgMinDecFac | real number      | RW                                | E                        | 32.11.9    |
| rpgMinRate   | unsigned integer | RW                                | E                        | 32.11.10   |

<sup>a</sup> RW = Read/Write access.

<sup>b</sup> E = Required for an end station that is congestion aware.

## 1 12.22 Stream Reservation Protocol (SRP) entities

2 The Bridge enhancements for support of SRP are defined in Clause 35.

3 This managed resource comprises the following objects:

- 4 a) SRP Bridge Base Table (12.22.1)
- 5 b) SRP Bridge Port Table (12.22.2)
- 6 c) SRP Latency Parameter Table (12.22.3)
- 7 d) SRP Stream Table (12.22.4)
- 8 e) SRP Reservations Table (12.22.5)

### 9 12.22.1 SRP Bridge Base Table

10 There is a set of parameters that configure SRP operation for the entire device. Those parameters are shown  
11 in Table 12-14.

**Table 12-14—SRP Bridge Base Table row elements**

| Name                    | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References          |
|-------------------------|------------------|-----------------------------------|--------------------------|---------------------|
| msrpEnabledStatus       | Boolean          | RW                                | B                        | 35.2.1.4(d)         |
| talkerPruning           | Boolean          | RW                                | B                        | 35.2.1.4(b)         |
| msrpMaxFanInPorts       | unsigned integer | RW                                | B                        | 35.2.1.4(f)         |
| msrpLatencyMaxFrameSize | unsigned integer | RW                                | B                        | 35.2.1.4(g)         |
| talkerVlanPruning       | Boolean          | RW                                | b                        | 35.2.1.4<br>item l) |
| maxSRclasses            | unsigned integer | R                                 | b                        | 35.2.1.4<br>item m) |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for Bridge or Bridge Component support of SRP; E = required for end station support of SRP; b = Optional for Bridge or Bridge Component support of SRP.

## 1 12.22.2 SRP Bridge Port Table

2 There is one SRP Configuration Parameter Table per Port of a Bridge Component. Each table row contains a  
3 set of parameters for each MSRP entity per Port, as detailed in Table 12-15.

**Table 12-15—SRP Bridge Port Table row elements**

| Name                      | Data type                 | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References               |
|---------------------------|---------------------------|-----------------------------------|--------------------------|--------------------------|
| msrpPortEnabledStatus     | Boolean                   | RW                                | B                        | 35.2.1.4(e)              |
| MSRP Failed Registrations | counter                   | R                                 | B                        | 10.7.12.1                |
| MSRP Last PDU Origin      | MAC address               | R                                 | B                        | 10.7.12.2                |
| SR_PVID                   | unsigned integer[1..4094] | RW                                | B                        | Table 9-2<br>35.2.1.4(i) |
| talkerPruningPerPort      | Boolean                   | RW                                | b                        | 35.2.1.4<br>item k)      |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for Bridge or Bridge Component support of SRP; E = required for end station support of SRP; b = Optional for Bridge or Bridge Component support of SRP.

## 4 12.22.3 SRP Latency Parameter Table

5 There is one SRP Latency Parameter Table per Port of a Bridge Component. Each table row contains a set of  
6 parameters for each traffic class supported on a port, as detailed in Table 12-16. Rows in the table can be  
7 created or removed dynamically in implementations that support dynamic configuration of ports and  
8 components.

**Table 12-16—SRP Latency Parameter Table row elements**

| Name             | Data type               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                 |
|------------------|-------------------------|-----------------------------------|--------------------------|----------------------------|
| Traffic class    | unsigned integer [0..7] | R                                 | BE                       | 34.3                       |
| portTcMaxLatency | unsigned integer        | R                                 | BE                       | 35.2.1.4(a),<br>35.2.2.8.6 |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for Bridge or Bridge Component support of SRP; E = required for end station support of SRP.

## 9 12.22.4 SRP Stream Table

10 There is one SRP Stream Table per Bridge Component. Each table contains a set of parameters for each  
11 StreamID that is registered on the Bridge, as detailed in Table 12-17. Rows in the table are created and  
12 removed dynamically as StreamIDs are registered and deregistered on the Bridge.

**Table 12-17—SRP Stream Table row elements**

| Name                       | Data type                    | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References    |
|----------------------------|------------------------------|-----------------------------------|--------------------------|---------------|
| StreamID                   | octet string(size(8))        | RW                                | BE                       | 35.2.2.8.2    |
| Stream Destination Address | MAC address                  | R                                 | BE                       | 35.2.2.8.3(a) |
| Stream VID                 | unsigned integer [0..4094]   | R                                 | BE                       | 35.2.2.8.3(b) |
| MaxFrameSize               | unsigned integer [0..65 535] | R                                 | BE                       | 35.2.2.8.4(a) |
| MaxIntervalFrames          | unsigned integer [0..65 535] | R                                 | BE                       | 35.2.2.8.4(b) |
| Data Frame Priority        | unsigned integer [0..7]      | R                                 | BE                       | 35.2.2.8.5(a) |
| Rank                       | unsigned integer [0..1]      | R                                 | BE                       | 35.2.2.8.5(b) |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for Bridge or Bridge Component support of SRP; E = required for end station support of SRP.

## 1 12.22.5 SRP Reservations Table

2 There is one SRP Reservations Table per reservation direction per port of a Bridge Component. Each table  
3 contains a set of parameters for each Talker or Listener Reservation that is registered on a port of the Bridge,  
4 as detailed in Table 12-18. Rows in the table can be created or removed dynamically as Talker and Listener  
5 declarations are registered and deregistered on a port of the Bridge.

6

**Table 12-18—SRP Reservations Table row elements**

| Name                | Data type                | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References    |
|---------------------|--------------------------|-----------------------------------|--------------------------|---------------|
| StreamID            | octet string(size(8))    | RW                                | BE                       | 35.2.2.8.2    |
| Direction           | unsigned integer[0..1]   | R                                 | BE                       | 35.2.1.2      |
| Declaration Type    | unsigned integer [0..4]  | R                                 | BE                       | 35.2.1.3      |
| Accumulated Latency | unsigned integer         | R                                 | BE                       | 35.2.2.8.6    |
| Failed system ID    | BridgeId                 | R                                 | BE                       | 35.2.2.8.7(a) |
| Failure Code        | unsigned integer [0..16] | R                                 | BE                       | 35.2.2.8.7(b) |
| Dropped Frames      | counter                  | R                                 | BE                       | 35.2.5.1      |
| Stream Age          | unsigned integer         | R                                 | BE                       | 35.2.1.4(c)   |

<sup>a</sup>R = Read only access; RW = Read/Write access.

<sup>b</sup>B = required for Bridge or Bridge Component support of SRP; E = required for end station support of SRP.

## 1 12.22.6 SRP Stream Preload Table

2 There is one SRP Stream Preload Table per Bridge Component. Each table contains a set of parameters for  
3 each StreamID that is preloaded on the Bridge as it initializes (i.e., powers up/reboots), as detailed in  
4 Table 12-17. The preloading of Table 12-17 on each Port of the Bridge is specified in 12.22.5. Rows in the  
5 table can be created or removed dynamically in implementations that support dynamic configuration of  
6 Ports and components.

**Table 12-19—SRP Stream Preload Table row elements**

| Name                       | Data type                   | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References         |
|----------------------------|-----------------------------|-----------------------------------|--------------------------|--------------------|
| StreamID                   | octet string(size(8))       | RW                                | b                        | 35.2.2.8.2         |
| Stream Destination Address | MAC Address                 | RW                                | b                        | 35.2.2.8.3 item a) |
| Stream VLAN ID             | unsigned integer [0..4094]  | RW                                | b                        | 35.2.2.8.3 item b) |
| MaxFrameSize               | unsigned integer [0..65535] | RW                                | b                        | 35.2.2.8.4 item a) |
| MaxIntervalFrames          | unsigned integer [0..65535] | RW                                | b                        | 35.2.2.8.4 item b) |
| Data Frame Priority        | unsigned integer [0..7]     | RW                                | b                        | 35.2.2.8.4 item a) |
| Rank                       | unsigned integer [0..1]     | RW                                | b                        | 35.2.2.8.5 item b) |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> b = Optional for Bridge or Bridge Component support of SRP.

## 7 12.22.7 SRP Reservations Preload Table

8 There is one SRP Reservations Preload Table per reservation direction per Port of a Bridge Component.  
9 Each table contains a set of parameters for each Talker or Listener registration that is preloaded on the  
10 Bridge as it initializes (i.e., powers up/reboots), as detailed in Table 12-18. Rows in the table can be created  
11 or removed dynamically in implementations that support dynamic configuration of Ports and  
12 components.

**Table 12-20—SRP Reservations Preload Table row elements**

| Name                | Data type              | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|---------------------|------------------------|-----------------------------------|--------------------------|------------|
| StreamID            | octet string(size(8))  | RW                                | b                        | 35.2.2.8.2 |
| Direction           | unsigned integer[0..1] | RW                                | b                        | 35.2.1.2   |
| Accumulated Latency | unsigned integer       | RW                                | b                        | 35.2.2.8.6 |

<sup>a</sup>R = Read only access; RW = Read/Write access.

<sup>b</sup>b = optional for Bridge or Bridge Component support of SRP.

13 The SRP preload tables (Table 12-17 and Table 12-18) are used to initialize Streams within each Bridge as it  
14 powers up, to preload the Stream registrations that will later be provided by operation of SRP. When the  
15 Bridge initializes, the SRP preload tables shall be used for a two phase operation as follows:

1 In the first phase, the Bridge iterates Table 12-18 to find rows for which the Direction is Talker. For each  
2 Talker row, if the StreamID in Table 12-18 is also found in Table 12-17, the Bridge shall:

- 3 a) Invoke the MVRP ES\_REGISTER\_VLAN\_MEMBER service primitive (11.2.3.2.1) on the Port.  
4 The attribute\_type parameter carries the VID Vector Attribute Type (11.2.3.1.6). The attribute\_value  
5 parameter carries the Stream VLAN ID for the associated StreamID in Table 12-17.
- 6 b) Invoke MSRP REGISTER\_STREAM.request (35.2.3.1.1) on the Port. The attribute\_type parameter  
7 carries the Talker Advertise Vector Attribute Type [item a) in 35.2.2.4]. The Declaration Type in the  
8 attribute\_value parameter is Talker Advertise. The attribute\_value parameter carries the following  
9 parameters from Table 12-17: StreamID, DataFrameParameters.destination\_address from Stream  
10 Destination Address, DataFrameParameters.vlan\_identifier from Stream VLAN ID,  
11 TSpec.MaxFrameSize, TSpec.MaxIntervalFrames, PriorityAndRank.Data Frame Priority, and  
12 PriorityAndRank.Rank. The attribute\_value parameter carries the following per-Port parameters  
13 from Table 12-18: Accumulated Latency. The Failure Information in the attribute\_value parameter  
14 is not applicable to Talker Advertise.

15 In the second phase, the Bridge iterates Table 12-18 to find rows for which the Direction is Listener. For  
16 each Listener row, if the StreamID was processed as a Talker during the first phase, then the Bridge shall:

- 17 c) Invoke MSRP REGISTER\_ATTACH.request (35.2.3.1.5) on the Port. The attribute\_type parameter  
18 carries the Listener Vector Attribute Type [item c) in 35.2.2.4]. The Declaration Type in the  
19 attribute\_value parameter is Listener Ready. The attribute\_value parameter carries StreamID from  
20 Table 12-18.
- 21 d) Invoke the MVRP ES\_REGISTER\_VLAN\_MEMBER service primitive (11.2.3.2.1) on the Port.  
22 The attribute\_type parameter carries the VID Vector Attribute Type (11.2.3.1.6). The attribute\_value  
23 parameter carries the Stream VLAN ID for the associated StreamID in Table 12-17.
- 24 e) Update the Dynamic Reservation Entries (8.8.7) for the Port to Forwarding, using the Stream  
25 Destination Address for the associated StreamID in Table 12-17.

26 For traffic class N that is mapped to the Data Frame Priority of Table 12-17, increase the *operIdleSlope(N)*  
27 variable [item d) in 34.3] using the bandwidth requirements of the Stream (MaxFrameSize and  
28 MaxIntervalFrames of Table 12-17).

## 29 12.23 Priority-based Flow Control objects

30 The following Priority-based Flow Control objects exist for each port that support PFC:

- 31 a) **PFCLinkDelayAllowance:** the allowance made for round-trip propagation delay of the link in bits
- 32 b) **PFCRequests:** a count of the invoked PFC M\_CONTROL.request primitives
- 33 c) **PFCIndications:** a count of the received PFC M\_CONTROL.indication primitives

Table 12-21 shows the format and applicability of these objects.

**Table 12-21—Priority-based Flow Control objects**

| Name                  | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> |
|-----------------------|------------------|-----------------------------------|--------------------------|
| PFCLinkDelayAllowance | unsigned integer | RW                                | BE                       |
| PFCRequests           | unsigned integer | R                                 | BE                       |
| PFCIndications        | unsigned integer | R                                 | BE                       |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of PFC; E = Required for end station support of PFC.

NOTE—The PFC Initiator (see 36.2.1) can use the PFCLinkDelayAllowance parameter as one of the factors to determine when to issue a PFC M\_CONTROL.request in order to not discard frames. The parameter can be written to adjust to different link characteristics that affect the link delay (e.g., link length or link technology). See Annex N for an example of how to compute this parameter.

## 12.24 1:1 PBB-TE IPS managed objects

The IPS managed objects model operations that create, modify, delete, or inquire about the configuration and the operation of IPS (26.11). To this end, they describe objects related to an Infrastructure Protection Group (IPG) (26.11.2.1). The following are the IPS managed objects associated with a Segment Endpoint Bridge (SEB):

- a) TE protection group list managed object (12.18.1)
- b) IPG managed object (12.24.2)

### 12.24.1 IPG list managed object

There is one TE protection group list managed object per SEB. The IPG list managed object contains a list of the IPGs that have been configured on the SEB.

The management operations that can be performed on the TE protection group list managed object are as follows:

- a) Read Maintenance Domain list (12.14.1.1)
- b) Create Maintenance Domain managed object (12.14.1.2)
- c) Delete Maintenance Association managed object (12.14.5.4)

#### 12.24.1.1 Read IPG list

##### 12.24.1.1.1 Purpose

To obtain information about the set of IPGs associated with a SEB.

##### 12.24.1.1.2 Inputs

None.

### 12.24.1.1.3 Outputs

A list, perhaps empty, of the IPG managed objects configured on the SEB. For each item in the list, the Read Maintenance Domain list command returns the following:

- a) A value identifying the IPG.
- b) A reference to the particular Maintenance Association managed object (12.14.6) identifying the Infrastructure Segment MA that corresponds to the working entity of the IPG.
- c) A reference to the particular Maintenance Association managed object identifying the Infrastructure Segment MA that corresponds to the protection entity of the IPG.
- d) In the case of M:1 IPS, a prioritized list of references to Maintenance Association managed object, each of which identifies a candidate Protection Segment associated with the IPG.

### 12.24.1.2 Create IPG managed object

#### 12.24.1.2.1 Purpose

To create a new IPG managed object in a SEB and add it to the TE protection group list managed object associated with the SEB.

#### 12.24.1.2.2 Inputs

- a) A reference to a particular Maintenance Association managed object identifying the Infrastructure Segment MA that corresponds to the working entity of the IPG.
- b) In the case of 1:1 IPS, a reference to a particular Maintenance Association managed object identifying the Infrastructure Segment MA that corresponds to the protection entity of the IPG or, in the case of M:1 IPS, a prioritized list of references to Maintenance Association managed object, each of which identifies an Infrastructure Segment MA associated with an Infrastructure Segment that is a candidate Protection Segment for the IPG.

#### 12.24.1.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected due to nonexistent MD.
  - 2) Operation rejected due to a nonexistent MA.
  - 3) Operation rejected because a referenced MA is not associated with an Infrastructure Segment.
  - 4) Operation rejected because the referenced MAs do not belong to the same MD.
  - 5) Operation rejected because two or more managed objects referenced are associated with the same MA.
  - 6) Operation rejected because neither Segment Monitoring Path Identifier (SMP-ID) associated with a SEG-ID identifying one of the referenced Infrastructure MAs contains in its SMP-SA field the MAC address of a PNP associated with the SEB.
  - 7) Operation accepted.

### 12.24.1.3 Delete IPG managed object

#### 12.24.1.3.1 Purpose

To remove a specific IPG managed object from the TE protection group list managed object associated with the SEB and to delete that IPG managed object.

### 1 12.24.1.3.2 Inputs

- 2 a) A reference to a particular IPG managed object (12.24.2).

### 3 12.24.1.3.3 Outputs

- 4 a) Operation status. This takes one of the following values:
- 5 1) Operation rejected due to nonexistent IPG
  - 6 2) Operation rejected because the IPG is enabled
  - 7 3) Operation accepted

## 8 12.24.2 IPG managed object

9 There can be any number of IPG managed objects per SEB.

10 The management operations that can be performed on the IPG managed object are as follows:

- 11 a) Read Maintenance Association managed object (12.14.6.1)
- 12 b) Write Maintenance Association managed object (12.14.6.2)
- 13 c) TE protection group administrative commands managed object (12.18.2.3)

### 14 12.24.2.1 Read IPG managed object

#### 15 12.24.2.1.1 Purpose

16 To obtain information from a SEB regarding a specified IPG managed object.

#### 17 12.24.2.1.2 Inputs

- 18 a) A reference to an IPG managed object.

#### 19 12.24.2.1.3 Outputs

- 20 a) Operation status. This takes one of the following values:
- 21 1) Operation rejected due to nonexistent IPG
  - 22 2) Operation accepted
- 23 b) The MAID and Port Number associated with the Working Segment and an indication (TRUE or  
24 FALSE) about whether the Working Segment is operational.
- 25 c) The MAID and Port Number associated with the Protection Segment and an indication (TRUE or  
26 FALSE) about whether the Protection Segment is operational.
- 27 d) (optional) In the case of M:1 IPS, the list of MAIDs and Port Numbers associated with Candidate  
28 Protection Segments ordered from highest to lowest priority and an indication (TRUE or FALSE)  
29 about whether each candidate Protection Segment is operational.
- 30 e) (writable) A list of TE-SIDs, possibly NULL, identifying TESIs protected by the IPG. If not NULL,  
31 the IPG is considered to be enabled.
- 32 f) An enumerated value indicating the operational state of the Service Mapping state machine  
33 (Figure 26-22) for each IPG:
- 34 1) WORKING\_SEGMENT
  - 35 2) PROTECTION\_SEGMENT
  - 36 3) WTR
  - 37 4) PROT\_ADMIN
- 38 g) An enumerated value indicating the status of active requests within the IPG:
- 39 1) **NoRequest:** No administrative command is in effect.
  - 40 2) **LoP:** Set if LoP (26.10.3.3.4) is TRUE, indicating that an administrative command to prohibit  
41 the use of the Protection Segment is in effect.

- 1 3) **FS:** Set if FS (26.10.3.3.5) is TRUE, indicating that an administrative command to perform  
2 forced switching to the Protection Segment is in effect.
- 3 4) **p.SFH:** Set if SFH (26.10.3.3.3) is TRUE on the Protection Segment.
- 4 5) **w.SFH:** Set if SFH is TRUE on the Working Segment.
- 5 6) **MStoProtection:** Set if MStoProtection (26.10.3.3.6) is TRUE, indicating that an  
6 administrative command to perform manual switching to the Protection Segment is in effect.
- 7 7) **MStoWorking:** Set if MStoWorking (26.10.3.3.7) is TRUE, indicating that an administrative  
8 command to perform manual switching to the Working Segment is in effect.
- 9 h) (writable) (optional) The wait-to-restore (WTR) period (26.10.3.3.8.) In revertive operation it may  
10 be configured in steps of 1 min between 5 and 12 min; the default value is 5 min. The value 0  
11 indicates nonrevertive operation. The value 0 is not permitted when the IPG is associated with M:1  
12 IPS.
- 13 i) (writable) (optional) The hold-off period (26.10.3.3.9). The range of the hold-off period is 0 to 10 s  
14 in steps of 100 ms; the default value is 0.
- 15 j) (optional) An enumerated value indicating the operational state of the Protection Segment Selection  
16 state machine (Figure 26-26) for each IPG:
  - 17 1) PS\_ASSIGNED
  - 18 2) SEGMENT\_OK
  - 19 3) SEGMENT\_FAILED
  - 20 4) ASSIGN\_NEW\_PS
  - 21 5) REVERT\_TO\_BETTER\_PS
- 22 k) (writable) (optional) The M:1 wait-to-restore (MWTR) period (26.11.5.4.7.). In revertive operation  
23 it may be configured in steps of 1 min between 5 and 12 min; the default value is 5 min. The value 0  
24 indicates nonrevertive operation.

## 25 12.24.2.2 Write IPG managed object

### 26 12.24.2.2.1 Purpose

27 To update a writable item associated with a specified IPG managed object.

### 28 12.24.2.2.2 Inputs

- 29 a) A reference to an IPG managed object.
- 30 b) The identity of a writable item in 12.18.2.1.3 that is to be updated.
- 31 c) The updated value of the specified item.

### 32 12.24.2.2.3 Outputs

- 33 a) Operation status. This takes one of the following values:
  - 34 1) Operation rejected due to specification of nonexistent IPG
  - 35 2) Operation rejected due to the selection of an item that is not writable
  - 36 3) Operation rejected due to lack of authority to set the value of this item
  - 37 4) Operation rejected due to the specification of an invalid value for the selected item
  - 38 5) Operation accepted

## 39 12.24.2.3 Apply administrative command to IPG managed object

### 40 12.24.2.3.1 Purpose

41 To apply a specified administrative command to an IPG managed object.

### 1 12.24.2.3.2 Inputs

- 2 a) A reference to an IPG managed object.
- 3 b) An enumerated value indicating the exercised administrative command:
  - 4 1) **Clear:** An indication to clear all other administrative commands.
  - 5 2) **Lockout of Protection:** An administrative command to prohibit the use of the Protection
  - 6 Segment.
  - 7 3) **Forced Switch:** An administrative command to perform forced switching to the Protection
  - 8 Segment.
  - 9 4) **Manual Switch To Protection:** An administrative command to perform manual switching to
  - 10 the Protection Segment if that Infrastructure Segment is operational.
  - 11 5) **Manual Switch To Working:** An administrative command to perform manual switching to the
  - 12 Working Segment if that Infrastructure Segment is operational.

### 13 12.24.2.3.3 Outputs

- 14 a) Operation status. This takes one of the following values:
  - 15 1) Operation rejected due to specification of a nonexistent IPG.
  - 16 2) Operation rejected due to lack of authority to apply the specified command to the identified
  - 17 IPG managed object.
  - 18 3) Operation rejected due to an active higher priority request.
  - 19 4) Operation accepted.

## 20 12.25 Shortest Path Bridging managed objects

21 The Shortest Path Bridging managed objects model operations that create, modify, delete, or inquire about  
22 the configuration and the operation of an SPT Bridge and the region in which it is operating. These managed  
23 objects model only behaviors unique to SPB. Figure 12-3 illustrates the hierarchical relationships among the  
24 various SPB managed objects.

25 IS-IS provides a logical topology instance and within each instance the SPT Domain defines a set of  
26 managed objects. The following are the managed objects in an SPT Bridge:

- 27 a) The SPB System managed object (12.25.1)
- 28 b) The SPB MTID Static managed object (12.25.2) (see Multi-Topology Identifier (MTID) in
- 29 Clause 3)
- 30 c) The SPB Topology Instance Dynamic managed object (12.25.3)
- 31 d) The SPB ECT Static Entry managed object (12.25.4)
- 32 e) The SPB ECT Dynamic Entry managed object (12.25.5)
- 33 f) The SPB Adjacency Static Entry managed object (12.25.6)
- 34 g) The SPB Adjacency Dynamic Entry managed object (12.25.7)
- 35 h) The SPBM BSI Static Entry managed object (12.25.8)
- 36 i) The SPB Topology Node Table managed object (12.25.9)
- 37 j) The SPB Topology ECT Table managed object (12.25.10)
- 38 k) The SPB Topology Edge Table managed object (12.25.11)
- 39 l) The SPBM Topology Service Table managed object (12.25.12)
- 40 m) The SPBV Topology Service Table managed object (12.25.13)
- 41 n) The ECMP ECT Static Entry managed object (12.25.14)
- 42 o) The PCR ECT Static Entry managed object (12.28.1)
- 43 p) The PCR Topology ECT Table managed object (12.28.2)

**Figure 12-3—SPB managed objects (MOs)**

## 12.25.1 The SPB System managed object

There is one SPB System managed object per ISIS-SPB area supported by an SPT Bridge. A single area only is supported in this version of the specification. It contains the fundamental SPB configuration parameters for the Bridge. It is persistent over reboot. The management operations that can be performed on the SPB System managed object are as follows:

- Create SPB System managed object (12.25.1.1)
- Write SPB System managed object (12.25.1.2)
- Read SPB System managed object (12.25.1.3)
- Delete SPB System managed object (12.25.1.4)

## 1 12.25.1.1 Create SPB System Managed object

### 2 12.25.1.1.1 Purpose

3 To create and configure the SPB System managed object on a Bridge.

### 4 12.25.1.1.2 Inputs

- 5 a) The part of the IS-IS Area Address that is domain specific (see Figure 4, ISO/IEC 10589:2002). This  
6 shall be set to zero in this version of this specification whenever SPB is the only protocol being  
7 supported by this IS-IS instance.
- 8 b) The MAC address to be used as the SPB System Identifier by all instances of ISIS-SPB on this  
9 Bridge. The System ID defaults to the Bridge Address if this input is not provided. The Bridge  
10 Address is the value returned by item a) of Discover Bridge (12.4.1.1.3) and Read Bridge  
11 (12.4.1.2.3).
- 12 c) The Group address used to address this ISIS-SPB instance (see Table 8-16). This address is  
13 configured to manage the transparency to ISIS-SPB of neighboring network elements, and also to  
14 specify the IS-IS Level at which this SPB instance is operating, which shall be Level 1 in this  
15 version of this specification.

### 16 12.25.1.1.3 Outputs

- 17 a) Operation status. This takes one of the following values:
  - 18 1) Operation rejected because the specified IS-IS Area Address is already in use.
  - 19 2) Operation rejected because the provided Group address does not correspond to an allowed  
20 address (Table 8-16).
  - 21 3) Operation rejected because the specified SPB System Identifier value is not valid.
  - 22 4) Operation rejected due to the Bridge's inability to support the requested IS-IS Level.
  - 23 5) Operation accepted.

## 24 12.25.1.2 Write SPB System managed object

### 25 12.25.1.2.1 Purpose

26 To configure an SPB System managed object on a Bridge.

### 27 12.25.1.2.2 Inputs

- 28 a) The part of the IS-IS Area Address that is domain specific (see Figure 4, ISO/IEC 10589:2002). This  
29 shall be zero in this version of this specification.
- 30 b) The SPB System Shortest Path Source Identifier (SPSourceID) (27.10).
- 31 c) If SPBV mode is used, whether the SPVIDs associated with this Bridge are assigned, or are to be  
32 auto-allocated. The use of SPBV mode is inferred from the assignment of at least one VID to the  
33 reserved MSTID value 0xFFD (27.4) in the FID to MSTID Allocation Managed Object (12.12.2.2).
- 34 d) If SPBM mode is used, whether the SPsourceID associated with this Bridge is assigned, or is to be  
35 auto-allocated. The use of SPBM mode is inferred from the assignment of at least one VID to the  
36 reserved MSTID value 0xFFC (27.4) in the FID to MSTID Allocation Managed Object (12.12.2.2).
- 37 e) The agreement digest Convention identifier (28.4.3), specifying the agreement rules being used. It  
38 can take the values 1 to 3 as specified in 28.4.3.

### 39 12.25.1.2.3 Outputs

- 40 a) Operation status. This takes one of the following values:
  - 41 1) Operation rejected due to the Bridge's inability to support the requested SPB capability
  - 42 2) Operation accepted

### 12.25.1.3 Read SPB System managed object

#### 12.25.1.3.1 Purpose

To obtain information about SPB System managed object on a Bridge.

#### 12.25.1.3.2 Inputs

- a) The part of the IS-IS Area Address that is domain specific (see Figure 4, ISO/IEC 10589:2002).

#### 12.25.1.3.3 Outputs

- a) The part of the IS-IS Area Address that is domain specific (see Figure 4, ISO/IEC 10589:2002).
- b) The SPB System Identifier used by all instances of ISIS-SPB on this Bridge.
- c) The Group address used to address this ISIS-SPB instance (Table 8-16). This address also identifies the IS-IS Level at which this SPB instance is operating.
- d) The SPB System Name used by all instances of ISIS-SPB. This takes the value configured by Set Bridge Name (12.4.1.3) and which can also be read as item b) of Read Bridge (12.4.1.2).
- e) The Bridge Priority (13.26.2). The value used by SPB is set in the CIST Bridge Protocol Parameters (12.8.1.3).
- f) The SPB System SPSourceID (27.10).
- g) The SPBV Mode, identifying whether, if SPBV mode is used, the SPVIDs associated with this Bridge are assigned, or are to be auto-allocated.
- h) The SPBM Mode, identifying whether, if SPBM mode is used, the SPsourceID associated with this Bridge is assigned, or is to be auto-allocated.
- i) The agreement digest Convention identifier (28.4.3), specifying the agreement rules being used.

### 12.25.1.4 Delete SPB System managed object

#### 12.25.1.4.1 Purpose

To delete the SPB System managed object on a Bridge, so disabling it as an SPT Bridge.

#### 12.25.1.4.2 Inputs

- a) The part of the IS-IS Area Address that is domain specific (see Figure 4, ISO/IEC 10589:2002).

#### 12.25.1.5 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because one or more SPB MTID Static managed objects still exist and have not been deleted for this SPB instance.
  - 2) Operation accepted.

### 12.25.2 The SPB MTID Static managed object

There is one SPB MTID Static managed object per IS-IS Multi-Topology Identifier (MTID) used for SPB operation. It contains the SPB MTID value and the ISIS-SPB Overload flag for this MTID. It is persistent over reboot. The management operations that can be performed on the SPB MTID Static managed object are as follows:

- a) Create SPB MTID Static managed object (12.25.2.1)
- b) Write SPB MTID Static managed object (12.25.2.2)
- c) Read SPB MTID Static managed object (12.25.2.3)
- d) Delete SPB MTID Static managed object (12.25.2.4)

## 1 **12.25.2.1 Create SPB MTID Static managed object**

### 2 **12.25.2.1.1 Purpose**

3 To create and configure an SPB MTID Static managed object on a Bridge.

### 4 **12.25.2.1.2 Inputs**

- 5 a) An MTID to support IS-IS MT operation.

### 6 **12.25.2.1.3 Outputs**

- 7 a) Operation status. This takes one of the following values:  
8 1) Operation rejected because the MTID is already in use  
9 2) Operation accepted  
10 b) A Topology Index value that uniquely identifies this MTID Static managed object.

## 11 **12.25.2.2 Write SPB MTID Static managed object**

### 12 **12.25.2.2.1 Purpose**

13 To configure an SPB MTID Static managed object.

### 14 **12.25.2.2.2 Inputs**

- 15 a) An MTID to support IS-IS MT operation.  
16 b) The Overload flag value, which has ISIS “no transit” semantics, applied only in this SPB topology.

### 17 **12.25.2.2.3 Outputs**

- 18 a) The MTID value.  
19 b) The Overload flag value, which has ISIS “no transit” semantics, but applied only in this SPB  
20 topology.

## 21 **12.25.2.3 Read SPB MTID Static managed object**

### 22 **12.25.2.3.1 Purpose**

23 To obtain information about an SPB MTID Static managed object.

### 24 **12.25.2.3.2 Inputs**

- 25 a) An MTID to support IS-IS MT operation.

### 26 **12.25.2.3.3 Outputs**

- 27 a) The MTID value.  
28 b) The Overload flag value, which has ISIS “no transit” semantics, but applied only in this SPB  
29 topology.  
30 c) A Topology Index value that uniquely identifies this MTID Static managed object.

## 31 **12.25.2.4 Delete SPB MTID Static managed object**

### 32 **12.25.2.4.1 Purpose**

33 To delete an SPB MTID Static managed object.

#### 1 **12.25.2.4.2 Inputs**

- 2 a) An MTID to support IS-IS MT operation.

#### 3 **12.25.2.4.3 Outputs**

- 4 a) Operation status. This takes one of the following values:
- 5 1) Operation rejected because not all peer links in the SPB Adjacency Static Entry managed object
- 6 for this MTID have an Administrative State of Disabled.
- 7 2) Operation accepted.

### 8 **12.25.3 The SPB Topology Instance Dynamic managed object**

9 There is one SPB Topology Instance Dynamic managed object for each SPB MTID Static managed object. It  
10 contains the dynamic parameters computed for this Bridge as a consequence of its participation in SPB in  
11 the ISIS-SPB topology defined by the specified MTID within this instance of SPB. This object is  
12 automatically created as a consequence of the creation of the SPB MTID Static managed object associated  
13 with the topology. It is deleted with the deletion of the SPB MTID Static managed object associated with the  
14 topology. The management operation that can be performed on the SPB Topology Instance Dynamic  
15 managed object is as follows:

- 16 a) Read SPB Topology Instance Dynamic managed object

#### 17 **12.25.3.1 Read SPB Topology Instance Dynamic managed object**

##### 18 **12.25.3.1.1 Purpose**

19 To obtain information about the dynamic parameters computed by this Bridge as a consequence of its  
20 participation in SPB in the ISIS-SPB topology defined by the specified MTID within this instance of SPB.

##### 21 **12.25.3.1.2 Inputs**

- 22 a) A Topology Index value that uniquely identifies a topology instance.

##### 23 **12.25.3.1.3 Outputs**

- 24 a) The Topology Index value that uniquely identifies this topology instance.
- 25 b) The value of the topology Agreement Digest (13.17.1) being advertised by this Bridge to its peers in
- 26 this ISIS-SPB Topology. This includes all parameters defined in the Agreement Digest (28.4).
- 27 c) The value of the MCID (8.9, 13.5, 13.8) being advertised by this Bridge to its peers.
- 28 d) The value of the Auxiliary MCID (27.4.1, 28.12.2) being advertised by this Bridge to its peers.

### 29 **12.25.4 The SPB ECT Static Entry managed object**

30 There is one SPB ECT Static Entry managed object per Base VID allocated to SPB operation. A Base VID  
31 exists in the context of a single ISIS-SPB MTID. The static Entry contains the SPB configuration parameters  
32 for the forwarding plane associated with the Base VID. It is persistent over reboot. The management  
33 operations that can be performed on the ECT Static Entry managed object are as follows:

- 34 a) Create an SPB ECT Static Entry managed object (12.25.4.1)
- 35 b) Read an SPB ECT Static Entry managed object (12.25.4.2)
- 36 c) Delete an SPB ECT Static Entry managed object (12.25.4.3)

## 1 12.25.4.1 Create SPB ECT Static Entry managed object

### 2 12.25.4.1.1 Purpose

3 To create and configure and interrogate an SPB ECT Static Entry managed object on a Bridge.

### 4 12.25.4.1.2 Inputs

- 5 a) A Topology Index value that uniquely identifies a topology instance.
- 6 b) A Base VID. This VID must have been assigned either to the reserved MSTID value 0xFFC for SPT  
7 Bridges in SPBM operation, or to the reserved MSTID value 0xFFD for SPBV (27.4) in the FID to  
8 MSTI Allocation table (12.12.2.2).
- 9 c) The identifier of the ECT Algorithm (ECT-ALGORITHM) to be used for this Base VID  
10 (Table 28-1, Table 44-1, Table 45-1). The Default is the LowPATHID 00-80-C2-01 (28.8).
- 11 d) The pre-configured value of the SPVID assigned to this Bridge if operating in SPBV mode. This  
12 input is ignored if auto-allocated is selected [item c) in 12.25.1.2.2]. This VID value must have been  
13 assigned to the SPVID-Pool-MSTID (27.4) in the FID to MSTI Allocation Managed Object  
14 (12.12.2.2).

### 15 12.25.4.1.3 Outputs

- 16 a) Operation status. This takes one of the following values:
  - 17 1) Operation rejected because the Topology Index value is not defined
  - 18 2) Operation rejected because the Base VID is already in use
  - 19 3) Operation rejected due to requested Base VID not assigned to specified SPB use
  - 20 4) Operation rejected due to requested SPVID not assigned to the SPBV pool
  - 21 5) Operation accepted

## 22 12.25.4.2 Read SPB ECT Static Entry managed object

### 23 12.25.4.2.1 Purpose

24 To obtain information about the SPB ECT Static Entry managed object for a Base VID.

### 25 12.25.4.2.2 Inputs

- 26 a) A Topology Index value that uniquely identifies a topology instance.
- 27 b) A Base VID. The value 4095 is a wildcard indicating that information, from any Base VID assigned  
28 to SPB operation, is requested.

### 29 12.25.4.2.3 Outputs

- 30 a) Operation status. This takes one of the following values:
  - 31 1) Operation rejected because the Base VID is not assigned to SPB use
  - 32 2) Operation accepted
- 33 b) A Topology Index value that uniquely identifies this topology instance.
- 34 c) The Base VID.
- 35 d) The identifier of the ECT algorithm (ECT-ALGORITHM) to be used for this Base VID.
- 36 e) The value of the SPVID to be used by this Bridge for this Base VID if operating in SPBV mode.

### 1 **12.25.4.3 Delete SPB ECT Static Entry managed object**

#### 2 **12.25.4.3.1 Purpose**

3 To delete the SPB ECT Static Entry managed object for a Base VID.

#### 4 **12.25.4.3.2 Inputs**

- 5 a) A Topology Index value that uniquely identifies a topology instance.
- 6 b) A Base VID.

#### 7 **12.25.4.3.3 Outputs**

- 8 a) Operation status. This takes one of the following values:
  - 9 1) Operation rejected because the Bridge has services currently assigned to this Base VID
  - 10 2) Operation rejected because the SPT Region has services currently using this Base VID
  - 11 3) Operation accepted

### 12 **12.25.5 The SPB ECT Dynamic Entry managed object**

13 There is one SPB ECT Dynamic Entry managed object per Base VID allocated to SPB operation. It contains  
14 the SPB dynamic parameters associated with the Base VID. This object is automatically created as a  
15 consequence of the creation of the SPB ECT Static Entry managed object. It is deleted with the deletion of  
16 the SPB ECT Static Entry managed object. The management operation that can be performed on the ECT  
17 Dynamic Entry managed object is as follows:

- 18 a) Read SPB ECT Dynamic Entry managed object

#### 19 **12.25.5.1 Read SPB ECT Dynamic Entry managed object**

##### 20 **12.25.5.1.1 Purpose**

21 To obtain information about the SPB ECT Dynamic Entry managed object for a Base VID.

##### 22 **12.25.5.1.2 Inputs**

- 23 a) A Topology Index value that uniquely identifies a topology instance.
- 24 b) A Base VID. The value 4095 is a wildcard indicating that information, from any Base VID assigned  
25 to SPB operation, is requested.

##### 26 **12.25.5.1.3 Outputs**

- 27 a) The Topology Index value that uniquely identifies this topology instance.
- 28 b) The Base VID.
- 29 c) A flag identifying whether the operational mode of this Base VID is SPBV or SPBM.
- 30 d) A flag indicating that this Bridge has services currently assigned to this Base VID.
- 31 e) A flag indicating that the SPT Region has services currently using this Base VID.
- 32 f) A count of the number of ingress check failures (an error condition) on this Base VID since creation  
33 of this SPB ECT Dynamic Entry managed object.

## 12.25.6 The SPB Adjacency Static Entry managed object

There is one SPB Adjacency Static Entry managed object per port per ISIS-SPB topology. It contains the SPB configuration parameters for the port in a topology. It is persistent over reboot. The management operations that can be performed on the SPB Adjacency Static Entry managed object are as follows:

- a) Write SPB Adjacency Static Entry managed object (12.25.6.1)
- b) Read SPB Adjacency Static Entry managed object (12.25.6.2)

### 12.25.6.1 Write SPB Adjacency Static Entry managed object

#### 12.25.6.1.1 Purpose

To configure an SPB Adjacency Static Entry managed object on a port for an ISIS-SPB topology.

#### 12.25.6.1.2 Inputs

- a) A Topology Index value that uniquely identifies a topology instance.
- b) The system interface index of a port.
- c) The value of the ieee802.1 SPB Link State metric for the link on this port. For MTID = 0, or when a single MTID only is in use, this value should be set equal to the Path Cost set in the CIST Port Parameters Managed Object (see 12.8.2.1 and 12.8.2.3).
- d) The SPB administrative state of a port.

NOTE—Item c) – The primary function of IS-IS MT is to allow different link metrics to be associated with each topology, so that different routes are preferentially favored in different topologies. However, care must be taken when configuring IS-IS MT that CIST path costs are assigned to one topology, and that this topology is the one used to compute the CIST, in order that SPB calculates its part of the CIST consistently.

#### 12.25.6.1.3 Outputs

- a) The Topology Index value that uniquely identifies this topology instance.
- b) The system interface index of the port.
- c) The value of the ieee802.1 SPB Link State metric for the link on this port.
- d) The SPB administrative state of this port.

### 12.25.6.2 Read SPB Adjacency Static Entry managed object

#### 12.25.6.2.1 Purpose

To read back the parameters of an SPB Adjacency Static Entry managed object on a port for an ISIS-SPB topology.

#### 12.25.6.2.2 Inputs

- a) A Topology Index value that uniquely identifies a topology instance.
- b) The system interface index of a port. The value of zero is a wildcard indicating information, for any interface on which SPB operation is enabled, is requested.

#### 12.25.6.2.3 Outputs

- a) The Topology Index value that uniquely identifies this topology instance.
- b) The system interface index of the port.
- c) The value of the ieee802.1 SPB Link State metric for the link on this port.
- d) The SPB administrative state of this port.

## 12.25.7 The SPB Adjacency Dynamic Entry managed object

There is one SPB Adjacency Dynamic Entry managed object per port per ISIS-SPB topology. It contains the dynamically discovered SPB parameters for the port in that topology. The management operation that can be performed on the SPB Adjacency Dynamic Entry managed object is as follows:

- a) Read SPB Adjacency Dynamic Entry managed object in a topology

### 12.25.7.1 Read SPB Adjacency Dynamic Entry managed object

#### 12.25.7.1.1 Purpose

To obtain information about an SPB Adjacency Dynamic Entry managed object on a port.

#### 12.25.7.1.2 Inputs

- a) A Topology Index value that uniquely identifies a topology instance.
- b) The system interface index of a port. The value of zero is a wildcard indicating information, for any interface on which SPB operation is enabled, is requested.
- c) The SPB System Identifier of a peer attached to the port.

#### 12.25.7.1.3 Outputs

- a) The Topology Index value that uniquely identifies this topology instance.
- b) The system interface index of the port.
- c) The SPB System Identifier of the peer attached to the port.
- d) The Bridge Port Number (same as item d1) in 12.4.1.2.3).
- e) The SPB operational state of this port.
- f) The IS-IS System name of the peer attached to the port.
- g) The value of the topology Agreement Digest (13.17.1) being advertised by the peer. This includes all parameters defined in the Agreement Digest (28.4).
- h) The value of the MCID (8.9, 13.5, 13.8) being advertised by the peer.
- i) The value of the Auxiliary MCID (27.4.1, 28.12.2) being advertised by the peer.
- j) The value of the Local Circuit ID of this node, used by ISIS to select a single adjacency if more than one link connects a pair of SPT Bridges.
- k) The value of the Local Circuit ID of the peer node, used by ISIS to select a single adjacency if more than one link connects a pair of SPT Bridges.
- l) The value of the Port Identifier on this node for the link selected by ISIS to form the adjacency, equal to the value read as item c) from the CIST Port Parameters Managed Object (see 12.8.2.1) on this node.
- m) The value of the Port Identifier on the peer node for the link selected by ISIS to form the adjacency with this node.
- n) An index pointing into the isisCircTable in the IS-IS MIB for cross-referencing.

## 12.25.8 The SPBM BSI Static Entry managed object

There is one SPBM BSI Static Entry managed object for each I-SID assigned to an SPBM VID on a CBP. It contains the SPBM configuration parameters for an I-SID. It is persistent over reboot. The management operations that can be performed on the SPBM BSI Static Entry managed object are as follows:

- a) Write SPBM BSI Static Entry managed object (12.25.8.1)
- b) Read SPBM BSI Static Entry managed object (12.25.8.2)

## 1 12.25.8.1 Write SPBM BSI Static Entry managed object

### 2 12.25.8.1.1 Purpose

3 To configure an SPBM BSI Static Entry managed object for an I-SID assigned to an SPBM VID on a CBP.

### 4 12.25.8.1.2 Inputs

- 5 a) A Topology Index value that uniquely identifies a topology instance.
- 6 b) The system interface index of a CBP.
- 7 c) The I-SID identifying the backbone service instance.
- 8 d) A B-VID associated with this I-SID. There may be more than one object for a given I-SID, allowing  
9 it to be associated with multiple B-VIDs. This B-VID may differ from the B-VID specified in  
10 12.16.5.2 that governs the VID assigned to the I-SID at the CBP; for example, to allow changing  
11 ISIS-SPB parameters when moving an I-SID from one B-VID to another. The B-VID to I-SID  
12 association in this managed object is advertised in ISIS-SPB so that forwarding state for the  
13 association is installed throughout the SPT domain, in addition to CBP state installed by 12.16.5.2. It  
14 is only the B-VID defined in 12.16.5.2 on which a CBP transmits; however, a CBP must receive  
15 from any B-VID with which its I-SID has an association.
- 16 e) Multicast transmit indication bit [item e) in 28.12.10].
- 17 f) Multicast receive indication bit [item f) in 28.12.10].
- 18 g) Shared tree transmit indication bit [item g) in 28.12.10].
- 19 h) Tie-Break Mask value [item h) in 28.12.10].

### 20 12.25.8.1.3 Outputs

- 21 a) Operation status. This takes one of the following values:
  - 22 1) Operation rejected because the Topology Index value is not defined
  - 23 2) Operation rejected because the identified port does not exist or is not a CBP
  - 24 3) Operation rejected because the I-SID is not assigned to an SPBM VID
  - 25 4) Operation accepted

## 26 12.25.8.2 Read SPBM BSI Static Entry managed object

### 27 12.25.8.2.1 Purpose

28 To read back the parameters of an SPBM BSI Static Entry managed object for an I-SID assigned to an  
29 SPBM VID on a CBP.

### 30 12.25.8.2.2 Inputs

- 31 a) A Topology Index value that uniquely identifies a topology instance.
- 32 b) The system interface index of a CBP. The value of zero is a wildcard indicating information, for any  
33 interface on which SPB operation is enabled, is requested.
- 34 c) An I-SID identifying a backbone service instance. The value 0xFFFFFFFF is a wildcard indicating that  
35 information on all I-SIDs on the specified port(s) is requested.
- 36 d) A B-VID associated with this I-SID. The value 4095 is a wildcard indicating that information for  
37 any B-VID associated with the specified I-SID(s) is requested.

### 12.25.8.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because the Topology Index value is not defined
  - 2) Operation rejected because the identified port does not exist or is not a CBP
  - 3) Operation rejected because the I-SID is not assigned to an SPBM VID
  - 4) Operation accepted
- b) The Topology Index value that uniquely identifies this topology instance.
- c) The system interface index of the port.
- d) The I-SID identifying a backbone service instance.
- e) The B-VID associated with this I-SID.
- f) Multicast transmit indication bit [item e) in 28.12.10].
- g) Multicast receive indication bit [item f) in 28.12.10].
- h) Shared tree transmit indication bit [item g) in 28.12.10].
- i) Tie-Break Mask value [item h) in 28.12.10].

If item b) in 12.25.8.2.2 is configured with the value 0, a list indexed by the CBP ports on the system containing item a) to item i) [with the exception of item a2)].

### 12.25.9 The SPB Topology Node Table managed object

There is one SPB Topology Node Table managed object per Bridge per ISIS-SPB topology. It is populated by ISIS-SPB with the nodal SPB parameters discovered for all SPT Bridges participating in that topology within the SPT Region. This object is automatically created as a consequence of the creation of the SPB MTID Static managed object for that topology. It is deleted with the deletion of that SPB MTID Static managed object. The management operation that can be performed on the SPB Topology Node Table managed object is as follows:

- a) Read SPB Topology Node Table managed object

#### 12.25.9.1 Read SPB Topology Node Table managed object

##### 12.25.9.1.1 Purpose

To obtain nodal information about all SPT Bridges in an SPT Region for an ISIS-SPB topology.

##### 12.25.9.1.2 Inputs

- a) A Topology Index value that uniquely identifies a topology instance.
- b) The SPB System Identifier of ISIS-SPB on a remote Bridge. The value zero is a wildcard indicating that information, from all remote Bridges in the SPT region, is requested.

##### 12.25.9.1.3 Outputs

A list, which may be empty, comprising one entry for each Bridge within the SPT Region of which the local IS-IS instance is aware. Each entry contains the following information about a remote Bridge:

- a) The Topology Index value that uniquely identifies this topology instance
- b) The SPB System Identifier of ISIS-SPB on the remote Bridge
- c) The Bridge Priority [the value set in CIST Protocol Parameters (12.8.1.3) for the remote Bridge]
- d) The SPSourceID (27.10) of the remote Bridge
- e) The SPB System Name of the remote Bridge

If b) identifies a specific remote Bridge then the list above will comprise one entry per Base VID, as specified in item c), containing only information about the specific remote Bridge.

## 12.25.10 The SPB Topology ECT Table managed object

There is one SPB Topology ECT Table managed object per Bridge per ISIS-SPB topology. It is populated by ISIS-SPB with the nodal ECT parameters discovered for all SPT Bridges participating in that topology within the SPT Region. This object is automatically created as a consequence of the creation of the SPB MTID Static managed object. It is deleted with the deletion of that SPB MTID Static managed object. The management operation that can be performed on the SPB Topology ECT Table managed object is as follows:

- a) Read SPB Topology ECT Table managed object

### 12.25.10.1 Read SPB Topology ECT Table managed object

#### 12.25.10.1.1 Purpose

To obtain nodal ECT information, including the binding of ECT Algorithms to Base VIDs, about all SPT Bridges in an SPT Region for an ISIS-SPB topology.

#### 12.25.10.1.2 Inputs

- a) A Topology Index value that uniquely identifies a topology instance.
- b) The SPB System Identifier of ISIS-SPB on a remote Bridge. The value zero is a wildcard indicating information, for all System identifiers, is requested.
- c) The Base VID. The value 4095 is a wildcard indicating that information, from any Base VID assigned for SPB operation, is requested.

#### 12.25.10.1.3 Outputs

A list, which may be empty, comprising one entry for each Bridge within the SPT Region of which the local ISIS-SPB instance is aware. Each entry contains the following information about a remote Bridge:

- a) The Topology Index value that uniquely identifies this topology instance
- b) The SPB System Identifier of ISIS-SPB on the remote Bridge
- c) The Base VID
- d) The identifier of the ECT Algorithm being used
- e) The SPB operational mode (SPBV or SPBM)
- f) The SPVID allocation mode (manual or automatic)
- g) The value of the SPVID when operating in SPBV mode
- h) A flag indicating that this Bridge has services currently assigned to this Base VID

If item b) identifies a specific remote Bridge then the list above will comprise one entry per Base VID as specified in item c), containing only information about the specific remote Bridge.

## 12.25.11 The SPB Topology Edge Table managed object

There is one SPB Topology Edge Table managed object per Bridge per ISIS-SPB topology. It is populated by ISIS-SPB with the discovered Edge (link) parameters for that topology within the SPT Region, referenced by the System Identifiers of the pair of SPT Bridges forming the end-points. This object is automatically created as a consequence of the creation of the SPB MTID Static managed object for that topology. It is deleted with the deletion of that SPB MTID Static managed object. The management operation that can be performed on the SPB Topology Edge Table managed object is as follows:

- a) Read SPB Topology Edge Table managed object

## 12.25.11.1 Read SPB Topology Edge Table managed object

### 12.25.11.1.1 Purpose

To obtain information about all Edges interconnecting SPT Bridges within an SPT Region for an ISIS-SPB topology.

NOTE—The use of the ISIS Local Circuit ID for tie breaking enables a single Edge (adjacency) per node pair and a unique Port Identifier on each node for spanning tree compatibility; refer to 28.11 and the Read operation on SPB Adjacency Dynamic Entry managed object.

### 12.25.11.1.2 Inputs

- a) A Topology Index value that uniquely identifies a topology instance.
- b) The SPB System Identifier used by the near Bridge on an Edge. The value zero is a wildcard indicating information, for all System identifiers, is requested.
- c) The SPB System Identifier used by the far Bridge on an Edge. The value zero is a wildcard indicating information, for all System identifiers, is requested.

### 12.25.11.1.3 Outputs

A list, which may be empty, comprising one entry for each Edge within the SPT Region of which the local IS-IS instance is aware. Each entry contains the following information about an Edge:

- a) The Topology Index value that uniquely identifies this topology instance.
- b) The SPB System Identifier used by the near Bridge on the Edge.
- c) The SPB System Identifier used by the far Bridge on the Edge.
- d) The value of the ieee802.1 SPB Link State metric for this Edge, which is being advertised by the near Bridge.
- e) The value of the ieee802.1 SPB Link State metric for this Edge, which is being advertised by the far Bridge.

NOTE—The terms “near” and “far” are used locally solely to distinguish the two ends of the Edge and associated metric values, and do not signify any relationship between the SPT Bridges advertising the Edge and the local Bridge supporting the SPB Topology Edge Table managed object. As a consequence of this definition, in a stable topology two Edges are created per physical link, one advertised in a Link State PDU (LSP) by each Bridge.

## 12.25.12 The SPBM Topology Service Table managed object

There is one SPBM Topology Service Table managed object per Bridge per ISIS-SPB topology. It is populated by ISIS-SPB with the mapping of Service instances to SPT Bridges operating in SPBM mode participating in that topology discovered within the SPT Region. This object is automatically created as a consequence of the creation of the SPB MTID Static managed object for that topology. It is deleted with the deletion of that SPB MTID Static managed object. The SPBM Topology Service Table managed object only exists to provide Region-wide visibility of I-SID instance locations. Configuration of local I-SID instances is performed using the BEB Management (12.16) and the mapping of VIPs to PIPs (and hence to the B-MAC address associated with an I-SID) by PIP Management (12.16.4).

The management operation that can be performed on the SPBM Topology Service Table managed object is as follows:

- a) Read SPBM Topology Service Table managed object

## 1 12.25.12.1 Read SPBM Topology Service Table managed object

### 2 12.25.12.1.1 Purpose

3 To obtain information about the location of all I-SID instances within an SPT Region in an ISIS-SPB  
4 topology.

### 5 12.25.12.1.2 Inputs

- 6 a) A Topology Index value that uniquely identifies a topology instance.
- 7 b) The SPB System Identifier of an SPT Bridges operating in SPBM mode hosting an I-SID. The value  
8 zero is a wildcard indicating information, from all remote Bridges in the SPT region hosting any  
9 I-SIDs, is requested.
- 10 c) An I-SID value. The value 0xFFFFF is a wildcard indicating that information, from the remote  
11 Bridge(s) specified in item b) above hosting any I-SID, is requested.
- 12 d) The Base VID associated with this I-SID instance. The value 4095 is a wildcard indicating that  
13 information, from any Base VID assigned to SPB operation, is requested.

### 14 12.25.12.1.3 Outputs

15 A list, which may be empty, comprising one entry for each I-SID assigned to a Base VID within the SPT  
16 Region of which the local IS-IS instance is aware. Each entry contains the following information about the  
17 I-SID:

- 18 a) The Topology Index value that uniquely identifies this topology instance.
- 19 b) The SPB System Identifier of the SPT Bridges operating in SPBM mode hosting an I-SID instance.
- 20 c) The I-SID value.
- 21 d) The Base VID associated with this I-SID (and hence the ECT-ALGORITHM applied to this  
22 service).
- 23 e) The B-MAC address associated with this I-SID. If multiple I-SID instances are configured on a  
24 single Bridge but are reachable by different B-MAC addresses, a separate record is returned for each  
25 B-MAC address associated with that I-SID.
- 26 f) The I-SID instance service characteristic; transmit-only, receive-only, or both [item e) and item f) in  
27 28.12.10; item e) and item f) in 12.25.8.1].
- 28 g) If ECMP is supported, the shared tree transmit indication [item g) in 28.12.10; item g) in  
29 12.25.8.1.2].
- 30 h) If ECMP is supported, the Tie-Break Mask value [item h) in 28.12.10; item h) in 12.25.8.1.2].

31 NOTE—In general, an I-SID will be assigned to a single Base VID. During the administratively mediated migration of  
32 traffic from one ECT-ALGORITHM to a new one, an I-SID may be assigned to two Base VIDs for the duration of the  
33 transition in order to achieve loss-less migration (28.9.2).

## 34 12.25.13 The SPBV Topology Service Table managed object

35 There is one SPBV Topology Service Table managed object per Bridge per ISIS-SPB topology. It is  
36 populated by ISIS-SPB with the mapping of group MAC addresses to SPT Bridges operating in SPBV mode  
37 participating in that topology discovered within the SPT Region. This object is automatically created as a  
38 consequence of the creation of the SPB MTID Static managed object. It is deleted with the deletion of that  
39 SPB MTID Static managed object. The SPBV Topology Service Table managed object only exists to  
40 provide Region-wide visibility of group MAC address instance locations. Local configuration of group  
41 MAC address instances is performed using the procedures for management of Static Filtering Entries  
42 (12.7.2), or MMRP procedures (10.9).

43 The management operation that can be performed on the SPBV Topology Service Table managed object is  
44 as follows:

- 45 a) Read SPBV Topology Service Table managed object

## 1 **12.25.13.1 Read SPBV Topology Service Table managed object**

### 2 **12.25.13.1.1 Purpose**

3 To obtain information about all group MAC address instances within an SPT Region in an ISIS-SPB  
4 topology.

### 5 **12.25.13.1.2 Inputs**

- 6 a) A Topology Index value that uniquely identifies a topology instance.
- 7 b) The SPB System Identifier of an SPT Bridges operating in SPBV mode hosting a group MAC  
8 address. The value zero is a wildcard indicating information, from all remote Bridges in the SPT  
9 region hosting group MAC addresses, is requested.
- 10 c) The group MAC address value. The value zero is a wildcard indicating information, about all Group  
11 MACs for the specific Bridge(s) with the System Identifier as specified by item b), is requested.

### 12 **12.25.13.1.3 Outputs**

13 A list, which may be empty, and comprising one entry for each group MAC address instance within the SPT  
14 Region of which the local IS-IS instance is aware. Each entry contains the following information about the  
15 group MAC address:

- 16 a) The Topology Index value that uniquely identifies this topology instance.
- 17 b) The SPB System Identifier of the SPT Bridges operating in SPBV mode hosting a group MAC  
18 address instance.
- 19 c) The group MAC address value.
- 20 d) The Base VID (and hence ECT-ALGORITHM applied to this service).
- 21 e) The group MAC address instance service characteristic; transmit-only, receive-only, or both.

22 If item b) identifies a specific remote Bridge hosting an group address, then the list above will comprise only  
23 information about the specific remote Bridge.

## 24 **12.25.14 The ECMP ECT Static Entry managed object**

25 There is one ECMP ECT Static Entry managed object per Tie-Break Mask. It contains the Bridge Priority to  
26 be used for shared tree root selection for that Tie-Break Mask value. It is persistent over reboot. The  
27 management operations that can be performed on the ECMP ECT Static Entry managed object are as  
28 follows:

- 29 a) Write ECMP ECT Static Entry managed object (12.25.14.1)
- 30 b) Read ECMP ECT Static Entry managed object (12.25.14.2)

### 31 **12.25.14.1 Write ECMP ECT Static Entry managed object**

#### 32 **12.25.14.1.1 Purpose**

33 To configure a different Bridge Priority to be used solely for shared tree root selection for a given Tie-Break  
34 Mask (28.12.6.1, 28.8).

#### 35 **12.25.14.1.2 Inputs**

- 36 a) A Topology Index value that uniquely identifies a topology instance.
- 37 b) A Tie-Break Mask value [item d) in 28.12.6.1].
- 38 c) Bridge Priority [item e) in 28.12.6.1].

### 12.25.14.1.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because the Topology Index value is not defined
  - 2) Operation accepted

### 12.25.14.2 Read ECMP ECT Static Entry managed object

#### 12.25.14.2.1 Purpose

To read back the Bridge Priority for a given Tie-Break Mask.

#### 12.25.14.2.2 Inputs

- a) A Topology Index value that uniquely identifies a topology instance.
- b) A Tie-Break Mask value [item d) in 28.12.6.1].

#### 12.25.14.2.3 Outputs

- a) Operation status. This takes one of the following values:
  - 1) Operation rejected because the Topology Index value is not defined
  - 2) Operation accepted
- b) The Topology Index value that uniquely identifies this topology instance.
- c) The Tie-Break Mask value [item d) in 28.12.6.1].
- d) The Bridge Priority [item e) in 28.12.6.1].

## 12.26 Edge Virtual Bridging (EVB) management

The conformance requirements for EVB Bridges and EVB stations are defined in 5.23 and 5.24, respectively. Each C-VLAN Component, ER (5.24.1), and Port-mapping S-VLAN Component can be managed using the managed objects of 12.4 through 12.12 along with the EVB managed objects specified in this subclause.

An EVB Bridge system (Figure 12-4) supports the EVB managed objects defined in 12.26.1 through 12.26.3 and 12.27. Optionally, an EVB Bridge supports the managed objects for S-channels defined in 12.26.4.

An EVB station system (Figure 12-5) supports the EVB managed objects defined in 12.26.1, 12.26.3, 12.26.5, and 12.27. Optionally, an EVB station supports the managed objects for S-channels defined in 12.26.4.

The EVB-specific managed objects defined here:

- a) Provide managed objects for identifying and configuring an EVB system and its system-wide default parameters for LLDP, Virtual Station Interface (VSI) Discovery and Configuration Protocol (VDP), and S-channel (12.26.1).
- b) Provide managed objects for configuring the Station-facing Bridge Ports (SBPs) of EVB Bridges (12.26.2).
- c) Provide a VSI table that contains the current VSI and VDP state for each VSI that is active in the EVB system (12.26.3).
- d) Provide managed objects for configuring the Port-mapping S-VLAN Components and S-channels (12.26.4).
- e) Provide managed objects for configuring the URPs of the ERs (12.26.5).

Figure 12-4—Relationships among EVB Bridge managed objects

Note 1: ISS table managed object is required when URP Port# != ISS Port#

Figure 12-5—Relationship among EVB station managed objects

1 For each EVB system, an EVB system configuration managed object exists containing the system-wide  
2 defaults used to initialize the other EVB objects.

3 Every Port of the EVB system (40.1, 40.2, 40.3) is uniquely identified by a ComponentID (12.3) and Port  
4 Number (12.3) [which together identify a Port Index (12.3)]. In EVB systems where the ISS and bound  
5 Bridge Port have different Port Numbers, an ISS table (12.5.1) allows determining the associated Bridge  
6 Port's ComponentID and Port Number from the scalar ISS Port Number. An example where the ISS table  
7 would be needed is an EVB station where the station has multiple LANs each attaching to different ERs and  
8 where the ERs each use the same Port Number (however different ComponentIDs) to identify their URPs  
9 (Figure 40-3). The ISS table is normally not necessary in an EVB Bridge since the single C-VLAN-aware  
10 Component provides a Bridge Port Number that is unique within the EVB Bridge for every ISS, allowing  
11 the ISS and the Bridge Port to use the same Port Number independent from the ComponentID.

12 The ERs of an EVB station have two types of ports. Each ER DRP provides attachment to one or more VSIs.  
13 No special EVB objects are used to manage the DRPs. URPs can attach to a LAN that can be externally  
14 accessible or attach through an internal LAN to a CAP of an S-channel. URPs are managed using the URP  
15 table. Each URP table entry identifies a URP within the system and allows configuration and monitoring of  
16 LLDP and VDP for the URP (12.26.5). For each URP there is also a ECP table entry that allows  
17 configuration and monitoring of ECP (12.27).

18 NOTE 1—The most common case is that a single VSI is associated with each DRP.

19 The C-VLAN Component of an EVB Bridge has two types of Ports. Each C-VLAN Bridge Port is  
20 externally accessible and does not provide any EVB capabilities. No special EVB objects are used to  
21 manage the C-VLAN Bridge Ports. Each SBP attaches to a LAN that can be externally accessible or attach  
22 though an internal LAN to a CAP of an S-channel. SBPs are managed using the SBP table. Each SBP table  
23 entry identifies a single SBP within the system and allows configuration and monitoring of LLDP and VDP  
24 for the SBP (12.26.2). For each SBP there is also a ECP table entry that allows configuration and monitoring  
25 of ECP (12.27).

26 Within each EVB station and EVB Bridge, a table holding the VSIs allows monitoring of the active VSIs  
27 (12.26.3). VSI table entries are keyed on the VSI Instance Identifier (VSIID) and the URP's or SBP's  
28 ComponentID and Port Number. During the movement of VSIs within the data center network (DCN) it is  
29 possible to have a transient condition where the same VSIID exists at two locations. When these two  
30 instances are at the same URP or SBP, they are indistinguishable; therefore, the table holds only the state for  
31 the most recent VSI command. However, when the movement is between different URPs or SBPs, the table  
32 will hold two copies of the same VSIID differentiated by the ComponentID and Port Number of the URPs or  
33 SBPs.

34 NOTE 2—In the case where a VSI is migrated between DRPs of the same ER, there is no reason to de-associate, as the  
35 table does not maintain any state that identifies the DRP of the ER to which the VSI is attached.

36 An association is identified by its URP and VSIID. If an association is established for a VSI, and a new  
37 association is established on the same URP for the same VSIID, then the new association replaces the old  
38 one. A subsequent de-association for that VSIID will remove the current association, regardless of the  
39 parameters.

40 In EVB systems supporting S-channels, the optional UAP table and S-channel interface table are used to  
41 configure and control the Port-mapping S-VLAN Components and CDCP (12.26.4).

42 Each ISS that is bound to an Uplink Access Port (UAP) automatically has a Port-mapping S-VLAN  
43 Component with a default S-channel (using S-VID 1). Each S-channel is identified by the ISS Port Number  
44 of the UAP and the S-VID, for SBPs, or S-channel Identifier (SCID), for URPs, identifying the S-channel.  
45 The default S-channel carries all the un-S-tagged traffic that traverses the Port-mapping S-VLAN  
46 Component.

1 In an EVB Bridge system, S-channels are automatically connected to SBPs when the S-Channel is created.  
2 If the S-channel is the default S-channel, it is connected to the SBP with the same Port Number as the ISS  
3 bound to the UAP. If the S-channel is not the default S-channel, a new SBP is allocated to the S-channel  
4 (which has a Port Number different from any ISS Port Number where a UAP or C-VLAN Bridge Port could  
5 be bound) and connected to the CAP through an internal LAN (6.14). With CDCP enabled and operating in  
6 the ‘B’ role, the S-channel interface table entries are automatically created (deleted) by CDCP to fill  
7 requests from the peer CDCP operating the ‘S’ role.

8 In an EVB station, S-channels are connected to URPs by the operating system. The URP Port Numbers are  
9 not reserved, so the UAP’s ISS Port Number may not be the same as the URP Port Number. The operating  
10 system is not required to automatically attach each S-channel to a URP; however, it can if it chooses. The  
11 URP Port Numbers have no restrictions beyond the normal requirement that every relay port be uniquely  
12 identified in the EVB system by a ComponentID and Port Number pair. With CDCP enabled and operating  
13 in the ‘S’ role, CDCP uses the S-channel interface table to build requests for creating (deleting) S-channels  
14 from the peer CDCP operating in the ‘B’ role and enables these S-channels after the peer grants an S-VID  
15 for use by the S-channel.

16 Management of the UAP, Port-mapping S-VLAN Component and CDCP is achieved through the UAP table  
17 (12.26.4.1). The management of CAPs and their LAN attachments is accomplished by the S-channel  
18 interface table entries (12.26.4.2). A UAP table entry along with the Port-mapping S-VLAN creation rules  
19 specified in 12.26.4 are sufficient to manage the Port-mapping S-VLAN Component. The Bridge managed  
20 objects in 12.4 through 12.12 can optionally be used, in addition to the objects of 12.26.4, to manage the  
21 Port-mapping S-VLAN Components.

22 The following managed objects, illustrated in Figure 12-4 and Figure 12-5, define the semantics of the  
23 management operations specific to EVB Bridges and stations:

- 24 — The EVB system base managed object (12.26.1)
- 25 — The SBP table entry managed object (12.26.2)
- 26 — The VSI table entry managed object (12.26.3)
- 27 — The MAC/VID pair table entry managed object (12.26.3)
- 28 — The UAP table entry managed object (12.26.4)
- 29 — The S-channels interface table entry managed object (12.26.4)
- 30 — The URP table entry managed object (12.26.5)

### 31 **12.26.1 EVB system base table**

32 An instance of the EVB system base table (Table 12-22) can be implemented by an EVB Bridge or EVB  
33 station. It comprises the identifiers for an EVB system (Clause 40) and system-wide default parameters used  
34 to support EVB services (D.2.12, 40.4), VSI discovery (Clause 41), and ECP (43.3).

35 The management operations that can be performed on an EVB system table entry are as follows:

- 36 a) Read EVB system table entry
- 37 b) Update EVB system table entry

#### 38 **12.26.1.1 System identifiers**

39 The evbSysType identifies the system type. The enumerated types for evbSysType are as follows:

- 40 a) sysB—EVB Bridge
- 41 b) sysS—EVB station

**Table 12-22—EVB system base table**

| Name                         | Data type               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References          |

| evbSysVdpDfltReinitKeepAlive | timer exp               | RW                                | BE                       | D.2.12,<br>41.5.5.5 |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> B = Required for an EVB Bridge system; E = Required for an EVB station system.

### 1 12.26.1.2 System defaults for EVB

2 The parameters evbSysEvpLldpTxEnable and evbSysEvpLldpManual are used to initialize the LLDP EVB  
3 objects for new SBPs and URPs. When evbSysLldpTxEnable is TRUE, a new SBP or URP will place the  
4 local EVB objects in the LLDP nearest Customer database; when FALSE, a new SBP or URP will not place  
5 the local EVB objects in the LLDP database. When evbSysLldpManual is FALSE, the operating  
6 configuration will be determined by the comparison between the local and remote LLDP EVB objects  
7 (automatic), regardless of the setting of evbSysLldpTxEnable. When evbSysLldpManual is TRUE, the  
8 configuration will be determined by the setting of the local EVB objects only (manual).

9 The evbSysLldpGidCapable parameter indicates if the port is capable of processing GroupIDs. GroupIDs  
10 can be used if both the EVB Bridge and EVB station indicate they are capable by setting the EVB LLDP  
11 object for GroupID capable to TRUE. On an EVB Station this means the station can provide GroupIDs  
12 rather than VIDs in VDP requests and accept VIDs in response from the EVB Bridge. On an EVB Bridge  
13 this means the Bridge can provide a VID corresponding to the GroupID provided by the EVB station.

14 The default value for evbSysEcpDfltAckTimerInit is 14, which provides a time of 164 ms. Systems are not  
15 required to implement smaller times and can reject requests to set the timers to small times; however,  
16 systems are required to implement 14 and above to allow fall back to the longest time proposed by the EVB  
17 Bridge or EVB station.

18 The default value for evbSysVdpDfltRsrcWaitDelay and evbSysVdpDfltReinitKeepAlive is system  
19 dependent. All systems support the values of 20 and above, which provide times of 10.5 seconds and greater.  
20 Systems are not required to implement smaller times and can reject requests to set the timers to small times;  
21 however, systems are required to implement 20 and above to allow fall back to the longest time proposed by  
22 the EVB Bridge or EVB station.

23 Table 12-23 shows how the system defaults are used to initialize the parameters in the SBP, URP, and ECP  
24 table entries.

**Table 12-23—EVB system parameter defaults**

| System parameter             | Default value            | LLDP, SBP, URP, ECP entry parameter                    |
|------------------------------|--------------------------|--------------------------------------------------------|
| evbSysEvpLldpTxEnable        | TRUE                     | LLDP Transmit Enable                                   |
| evbSysEvpLldpManual          | FALSE                    | sbpLldpManual, urpLldpManual                           |
| evbSysEvpLldpGidCapable      | system dependent         | LLDP GID Capable                                       |
| evbSysEcpDfltAckTimerInit    | 14, for 164 milliseconds | ecpAdminAckTimerInit                                   |
| evbSysEcpDfltMaxTries        | 3                        | ecpAdminMaxTries                                       |
| evbSysVdpDfltRsrcWaitDelay   | system dependent         | sbpVdpAdminRsrcWaitDelay, urpVdpAdminRsrcWaitDelay     |
| evbSysVdpDfltReinitKeepAlive | system dependent         | sbpVdpAdminReinitKeepAlive, urpVdpAdminReinitKeepAlive |

### 1 12.26.2 SBP table entry

2 SBP table entries (Table 12-24) may be created explicitly or implicitly as a result of creating an entry in the  
3 S-channel interface table. When an SBP table entry is created, the port type in the Port table entry  
4 (Table 12-2) changes to type ‘Station-facing Bridge Port’. When an SBP table entry is deleted, the Port table  
5 entry returns to type C-VLAN Bridge Port.

**Table 12-24—SBP table entry**

| Name                      | Data type   | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References        |
|---------------------------|-------------|-----------------------------------|--------------------------|-------------------|
| sbpComponentID            | ComponentID | R                                 | B                        | 12.4.1.5          |
| sbpPortNumber             | Port Number | R                                 | B                        | 12.4.2            |
| sbpLldpManual             | Boolean     | RW                                | B                        | —                 |
| sbpVdpOperRsrcWaitDelay   | timer exp   | R                                 | B                        | D.2.12, 41.5.5.7  |
| sbpVdpOperReinitKeepAlive | timer exp   | R                                 | B                        | D.2.12, 41.5.5.5  |
| sbpVdpOperToutKeepAlive   | unsigned    | R                                 | B                        | D.2.12, 41.5.5.13 |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> B = Required for an EVB Bridge system.

6 Whenever a new SBP table entry is created, a new entry is also created in the ECP table (12.27) keyed under  
7 the ComponentID and Port Number of the SBP. Whenever an SBP table entry is deleted, the corresponding  
8 entry in the ECP table is deleted.

9 The management operations that can be performed on an SBP table entry are as follows:

- 10 a) Read SBP table entry
- 11 b) Update SBP table entry
- 12 c) Create SBP table entry
- 13 d) Delete SBP table entry

### 12.26.3 VSI table entry

Each EVB system maintains a table of the active VSIs. The structure of a VSI table entry is shown in Table 12-25. This read-only table provides the current operation parameters of each VSI along with the VDP state associated with the VSI. The table is keyed on the SBP's or URP's ComponentID and Port Number and on the VSIID. The operation that can be performed on the VSI table is as follows:

- a) Read entry for a ComponentID, Port Number, and VSIID

**Table 12-25—VSI table entry**

| Name                  | Data type                | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References         |
|-----------------------|--------------------------|-----------------------------------|--------------------------|--------------------|
| evbVsiComponentID     | ComponentID              | R                                 | BE                       | 12.4.1.5           |
| evbVsiPortNumber      | Port Number              | R                                 | BE                       | 12.4.2             |
| evbVsiIDType          | enumerated               | R                                 | BE                       | 41.2.6, Table 41-5 |
| evbVsiID              | Latin1 String (SIZE(16)) | R                                 | BE                       | 41.2.7             |
| evbVsiTimeSinceCreate | time interval            | R                                 | BE                       | Clause 41          |
| evbVsiVdpOperCmd      | enumerated               | R                                 | BE                       | 41.2.1, Table 41-1 |

| evbVdpCmdsFailed      | counter                  | R                                 | BE                       | 41.5               |
| evbVdpCmdsReverts     | counter                  | R                                 | BE                       | 41.5               |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> B = Required for an EVB Bridge system; E = Required for an EVB station system.

Each EVB Bridge or EVB station maintains a table of the VID/MACs on each VSI. The structure of a VSI MAC/VLAN table entry is shown in Table 12-26. This read-only table provides the current GroupID/VID/MAC assignments for each VSI. The operations that can be performed on the VSI table are as follows:

- b) Read entries for a ComponentID, Port Number, and VSIID
- c) Read entries for a ComponentID and Port Number

**Table 12-26—VSI MAC/VLAN table entry**

| Name              | Data type                | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References         |
|-------------------|--------------------------|-----------------------------------|--------------------------|--------------------|
| evbMvComponentID  | ComponentID              | R                                 | BE                       | 12.4.1.5           |

| evbMvVsiIDType    | enumerated               | R                                 | BE                       | 41.2.6, Table 41-5 |
| evbMvVsiID        | Latin1 String (SIZE(16)) | R                                 | BE                       | 41.2.7             |
| evbMvVsiGroupID   | unsigned                 | R                                 | BE                       | 41.2.9             |
| evbMvVsiVID       | unsigned (1..4094)       | R                                 | BE                       | 41.2.9             |
| evbMvVsiMAC       | MAC address              | R                                 | BE                       | 41.2.9             |
| evbMvVsiIpAddress | IP address               | R                                 |                          | 41.2.9             |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> B = Required for an EVB Bridge system; E = Required for an EVB station system.

#### 1 12.26.4 S-channel configuration and management

2 The S-channel managed objects are not required unless the system implements S-channels.

3 Creating a UAP table entry (40.2) causes a Port-mapping S-VLAN Component (15.6) to be instantiated and  
4 sets the portType parameter of the Port table entry (12.4.2) to type ‘Uplink Access Port’. The Port-mapping  
5 S-VLAN Component automatically includes a default S-channel with one CAP that can attach to an SBP or  
6 a URP through an internal LAN (6.14). Each UAP is identified by the ISS Port Number where the UAP is  
7 attached. The default S-channel and CAP shall be identified by the S-VID 1 and SCID 1.

**Table 12-27—UAP table entry parameters**

| UAP table name             | Default values                                |
|----------------------------|-----------------------------------------------|
| uapSchCdcAdminEnable       | TRUE                                          |
| uapSchCdcAdminRole         | schS if EVB station and<br>schB if EVB Bridge |
| uapSchCdcAdminChnCap       | 1                                             |
| uapSchAdminCdcSvidPoolLow  | 0                                             |
| uapSchAdminCdcSvidPoolHigh | 0                                             |

#### 8 12.26.4.1 UAP table entry

9 The management operations that can be performed on the UAP table entry (Table 12-28) managed object are  
10 as follows:

- 11 a) Read UAP table entry
- 12 b) Update UAP table entry
- 13 c) Create UAP table entry

- 1 d) Delete UAP table entry

**Table 12-28—UAP table entry**

| Name                        | Data type             | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References     |
|-----------------------------|-----------------------|-----------------------------------|--------------------------|----------------|
| uapISSPortNumber            | Port Number           | R                                 | BE                       | 12.4.2, 12.5.1 |
| uapComponentID              | ComponentID           | R                                 | be                       | 12.4.1.5       |
| uapPortNumber               | Port Number           | R                                 | be                       | 12.4.2         |
| uapSchCdcPAdminEnable       | Boolean               | RW                                | BE                       | 42.4.2         |
| uapSchCdcPAdminRole         | enumerated            | RW                                | BE                       | 42.4.2         |
| uapSchCdcPAdminChnCap       | unsigned [1...167]    | RW                                | BE                       | 42.4.1         |
| uapSchCdcPOperChnCap        | unsigned [1...167]    | R                                 | BE                       | 42.4.8         |
| uapSchAdminCdcPSvidPoolLow  | unsigned [0,2...4094] | RW                                | BE                       | 42.4.7         |
| uapSchAdminCdcPSvidPoolHigh | unsigned [0,2...4094] | RW                                | BE                       | 42.4.7         |
| uapSchOperState             | enumerated            | R                                 | BE                       | 42.4.14        |
| uapSchCdcPRemoteEnabled     | Boolean               | R                                 | BE                       | 42.4.14        |
| uapSchCdcPRemoteRole        | enumerated            | R                                 | BE                       | 42.4.12        |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> B = Required for an EVB Bridge system; E = Required for an EVB station system; b = Optional for an EVB Bridge system; e = Optional for an EVB station system.

2 Table 12-27 shows the default values for the UAP table entry parameters.

3 The available SVIDs determined by the range of uapSchAdminCdcPSvidPoolLow and  
4 uapSchAdminCdcPSvidPoolHigh limit the S-channel capacity indicated by uapSchCdcPAdminChnCap to  
5 the available SVIDs plus one for the default S-channel. If the capacity is greater than the VID range plus  
6 one, then the VID range overrides the capacity (i.e., the actual capacity is never bigger than the available  
7 VID range plus one).

#### 8 **12.26.4.2 S-channel interface table entry**

9 The S-channel interface table entry applies to each internal S-channel configured on an EVB Bridge or EVB  
10 station, as shown in Table 12-29. The management operations that can be performed on an S-channel  
11 interface table entry are as follows:

- 12 a) Read S-channel interface table entry  
13 b) Update S-channel interface table entry  
14 c) Create S-channel interface table entry  
15 d) Delete S-channel interface table entry

16 If the S-channel interface table is being used with a UAP operating in the cdcP role, then the table is keyed  
17 on schUapISSPortNumber and schScId. If the S-channel interface table is being used with a UAP operating  
18 in the cdcPB role, then the table is keyed on the schUapISSPortNumber and schSvid.

19 The schComponentID and schCapPortNumber refer to the Port-mapping S-VLAN Component and the Port,  
20 which may also be identified by the schISSPortNumber and S-VID (or SCID).

**Table 12-29—S-channel interface table entry**

| Name                   | Data type           | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References     |
|------------------------|---------------------|-----------------------------------|--------------------------|----------------|
| schUapISSPortNumber    | Port Number         | R                                 | BE                       | 12.4.2, 12.5.1 |
| schScid                | unsigned [1...4094] | R                                 | bE                       | 42.4.3         |
| schSvid                | unsigned [0...4094] | R                                 | BE                       | 42.4.3         |
| schComponentID         | ComponentID         | R                                 | be                       | 42.1, 12.4.1.5 |
| schCapPortNumber       | Port Number         | R                                 | be                       | 42.1, 12.4.2   |
| schSbpOrUrpComponentID | ComponentID         | RW                                | BE                       | 12.4.1.5       |
| schSbpOrUrpPortNumber  | Port Number         | RW                                | BE                       | 12.4.2         |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> B = Required for an EVB Bridge system; E = Required for an EVB station system; b = Optional for an EVB Bridge system; e = Optional for an EVB station system.

1 The schSbpOrUrpComponentID and schSbpOrUrpPortNumber are the ComponentID and Port Number of  
2 the attached SBP or URP.

### 3 **12.26.5 ER management**

4 ERs can be built dynamically or statically within an EVB station. Each ER is assigned a ComponentID that  
5 is unique for the EVB station system. An ER always has a single URP that exists as long as the ER exists.  
6 The DRPs of an ER may be built either along with the ER or on demand.

#### 7 **12.26.5.1 URP table entry**

8 When a URP table entry is created, a corresponding Component table entry is created for the ER along with  
9 a Port table entry for the URP. When a URP table entry is deleted, the corresponding Component table entry  
10 is deleted along with the corresponding Port table entry.

11 When each URP table entry is created, a corresponding entry is created in the ECP table (12.27) and keyed  
12 under the ComponentID and Port Number of the URP. Whenever a URP table entry is deleted, the  
13 corresponding entry in the ECP table is deleted.

14 The management operations that can be performed on the URP table entry (Table 12-30) managed object are  
15 as follows:

- 16 a) Read URP table entry
- 17 b) Update URP table entry
- 18 c) Create URP table entry
- 19 d) Delete URP table entry

**Table 12-30—URP table entry**

| Name                      | Data type           | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References          |
|---------------------------|---------------------|-----------------------------------|--------------------------|---------------------|
| urpComponentID            | ComponentID         | R                                 | E                        | 12.4.1.5            |
| urpPortNumber             | Port Number         | R                                 | E                        | 12.4.2              |
| urpBindToISSPortNumber    | unsigned [0...4095] | RW                                | e                        | 12.5.1              |
| urpLdpManual              | Boolean             | RW                                | E                        |                     |
| urpVdpOperRsrcWaitDelay   | timer exp           | R                                 | E                        | D.2.12,<br>41.5.5.7 |
| urpVdpOperRespWaitDelay   | unsigned            | R                                 | E                        | D.2.12,<br>41.5.5.9 |
| urpVdpOperReinitKeepAlive | timer exp           | R                                 | E                        | D.2.12,<br>41.5.5.5 |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> E = Required for an EVB station system; e = Optional for an EVB station system.

## 1 12.27 Edge Control Protocol (ECP) management

### 2 12.27.1 ECP table entry

3 The management operation that can be performed on the ECP table entry managed object is as follows:

4 a) Read ECP table entry

5 ECP table entries (Table 12-31) are created or deleted implicitly as a result of the creation or deletion of  
6 other port objects.

**Table 12-31—ECP table entry**

| Name                | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References          |
|---------------------|------------------|-----------------------------------|--------------------------|---------------------|
| ecpComponentID      | ComponentID      | R                                 | BE                       | 12.4.1.5            |
| ecpPortNumber       | Port Number      | R                                 | BE                       | 12.4.2              |
| ecpOperAckTimerInit | timer exp        | R                                 | BE                       | D.2.12,<br>43.3.7.1 |
| ecpOperMaxRetries   | unsigned [0...7] | R                                 | BE                       | D.2.12,<br>43.3.7.4 |
| ecpTxFrameCount     | counter          | R                                 | BE                       | Clause 43           |
| ecpTxRetryCount     | counter          | R                                 | BE                       | Clause 43           |
| ecpTxFailures       | counter          | R                                 | BE                       | Clause 43           |
| ecpRxFrameCount     | counter          | R                                 | BE                       | Clause 43           |

<sup>a</sup> R = Read-only access; RW = Read/Write access.

<sup>b</sup> B = Required for an EVB Bridge system; E = Required for an EVB station system.

## 12.28 Path Control and Reservation (PCR) management

The VLAN Bridges that support IS-IS implement the following SPB managed objects because they are required for IS-IS operations in a Bridged Network. Therefore, these SPB managed objects are required for explicit path control via IS-IS, i.e., for PCR operations:

- SPB System managed object (12.25.1)
- SPB MTID Static managed object (12.25.2)
- SPB Topology Instance Dynamic managed object (12.25.3)
- SPB ECT Static Entry managed object (12.25.4)
- SPB ECT Dynamic Entry managed object (12.25.5)
- SPB Adjacency Static Entry managed object (12.25.6)
- SPB Adjacency Dynamic Entry managed object (12.25.7)
- SPBM BSI Static Entry managed object (12.25.8)
- SPB Topology Node Table managed object (12.25.9)
- SPB Topology ECT Table managed object (12.25.10)
- SPB Topology Edge Table managed object (12.25.11)
- SPBM Topology Service Table managed object (12.25.12)
- SPBV Topology Service Table managed object (12.25.13)

The above listed SPB managed objects shall be used to configure PCR operations in SPT Bridges as specified in Clause 45. For instance, if a VLAN is under explicit path control via IS-IS, then the corresponding explicit ECT Algorithm value of Table 45-1 has to be used for the VLAN's Base VID when the SPB ECT Static Entry managed object (12.25.4) is created.

NOTE—The SPBM BSI Static Entry managed object (12.25.8) and the SPBM Topology Service Table managed object (12.25.12) are not required if no backbone Service Instance is present in the SPT Region.

Managed objects dedicated to PCR are needed only for Maximally Redundant Trees (MRTs). Due to the dependence on SPB managed objects, the PCR managed objects are specified as part of the SPB managed object hierarchy as illustrated in Figure 12-3. The following are the PCR managed objects in an SPT Bridge:

- a) The PCR ECT Static Entry managed object (12.28.1)
- b) The PCR Topology ECT Table managed object (12.28.2)

The SPVID parameter of an ISIS-SPB sub-TLV and an SPB managed object does not convey Shortest Path VID if it refers to an explicit tree (Clause 45), but the SPVID parameter is used to carry another type of VID as specified by 45.1.3, e.g., an MRT VID. These VIDs are always configured and never auto-allocated.

If the ECT Algorithm takes the value of the LTS ECT Algorithm (Table 45-1) and it is a learning VLAN (45.1.3), i.e., the VLAN's Base VID is allocated to the SPBV-MSTID (0xFFD), then the Bridge's VID [also allocated to the SPBV-MSTID, and not to the SPVID pool (SPVID-Pool-MSTID: 0xFFFF) as is done for Shortest Path Bridging operation] has to be configured in place of the SPVID parameter of the SPB ECT Static Entry managed object [item d) in 12.25.4.1.2].

If the ECT Algorithm is one of the MRT algorithms (Table 45-1), then MRT VID values are domain-wide for a non-learning VLAN, whereas they are Bridge-local for a learning VLAN. If it is a learning VLAN (45.1.3), i.e., the VLAN's Base VID is allocated to the SPBV-MSTID, then the Bridge's MRT VIDs (also allocated to the SPBV-MSTID) have to be configured as the MRT-Blue VID and MRT-Red VID parameters of the PCR ECT Static Entry managed object (12.28.1). MRT VIDs are configured; they cannot be auto-allocated. The Base VID's SPVID entry in the SPB ECT Static managed object (12.25.2) is ignored for learning VLANs if the MRTs protect each other. If the MRTs protect an SPT for a learning VLAN, then a Shortest Path VID (a real SPVID allocated to the SPVID-Pool-MSTID) has to be associated with the SPT Bridge, in addition to its MRT VIDs, which is provided as specified by 12.25. The Shortest Path VID is

1 configured via the SPB ECT Static Entry managed object (see item d) in 12.25.4.1.2] and its allocation  
2 method (automatic or manual) is configured via the SPB System managed object (see item c) in  
3 12.25.1.2.2].

#### 4 **12.28.1 The PCR ECT Static Entry managed object**

5 Each Bridge has one PCR ECT Static Entry managed object per Base VID assigned with MRT operation  
6 (45.3.3, 45.3.4). The static Entry contains the MRT VID configuration parameters for the Base VID. It is  
7 persistent over reboot. The management operations that can be performed on the ECT Static Entry managed  
8 object are as follows:

- 9 a) Create a PCR ECT Static Entry managed object (12.28.1.1)
- 10 b) Read a PCR ECT Static Entry managed object (12.28.1.2)
- 11 c) Write a PCR ECT Static Entry managed object (12.28.1.3)
- 12 d) Delete a PCR ECT Static Entry managed object (12.28.1.4)

#### 13 **12.28.1.1 Create PCR ECT Static Entry managed object**

##### 14 **12.28.1.1.1 Purpose**

15 To create, configure, and interrogate a PCR ECT Static Entry managed object on a Bridge.

##### 16 **12.28.1.1.2 Inputs**

- 17 a) A Topology Index value that uniquely identifies a topology instance.
- 18 b) A Base VID. This VID has been allocated either to the SPBM-MSTID (0xFFC) for non-learning  
19 VLANs or to the SPBV-MSTID (0xFFD) for learning VLANs in the FID to MSTI Allocation table  
20 (12.12.2.2). An SPB ECT Static Entry managed object (12.25.4) has to be created for the Base VID  
21 and Topology Index prior to the creation of the PCR ECT Static Entry managed object.
- 22 c) The MRT-Blue VID assigned with the Base VID of the corresponding SPB ECT Static Entry  
23 managed object. The MRT-Blue VID has to be allocated to the same MSTID as the Base VID. If it is  
24 a non-learning VLAN, i.e., the Base VID is allocated to the SPBM-MSTID (0xFFC), and the MRTs  
25 are used to protect each other, then the value of the MRT-Blue VID has to take the value of the Base  
26 VID. An MRT-Blue VID is always assigned by configuration. In the case of a learning VLAN or if  
27 the MRTs protect SPTs of a non-learning VLAN, the values of Base VID, MRT-Blue VID, and  
28 MRT-Red VID are all different.
- 29 d) The MRT-Red VID assigned with the Base VID of the corresponding SPB ECT Static Entry  
30 managed object. The MRT-Red VID has to be allocated to the same MSTID as the Base VID. An  
31 MRT-Red VID is always assigned by configuration.

##### 32 **12.28.1.1.3 Outputs**

- 33 a) Operation status. This takes one of the following values:
  - 34 1) Operation rejected because the Topology Index value is not defined.
  - 35 2) Operation rejected because the SPB ECT Static Entry managed object does not exist for the  
36 Base VID and Topology Index.
  - 37 3) Operation rejected because the requested Base VID was not assigned with MRT operation.
  - 38 4) Operation rejected due to MRT-Blue VID not allocated to the same MSTID as the Base VID.
  - 39 5) Operation rejected due to MRT-Red VID not allocated to the same MSTID as the Base VID.
  - 40 6) Operation accepted.

## 1 12.28.1.2 Read PCR ECT Static Entry managed object

### 2 12.28.1.2.1 Purpose

3 To obtain information about the PCR ECT Static Entry managed object for a Base VID.

### 4 12.28.1.2.2 Inputs

- 5 a) A Topology Index value that uniquely identifies a topology instance.
- 6 b) A Base VID. The value 4095 is a wildcard indicating that information on any Base VID assigned  
7 with MRT operation is requested.

### 8 12.28.1.2.3 Outputs

- 9 a) Operation status. This takes one of the following values:
  - 10 1) Operation rejected
  - 11 2) Operation accepted
- 12 b) A Topology Index value that uniquely identifies this topology instance.
- 13 c) A list of <Base VID, MRT-Blue VID, MRT-Red VID> 3-tuples assigned with MRT operation. The  
14 list is null if no VLAN is assigned with MRT operation. The list comprises a single 3-tuple if the  
15 Base VID parameter is not the wildcard (12.28.1.2.2).

## 16 12.28.1.3 Write PCR ECT Static Entry managed object

### 17 12.28.1.3.1 Purpose

18 To configure a PCR ECT Static Entry managed object for a Base VID.

### 19 12.28.1.3.2 Inputs

- 20 a) A Topology Index value that uniquely identifies a topology instance.
- 21 b) A Base VID. This VID has been allocated either to the SPBM-MSTID (0xFFC) for non-learning  
22 VLANs, or to the SPBV-MSTID (0xFFD) for learning VLANs in the FID to MSTI Allocation table  
23 (12.12.2.2). An SPB ECT Static Entry managed object (12.25.4) has to be created for the Base VID  
24 and Topology Index prior to the creation of the PCR ECT Static Entry managed object.
- 25 c) The MRT-Blue VID assigned with the Base VID of the corresponding SPB ECT Static Entry  
26 managed object. The MRT-Blue VID has to be allocated to the same MSTID as the Base VID. If it is  
27 a non-learning VLAN, i.e., the Base VID is allocated to the SPBM-MSTID (0xFFC), and the MRTs  
28 are used to protect each other, then the value of the MRT-Blue VID has to take the value of the Base  
29 VID. An MRT-Blue VID is always assigned by configuration. In the case of a learning VLAN or if  
30 the MRTs protect SPTs of a non-learning VLAN, the values of Base VID, MRT-Blue VID, and  
31 MRT-Red VID are all different.
- 32 d) The MRT-Red VID assigned with the Base VID of the corresponding SPB ECT Static Entry  
33 managed object. The MRT-Red VID has to be allocated to the same MSTID as the Base VID. An  
34 MRT-Red VID is always assigned by configuration.

### 35 12.28.1.3.3 Outputs

- 36 a) Operation status. This takes one of the following values:
  - 37 1) Operation rejected because the Topology Index value is not defined.
  - 38 2) Operation rejected because the SPB ECT Static Entry managed object does not exist for the  
39 Base VID and Topology Index.
  - 40 3) Operation rejected because the requested Base VID was not assigned with MRT operation.
  - 41 4) Operation rejected due to MRT-Blue VID not allocated to the same MSTID as the Base VID.
  - 42 5) Operation rejected due to MRT-Red VID not allocated to the same MSTID as the Base VID.

- 1           6)   Operation accepted.

## 2 **12.28.1.4 Delete PCR ECT Static Entry managed object**

### 3 **12.28.1.4.1 Purpose**

4 To delete the PCR ECT Static Entry managed object for a Base VID.

### 5 **12.28.1.4.2 Inputs**

- 6   a)   A Topology Index value that uniquely identifies a topology instance.  
7   b)   A Base VID.

### 8 **12.28.1.4.3 Outputs**

- 9   a)   Operation status. This takes one of the following values:  
10       1)   Operation rejected because the Bridge has services currently assigned with this Base VID.  
11       2)   Operation rejected because the SPT Region has services currently using this Base VID.  
12       3)   Operation rejected because PCR ECT Static Entry managed object does not exist for the Base  
13       VID.  
14       4)   Operation accepted.

## 15 **12.28.2 The PCR Topology ECT Table managed object**

16 There is one PCR Topology ECT Table managed object per Bridge per IS-IS topology. It is populated by  
17 IS-IS with the nodal ECT parameters discovered for all SPT Bridges participating in that topology within the  
18 SPT Region. This object is automatically created as a consequence of the creation of a PCR ECT Static  
19 Entry managed object for the given IS-IS topology. It is automatically deleted with the deletion of the last  
20 PCR ECT Static Entry managed object for the given IS-IS topology. The management operation that can be  
21 performed on the PCR Topology ECT Table managed object is as follows:

- 22   a)   Read PCR Topology ECT Table managed object

## 23 **12.28.2.1 Read PCR Topology ECT Table managed object**

### 24 **12.28.2.1.1 Purpose**

25 To obtain nodal information from all SPT Bridges of an SPT Region on the binding of Base VIDs to the  
26 MRT algorithms in an IS-IS topology.

### 27 **12.28.2.1.2 Inputs**

- 28   a)   A Topology Index value that uniquely identifies a topology instance.  
29   b)   The System Identifier of a remote Bridge. The value zero is a wildcard indicating the information on  
30       all System identifiers is requested.  
31   c)   The Base VID. The value 4095 is a wildcard indicating that information on any Base VID assigned  
32       with MRT operation is requested.

### 33 **12.28.2.1.3 Outputs**

34 A list comprising one entry for each Base VID assigned to MRT operation at a Bridge within the SPT  
35 Region that the local IS-IS instance is aware. The list can be empty. Each entry contains the following  
36 information about a remote Bridge:

- 37   a)   The Topology Index value that uniquely identifies this topology instance  
38   b)   The System Identifier of the remote Bridge

- 1 c) The Base VID
- 2 d) The VLAN's operational mode (learning or non-learning)
- 3 e) MRT-Blue VID
- 4 f) MRT-Red VID

5 If item b) identifies a specific remote Bridge, then the above list comprises one entry per Base VID as  
6 specified in item c), containing only information about the specific remote Bridge.

## 7 **12.29 Managed objects for scheduled traffic**

8 The Bridge enhancements for support of scheduled traffic are defined in 8.6.8 and 8.6.8.4.

9 This managed resource comprises the following object:

- 10 a) The Gate Parameter Table (12.29.1)

### 11 **12.29.1 The Gate Parameter Table**

12 There is one Gate Parameter Table per Port of a Bridge Component. Each table row contains a set of  
13 parameters that supports the enhancements for scheduled traffic (8.6.8.4), as detailed in Table 12-32. Rows  
14 in the table can be created or removed dynamically in implementations that support dynamic configuration  
15 of ports and components.

**Table 12-32—The Gate Parameter Table**

| Name                          | Data type                    | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                         |
|-------------------------------|------------------------------|-----------------------------------|--------------------------|------------------------------------|
| queueMaxSDUTable <sup>c</sup> | sequence of queueMaxSDU      | RW                                | B, E                     | 8.6.8.4, 12.29.1.1, 12.29.1.1.1    |
| GateEnabled                   | Boolean                      | RW                                | B, E                     | 8.6.9.4.14                         |
| AdminGateStates               | gateStatesValue              | RW                                | B, E                     | 8.6.9.4.5, 12.29.1.2, 12.29.1.2.2  |
| OperGateStates                | gateStatesValue              | R                                 | B, E                     | 8.6.9.4.21, 12.29.1.2, 12.29.1.2.2 |
| AdminControlListLength        | unsigned integer             | RW                                | B, E                     | 8.6.9.4.6, 12.29.1.2               |
| OperControlListLength         | unsigned integer             | R                                 | B, E                     | 8.6.9.4.22, 12.29.1.2              |
| AdminControlList              | sequence of GateControlEntry | RW                                | B, E                     | 8.6.9.4.2, 12.29.1.2, 12.29.1.2.1  |
| OperControlList               | sequence of GateControlEntry | R                                 | B, E                     | 8.6.9.4.18, 12.29.1.2, 12.29.1.2.1 |
| AdminCycleTime                | RationalNumber (seconds)     | RW                                | B, E                     | 8.6.9.4.3, 12.29.1.3               |
| OperCycleTime                 | RationalNumber (seconds)     | R                                 | B, E                     | 8.6.9.4.19, 12.29.1.3              |
| AdminCycleTimeExtension       | Integer (nanoseconds)        | RW                                | B, E                     | 8.6.9.4.4                          |
| OperCycleTimeExtension        | Integer (nanoseconds)        | R                                 | B, E                     | 8.6.9.4.20                         |
| AdminBaseTime                 | PTPtime                      | RW                                | B, E                     | 8.6.9.4.1, 12.29.1.4               |

**Table 12-32—The Gate Parameter Table (continued)**

| Name                 | Data type                       | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                    |
|----------------------|---------------------------------|-----------------------------------|--------------------------|-------------------------------|
| OperBaseTime         | PTPtime                         | R                                 | B, E                     | 8.6.9.4.17, 12.29.1.4         |
| ConfigChange         | Boolean                         | RW                                | B, E                     | 8.6.9.4.7                     |
| ConfigChangeTime     | PTPtime                         | R                                 | B, E                     | 8.6.9.4.9, 12.29.1.4          |
| TickGranularity      | Integer (tenths of nanoseconds) | R                                 | B, E                     | 8.6.9.4.16                    |
| CurrentTime          | PTPtime                         | R                                 | B, E                     | 8.6.9.4.10, 12.29.1.4         |
| ConfigPending        | Boolean                         | R                                 | B, E                     | 8.6.9.3, 8.6.9.4.8            |
| ConfigChangeError    | Integer                         | R                                 | B, E                     | 8.6.9.3.1                     |
| SupportedListMax     | Integer                         | R                                 | B, E                     | 12.29.1.5                     |
| SupportedCycleMax    | RationalNumber (seconds)        | R                                 | B, E                     | 8.6.8.4, 12.29.1.3, 12.29.1.6 |
| SupportedIntervalMax | Integer                         | R                                 | B, E                     | 8.6.8.4, 12.29.1.7            |

<sup>a</sup> R= Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of enhancements for scheduled traffic; E = Required for end station support of enhancements for scheduled traffic.

<sup>c</sup> The number of queues supported by a Port is available from the traffic class table (12.6.3)

#### 1 12.29.1.1 The queueMaxSDUTable structure and data types

2 The queueMaxSDUTable consists of up to 8 entries, one per traffic class supported by the implementation,  
3 each entry consisting of a queueMaxSDU value (12.29.1.1.1) and a TransmissionOverrun counter.

##### 4 12.29.1.1.1 queueMaxSDU

5 An unsigned integer value, denoting the maximum SDU size supported by the queue.

##### 6 12.29.1.1.2 TransmissionOverrun

7 A counter that is incremented when the implementation detects that the transmission gate associated with a  
8 queue has closed and a frame that originated from the queue is still being transmitted by the MAC.

#### 9 12.29.1.2 The gate control list structure and data types

10 The AdminControlList and OperControlList are ordered lists containing AdminControlListLength or  
11 OperControlListLength entries, respectively. Each entry represents a gate operation as defined in Table 8-7.  
12 Each entry in the list is structured as a GateControlEntry (12.29.1.2.1).

##### 13 12.29.1.2.1 GateControlEntry

14 A GateControlEntry consists of an operation name, followed by two parameters associated with the  
15 operation, as detailed in Table 8-7. The first parameter is a gateStatesValue (12.29.1.2.2); the second  
16 parameter is a timeIntervalValue (12.29.1.2.3).

## 1 **12.29.1.2.2 gateStatesValue**

2 A list of up to 8 tuples, one for each traffic class supported by the Port, each of which consists of a traffic  
3 class number in the range 0–7 and a gate state that is an enumerated value representing the gate state, *open*  
4 or *closed*, for that traffic class (see GateState in Table 8-7).

## 5 **12.29.1.2.3 timeIntervalValue**

6 An unsigned integer, denoting a TimeInterval in nanoseconds (see TimeInterval in Table 8-7).

## 7 **12.29.1.3 RationalNumber**

8 A rational number represented by an integer numerator and an integer denominator.

## 9 **12.29.1.4 PTPtime**

10 A time value, expressed as a PTP timescale (see IEEE Std 802.1AS).

## 11 **12.29.1.5 SupportedListMax**

12 The maximum value supported by this Port of the AdminControlListLength and OperControlListLength  
13 parameters. It is available for use by schedule computation software to determine the port's control list  
14 capacity prior to computation.

## 15 **12.29.1.6 SupportedCycleMax**

16 The maximum value supported by this Port of the AdminCycleTime (8.6.9.4.3) and OperCycleTime  
17 (8.6.9.4.19) parameters.

## 18 **12.29.1.7 SupportedIntervalMax**

19 The maximum value supported by this Port of the timeIntervalValue (12.29.1.2.3) parameter.

## 20 **12.29.2 Timing points for scheduled traffic**

21 Table 12-32 specifies times (e.g., AdminBaseTime) with reference to the on-the-wire timing point at which  
22 the start of a frame crosses the boundary between the physical network media and the PHY. This is the  
23 message timestamp point specified by IEEE Std 802.1AS for various media.

24 Figure 12-6 shows both the on-the-wire timing point and the transmission selection timing point within the  
25 interface stack (above MAC and PHY) that is used for gate open/close as described in 8.6.8.4. Each timing  
26 point will have variance. A delay exists between the transmission selection timing point and the on-the-wire  
27 timing point. This delay will have variance that is bounded (minimum/maximum).

**Figure 12-6—Timing points for scheduled traffic**

1 The Bridge contains the information needed in order to compute the minimum/maximum delay from the  
2 transmission selection timing point to the on-the-wire timing point. The Bridge shall adjust using the  
3 minimum delay, such that a frame's on-the-wire timing point occurs no earlier than the gate events  
4 represented in managed objects.

5 NOTE 1—As an example, consider an IEEE 802.3 port configured to transmit a single traffic class with known frame  
6 lengths, where the managed objects are configured for a cycle of open for two milliseconds, then closed for two  
7 milliseconds. If a one millisecond burst of frames is transmitted through the Bridge to the port, the preamble and SFD  
8 can be transmitted during the closed window, but no other symbol of a frame can be transmitted from the PHY during  
9 the closed window (including the FCS).

10 NOTE 2—Although the managed objects apply to a Bridge, the preceding specification of on-the-wire timing point can  
11 be applied to an end station.

## 12 **12.30 Managed objects for frame preemption**

13 The Bridge enhancements for support of frame preemption are defined in 8.6.8, 8.6.8.4, and 6.7.2.

14 This managed resource comprises the following object:

- 15 a) Frame Preemption Parameter Table (12.30.1)

### 16 **12.30.1 Frame Preemption Parameter Table**

17 There is one Frame Preemption Parameter table per Port of a Bridge Component or end station. Each table  
18 row contains a set of parameters that supports the enhancements for frame preemption (6.7.2), as detailed in  
19 Table 12-33. Rows in the table can be created or removed dynamically in implementations that support  
20 dynamic configuration of ports and components.

#### 21 **12.30.1.1 framePreemptionStatusTable structure and data types**

22 The framePreemptionStatusTable (6.7.2) consists of 8 framePreemptionAdminStatus values (12.30.1.1.1),  
23 one per priority.

**Table 12-33—Frame Preemption Parameter table**

| Name                       | Data type                                     | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                     |
|----------------------------|-----------------------------------------------|-----------------------------------|--------------------------|--------------------------------|
| framePreemptionStatusTable | sequence of framePreemptionAdminStatus values | RW                                | B, E                     | 6.7.2, 12.30.1.1, 12.30.1.1.1. |
| holdAdvance                | Integer, nanoseconds                          | R                                 | B, E                     | Table 8-7, 12.30.1.2           |
| releaseAdvance             | Integer, nanoseconds                          | R                                 | B, E                     | Table 8-7, 12.30.1.3           |
| preemptionActive           | Boolean                                       | R                                 | B, E                     | 12.30.1.4                      |
| holdRequest                | Integer {hold (1), release (2)}               | R                                 | B, E                     | Table 8-7, 12.30.1.5           |

<sup>a</sup> R = Read only access; RW = Read/Write access

<sup>b</sup> B = Required for Bridge or Bridge Component support of enhancements for frame preemption; E = Required for end station support of enhancements for frame preemption.

#### 1 12.30.1.1.1 framePreemptionAdminStatus

2 This parameter is the administrative value of the preemption status for the priority. It takes value *express* if  
3 frames queued for the priority are to be transmitted using the express service for the Port, or *preemptable* if  
4 frames queued for the priority are to be transmitted using the preemptable service for the Port and  
5 preemption is enabled for the Port.

6 Priorities that all map to the same traffic class should be constrained to use the same value of preemption  
7 status.

#### 8 12.30.1.2 holdAdvance object

9 The holdAdvance object contains an integer value representing the maximum number of nanoseconds that  
10 can elapse between issuing a HOLD (12.30.1.5) to the MAC and the MAC ceasing to transmit any  
11 preemptable frame that is in the process of transmission or any preemptable frames that are queued for  
12 transmission, including any MAC-specific delay before transmission of an express frame could start once  
13 preemptable frame transmission has ceased. This object exists per Port, and is a characteristic of the  
14 underlying MAC.

#### 15 12.30.1.3 releaseAdvance object

16 The releaseAdvance object contains an integer value representing the maximum number of nanoseconds that  
17 can elapse between issuing a RELEASE (12.30.1.5) to the MAC and the MAC being ready to resume  
18 transmission of preemptable frames, in the absence of there being any express frames available for  
19 transmission. This object exists per Port, and is a characteristic of the underlying MAC.

#### 20 12.30.1.4 preemptionActive object

21 TRUE if preemption is both supported by the MAC and currently active.

### 1 **12.30.1.5 holdRequest object**

2 The holdRequest object contains an enumerated integer value, with *hold (1)* indicating that a  
3 MM\_CTL.request(HOLD) has been issued, and release (2) indicating that a MM\_CTL.request(RELEASE)  
4 has been issued. This object exists per Port.

5 NOTE 1—In order that the operations enumerated in the table occur at the specified times (8.6.8.4), an implementation  
6 needs to trigger the MM\_CTL.request in advance, as appropriate.

7 NOTE 2—In order to determine support of frame preemption by the Bridge, a network management  
8 application could attempt to read the preemptionActive object. If the read operation returns an error, frame  
9 preemption is not supported. Determining whether the MAC supports preemption could similarly be achieved  
10 by examining the objects in the MAC MIB.

## 12.31 Managed objects for per-stream classification and metering

The Bridge enhancements for support of per-stream classification and metering are defined in 8.6.5.2, 8.6.5.3, 8.6.5.4, 8.6.5.5, and 8.6.5.6. The associated state machines are defined in 8.6.10 and 8.6.11.

This managed resource comprises the following objects:

- a) The Stream Parameter Table (12.31.1)
- b) The Stream Filter Instance Table (12.31.2)
- c) The Stream Gate Instance Table (12.31.3)
- d) The Flow Meter Instance Table (12.31.4)
- e) The Scheduler Instance Table (12.31.5)
- f) The Scheduler Group Instance Table (12.31.6)
- g) The Scheduler Port Parameter Table (12.31.7)
- h) The Scheduler Timing Characteristics Table (12.31.8)

### 12.31.1 The Stream Parameter Table

There is one Stream Parameter Table per Bridge Component. The table contains a set of parameters that supports PSFP (8.6.5.2.1), ATS (8.6.5.2.2), and CI (8.6.5.2.3), as detailed in Table 12-34. Tables can be created or removed dynamically in implementations that support dynamic configuration of Bridge components.

**Table 12-34—The Stream Parameter Table**

| Name                       | Data type                | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                    |
|----------------------------|--------------------------|-----------------------------------|--------------------------|-------------------------------|
| MaxStreamFilterInstances   | integer                  | R                                 | PSFP, ATS, CI            | 8.6.5.3, 12.31.2              |
| MaxStreamGateInstances     | integer                  | R                                 | PSFP, ATS, CI            | 8.6.5.4, 12.31.3              |
| MaxFlowMeterInstances      | integer                  | R                                 | PSFP, ats                | 8.6.5.5, 12.31.4              |
| SupportedListMax           | integer                  | R                                 | PSFP, ats                | 8.6.5.4, 12.31.4              |
| MaxSchedulerInstances      | integer                  | R                                 | psfp, ATS                | 8.6.5.4, 12.31.4              |
| MaxSchedulerGroupInstances | integer                  | R                                 | psfp, ATS                | 8.6.5.4, 12.31.4              |
| SupportedCycleMax          | RationalNumber (seconds) | R                                 | PSFP, ATS                | 8.6.5.4, 12.29.1.3, 12.29.1.6 |
| SupportedIntervalMax       | Integer                  | R                                 | PSFP, ATS                | 8.6.5.4, 12.29.1.7            |

<sup>a</sup> R= Read only access; RW = Read/Write access.

<sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.

psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.

ATS = Required for Bridge or Bridge Component support of ATS.

ats = Optional for Bridge or Bridge Component support of ATS.

CI = Required for Bridge or Bridge Component support of CI.

#### 12.31.1.1 MaxStreamFilterInstances

The maximum number of Stream Filter instances supported by this Bridge Component (8.6.5.3).

1 **12.31.1.2 MaxStreamGateInstances**

2 The maximum number of Stream Gate instances supported by this Bridge Component (8.6.5.4).

3 **12.31.1.3 MaxFlowMeterInstances**

4 The maximum number of Flow Meter instances supported by this Bridge Component (8.6.5.5).

5 **12.31.1.4 SupportedListMax**

6 The maximum value supported by this Bridge Component of the AdminControlListLength (8.6.9.4.6) and  
7 OperControlListLength (8.6.9.4.22) parameters. It is available for use by schedule computation software to  
8 determine the Bridge Component's control list capacity prior to computation.

9 **12.31.1.5 MaxSchedulerInstances**

10 The maximum number of ATS scheduler instances supported by this Bridge Component (8.6.5.6).

11 **12.31.1.6 MaxSchedulerGroupInstances**

12 The maximum number of ATS scheduler group instances supported by this Bridge Component (8.6.5.6).

13 **12.31.1.7 SupportedCycleMax**

14 The maximum value supported by this Port of the AdminCycleTime (8.6.9.4.3) and OperCycleTime  
15 (8.6.9.4.19) parameters.

16 **12.31.1.8 SupportedIntervalMax**

17 The maximum value supported by this Bridge Component of the timeIntervalValue (12.31.3.2.4) parameter.

18 **12.31.2 The Stream Filter Instance Table**

19 There is one Stream Filter Instance Table per Bridge Component. Each table row contains a set of  
20 parameters that defines a single Stream Filter (8.6.5.3), as detailed in Table 12-35. The table rows form an  
21 ordered list of filter instances, the order being determined by the StreamFilterInstance parameter. Tables can  
22 be created or removed dynamically in implementations that support dynamic configuration of Bridge  
23 Components. Rows in the table can be created or removed dynamically in implementations that support  
24 dynamic configuration of stream filters.

25 **12.31.2.1 StreamFilterInstance**

26 An integer index value that determines the place of the stream filter in the ordered list of stream filter  
27 instances. The values of StreamFilterInstance are ordered according to their integer value; smaller values  
28 appear earlier in the ordered list.

29 **12.31.2.2 stream\_handle specification data type**

30 The stream\_handle specification data type allows either of the following to be represented:

- 31 a) A stream\_handle value, represented as an integer
- 32 b) The wild card value
- 33 c) If congestion isolation is supported, the null-handle value.

**Table 12-35—Stream Filter Instance Table**

| Name                                  | Data type                   | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References           |
|---------------------------------------|-----------------------------|-----------------------------------|--------------------------|----------------------|
| StreamFilterInstance                  | integer                     | R                                 | PSFP, ATS, CI            | 8.6.5.3              |
| StreamHandleSpec                      | stream_handle specification | RW                                | PSFP, ATS, CI            | 8.6.5.3              |
| PrioritySpec                          | priority specification      | RW                                | PSFP, ATS, CI            | 8.6.5.3              |
| MaximumSDUSize                        | integer                     | RW                                | PSFP, ATS                | 8.6.5.3.1, 12.31.2.5 |
| StreamGateInstanceID                  | integer                     | RW                                | PSFP, ATS, CI            | 8.6.5.2, 8.6.5.4     |
| FlowMeterInstanceID                   | integer                     | RW                                | PSFP, ats                | 8.6.5.5, 12.31.2.5   |
| FlowMeterEnable                       | Boolean                     | RW                                | PSFP, ats                |                      |
| SchedulerInstanceID                   | integer                     | RW                                | psfp, ATS                |                      |
| SchedulerEnable                       | Boolean                     | RW                                | psfp, ATS                |                      |
| MatchingFramesCount                   | counter                     | R                                 | PSFP, ats, ci            | 8.6.5.3              |
| PassingFramesCount                    | counter                     | R                                 | PSFP, ats                | 8.6.5.3, 8.6.5.4     |
| NotPassingFramesCount                 | counter                     | R                                 | PSFP, ats                | 8.6.5.3, 8.6.5.4     |
| PassingSDUCount                       | counter                     | R                                 | PSFP, ats                | 8.6.5.3, 8.6.5.3.1   |
| NotPassingSDUCount                    | counter                     | R                                 | PSFP, ats                | 8.6.5.3, 8.6.5.3.1   |
| REDFramesCount                        | counter                     | R                                 | PSFP, ats                | 8.6.5.3              |
| StreamBlockedDueToOversizeFrameEnable | Boolean                     | RW                                | PSFP, ATS                | 8.6.5.3, 8.6.5.3.1   |
| StreamBlockedDueToOversizeFrame       | Boolean                     | RW                                | PSFP, ATS                | 8.6.5.3, 8.6.5.3.1   |

<sup>a</sup> R= Read only access; RW = Read/Write access.

<sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.

psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.

ATS = Required for Bridge or Bridge Component support of ATS.

ats = Optional for Bridge or Bridge Component support of ATS.

CI = Required for Bridge Component or end station support of CI.

ci = Optional for Bridge Component or end station support of CI.

### 1 12.31.2.3 priority specification data type

2 The priority specification data type allows either of the following to be represented:

- 3 a) A priority value, represented as an integer
- 4 b) The wild card value

#### 12.31.2.4 MaxSDUSize

The MaxSDUSize parameter defines the maximum SDU size to be accepted by the stream filter (8.6.5.3). A value of 0 disables the maximum SDU size filtering for frames associated with the stream filter.

#### 12.31.2.5 StreamGateInstanceID

The StreamGateInstanceID parameter identifies the stream gate instance (12.31.3) that is associated with the stream filter. The relationship between stream filters and stream gates is many to one; a given stream filter can be associated with only one stream gate, but there can be multiple stream filters associated with a given stream gate.

#### 12.31.2.6 FlowMeterInstanceID and FlowMeterEnable

If FlowMeterEnable is set to TRUE, the FlowMeterInstanceID parameter identifies the flow meter instance (12.31.4) that is associated with the stream filter. The relationship between stream filters and flow meters is many to one; a given stream filter can be associated with only one flow meter, but there can be multiple stream filters associated with a given flow meter. If FlowMeterEnable is set to FALSE, no flow meter instance is associated with the stream filter.

#### 12.31.2.7 SchedulerInstanceID and SchedulerEnable

If SchedulerEnable is set to TRUE, the SchedulerInstanceID parameter identifies the ATS scheduler instance (12.31.5) that is associated with the stream filter. The relationship between stream filters and ATS schedulers is many to one; a given stream filter can be associated with only one ATS scheduler, but there can be multiple stream filters associated with a given ATS scheduler instance. If SchedulerEnable is set to FALSE, no ATS scheduler instance is associated with the stream filter.

#### 12.31.3 The Stream Gate Instance Table

There is one Stream Gate Instance Table per Bridge Component. Each table row contains a set of parameters that defines a single Stream Gate (8.6.5.4), as detailed in Table 12-36. Tables can be created or removed dynamically in implementations that support dynamic configuration of Bridge Components. Rows in the table can be created or removed dynamically in implementations that support dynamic configuration of stream gates.

**Table 12-36—The Stream Gate Instance Table**

| Name                             | Data type             | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References               |
|----------------------------------|-----------------------|-----------------------------------|--------------------------|--------------------------|
| StreamGateInstance               | integer               | R                                 | PSFP, ATS, CI            | 8.6.5.4                  |
| StreamGateEnabled                | Boolean               | RW                                | PSFP, ATS, CI            | 8.6.9.4.14               |
| StreamGateAdminGateStates        | StreamGateStatesValue | RW                                | PSFP, ATS, CI            | 8.6.10.4,<br>12.29.1.2.2 |
| StreamGateOperGateStates         | StreamGateStatesValue | R                                 | PSFP, ATS, CI            | 8.6.10.5,<br>12.29.1.2.2 |
| StreamGateAdminControlListLength | unsigned integer      | RW                                | PSFP, ats                | 8.6.9.4.6,<br>12.31.3.2  |
| StreamGateOperControlListLength  | unsigned integer      | R                                 | PSFP, ats                | 8.6.9.4.22,<br>12.31.3.2 |

**Table 12-36—The Stream Gate Instance Table (*continued*)**

| Name                                           | Data type                               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                         |
|------------------------------------------------|-----------------------------------------|-----------------------------------|--------------------------|------------------------------------|
| StreamGateAdminControlList                     | sequence of StreamGateGateControl Entry | RW                                | PSFP, ats                | 8.6.9.4.2, 12.31.3.2, 12.31.3.2.2  |
| StreamGateOperControlList                      | sequence of StreamGateGateControl Entry | R                                 | PSFP, ats                | 8.6.9.4.18, 12.31.3.2, 12.31.3.2.2 |
| StreamGateAdminCycleTime                       | RationalNumber                          | RW                                | PSFP, ats                | 8.6.9.4.3, 12.29.1.3               |
| StreamGateOperCycleTime                        | RationalNumber (seconds)                | R                                 | PSFP, ats                | 8.6.9.4.19, 12.29.1.3              |
| StreamGateAdminCycleTime Extension             | Integer (nanoseconds)                   | RW                                | PSFP, ats                | 8.6.9.4.4                          |
| StreamGateOperCycleTimeExtension               | Integer (nanoseconds)                   | R                                 | PSFP, ats                | 8.6.9.4.20                         |
| StreamGateAdminBaseTime                        | PTPtime                                 | RW                                | PSFP, ats                | 8.6.9.4.1, 12.29.1.4               |
| StreamGateOperBaseTime                         | PTPtime                                 | R                                 | PSFP, ats                | 8.6.9.4.17, 12.29.1.4              |
| StreamGateConfigChange                         | Boolean                                 | RW                                | PSFP, ats                | 8.6.9.4.7                          |
| StreamGateConfigChangeTime                     | PTPtime                                 | R                                 | PSFP, ats                | 8.6.9.4.9, 12.29.1.4               |

| StreamGateOperIPV                              | IPV                                     | RW                                | PSFP, ats, CI            | 8.6.5.4, 8.6.10.7, 12.31.3.3       |
| StreamGateGateClosedDueToInvalid Rx-Enable     | Boolean                                 | RW                                | PSFP, ats                | 8.6.5.4                            |
| StreamGateGateClosedDueToInvalid Rx            | Boolean                                 | RW                                | PSFP, ats                | 8.6.5.4                            |
| StreamGateGateClosedDueToOctets ExceededEnable | Boolean                                 | RW                                | PSFP, ats                | 8.6.5.4                            |
| StreamGateGateClosedDueToOctets Exceeded       | Boolean                                 | RW                                | PSFP, ats                | 8.6.5.4                            |

<sup>a</sup> R= Read only access; RW = Read/Write access.

- <sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.  
psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.  
ATS = Required for Bridge or Bridge Component support of ATS.  
ats = Optional for Bridge or Bridge Component support of ATS.  
CI = Required for Bridge Component or end station support of CI.

### 1 **12.31.3.1 StreamGateInstance**

2 An integer table index that allows the stream gate to be referenced from Stream Filter Instance Table entries.

### 3 **12.31.3.2 The gate control list structure and data types**

4 The AdminControlList and OperControlList are ordered lists containing AdminControlListLength or  
5 OperControlListLength entries, respectively. Each entry represents a gate operation as defined in Table 8-4.  
6 Each entry in the list is structured as a GateControlEntry (12.31.3.2.2).

#### 7 **12.31.3.2.1 StreamGateStatesValue**

8 The StreamGateStatesValue indicates the desired gate state, *open* or *closed*, for the stream gate.

#### 9 **12.31.3.2.2 StreamGateControlEntry**

10 A StreamGateControlEntry consists of an operation name, followed by three mandatory parameters and one  
11 optional parameter associated with the operation, as detailed in Table 8-4. The first parameter is a  
12 StreamGateStatesValue (8.6.10.5, 12.31.3.2.1); the second parameter is an IPV value (8.6.10.7, 12.31.3.2.3);  
13 the third parameter is a timeIntervalValue (8.6.9.4.23, 12.31.3.2.4); and the fourth parameter is an  
14 IntervalOctetMaxValue (8.6.10.1, 12.31.3.2.5). IntervalOctetMaxValue is optional.

#### 15 **12.31.3.2.3 IPV value**

16 The IPV value indicates the IPV (12.31.3.3) to be associated with frames that pass the gate (8.6.10.7).

#### 17 **12.31.3.2.4 timeIntervalValue**

18 An unsigned integer, denoting a TimeInterval in nanoseconds (see TimeInterval in Table 8-4).

#### 19 **12.31.3.2.5 IntervalOctetMaxValue**

20 An unsigned integer, denoting an IntervalOctetMax in MSDU octets (see IntervalOctetMax in Table 8-4).

### 21 **12.31.3.3 The internal priority value specification (IPV) data type**

22 The IPV data type represents an IPV value (8.6.5.4); this is either the null value or an internal priority value.

### 23 **12.31.3.4 Representation of times**

24 Table 12-36 specifies times (e.g., StreamGateAdminBaseTime) with reference to the on-the-wire timing  
25 point at which the start of a frame crosses the boundary between the physical network media and PHY. This  
26 is the message timestamp point specified by IEEE Std 802.1AS for various media.

27 Figure 12-7 shows both the on-the-wire timing point and the Stream Gate timing point within the interface  
28 stack (above MAC and PHY) that is used for gate open/close as described in 8.6.5.4. Each timing point will  
29 have variance. A delay exists between the on-the-wire timing point and the Stream Gate timing point. This  
30 delay will have variance that is bounded (minimum/maximum).

**Figure 12-7—Timing points for PSFP**

1 The Bridge contains the information needed in order to compute the minimum/maximum delay from the  
2 on-the-wire timing point to the Stream Gate timing point. The Bridge shall adjust using the maximum delay,  
3 such that a frame's on-the-wire timing point occurs no later than the gate events represented in managed  
4 objects.

5 NOTE—Although the managed objects apply to a Bridge, the preceding specification of on-the-wire timing point can be  
6 applied to an end station.

#### 7 **12.31.4 The Flow Meter Instance Table**

8 There is one Flow Meter Instance Table per Bridge Component. Each table row contains a set of parameters  
9 that defines a single Flow Meter Instance (8.6.5.5), as detailed in Table 12-37. Tables can be created or  
10 removed dynamically in implementations that support dynamic configuration of Bridge Components. Rows  
11 in the table can be created or removed dynamically in implementations that support dynamic configuration  
12 of flow meters.

#### 13 **12.31.5 The Scheduler Instance Table**

14 There is one Scheduler Instance Table per Bridge Component. Each table row in the Scheduler Instance  
15 Table comprises a set of parameters that defines a single ATS scheduler instance, as detailed in Table 12-38.

16 NOTE—ATS scheduler groups establish the relationship between ATS scheduler instances and the per port management  
17 variables (12.31.7), as described in 8.6.5.6. As a result, the scheduler instance table does not contain references to ports.

##### 18 **12.31.5.1 SchedulerInstanceID**

19 An integer table index that allows the ATS scheduler instance to be referenced from Stream Filter Instance  
20 Table entries.

##### 21 **12.31.5.2 CommittedBurstSize**

22 As specified in 8.6.11.3.5.

##### 23 **12.31.5.3 CommittedInformationRate**

24 As specified in 8.6.11.3.6.

**Table 12-37—The Flow Meter Instance Table**

| Name                   | Data type                              | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References       |
|------------------------|----------------------------------------|-----------------------------------|--------------------------|------------------|
| FlowMeterInstanceID    | integer                                | R                                 | PSFP, ats                | 8.6.5.2, 8.6.5.5 |

| CBS                    | integer, octets                        | RW                                | PSFP, ats                | 8.6.5.5          |
| EIR                    | integer, bit/second                    | RW                                | PSFP, ats                | 8.6.5.5          |
| EBS                    | integer, octets                        | RW                                | PSFP, ats                | 8.6.5.5          |
| CF                     | integer, 0 or 1                        | RW                                | PSFP, ats                | 8.6.5.5          |
| CM                     | enumerated, color-blind or color-aware | RW                                | PSFP, ats                | 8.6.5.5          |
| DropOnYellow           | Boolean                                | RW                                | PSFP, ats                | 8.6.5.5          |
| MarkAllFramesRedEnable | Boolean                                | RW                                | PSFP, ats                | 8.6.5.5          |
| MarkAllFramesRed       | Boolean                                | RW                                | PSFP, ats                | 8.6.5.5          |

<sup>a</sup> R= Read only access; RW = Read/Write access.

<sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.  
psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.  
ATS = Required for Bridge or Bridge Component support of ATS.  
ats = Optional for Bridge or Bridge Component support of ATS.

**Table 12-38—The Scheduler Instance Table**

| Name                     | Data type       | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                     |
|--------------------------|-----------------|-----------------------------------|--------------------------|--------------------------------|
| SchedulerInstanceID      | integer         | R                                 | psfp, ATS                | 8.6.5.6, 12.31.5.1             |
| CommittedBurstSize       | integer, bits   | RW                                | psfp, ATS                | 8.6.5.6, 8.6.11.3.5, 12.31.5.2 |
| CommittedInformationRate | integer, bits/s | RW                                | psfp, ATS                | 8.6.5.6, 8.6.11.3.6, 12.31.5.3 |
| SchedulerGroupInstanceID | integer         | RW                                | psfp, ATS                | 8.6.5.6, 12.31.5.4             |

<sup>a</sup> R= Read only access; RW = Read/Write access.

<sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.  
psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.  
ATS = Required for Bridge or Bridge Component support of ATS.  
ats = Optional for Bridge or Bridge Component support of ATS.

#### 12.31.5.4 SchedulerGroupInstanceID

The SchedulerGroupInstanceID parameter identifies the ATS scheduler group (12.31.6) that is associated with the ATS scheduler instance. Multiple scheduler instance can be associated to one ATS scheduler group, as detailed in 8.6.5.6.

#### 12.31.6 The Scheduler Group Instance Table

There is one Scheduler Group Instance Table per Bridge Component. Each table row in the Scheduler Group Instance Table comprises a set of parameters that defines a single ATS scheduler group instance (8.6.5.6), as detailed in Table 12-39.

**Table 12-39—The Scheduler Group Instance Table**

| Name                     | Data type            | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References            |
|--------------------------|----------------------|-----------------------------------|--------------------------|-----------------------|
| SchedulerGroupInstanceID | integer              | R                                 | psfp, ATS                | 8.6.5.6,<br>12.31.6.1 |
| MaxResidenceTime         | integer, nanoseconds | RW                                | psfp, ATS                | 8.6.5.6,<br>12.31.6.2 |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.

psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.

ATS = Required for Bridge or Bridge Component support of ATS.

ats = Optional for Bridge or Bridge Component support of ATS.

#### 12.31.6.1 SchedulerGroupInstanceID

An integer table index that allows the ATS scheduler group instance to be referenced from Scheduler Instance Table entries.

#### 12.31.6.2 MaxResidenceTime

As specified in 8.6.11.3.13.

#### 12.31.7 The Scheduler Port Parameter Table

There is one Scheduler Port Parameter Table per Bridge. Each table row in the Scheduler Port Parameter Table comprises a set of parameters shared by all ATS scheduler instance associated with a reception Port, as detailed in Table 12-40.

**Table 12-40—The Scheduler Port Parameter Table**

| Name                 | Data type | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                           |
|----------------------|-----------|-----------------------------------|--------------------------|--------------------------------------|
| PortNumber           | integer   | R                                 | psfp, ATS                | 12.31.7.1                            |
| DiscardedFramesCount | integer   | R                                 | psfp, ATS                | 8.6.5.6,<br>8.6.11.3.7,<br>12.31.7.2 |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.

psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.

ATS = Required for Bridge or Bridge Component support of ATS.

ats = Optional for Bridge or Bridge Component support of ATS.

### 12.31.7.1 PortNumber

An unique index of the associated Bridge Port (12.4.2).

### 12.31.7.2 DiscardedFramesCount

As specified in 8.6.5.6 and 8.6.11.3.7.

### 12.31.8 The Scheduler Timing Characteristics Table

There is one Scheduler Timing Characteristics Table per Bridge Component. Each row in this table comprises the timing characteristics of a reception Port transmission Port pair, as detailed in Table 12-41.

**Table 12-41—The Timing Characteristics Table**

| Name                       | Data type | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References               |
|----------------------------|-----------|-----------------------------------|--------------------------|--------------------------|
| ReceptionPortNumber        | integer   | R                                 | psfp, ATS                | 12.31.8.1                |
| TransmissionPortNumber     | integer   | R                                 | psfp, ATS                | 12.31.8.2                |
| ClockOffsetVariationMax    | integer   | R                                 | psfp, ATS                | 8.6.11.2,<br>12.31.8.3   |
| ClockRateDeviationMax      | integer   | R                                 | psfp, ATS                | 8.6.11.2,<br>12.31.8.4   |
| ArrivalRecognitionDelayMax | integer   | R                                 | psfp, ATS                | 8.6.11.3.1,<br>12.31.8.5 |
| ProcessingDelayMin         | integer   | R                                 | psfp, ATS                | 8.6.11.3.2,<br>12.31.8.6 |
| ProcessingDelayMax         | integer   | R                                 | psfp, ATS                | 8.6.11.3.2,<br>12.31.8.7 |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> PSFP = Required for Bridge, Bridge Component, or end station support of PSFP.

psfp = Optional for Bridge, Bridge Component, or end station support of PSFP.

ATS = Required for Bridge or Bridge Component support of ATS.

ats = Optional for Bridge or Bridge Component support of ATS.

### 12.31.8.1 ReceptionPortNumber

An unique index of the associated reception Port of the Bridge (12.4.2).

### 12.31.8.2 TransmissionPortNumber

An unique index of the associated transmission Port of the Bridge (12.4.2).

1 **12.31.8.3 ClockOffsetVariationMax**

2 As specified in 8.6.11.2, in nanoseconds, rounded to the next numerically higher representable value.

3 **12.31.8.4 ClockRateDeviationMax**

4 As specified in 8.6.11.2, in ppm, rounded to the next numerically higher representable value.

5 **12.31.8.5 ArrivalRecognitionDelayMax**

6 As specified in 8.6.11.3.1, in nanoseconds, rounded to the next numerically higher representable value.

7 **12.31.8.6 ProcessingDelayMin**

8 As specified in 8.6.11.3.2, in nanoseconds, rounded to the next numerically lower representable value.

9 **12.31.8.7 ProcessingDelayMax**

10 As specified in 8.6.11.3.2, in nanoseconds, rounded to the next numerically higher representable value.

## 12.32 Stream reservation remote management

Clause 46 defines Time-Sensitive Networking (TSN) configuration, including a Centralized Network Configuration (CNC) station that uses managed objects for configuration of each Bridge. This subclause specifies managed objects within the Bridge that can be used by the TSN CNC station or any other management component.

This managed resource comprises the following objects:

- c) Bridge Delay (12.32.1)
- d) Propagation Delay (12.32.2)
- e) Static Trees (12.32.3)
- f) MRP External Control (12.32.4)

### 12.32.1 Bridge Delay

This subclause specifies attributes of a managed object that is used to determine the delay of frames as they pass through the Bridge's relay. There is one Bridge Delay managed object per Port pair per traffic class of a Bridge Component. Each set of Bridge Delay attributes is accessed using three indices: ingress Port, egress Port, and traffic class. The set of managed object attributes is shown in Table 12-42.

**Table 12-42—Bridge Delay attributes**

| Name                | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|---------------------|------------------|-----------------------------------|--------------------------|------------|
| independentDelayMin | unsigned integer | R                                 | B                        | 12.32.1.1  |
| independentDelayMax | unsigned integer | R                                 | B                        | 12.32.1.1  |
| dependentDelayMin   | unsigned integer | R                                 | B                        | 12.32.1.2  |
| dependentDelayMax   | unsigned integer | R                                 | B                        | 12.32.1.2  |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of Stream reservation remote management; b = Optional for Bridge or Bridge Component support of Stream reservation remote management.

For each set of Bridge Delay attributes, the total delay through the Bridge consists of the delay that is independent of frame length, plus the delay that is dependent on frame length.

Each delay is provided as a range, with both minimum attribute and maximum attribute.

The delays represent the worst-case range per the design of the Bridge, and are not measured. If the Bridge design varies based on the configuration of features in the Bridge, the delays are returned according to the current configuration of the Bridge.

NOTE 1—In order to obtain the most accurate delays, the TSN CNC typically configures the Stream from Talker to Listeners, and then reads the delays for the Ports that ingress/egress that Stream. For example, use of IEEE Std 802.1CB could change the implementation in the Bridge, and therefore it is best to configure those features in the Bridge prior to reading the delays.

Each delay is provided as if the corresponding frame encounters zero delay for transmission selection (8.6.8). This occurs when the queue for the frame's traffic class is empty, the frame's traffic class has permission to transmit, and the egress Port is idle (not transmitting).

1 NOTE 2—Computation of delay factors due to use of multiple traffic classes, frame preemption, traffic shaping, and  
2 traffic scheduling is the responsibility of the TSN CNC, and therefore these factors are not included in the delay  
3 attributes of this managed object. For example, assume that a frame of a TSN Stream encounters 12  $\mu$ s of delay due to  
4 traffic scheduling (i.e., waiting for gate to open), 5  $\mu$ s due to a previous frame of the same traffic class, and 700 ns to  
5 800 ns of hardware delay (e.g., PHYs and relay). For this example, independentDelayMin is 700, and  
6 independentDelayMax is 800 (i.e., the extra 17  $\mu$ s for queuing/scheduling is not included in this managed object).

### 7 **12.32.1.1 independentDelayMin/Max**

8 These attributes provide the portion of delay that is independent of frame length.

9 Each length-independent delay attribute is an unsigned integer in units of nanoseconds.

10 The independentDelayMin attribute provides the minimum length-independent delay for a frame to forward  
11 from ingress Port to egress Port for this traffic class. If the actual delay is a fraction of a nanosecond,  
12 independentDelayMin shall be the greatest integer number of nanoseconds that is less than or equal to the  
13 actual delay.

14 The independentDelayMax attribute provides the maximum length-independent delay for a frame to forward  
15 from ingress Port to egress Port for this traffic class. If the actual delay is a fraction of a nanosecond,  
16 independentDelayMax shall be the least integer number of nanoseconds that is greater than or equal to the  
17 actual delay.

18 NOTE 1—Since the minimum to maximum range is intended to be worst-case, the rules for handling a fraction of a  
19 nanosecond are intended to result in the widest range.

20 The delay begins when the message timestamp point of the ingress frame passes the reference plane marking  
21 the boundary between the network media and PHY. The delay ends when the message timestamp point of  
22 the egress frame passes the reference plane marking the boundary between the network media and PHY. The  
23 message timestamp point is specified by IEEE Std 802.1AS for various media, near the start of the frame.

24 NOTE 2—This delay includes all aspects of length-independent delay for a frame that is forwarded, including handling  
25 of error conditions.

### 26 **12.32.1.2 dependentDelayMin/Max**

27 These attributes provide the portion of delay that is dependent on frame length, where frame length is the  
28 number of octets that transfer across the MAC Service interfaces. Each length-dependent delay attribute  
29 specifies the time for a single octet of the frame to transfer from ingress to egress.

30 Each length-dependent delay attribute is an unsigned integer in units of picoseconds.

31 The dependentDelayMin attribute provides the minimum length-dependent delay from ingress Port to egress  
32 Port for this traffic class. If the actual delay is a fraction of a picosecond, dependentDelayMin shall be the  
33 greatest integer number of picoseconds that is less than or equal to the actual delay.

34 The dependentDelayMax attribute provides the maximum length-dependent delay from ingress Port to  
35 egress Port for this traffic class. If the actual delay is a fraction of a picosecond, dependentDelayMax shall  
36 be the least integer number of picoseconds that is greater than or equal to the actual delay.

37 NOTE—The length-dependent delay typically includes the time to receive and store each octet of the frame, and this  
38 time depends on the link speed of the ingress Port. For example, if the ingress Port is operating at 1 Gb/s, both  
39 dependentDelayMin and dependentDelayMax can return 8000. If an internal communication mechanism exists within  
40 the Bridge's architecture (i.e., in the relay), the time for that mechanism is added to the frame-dependent delay. For  
41 example, if a 100 Mb/s serial link connects the ingress and egress Ports, the previous example with 1 Gb/s link speed can  
42 return 88000 for both dependentDelayMin and dependentDelayMax.

## 12.32.2 Propagation Delay

This subclause specifies attributes of a managed object used to determine the delay along the network media (e.g., cable) for a frame transmitted from the specified Port of this station to the neighboring Port on a different station. There is one Propagation Delay managed object per Port of a station (i.e., Bridge or end station). The set of managed object attributes is shown in Table 12-43.

**Table 12-43—Propagation Delay attributes**

| Name               | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|--------------------|------------------|-----------------------------------|--------------------------|------------|
| txPropagationDelay | unsigned integer | R                                 | BE                       | 12.32.2.1  |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of Stream reservation remote management; E = Required for end station support of Stream reservation remote management.

### 12.32.2.1 txPropagationDelay

The txPropagationDelay begins when the message timestamp point of an egress frame passes the reference plane marking the boundary between the network media and PHY of this station's Port. The txPropagationDelay ends when the message timestamp point of an ingress frame on the neighboring station's Port passes the reference plane marking the boundary between the network media and PHY. The message timestamp point is specified by IEEE Std 802.1AS for various media, near the start of the frame.

The txPropagationDelay attribute is an unsigned integer in units of nanoseconds. If the actual propagation delay is measured to a fraction of a nanosecond, the txPropagationDelay value shall be least integer number of nanoseconds that is greater than or equal to the actual delay.

NOTE 1—Propagation delay in one direction of transmit is not necessarily the same as propagation delay of transmit in the reverse direction. In order to determine if a delay asymmetry exists, management can read the txPropagationDelay attribute on the neighboring station's Port. The txPropagationDelay attribute of the neighboring station's Port effectively provides the propagation delay for receiving frames on this station's Port.

NOTE 2—The txPropagationDelay attribute is typically measured using a time synchronization protocol. For example, when IEEE Std 802.1AS is in use, the value of this attribute can be obtained using the managed objects neighborPropDelay and delayAsymmetry.

NOTE 3—One of the primary purposes of the txPropagationDelay attribute is to add to Bridge Delay in order to compute total latency for a Stream. Although time synchronization protocols based on IEEE Std 1588 typically measure propagation delay to units of 2–16 ns, that degree of precision is not required for txPropagationDelay, since Bridge Delay is expressed as nanoseconds.

## 12.32.3 Static Trees

This subclause specifies attributes of a managed object used to determine if the static trees feature is supported by the Bridge. There is one Static Trees managed object that applies to the Bridge. The set of managed object attributes is shown in Table 12-44.

**Table 12-44—Static Trees attributes**

| Name                 | Data type | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|----------------------|-----------|-----------------------------------|--------------------------|------------|
| staticTreesSupported | Boolean   | R                                 | B                        | 12.32.3.1  |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component support of Stream reservation remote management.

### 1 **12.32.3.1 staticTreesSupported**

2 For some use cases, the TSN CNC needs to configure static (persistent) trees through Bridges from Talker to  
3 Listeners (e.g., for use of IEEE Std 802.1CB). The Traffic Engineering Multiple Spanning Tree Instance  
4 Identifier (TE-MSTID) can be leveraged for these use cases. A VLAN ID is allocated to the TE-MSTID in  
5 the MST Configuration Table if it is not under control of either a spanning tree protocol or IS-IS. Static  
6 Filtering Entries (8.8.1) specify frame forwarding and filtering for VLAN IDs allocated to the TE-MSTID.

7 The TE-MSTID feature is used as the basis of a set of features called Provider Backbone Bridge Traffic  
8 Engineering (PBB-TE) as specified in 25.10. For many TSN CNCs, use of the TE-MSTID feature is  
9 essential, but the additional features of PBB-TE are not necessary. The TSN CNC uses the  
10 staticTreesSupported attribute to determine that TE-MSTID is supported by the Bridge. A Bridge that  
11 supports PBB-TE without support of Stream reservation remote management is not required to implement  
12 the staticTreesSupported attribute.

13 A Bridge that supports Stream reservation remote management shall return the value TRUE from the  
14 staticTreesSupported attribute, and shall support the TE-MSTID as specified in 5.5.2.

15 NOTE—In order to determine support for TE-MSTID by the Bridge, the TSN CNC attempts to read the  
16 staticTreesSupported attribute. If the read operation returns an error, or if the read returns FALSE, then the TSN CNC  
17 concludes that TE-MSTID is not supported.

### 18 **12.32.4 MRP External Control**

19 In the Centralized network/distributed user model shown in Figure 46-2, user configuration data is  
20 exchanged in a distributed manner by each Talker/Listener end station, and the network is configured in a  
21 centralized manner (using a CNC). A Bridge near the Talker/Listener acts as a proxy with the CNC. One  
22 protocol solution for this model is to use the MRP protocol for user data (i.e., MSRP, MVRP, and/or MMRP  
23 applications), and a network management protocol as the proxy with the network manager (i.e., CNC). This  
24 enables the end stations to use the same MRP protocol as the Fully distributed model of Figure 46-1.

25 This subclause specifies attributes of a managed object that the network manager uses to:

- 26 a) Disable MRP attribute propagation (MAP) for the MRP Participant of a Bridge Port.
- 27 b) Read MRP attribute registrations that the MRP Participant receives.
- 28 c) Write MRP attribute values for the MRP Participant to declare.

29 There is one MRP External Control managed object for each MRP Participant (per Port per MRP application  
30 per MAP Context, as specified in 10.2 and 10.3.1).

31 For the MSRP application, although 35.2.4.5 implies that a single MAP Context exists, the specifications of  
32 35.1.3.1 ensure that every distinct value of vlan\_identifier propagates along the corresponding VLAN  
33 context (10.3.1). Therefore, for the purposes of indexing this managed object, MSRP uses the  
34 vlan\_identifier as the MAP Context identifier.

35 The set of managed object attributes is shown in Table 12-45.

### 36 **12.32.4.1 externalControl**

37 When the externalControl attribute is FALSE, MRP attributes propagate on the MRP Participant according  
38 to the specifications for MAP in 10.3 and specifications of the MRP Application (e.g., 35.2.4). Ports with the  
39 externalControl attribute FALSE are considered as candidates for the MRP Application's MAP Context. The  
40 remaining attributes of this managed object (12.32.4.2 through 12.32.4.8) are ignored by Ports with the  
41 externalControl attribute FALSE.

**Table 12-45—MRP External Control attributes**

| Name                    | Data type        | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|-------------------------|------------------|-----------------------------------|--------------------------|------------|
| externalControl         | Boolean          | RW                                | B                        | 12.32.4.1  |
| indicationList          | octet string     | R                                 | B                        | 12.32.4.2  |
| indicationListLength    | unsigned integer | R                                 | B                        | 12.32.4.3  |
| indicationChangeCounter | counter          | R                                 | B                        | 12.32.4.4  |
| adminRequestList        | octet string     | RW                                | B                        | 12.32.4.5  |
| adminRequestListLength  | unsigned integer | RW                                | B                        | 12.32.4.6  |
| operRequestList         | octet string     | R                                 | B                        | 12.32.4.7  |
| operRequestListLength   | unsigned integer | R                                 | B                        | 12.32.4.8  |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = Required for Bridge or Bridge Component when both Stream reservation remote management and the corresponding MRP application are supported.

1 When the externalControl attribute is TRUE, the MRP Participant is removed from the MRP Application's  
2 MAP Context. The MRP Participant performs all other aspects of MRP, including MRP operation (10.6),  
3 MRP specifications (10.7), and MRPDUs encodings (10.8). The remaining attributes of this managed object  
4 (12.32.4.2 through 12.32.4.8) act as an application component as specified in 10.2. The application  
5 component stores MAD indications for registration received on the Port, and invokes MAD requests for  
6 declarations on the Port.

7 The default value of the externalControl attribute is FALSE.

#### 8 **12.32.4.2 indicationList**

9 As specified in 10.2, the MAD\_Join.indication primitive is invoked in the application component when  
10 MRP detects that an MRP attribute has joined (i.e., registered), and the MAD\_Leave.indication primitive is  
11 invoked in the application component when MRP detects that the MRP attribute has left (i.e., no longer  
12 registered). When the externalControl attribute is TRUE, the indicationList attribute stores the list of all  
13 joined MRP attributes for the MRP Participant.

14 When the MAD\_Join.indication primitive is invoked, the MRP Participant forms a sequence of octets,  
15 *temporaryIndication*, from the MAD\_Join.indication parameters as follows:

- 16 d) The first octet of *temporaryIndication* contains the *attribute\_type* parameter.
- 17 e) The second octet of *temporaryIndication* contains the length of the *attribute\_value* parameter as a  
18 single octet.
- 19 f) Subsequent octets of *temporaryIndication* contain the sequence of octets for the *attribute\_value*  
20 parameter.

21 NOTE 1—The *new* parameter is not used for indicationList.

22 The MRP Participant searches the indicationList to determine if the same octets as *temporaryIndication*  
23 (i.e., same *attribute\_type* and *attribute\_value*) exist. If no match is found, the contents of  
24 *temporaryIndication* are appended to the end of indicationList. The result of this specification is that the  
25 indicationList consists of an octet string that represents multiple MAD\_Join.indication primitives in the  
26 order initially invoked.

1 When the `MAD_Leave.indication` primitive is invoked, the MRP Participant forms a sequence of octets,  
2 *temporaryIndication*, as specified for `MAD_Join.indication`. The MRP Participant searches the  
3 `indicationList` to determine if the same octets as *temporaryIndication* exist. If a match is found, the  
4 attribute's octets (i.e., matching *temporaryIndication*) are removed from the `indicationList`.

5 NOTE 2—When the indication's *attribute\_type* is Listener Vector Attribute Type, the Listener's Declaration Type  
6 (35.2.1.3) is encoded as the last octet of *attribute\_value*, even though the Declaration Type is not encoded in the MRP  
7 FirstValue (10.8.2.7), but the MRP FourPackedEvent (10.8.2.10.2). For the Listener Enhanced Vector Attribute Type,  
8 the Listener's Declaration Type is not encoded as the last octet, since the equivalent information is available in the  
9 ListenerStatus element (46.2.5.1).

10 The default value of the `indicationList` attribute is the empty octet string.

11 NOTE 3—The attribute encoding of `indicationList` does not correspond directly to the MRPDU. For example, if the  
12 received MRPDU uses `NumberOfValues` of three, then the MRPDU encodes only one attribute value (FirstValue),  
13 whereas `indicationList` encodes three distinct attribute type/length/value triplets.

14 When the `externalControl` attribute is `FALSE`, the `indicationList` attribute is ignored by the MRP Participant,  
15 and returns the empty octet string.

#### 16 **12.32.4.3 indicationListLength**

17 The `indicationListLength` attribute returns the number of octets in the `indicationList` attribute.

18 When the `externalControl` attribute is `FALSE`, the `indicationListLength` attribute returns zero.

#### 19 **12.32.4.4 indicationChangeCounter**

20 The `indicationChangeCounter` attribute increments by one for each change to `indicationList` as specified in  
21 12.32.4.2.

22 The default value of the `indicationChangeCounter` attribute is zero.

23 When the `externalControl` attribute is `FALSE`, the `indicationChangeCounter` attribute returns zero.

#### 24 **12.32.4.5 adminRequestList**

25 The `adminRequestList` attribute provides the administrative value of the current list of MAD requests for the  
26 MRP Participant (`operRequestList`). Changes to `adminRequestList` result in invocation of  
27 `MAD_Join.request` and `MAD_Leave.request` primitives (12.32.4.7). Each attribute in `adminRequestList` is  
28 encoded as the *attribute\_type* parameter as a single octet, followed by the length of the *attribute\_value*  
29 parameter as a single octet, followed by a sequence of octets for the *attribute\_value* parameter.

30 NOTE—The *new* parameter is not used for `adminRequestList`.

31 The default value of the `adminRequestList` attribute is the empty octet string.

32 When the `externalControl` attribute is `TRUE`, the `adminRequestList` attribute is copied to the  
33 `operRequestList` attribute as soon as possible according to the implementation. For example, the  
34 implementation could copy the list between each MRPDU transmit, or it could copy the list after all  
35 attributes in the previous `operRequestList` complete transmission as MRPDUs.

36 When the `externalControl` attribute is `FALSE`, the `adminRequestList` attribute is ignored by the MRP  
37 Participant, but it retains its value.

#### 1 **12.32.4.6 adminRequestListLength**

2 The adminRequestListLength attribute provides the administrative value for the number of octets in  
3 adminRequestList.

4 The default value of the adminRequestListLength attribute is zero.

5 When the externalControl attribute is TRUE, the adminRequestListLength attribute is copied to the  
6 operRequestListLength attribute at the same time that the adminRequestList attribute is copied to the  
7 operRequestList attribute.

8 When the externalControl attribute is FALSE, the adminRequestListLength attribute is ignored by the MRP  
9 Participant, but it retains its value.

#### 10 **12.32.4.7 operRequestList**

11 The operRequestList attribute is the operational value of the current list of MAD requests for the MRP  
12 Participant. Prior to copying adminRequestList to operRequestList, the lists are compared as follows:

- 13 g) If an attribute exists in adminRequestList that does not exist in operRequestList, invoke  
14 MAD\_Join.request for that attribute, with the *new* parameter set TRUE.
- 15 h) If an attribute exists in operRequestList that does not exist in adminRequestList, invoke  
16 MAD\_Leave.request for that attribute.

17 When the comparison is complete, adminRequestList is copied to operRequestList.

18 The default value of the operRequestList attribute is the empty octet string.

#### 19 **12.32.4.8 operRequestListLength**

20 The operRequestListLength attribute is the operational value of the adminRequestListLength attribute, and  
21 it is copied at the same time that adminRequestList attribute is copied to operRequestList.

22 The default value of the operRequestListLength attribute is zero.

### 23 **12.33 Congestion Isolation managed objects**

24 Several variables control the operation of Congestion Isolation in a congestion isolation aware Bridge. The  
25 managed objects are as follows:

- 26 a) CI entity managed object (12.33.1)
- 27 b) CI Peer Table (12.33.2)
- 28 c) CI Stream Table (12.33.3)
- 29 d) CIP entity managed object (12.33.4)

#### 30 **12.33.1 CI entity managed object**

31 A single instance of the CI entity managed object shall be implemented by a Bridge Component or end  
32 station that is congestion isolation aware. It comprises all the variables included in the CI entity variables  
33 (49.4.1.1) as illustrated in Table 12-42.

**Table 12-42—CI entity managed object**

| Name                  | Data type               | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|-----------------------|-------------------------|-----------------------------------|--------------------------|------------|
| ciMasterEnable        | Boolean                 | RW                                | CI                       | 49.4.1.1.1 |
| ciCIMTransmitPriority | unsigned integer [0..7] | R                                 | CI                       | 49.4.1.1.2 |
| ciMaxFlowLife         | unsigned integer        | R                                 | CI                       | 49.4.1.1.3 |

<sup>a</sup> R= Read only access; RW = Read/Write access.

<sup>b</sup> CI = Required for Bridge Component or end station support of CI.

### 1 12.33.2 CI Peer Table

2 A single instance of the CI Peer Table shall be implemented by a Bridge Component or end station that is  
3 congestion isolation aware. Each table row contains the parameters needed to assist in the creation of a CIM  
4 as illustrated in Table 12-43. There is a row in the table for each port of the Bridge or router that is  
5 supporting congestion isolation.

**Table 12-43—CI Peer Table entry**

| Name              | Data type             | Operations supported <sup>a</sup> | Conformance   | References |
|-------------------|-----------------------|-----------------------------------|---------------|------------|
| ciCIMtype         | enum {12, ipv4, ipv6} | R                                 |               | 49.3.6     |
| ciPeerMacAddress  | MAC address           | R                                 |               | 49.3.6     |
| ciPeerIPv4Address | IPv4 address          | R                                 | IETF RFC 791  | 49.3.6     |

<sup>a</sup> R= Read only access; RW = Read/Write access.

### 6 12.33.3 CI Stream Table

7 A single instance of the CI Stream Table (49.3.7) shall be implemented by a Bridge Component or end  
8 station that is congestion isolation aware. Each table row contains stream management variables associated  
9 with a tsnStreamIdEntry object created in the IEEE Std 802.1CB Stream identity table. The variables assist  
10 in the processes associated with the isolating and de-isolating of congesting flows. There is a row in the table  
11 for each congesting flow as illustrated in Table 12-44.

### 12 12.33.4 CIP entity managed object

13 There is one Congestion Isolation Point (CIP) managed object for each CIP in a Bridge Component or end  
14 station that is congestion isolation aware. The CIP managed object comprises some of the variables included  
15 in the CIP variables (49.4.1.2) as illustrated in Table 12-45.

**Table 12-44—CI Stream Table entry**

| Name                  | Data type                   | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|-----------------------|-----------------------------|-----------------------------------|--------------------------|------------|
| ciStreamIdHandle      | stream_handle value         | R                                 | IEEE Std 802.1CB         | 49.4.1.5.1 |
| ciCIMCount            | integer                     | RW                                | CI                       | 49.4.1.5.2 |
| ciCreateTime          | sysUpTime (IETF RFC 3418)   | R                                 | IETF RFC 3418            | 49.4.1.5.3 |
| ciStreamCreateMask    | 2-bit mask                  | RW                                | CI                       | 49.4.1.5.4 |

<sup>a</sup> R= Read only access; RW = Read/Write access.

<sup>b</sup> CI = Required for Bridge Component or end station support of CI.

## 12.34 Managed objects for PBBN Auto Attach

The conformance requirements for PBBN Auto Attach support are specified in 5.9.2, 5.10.3, 5.12.2, 5.14.2, and 5.33. PBBN Auto Attach is specified in Clause 50.

The PBBN Auto Attach specific managed objects defined here:

- a) Provide managed objects for identifying and configuring an Auto Attach System (12.34.1).
- b) Provide managed objects for configuring Bridge Ports, LAGs, and DRNIs for Auto Attach (12.34.2).
- c) Provide managed objects to catalog discovered remote ports supporting Auto Attach (12.34.3).
- d) Provide managed objects that indicate the desired VID to I-SID assignments for AADs and the operating assignments for AABs for each Bridge Port, LAG, or DRNI (12.34.4).
- e) Provide per port PBBN Auto Attach statistics (12.34.5).

### 12.34.1 PBBN Auto Attach System objects

The PBBN Auto Attach System objects (Table 12-46) identify the AAS within the administrative domain, indicate the type of AAS, either AAB or one of the AAD types, and enable Auto Attach within the AAS. The aaSystemMAC uniquely identifies the system including all associated components.

**Table 12-46—PBBN Auto Attach System objects**

| Name              | Data type                                                            | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|-------------------|----------------------------------------------------------------------|-----------------------------------|--------------------------|------------|
| aaSystemEnable    | Boolean                                                              | RW                                | B, D                     | 50.4.2.1   |
| aaSystemMAC       | macAddress                                                           | R                                 | B, D                     | 50.4.2.4   |
| aaSystemType      | enumerated {AAB, CVLAN-AWARE-AAD, VLAN-UNAWARE-AAD, SVLAN-AWARE-AAD} | R                                 | B, D                     | 50.4.2.5   |
| aaSystemResetTime | unsigned (1...1200)                                                  | RW                                | B, D                     | 50.4.2.6   |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for AAB; D= required for AAD.

In the case of an AAB a single aaSystemMAC identifies all I-components and T-components as well as all embedded S-components and C-components used to support external C-VLAN and S-VLAN interfaces. In the case where a pair of BEBs form a DRNI, the single aaSystemMAC identifies all components of both BEBs coupled to form a DRNI.

For an AAD the single aaSystemMAC identifies all end station and Bridge components within the AAD.

The object aaSystemEnable defaults to FALSE allowing configuration of the system before Auto Attach operation. Changing aaSystemEnable from FALSE to TRUE starts Auto Attach on all configured and enabled ports. Setting aaSystemEnable to FALSE breaks all attachments and disables the Auto Attach feature on all ports of the AAS.

## 12.34.2 PBBN Auto Attach port table

Each AAS has a port table that lists the ports that can be advertised by this system using the AAP. Each entry in the PBBN Auto Attach port table (Table 12-47) can be created, deleted, and updated by the system administrator to configure ports for Auto Attach.

**Table 12-47—PBBN Auto Attach port table**

| Name         | Data type | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                                      |
|--------------|-----------|-----------------------------------|--------------------------|-------------------------------------------------|
| aaPortId     | If-ref    | R                                 | B, D                     | 50.4.3.13                                       |
| aaPortNetId  | String    | R                                 | B, D                     | 50.4.3.9,<br>50.4.1.3<br>portNetId <sup>c</sup> |
| aaPortEnable | Boolean   | RW                                | B, D                     | 50.4.3.1                                        |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for AAB; D= required for AAD.

<sup>c</sup> This is the object within the referenced structure.

Each local port is uniquely identified within the AAS by its aaPortId and uniquely identified over the administrative domain by aaPortNetId. The aaPortNetId is composed of the aaSystemMAC and the aaPortID. The management object aaPortNetId reflects the content of the state machine variable aaOperLocSysTlv.portNetId.

The object aaPortEnable controls the state machine variable aaAdminPortEnable that enables/disables Auto Attach operation on this port. Setting aaPortEnable = FALSE forces the AAP state machines for this port to restart, detaching all active associations and clearing the current statistics.

### 1 12.34.3 PBBN Discovered Auto Attach Systems table

2 The PBBN Discovered AAS table (Table 12-48) object provides information about active remote Auto  
3 Attach ports identified by the Auto Attach Protocol (AAP) through the Auto Attach LLDP database system  
4 objects. The discovered Auto Attach Systems table is read only.

**Table 12-48—PBBN Discovered Auto Attach Systems table**

| Name                    | Data type                                                                                                                                                                                                       | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                                                      |

<sup>a</sup> Operations Supported: R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for AAB; D= required for AAD.

<sup>c</sup> This is the object within the referenced structure

5 The aaDiscLocPortId provides a reference to the local port, LAG, or DRNI where the remote attach port was  
6 discovered. The aaDiscRemPortNetId uniquely identifies the remote port, LAG, or DRNI discovered at the  
7 local port.

## 12.34.4 PBBN Auto Attach assignment table

There is one PBBN Auto Attach assignment table for each port configured in the Auto Attach port table (12.34.2). The Auto Attach assignment table is used by management to set the VLAN ID/I-SID assignments desired by the AAD and to monitor the current Auto Attach assignment requests received at the AAB. Entries in the Auto Attach assignment table can be created, updated, and deleted for the AAD, but are read only for the AAB.

Each entry of the Auto Attach assignment table (Table 12-49) contains three variables specifying the VID, I-SID, and status of each assignment. In an AAD the desired assignments are stored and read from the per port state machine variable aaAdminVidIsidAsgns[] (50.4.3.2). One aaAdminVidIsidAsgns[] exists for each local port identified by the Auto Attach port table.

**Table 12-49—PBBN Auto Attach assignment table**

| Name                 | Data type                                                                                                                                                                                  | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References                                                                         |

| aaVidIsidAsgnsIsid   | unsigned [1, 256...16777214]                                                                                                                                                               | R for AAB,<br>RW for AAD          | B, D                     | 50.4.3.2<br>isid <sup>c</sup>                                                      |
| aaVidIsidAsgnsStatus | Enumerated { PENDING,<br>ACCEPTED, REJECTED,<br>REJ-RES-UNAVAIL,<br>REJ-INVALID-VID,<br>REJ-VLAN-UNAVAIL,<br>REJ-INVALID-I-SID,<br>REJ-I-SID-UNAVAIL,<br>REJ-APP-ISSUE,<br>REJ-NOT-ALLOWED | R                                 | B, D                     | AAD 50.4.3.10,<br>AAB 50.4.3.8,<br>50.4.1.1<br>asgnsArray[]<br>status <sup>c</sup> |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for AAB; D= required for AAD.

<sup>c</sup> This is the object within the referenced structure

The status indicated in the Auto Attach assignment table for each VID to I-SID assignment is determined from the state machine variable aaOperRemAsgnsTlv.asgnsArray.status (50.4.3.10) in AADs or from the state machine variable aaOperLocAsgnsTlv.asgns.status (50.4.3.8) in AABs. The status at the AAD is the status from the VID/ I-SID assignments reported in the remote LLDP assignment objects received from the AAB. The status at the AAB is the status determined by the AAB for the VID/ I-SID assignment requests received from the AAD. At the AAD, if no remote LLDP assignment objects exist in the LLDP database or if the VID/I-SID assignment is not listed in the remote AAB LLDP database objects, then the status is set to PENDING in the Auto Attach assignment table.

The AAD administrator can create new entries, delete entries, and update entries in the Auto Attach assignment table. When the administrator deletes, adds, or updates an entry in the Auto Attach assignment table the AAP state machine variable aaAdminVidIsidAsgn[] associated with the affected port is updated to match the Auto Attach assignment table. When a new entry is created or updated, the new VID and I-SID is provided by management and the status begins as PENDING and then transitions to reflect the current status indicated in the remote AAB LLDP objects.

<sup>1</sup> In an AAB the Auto Attach assignment table is read only and reflects the current assignments within the  
<sup>2</sup> local LLDP assignment database. The Auto Attach assignment table contains the status, VID, and I-SID  
<sup>3</sup> (D.2.18.6, D.2.18.7, D.2.18.8) from the local LLDP assignment database objects.

#### <sup>4</sup> **12.34.5 PBBN Auto Attach statistics table**

<sup>5</sup> There is one PBBN Auto Attach statistics table for each port configured in the Auto Attach port table  
<sup>6</sup> (Table 12-47). Each Auto Attach statistics table (Table 12-50) provides per port statistics. All objects of the  
<sup>7</sup> Auto Attach statistics table are read only. The contents of the table is maintained by the Auto Attach state  
<sup>8</sup> machines (50.6, 50.7). All statistic counters on all ports are cleared on system reset.

**Table 12-50—PBBN Auto Attach statistics table**

| Name                         | Data type | Operations supported <sup>a</sup> | Conformance <sup>b</sup> | References |
|------------------------------|-----------|-----------------------------------|--------------------------|------------|
| aaStatsAssocAttached         | Counter32 | R                                 | B, D                     | 50.4.3.18  |
| aaStatsAssocFailed           | Counter32 | R                                 | B, D                     | 50.4.3.19  |
| aaStatsAssocReset            | Counter32 | R                                 | B, D                     | 50.4.3.20  |
| aaStatsAssocStandby          | Counter32 | R                                 | B, D                     | 50.4.3.21  |
| aaStatsVidIsidAsgnsAccepted  | Counter32 | R                                 | B, D                     | 50.4.3.22  |
| aaStatsVidIsidAsgnsRejected  | Counter32 | R                                 | B, D                     | 50.4.3.23  |
| aaStatsVidIsidAsgnsRequested | Counter32 | R                                 | B, D                     | 50.4.3.24  |
| aaStatsVidIsidAsgnsWithdrawn | Counter32 | R                                 | B, D                     | 50.4.3.25  |

<sup>a</sup> R = Read only access; RW = Read/Write access.

<sup>b</sup> B = required for AAB; D= required for AAD.

<sup>9</sup> The counters provided are as follows:

- <sup>10</sup> a) aaStatsAssocAttached: Counts the number of associations that were attached.
- <sup>11</sup> b) aaStatsAssocFailed: Counts the number of associations that failed.
- <sup>12</sup> c) aaStatsAssocReset: Counts the number of association resets.
- <sup>13</sup> d) aaStatsAssocStandby: Counts the number of associations that were standby.
- <sup>14</sup> e) aaStatsVidIsidAsgnsRequested: Counts the number of new VID to I-SID assignments requested.
- <sup>15</sup> f) aaStatsVidIsidAsgnsAccepted: Counts the number of VID to I-SID assignment requests accepted.
- <sup>16</sup> g) aaStatsVidIsidAsgnsRejected: Counts the number of VID to I-SID assignment requests rejected.
- <sup>17</sup> h) aaStatsVidIsidAsgnsWithdrawn: Counts the number of VID to I-SID assignment requests  
<sup>18</sup> withdrawn.

## 13. Spanning tree protocols

The spanning tree algorithms and protocols specified by this standard provide simple and full connectivity throughout a Bridged Network comprising arbitrarily interconnected Bridges. Each Bridge can use Rapid Spanning Tree Algorithm and Protocol (RSTP), Multiple Spanning Tree Algorithm and Protocol (MSTP), or Shortest Path Bridging (SPB) protocols.

NOTE 1—The spanning tree protocols specified by this standard supersede the STP specified in IEEE Std 802.1D revisions prior to 2004 ([B12], [B13]), but facilitate migration by interoperating with the latter without configuration restrictions beyond those previously imposed by STP. However, networks that include Bridges using STP can reconfigure slowly and constrain active topologies.

NOTE 2—Although the active topologies determined by the spanning tree protocols connect all the components of a Bridged Network, filtering (MVRP, etc.) can restrict frames to a subset of each active topology.

RSTP assigns all frames to a Common Spanning Tree (CST), without being aware of the active topology assignments made by MSTP or SPB that allow frames to follow separate paths within Multiple Spanning Tree (MST) or Shortest Path Tree (SPT) Regions. Each of these regions comprises MST or SPT Bridges that consistently assign any given frame to the same active topology (see 8.4) and the LANs that interconnect those Bridges. These regions and other Bridges and LANs are connected into the CST, to provide loop-free network wide connectivity even if active topology assignments or spanning tree protocols differ locally.

MSTP and SPB connect all Bridges and LANs with a single Common and Internal Spanning Tree (CIST) that supports the automatic determination of each region, choosing its maximum possible extent. The connectivity calculated for the CIST provides the CST for interconnecting the regions, and an Internal Spanning Tree (IST) within each region. MSTP calculates a number of independent Multiple Spanning Tree Instances (MSTIs) within each region, and ensures that frames with a given VID are assigned to one and only one of the MSTIs or the IST within the region (or reserved for use by SPB or PBB-TE), that the assignment is consistent among all Bridges within the region, and that the stable connectivity of each MSTI and the IST at the boundary of the region matches that of the CST. SPB calculates symmetric sets of SPTs, each rooted at a Bridge within a region, and ensures that frames for any given VLAN are assigned to the same symmetric SPT set within the region (or to the IST, an MSTI, or PBB-TE). Within an SPT Region, all Bridges that receive a given shortest path bridged frame assign that frame to the same SPT. The assignment process is specified in Clause 27, and can be done in one of two ways: by using additional VIDs (SPBV, Clause 3), or by using the frame's MAC addresses (SPBM, Clause 3). SPT Bridges use the VID of each received frame to decide whether to use the IST, MSTI, PBB-TE, SPBV, or SPBM. ISIS-SPB can dynamically allocate the additional VIDs (SPVIDs) used by SPBV mode, and ensure that their allocation is consistent within a region.

Spanning Tree Protocol Entities transmit and receive BPDUs (Clause 14) to convey parameters used by RSTP and MSTP to calculate CST, CIST, and MSTI spanning trees. BPDUs also convey parameters that all the spanning tree protocols use to interoperate with each other, that determine the extent of MST and SPT Regions, and that ensure that temporary loops are not created when neighboring Bridges are acting on different topology information. SPB uses ISIS-SPB (see Clause 28) to share information used to calculate the IST and SPTs, and to perform that calculation. SPT BPDUs that ensure loop-free connectivity even if neighboring Bridges' views of the topology differ (13.17) is also carried in SPB Hello PDUs (28.12.2).

This clause:

- a) Specifies protocol design and support requirements (13.1, 13.2) and design goals (13.3).
- b) Provides an overview of RSTP (13.4), MSTP (13.5), SPBV, and SPBM (13.6) operation.
- c) Describes how the spanning tree protocols interoperate and coexist (13.7).
- d) Specifies how spanning tree priority vectors (13.9) are calculated (13.10, 13.11) and used to assign the Port Roles (13.12) that determine the Port States, i.e., forwarding and learning (8.4), for each tree.

- 1 e) Shows that RSTP, MSTP, and ISIS-SPB provide stable connectivity (13.13).
- 2 f) Describes how spanning tree priority vectors are communicated (13.14) and changed (13.15).
- 3 g) Describes how Port Roles are used to change Port States without introducing loops (13.16).
- 4 h) Recommends defaults and ranges for the parameters that determine each tree's topology (13.18).
- 5 i) Describes the updating of learned station location information when a tree reconfigures (13.19).
- 6 j) Specifies additional controls that can speed reconfiguration or prevent unwanted outcomes (13.20).
- 7 k) Describes how loops are prevented when a LAN is only providing one-way connectivity (13.21),  
8 and can be prevented when the network includes Bridges whose protocol operation can fail (13.23).
- 9 l) Describes how a Bridge's protocol processing can be 'hot upgraded' in an active network (13.22).
- 10 m) Specifies RSTP, MSTP, and support for SPB using state machines (13.24–13.40).
- 11 n) Specifies the use and configuration of the spanning tree protocols for the special cases of a Provider  
12 Edge Bridge's CEPs (13.41), a BEB's VIPs (13.42), and an L2 Gateway Port connecting a customer  
13 to a provider (13.20, 13.40).

14 NOTE 3—Readers of this specification are urged to begin by familiarizing themselves with RSTP.

15 Clause 14 specifies the format of BPDUs. Clause 27 describes the uses of SPB. Clause 28 specifies  
16 ISIS-SPB. The text of this clause (Clause 13) takes precedence should any conflict be apparent between it  
17 and the text in other parts of this standard (in particular, Clause 12, Clause 14, and Annex A). Within this  
18 clause (Clause 13) the state machine specifications (13.24–13.40) take precedence over the general  
19 description (13.1–13.23). A distinctive font is used to highlight references to state machine variables,  
20 procedures, and STATES in the general description.

## 21 13.1 Protocol design requirements

22 The spanning tree algorithm and its associated protocols operate in Bridged Networks of arbitrary physical  
23 topology comprising MST or SST Bridges connecting shared media or point-to-point LANs, to support,  
24 preserve, and maintain the quality of the MAC Service in all its aspects as specified by Clause 6.

25 RSTP configures the Port State (8.4) of each Bridge Port. MSTP configures the Port State for the CIST and  
26 each MSTI, and verifies the allocation of VIDs to FIDs and FIDs to trees. ISIS-SPB configures the Port  
27 State for the CIST and each SPT, configures the VID Translation Table for each Bridge Port, allocates FIDs  
28 to SPT sets, and assigns frames to SPTs using SPVIDs or MAC addresses (for SPBV and SPBM,  
29 respectively, see Clause 27). Operating both independently and together RSTP, MSTP, and ISIS-SPB meet  
30 the following requirements:

- 31 a) They configure one or more active topologies that fully connect all physically connected LANs and  
32 Bridges, and stabilize (with high probability) within a short, known bounded interval after any  
33 change in the physical topology, maximising service availability (6.5.1).
- 34 b) The active topology for any given frame remains simply connected at all times (6.5.3, 6.5.4), and  
35 will (with high probability) continue to provide simple and full connectivity for frames even in the  
36 presence of administrative errors (e.g., in the allocation of VIDs to MSTIs).
- 37 c) The configured stable active topologies are unicast multicast congruent, downstream congruent, and  
38 reverse path congruent (symmetric) (3.295, 3.83, 6.3).
- 39 d) The same symmetric active topology is used, in a stable network, for all frames using the same FID,  
40 i.e., between any two LANs all such frames are forwarded through the same Bridge Ports (6.3).
- 41 e) The active topology for a given VID can be chosen by the network administrator to be a common  
42 spanning tree, one of multiple spanning trees (if MSTP is implemented), or shortest path (if  
43 ISIS-SPB is implemented).
- 44 f) Each active topology is predictable, reproducible, and manageable, allowing Configuration  
45 Management (following traffic analysis) to meet Performance Management goals (6.5 and 6.5.10).

- 1 g) The configured network can support VLAN-unaware end stations, such that they are unaware of  
2 their attachment to a single LAN or a Bridged Network, or their use of a VID (6.2).
- 3 h) The communications bandwidth on any particular LAN is always a small fraction of the total  
4 available bandwidth (6.5.10).

5 NOTE—The spanning tree protocols cannot protect against temporary loops caused by the interconnection of LANs by  
6 devices other than Bridges (e.g., LAN repeaters) that operate invisibly with respect to support of the MAC ISS and the  
7 MAC\_Operational status parameter (IEEE Std 802.1AC).

## 8 **13.2 Protocol support requirements**

9 In order for the spanning tree protocols to operate, the following are required:

- 10 a) A unique group MAC address used by the Spanning Tree Protocol Entities (8.10) of participating  
11 Bridges or Bridge components (5.2), and recognized by all the Bridges attached to a LAN.
- 12 b) An identifier for each Bridge or Bridge component, unique within the Bridged Network.
- 13 c) An identifier for each Bridge Port, unique within a Bridge or Bridge component.

14 Values for each of these parameters shall be provided by each Bridge. The unique MAC address that  
15 identifies the Spanning Tree Protocol Entities of MAC Bridges, VLAN Bridges (5.9), and C-VLAN  
16 components (5.5) is the Bridge Group Address (Table 8-1). The unique MAC address that identifies the  
17 Spanning Tree Protocol Entities of S-VLAN components is the Provider Bridge Group Address (Table 8-2).

18 To allow management of active topology (for RSTP, MSTP, or SPB) means of assigning values to the  
19 following are required:

- 20 d) The relative Bridge Priority of each Bridge in the network
- 21 e) A Port Path Cost for each Bridge Port
- 22 f) The relative Port Priority of each Bridge Port

### 23 **13.2.1 MSTP support requirements**

24 MSTP does not require any additional configuration, provided that communication between end stations is  
25 supported by a number of VLANs. However, to realize the improved throughput and associated frame loss  
26 and transit delay performance improvements made possible by the use of multiple spanning trees, the  
27 following are required:

- 28 a) Assessment of the probable distribution of traffic between VLANs and between sets of  
29 communicating end stations using those VLANs.
- 30 b) Per MSTI assignment of Bridge Priority and Internal Port Path Costs to configure the MSTIs.
- 31 c) Consistent assignment of VIDs to MSTIDs within each potential MST Region (3.174).
- 32 d) Administrative agreement on the Configuration Name and Revision Level used to represent the  
33 assignments of VIDs to MSTIDs.

### 34 **13.2.2 SPB support requirements**

35 In order for the ISIS-SPB protocol to operate, the following are required:

- 36 a) An MTID indicating the topology information to be used for route calculation.
- 37 b) An IS-IS Area Address for the IS-IS routing area.
- 38 c) An IS-IS system ID for the SPT Bridge, normally the Bridge Identifier.
- 39 d) A group MAC address for use by IS-IS SPB (Table 8-17).
- 40 e) A Base VID for each SPB VLAN.
- 41 f) An ECT-ALGORITHM identifying the algorithm for calculating SPTs and selecting from among  
42 Equal Cost Trees.

1 SPBV can provide both CST and SPT support for VLANs without further configuration. To support default  
2 SPB operation this standard specifies a default configuration for SPT Bridges (13.8).

### 3 **13.3 Protocol design goals**

4 All the spanning tree protocols meet the following goal, which simplifies operational practice:

- 5 a) Bridges do not have to be individually configured before being added to the network, other than  
6 having their MAC addresses assigned through normal procedures.
- 7 b) In normal operation, the time taken to configure the active topology of a network comprising  
8 point-to-point LANs is independent of the timer values of the protocol.

9 RSTP and MSTP meet the following goal, which limits the complexity of Bridges and their configuration:

- 10 c) The memory requirements associated with each Bridge Port are independent of the number of  
11 Bridges and LANs in the network.

12 It is highly desirable that the operation of ISIS-SPB supports updating of the SPB configuration so that:

- 13 d) SPT Bridges can be added to a region without disrupting communication for existing VLANs.
- 14 e) Additional VLANs can be supported by SPB without disrupting communication for the VLANs that  
15 are already supported by SPB, or for those VLANs that are supported by RSTP or MSTP.
- 16 f) SPB support can be enabled or disabled for individual VLANs that are being used to support user  
17 communication, with the minimum of frame loss on those VLANs.

### 18 **13.4 RSTP overview**

19 RSTP configures the Port State (8.4) of each Bridge Port in the Bridge Local Area Network. RSTP ensures  
20 that the stable connectivity provided by each Bridge between its ports and by the individual LANs attached  
21 to those ports is predictable, manageable, full, simple, and symmetric. RSTP further ensures that temporary  
22 loops in the active topology do not occur if the network has to reconfigure in response to the failure,  
23 removal, or addition of a network component, and that erroneous station location information is removed  
24 from the FDB after reconfiguration.

25 Each of the Bridges in the network transmits Configuration Messages (13.14). Each message contains  
26 spanning tree priority vector (13.9) information that identifies one Bridge as the Root Bridge of the network,  
27 and allows each Bridge to compute its own lowest path cost to that Root Bridge before transmitting its own  
28 Configuration Messages. A Port Role (13.12) of Root Port is assigned to the one port on each Bridge that  
29 provides that lowest cost path to the Root Bridge, and a Port Role of Designated Port to the one Bridge Port  
30 that provides the lowest cost path from the attached LAN to the Root Bridge. Alternate Port and Backup Port  
31 roles are assigned to Bridge Ports that can provide connectivity if other network components fail.

32 State machines associated with the Port Roles maintain and change the Port States that control forwarding  
33 (8.6) and learning (8.7) of frames. In a stable network, Root Ports and Designated Ports are Forwarding,  
34 while Alternate, Backup, and Disabled Ports are Discarding. Each Port's role can change if a Bridge, Bridge  
35 Port, or LAN fails, is added to, or removed from network. Port state transitions to Learning and Forwarding  
36 are delayed, and ports can temporarily transition to the Discarding state to prevent loops and to ensure that  
37 misordering (6.5.3) and duplication (6.5.4) rates remain negligible.

38 RSTP provides rapid recovery of connectivity to minimize frame loss (6.5.2). A new Root Port, and  
39 Designated Ports attached to point-to-point LANs, can transition to Forwarding without waiting for protocol  
40 timers to expire. A Root Port can transition to Forwarding without transmitting or receiving messages from  
41 other Bridges, while a Designated Port attached to a point-to-point LAN can transition when it receives an  
42 explicit agreement transmitted by the other Bridge attached to that LAN. The forwarding transition delay

1 used by a Designated Port attached to a shared media LAN is long enough for other Bridges attached to that  
2 LAN to receive and act on transmitted messages, but is independent of the overall network size. If all the  
3 LANs in a network are point-to-point, RSTP timers define worst-case delays that only occur if protocol  
4 messages are lost or rate transmission limits are exceeded.

5 A Bridge Port attached to a LAN that has no other Bridges attached to it may be administratively configured  
6 as an Edge Port. RSTP monitors the LAN to ensure that no other Bridges are connected, and may be  
7 configured to automatically detect an Edge Port. Each Edge Port transitions directly to the Forwarding Port  
8 State, since there is no possibility of it participating in a loop.

#### 9 **13.4.1 Computation of the active topology**

10 The Bridge with the best Bridge Identifier is selected as the Root Bridge. The unique Bridge Identifier for  
11 each Bridge is derived, in part, from the Bridge Address (8.13.8) and, in part, from a manageable priority  
12 component (13.26). The relative priority of Bridges is determined by the numerical comparison of the  
13 unique identifiers, with the lower numerical value indicating the better identifier.

14 Every Bridge has a Root Path Cost associated with it. For the Root Bridge this is zero. For all other Bridges,  
15 it is the sum of the Port Path Costs on the least cost path to the Root Bridge. Each port's Path Cost may be  
16 managed, 13.18 recommends default values for ports attached to LANs of various speeds.

17 The Bridge Port on each Bridge with the lowest Root Path Cost is assigned the role of Root Port for that  
18 Bridge (the Root Bridge does not have a Root Port). If a Bridge has two or more ports with the same Root  
19 Path Cost, then the port with the best Port Identifier is selected as the Root Port. Part of the Port Identifier is  
20 fixed and different for each port on a Bridge, and part is a manageable priority component (13.26). The  
21 relative priority of Bridge Ports is determined by the numerical comparison of the unique identifiers, with  
22 the lower numerical value indicating the better identifier.

23 Each LAN in the Bridged Network also has an associated Root Path Cost. This is the Root Path Cost of the  
24 lowest cost Bridge with a Bridge Port connected to that LAN. This Bridge is selected as the Designated  
25 Bridge for that LAN. If there are two or more Bridges with the same Root Path Cost, then the Bridge with  
26 the best priority (least numerical value) is selected as the Designated Bridge. The Bridge Port on the  
27 Designated Bridge that is connected to the LAN is assigned the role of Designated Port for that LAN. If the  
28 Designated Bridge has two or more ports connected to the LAN, then the Bridge Port with the best priority  
29 Port Identifier (least numerical value) is selected as the Designated Port.

30 In a Bridged Network whose physical topology is stable, i.e., RSTP has communicated consistent  
31 information throughout the network, every LAN has one and only one Designated Port, and every Bridge  
32 with the exception of the Root Bridge has a single Root Port connected to a LAN. Since each Bridge  
33 provides connectivity between its Root Port and its Designated Ports, the resulting active topology connects  
34 all LANs (is "spanning") and will be loop-free (is a "tree").

35 Any Bridge Port that is enabled, but not a Root or Designated Port, is a Backup Port if that Bridge is the  
36 Designated Bridge for the attached LAN, and an Alternate Port otherwise. An Alternate Port offers an  
37 alternate path in the direction of the Root Bridge to that provided by the Bridge's own Root Port, whereas a  
38 Backup Port acts as a backup for the path provided by a Designated Port in the direction of the leaves of the  
39 spanning tree. Backup Ports exist only where there are two or more connections from a given Bridge to a  
40 given LAN; hence, they (and the Designated Ports that they back up) can only exist where the Bridge has  
41 two or more ports attached to a shared media LAN, or directly connected by a point-to-point LAN.

## 1 13.4.2 Example topologies

2 The spanning tree examples in this clause use the conventions of Figure 13-1.

A template for and an example of an MSTP Bridge. **B.b** is the CIST Bridge Identifier. **R.r**, **ERC**, **RR.rr** are the CIST Root Identifier, External Root Path Cost, and Regional Root Identifier. **CI** identifies the Configuration Identifier for the Bridge. **RR.rr**, **IRC** the CIST Regional Root Identifier and the Internal Root Path Cost **T:RR.rr**, **IRC**, **B.b** is the Regional Root Identifier, Internal Root Path Cost IRC, and Bridge Identifier for the MSTI with MSTID **T**.

**0:p.p**, **epc**, **ipc** are the CIST Port Identifier, External Port Path Cost, and Internal Port Path Cost for a Bridge Port. **T:p.p**, **ipc** are the Port Identifiers and their Regional Costs for MSTI **T**.

Any of the above information may be selectively omitted if deemed irrelevant for the purposes of a diagram.

Figure 13-1—Diagrammatic conventions for spanning tree topologies

Figure 13-2 shows a simple, redundantly connected, structured wiring configuration, with Bridges connected by point-to-point LANs A through N, and a possible spanning tree active topology of the same network. Bridge 111 has been selected as the Root (though one cannot tell simply by looking at the active topology which Bridge is the Root).

Figure 13-2—Physical topology and active topology

Figure 13-3 shows the Port Roles and Port States of each Bridge Port. It can be seen that Bridge 111 is the Root, as its Ports are all Designated Ports, each of the remaining Bridges have one Root Port.

Figure 13-3—Port Roles and Port States

1 Figure 13-4 shows the result of connecting two of the ports of Bridge 888 to the same LAN. As port 4 of  
2 Bridge 888 has worse priority than port 3 and both offer the same Root Path Cost, port 4 will be assigned the  
3 Backup Port Role and will therefore be in the Discarding Port State. Should port 3 or its connection to LAN  
4 O fail, port 4 will be assigned the Designated Port Role and will transition to the Forwarding Port State.

Figure 13-4—A Backup Port

5 Figure 13-5 shows a “ring” topology constructed from point-to-point links, as in some resilient backbone  
6 configurations. Bridge 111 is the Root, as in previous examples.

Figure 13-5—“Ring Backbone” example

## 13.5 MSTP overview

MSTP specifies the following:

- a) An MST Configuration Identifier (MCID) (13.8) that allows each Bridge to advertise its assignment, to a specified MSTI or to the IST, of frames with any given VID.
- b) A priority vector (13.9) that comprises Bridge identifier and path cost information for constructing a deterministic and manageable single spanning tree active topology, the CIST, that:
  - 1) Fully and simply connects all Bridges and LANs in a Bridged Network.
  - 2) Permits the construction and identification of MST Regions of Bridges and LANs that are guaranteed fully connected by the Bridges and LANs within each region.
  - 3) Ensures that paths within each MST Region are always preferred to paths outside the region.
- c) An MSTI priority vector (13.9), comprising information for constructing a deterministic and independently manageable active topology for any given MSTI within each region.
- d) Comparisons and calculations performed by each Bridge in support of the distributed spanning tree algorithm (13.10). These select a CIST priority vector for each Bridge Port, based on the priority vectors and MCIDs received from other Bridges and on an incremental Path Cost associated with each reception port. The resulting priority vectors are such that in a stable network:
  - 1) One Bridge is selected to be the CIST Root of the Bridged Network as a whole.
  - 2) A minimum cost path to the CIST Root is selected for each Bridge and LAN, thus preventing loops while ensuring full connectivity.
  - 3) The one Bridge in each MST Region whose minimum cost path to the Root is not through another Bridge using the same MCID is identified as its region's CIST Regional Root.
  - 4) Conversely, each Bridge whose minimum cost path to the Root is through a Bridge using the same MCID is identified as being in the same region as that Bridge.
- e) Priority vector comparisons and calculations performed by each Bridge for each MSTI (13.11). In a stable network:
  - 1) One Bridge is independently selected for each MSTI to be the MSTI Regional Root.
  - 2) A minimum cost path to the MSTI Regional Root that lies wholly within the region is selected for each Bridge and LAN.
- f) CIST Port Roles (13.12) that identify the role in the CIST active topology played by each port on a Bridge:
  - 1) The Root Port provides the minimum cost path from the Bridge to the CIST Root (if the Bridge is not the CIST Root) through the Regional Root (if the Bridge is not a Regional Root).
  - 2) A Designated Port provides the least cost path from the attached LAN through the Bridge to the CIST Root.
  - 3) Alternate or Backup Ports provide connectivity if other Bridges, Bridge Ports, or LANs fail or are removed.
- g) MSTI and SPT Port Roles (13.12) that identify the role played by each port on a Bridge for each MSTI's or SPT's active topology within and at the boundaries of a region.
  - 1) The Root Port provides the minimum cost path from the Bridge to the Regional Root (if the Bridge is not the Regional Root for the tree).
  - 2) A Designated Port provides the least cost path from the attached LAN through the Bridge to the Regional Root.
  - 3) A Master Port provides connectivity from the region to a CIST Root that lies outside the region. The Bridge Port that is the CIST Root Port for the CIST Regional Root is the Master Port for all MSTIs and SPTs.
  - 4) Alternate or Backup Ports provide connectivity if other Bridges, Bridge Ports, or LANs fail or are removed.

- #### 4 13.5.1 Example topologies

[illegible]

7 Figure 13-7 is the same network showing Bridges and LANs with better CIST spanning tree priorities higher  
8 on the page, and including CIST priority vectors, port roles, and MST Regions. In this example:

- 547

- 1 c) LANs A, B, C, and D are in Region 1 because their CIST Designated Bridge is a Region 1 MST
- 2 Bridge, and no STP Bridges are attached to those LANs. LAN E is not in an MST Region (or in its
- 3 own region—an equivalent view) because it is attached to Bridge 0.53, which is not an MST Bridge.
- 4 d) Bridges 0.77, 0.65, 0.97, 0.86, 3.84, and 3.72 are in the same MST Region (2) since they have the
- 5 same MCID and are interconnected by LANs for which one of them is the CIST Designated Bridge.
- 6 e) Bridge 0.86 is the CIST Regional Root for Region 2 because it is has the lowest External Root Path
- 7 Cost through a Boundary Port.
- 8 f) LAN N is in Region 2 because its CIST Designated Bridge is in Region 2. Frames assigned to
- 9 different MSTIDs may reach N from Bridge 0.86 (for example) by either Bridge 0.65 or Bridge
- 10 3.72, even though Bridges 0.94 and 0.69 with MCIDs that differ from those for Bridges in Region 2
- 11 are attached to this shared LAN.
- 12 g) Bridges 0.94 and 0.69 are in different regions, even though they have the same MCID, because the
- 13 LAN that connects them (N) is in a different region.

14 Figure 13-8 shows a possible active topology of MSTI 2 within Region 2.

**Figure 13-8—MSTI Active Topology in Region 2**

- 15 h) Bridge 0.65 has been chosen as the MSTI Regional Root because it has the best (numerically the
- 16 lowest) Bridge Identifier of all Bridges in the region for this MSTI.

Figure 13-7—CIST Priority Vectors, Port Roles, and MST Regions

- i) The connectivity between the whole of Region 2 and Region 1 is provided through a single Bridge Port, the Master Port on Bridge 0.86. This port was selected for this role because it is the CIST Root Port on the CIST Regional Root for the region (see Figure 13-7).
- j) The connectivity between the whole of Region 2 and LANs and Bridges outside the region for the MSTI is the same as that for the CIST. This connectivity is similar to that which might result by replacing the entire region by a single SST Bridge. The region has a single Root Port (this port is the Master Port for each MSTI) and a number of Designated Ports.

### 13.5.2 Relationship of MSTP to RSTP

MSTP is based on RSTP, extended so frames for different VLANs can follow different trees within regions.

- a) The same fundamental spanning tree algorithm selects the CIST Root Bridge and Port Roles, but extended priority vector components are used within (13.9, 13.10) in each region. As a result each region resembles a single Bridge from the point of view of the CST as calculated by RSTP.
- b) Each MSTI's Regional Root Bridge and Port Roles are also computed using the same fundamental spanning tree algorithm with modified priority vector components (13.11).
- c) Different Bridges may be selected as the Regional Root for different MSTIs by modifying the manageable priority component of the Bridge Identifier differently for the MSTIs.
- d) MST Configuration Identification is not applicable to RSTP.
- e) The Port Roles used by the CIST (Root, Designated, Alternate, Backup, or Disabled Port) are the same as those of RSTP. The MSTIs use the additional port role Master Port. The Port States associated with each spanning tree and port are the same as those of RSTP.
- f) The state variables for each Bridge Port for each tree and for the Bridge itself are those specified for RSTP as per port and per Bridge with a few exceptions, additions, and enhancements.
- g) The performance parameters specified for RSTP apply to the CIST, with a few exceptions, additions, and enhancements. A simplified set of performance parameters apply to the MSTIs.
- h) This standard specifies RSTP state machines and procedures as a subset of MSTP.

### 13.5.3 Modeling an MST or SPT Region as a single Bridge

The nominal replacement of an entire region by a single RST Bridge leads to little impact on the remainder of the Bridged Network. This design is intended to assist those familiar with RSTP to comprehend and verify MSTP, and to administer networks using MSTP. Treating the MST Regions as single Bridges provides the network administrator with a natural hierarchy. The internal management of MST Regions can be largely separated from the management of the active topology of the network as a whole.

The portion of the active topology of the network that connects any two Bridges in the same MST Region traverses only MST Bridges and LANs in that region and never Bridges of any kind outside the region; in other words, connectivity within the region is independent of external connectivity. This is because the protocol parameters that determine the active topology of the network as a whole, the Root Identifier and Root Path Cost (known in the MSTP specification as the CIST Root Identifier and CIST External Root Path Cost) are carried unchanged throughout and across the MST Region, so Bridges within the region will always prefer spanning tree information that has been propagated within the region to information that has exited the region and is attempting to reenter it.

NOTE 1—No LAN can be in more than one MST Region at a time, so two Bridges (0.11 and 0.22 say) that would otherwise be in the same region by virtue of having the same MST Configuration and of being directly connected by a LAN, may be in distinct regions if that is a shared LAN with other Bridges attached (having a different MST Configuration) and no other connectivity between 0.11 and 0.22 and lying wholly within their region is available. The region that the shared LAN belongs to may be dynamically determined. No such dynamic partitioning concerns arise with single Bridges. Obviously the sharing of LANs between administrative regions militates against the partitioning of concerns and should only be done following careful analysis.

1 The Port Path Cost (MSTP's External Port Path Cost) is added to the Root Path Cost just once at the Root  
2 Port of the CIST Regional Root, the closest Bridge in the region to the Root Bridge of the entire network.  
3 The Message Age used by STP and RSTP is also only incremented at this port. If the CIST Root is within a  
4 region, it also acts as the Regional Root, and the Root Path Cost and Message Age advertised are zero, just  
5 as for a single Bridge.

6 Within an MST Region, each MSTI operates in much the same way as an independent instance of RSTP  
7 with dedicated Regional Root Identifier, Internal Root Path Cost, and Internal Port Path Cost parameters.  
8 Moreover, the overall spanning tree (the CIST) includes a fragment (the IST) within each MST Region that  
9 can be viewed as operating in the same way as an MSTI with the Regional Root as its root.

10 NOTE 2—Since an MST Region behaves like a single Bridge and does not partition (except in the unusual configuration  
11 involving shared LANs noted above), it has a single Root Port in the CST active topology. Partitioning a network into  
12 two or more regions can therefore force nonoptimal blocking of Bridge Ports at the boundaries of those regions.

### 13 13.6 SPB overview

14 Clause 27 provides a comprehensive overview of SPT Bridges using SPBV and SPBM mode operation.  
15 This subclause (13.6) summarizes aspects of SPB operation that relate to the transmission and reception of  
16 BPDUs, and their role in providing interoperability with RSTP and MSTP, and in carrying the agreements  
17 that ensure that each SPT provides loop-free connectivity throughout an SPT Region. The details of  
18 agreements are considered in 13.17, the assignment of frames to SPTs in 8.4 and Clause 27, and protocols  
19 and procedures to allow plug-and-play generation of SPVIDs in Clause 28.

20 Considerations of backward and forward compatibility and interoperability figure largely in this clause  
21 (Clause 13) and to some extent these consideration revolve around the notion of MST or SPT Region, with  
22 each region capable of using different protocols or different configurations. These considerations should not  
23 be allowed to obscure the fact that the ideal network configuration (from the point of view of connectivity  
24 and bandwidth efficiency) comprises a single region, or possibly one core region with RST Bridges  
25 attached, and that separate regions are most likely to arise when continued connectivity is being provided by  
26 the CST as configuration changes are made to Bridges in the network. If an SPT Region is bounded by  
27 BEBs or LAN with no other Bridges attached, B-VLANs can be supported by SPBM mode, with frames  
28 assigned to SPTs using their MAC addresses, while other B-VLANs and S-VLANs can be supported by  
29 SPBV mode, with frames assigned to each SPT by SPVID. In both cases, however, SPTs are calculated in  
30 the same way and the effects on this clause (Clause 13) are limited to allowing loop mitigation (6.5.4.2) for  
31 unicast frames supported by SPBM mode as well as loop prevention (6.5.4.1). The need for unicast multicast  
32 congruence (Clause 3), the simplification possible by not introducing differences between SPBM mode  
33 unicast forwarding and the other uses of SPTs, and the need for source address lookup to support loop  
34 mitigation means that all shortest path bridged frames are assigned to an SPT rooted at the source Bridge and  
35 follow the standard bridging paradigm of multicast distribution with filtering, even when the frame has a  
36 single destination and the path to the destination is known through the use of routing protocol (ISIS-SPB).

37 NOTE—When loop mitigation is used for unicast frames, the Port State used to prevent loops (as expressed by the state  
38 machine variables forwarding and learning) need only apply to frames with group destination addresses.

39 SPT Bridges send and receive BPDUs in order to advertise their presence to, and recognize the presence of,  
40 other Bridges. The requirement for loop-free SPT connectivity also means that SPT Bridges have to  
41 communicate with their nearest neighbors, when calculations that follow the reception of ISIS-SPB  
42 messages have been completed rather than as a part of the IS-IS protocol itself. The agreements (13.17) that  
43 satisfy this requirement could be separated conceptually from other uses of BPDUs, but the opportunity to  
44 share common information elements, synchronization of neighbor state, and an overall reduction in the  
45 number of protocol frames sent make it convenient to use BPDUs to integrate its specification with the other  
46 protocol variables, procedures, and state machines in this clause (13.24–13.40). Agreement Protocol

1 variables with exactly the same semantics are also carried in SPB Hello PDUs. The protocol handles  
2 duplicated and misordered agreement information, so that updated information can be received from SPB  
3 Hello PDUs or both SPB Hello PDUs and BPDUs.

4 SPT Bridges use the configuration and active topology management parameters (Bridge Identifiers, Port  
5 Path Costs) already required for the CIST. They also retain MSTP capabilities as a subset of their operation,  
6 though it is always possible to configure zero MSTIs.

## 7 **13.7 Compatibility and interoperability**

8 RSTP, MSTP, and the ISIS-SPB are designed to interoperate with each other and with STP. This subclause  
9 (13.7) reviews aspects of their design that are important to meeting that requirement. ISIS-SPB and SPT  
10 BPDUs include the functionality provided by MSTP and MST BPDUs, so the compatibility with RSTP and  
11 STP provided by the latter extends to SPB.

### 12 **13.7.1 Designated Port selection**

13 Correct operation of the spanning tree protocols requires that all Bridge Ports attached to any given LAN  
14 agree on a single CIST Designated Port after a short interval sufficient for any Bridge Port to receive a  
15 configuration message from that Designated Port.

16 A unique spanning tree priority (13.9) is required for each Bridge Port for STP, which has no other way of  
17 communicating port roles. Since port numbers on different Bridges are not guaranteed to be unique, this  
18 necessitates the inclusion of the transmitting Bridge's Bridge Identifier in the STP BPDU. RSTP and  
19 MSTP's Port Protocol Migration state machines (13.32) ensure that all Bridges attached to any LAN with an  
20 attached STP Bridge send and receive STP BPDUs exclusively.

21 NOTE 1—This behavior satisfies the requirement for unique, agreed Designated Port for LANs with attached STP  
22 Bridges, but means that an MST Region cannot completely emulate a single Bridge since the transmitted Designated  
23 Bridge Identifier can differ on Bridge Ports at the region's boundary.

24 MSTP transmits and receives the Regional Root Identifier and not the Designated Bridge Identifier in the  
25 BPDU fields recognized by RSTP (14.4) to allow both the MST and the RST Bridges potentially connected  
26 to a single LAN to perform comparisons (13.9, 13.10) between all spanning tree priority vectors transmitted  
27 that yield a single conclusion about which RST Bridge or MST Region includes the Designated Port. MST  
28 and RST BPDUs convey the transmitting port's CIST Port Role. This is checked on receipt by RSTP when  
29 receiving messages from a Designated Bridge, thus ensuring that an RST Bridge does not incorrectly  
30 identify one MST Bridge Port as being Designated rather than another, even while omitting the competing  
31 Bridge Ports' Designated Bridge Identifiers from comparisons.

32 NOTE 2—This ability of MST Bridges to communicate the full set of MSTP information on shared LANs to which RST  
33 Bridges are attached avoids the need for the Port Protocol Migration machines to detect RST Bridges. Two or more MST  
34 and one or more RST Bridges may be connected to a shared LAN, with full MSTP operation. This includes the  
35 possibility of different MSTI Designated Ports (see 13.5.1).

### 36 **13.7.2 Force Protocol Version**

37 A Force Protocol Version parameter, controlled by management, permits emulation of aspects of the  
38 behavior of earlier versions of spanning tree protocol that are not strictly required for interoperability. The  
39 value of this parameter applies to all Bridge Ports.

- 40 a) STP BPDUs, rather than MST BPDUs, are transmitted if Force Protocol Version is 0.
- 41 b) RST BPDUs, rather than MST BPDUs, are transmitted if Force Protocol Version is 2. RST BPDUs  
42 omit the MCID and all MSTI Information.
- 43 c) All received BPDUs are treated as being from a different MST Region if Force Protocol Version is 0  
44 or 2.

- 1 d) Rapid transitions are disabled if Force Protocol Version is 0. This allows MST Bridges to support
- 2 applications and protocols that can be sensitive to the increased rates of frame duplication and
- 3 misordering that can arise under some circumstances, as discussed in Annex P.
- 4 e) The MSTP state machines allow full MSTP behavior if Force Protocol Version is 3 or more.
- 5 f) SPT BPDUs are transmitted if Force Protocol Version is 4 or more.
- 6 NOTE—Force Protocol Version does not support multiple spanning trees with rapid transitions disabled.

### 7 **13.8 MST Configuration Identifier (MCID)**

8 It is essential that all Bridges within an MST or SPT Region agree on the allocation of VIDs to spanning  
9 trees. If the allocation differs, frames for some VIDs may be duplicated or not delivered to some LANs at all.  
10 MST and SPT Bridges check that they are allocating VIDs to the same spanning trees as their neighbors in  
11 the same region by transmitting and receiving MCIDs in BPDUs. Each MCID includes a Configuration  
12 Digest that is compact but designed so that two matching identifiers have a very high probability of denoting  
13 the same allocation of VIDs to MSTIDs (Clause 3, 8.4) even if the identifiers are not explicitly managed.  
14 Suitable management practices for equipment deployment and for choosing Configuration Names and  
15 Revision Levels (see below) can guarantee that the identifiers will differ if the VID to tree allocation differs  
16 within a single administrative domain.

17 An MST or SPT Region comprises one or more MST or SPT Bridges with the same MCIDs, interconnected  
18 by and including LANs for which one of those Bridges is the Designated Bridge for the CIST and which  
19 have no Bridges attached that cannot receive and transmit RST BPDUs.

20 SPT BPDUs are a superset of MST BPDUs received and validated by MST Bridges as if they were MST  
21 BPDUs, so MSTP operates within an SPT Region just as if it were an MST Region. However, each shortest  
22 path VLAN is represented by a reserved MSTID value that is included in the Configuration Digest, so an  
23 SPT Region contains only SPT Bridges.

24 Each MCID contains the following components:

- 25 a) A Configuration Identifier Format Selector, the value 0 encoded in a fixed field of one octet to
- 26 indicate the use of the following components as specified in this standard.
- 27 b) The Configuration Name, a variable length text string encoded within a fixed field of 32 octets,
- 28 conforming to IETF RFC 2271's definition of SnmpAdminString. If the Configuration Name is less
- 29 than 32 characters, the text string should be terminated by the NUL character, with the remainder of
- 30 the 32-octet field filled with NUL characters. Otherwise, the text string is encoded with no
- 31 terminating NUL character.
- 32 c) The Revision Level, an unsigned integer encoded within a fixed field of 2 octets.
- 33 d) The Configuration Digest, a 16-octet signature of type HMAC-MD5 (see IETF RFC 2104) created
- 34 from the MST Configuration Table (Clause 3, 8.9). To calculate the digest, the table is considered to
- 35 contain 4096 consecutive two octet elements, where each element of the table (with the exception of
- 36 the first and last) contains an MSTID value encoded as a binary number, with the first octet being
- 37 most significant. The first element of the table contains the value 0, the second element the MSTID
- 38 value corresponding to VID 1, the third element the MSTID value corresponding to VID 2, and so
- 39 on, with the next to last element of the table containing the MSTID value corresponding to VID
- 40 4094, and the last element containing the value 0. The key used to generate the signature consists of
- 41 the 16-octet string specified in Table 13-1.

42 NOTE—The formulation of the signature as described above does not imply that a separate VID to MSTID translation  
43 table has to be maintained by the implementation; rather that it should be possible for the implementation to derive the  
44 logical contents of such a table, and the signature value as specified above, from the other configuration information  
45 maintained by the implementation, as described in Clause 12.

**Table 13-1—Configuration Digest Signature Key**

| Parameter                          | Mandatory value                    |
|------------------------------------|------------------------------------|
| Configuration Digest Signature Key | 0x13AC06A62E47FD51F95D2BA243CD0346 |

<sup>1</sup> The Configuration Digests of some VID to MSTID translations are shown in Table 13-2 to help verify  
<sup>2</sup> implementations of this specification.

**Table 13-2—Sample Configuration Digest Signature Keys**

| VID to MSTID translation                                    | Configuration Digest               |
|-------------------------------------------------------------|------------------------------------|
| All VIDs map to the CIST,<br>no VID mapped to any MSTI      | 0xAC36177F50283CD4B83821D8AB26DE62 |
| All VIDs map to MSTID 1                                     | 0xE13A80F11ED0856ACD4EE3476941C73B |
| Every VID maps to the MSTID<br>equal to (VID modulo 32) + 1 | 0x9D145C267DBE9FB5D893441BE3BA08CE |

<sup>3</sup> It is recommended that MST Bridge implementations provide an easily selectable or default configuration  
<sup>4</sup> comprising a Configuration Name of the Bridge Address as a text string using the Hexadecimal  
<sup>5</sup> Representation specified in IEEE Std 802, a Revision Level of 0, and a Configuration Digest representing a  
<sup>6</sup> VID to MSTID translation table containing the value 0 for every element. Such a table represents the  
<sup>7</sup> mapping of all VIDs to the CIST. Since the Bridge Address is unique to each Bridge, no two Bridges using  
<sup>8</sup> this default configuration will be identified as belonging to the same region.

<sup>9</sup> It is recommended that SPT Bridge implementations provide an easily selectable or default configuration  
<sup>10</sup> comprising a Configuration Name of 'IEEE802.1 SPB Default', a Revision Level of 0, and a Configuration  
<sup>11</sup> Digest representing an MST Configuration Table containing the value 0xFFD for VID 1, the value 0xFFFF  
<sup>12</sup> for VIDs 3600 to 3999, and the value 0 for every other element. Such a table represents the mapping of the  
<sup>13</sup> default PVID to SPBV, an SPVID pool containing VIDs 3600 to 3999, and mapping all other VLANs to the  
<sup>14</sup> CIST. This will allow SPT Bridges using the default configuration to form an SPT Region and operate the  
<sup>15</sup> default VLAN in SPBV mode.

<sup>16</sup> An Auxiliary MCID (14.4, 27.4.1, 28.12.2) is specified for SPB configuration and is conveyed in SPT  
<sup>17</sup> BPDUs and SPB Hello PDUs. When a configuration change that cannot introduce loops is made, the  
<sup>18</sup> previous MCID can be retained in the Auxiliary MCID, allowing a neighboring Bridge whose configuration  
<sup>19</sup> has not yet been changed to maintain communication without creating a region boundary. This allows an  
<sup>20</sup> operator to increase the number of SPVIDs available to SPBV mode or the number of Base VIDs for SPBV  
<sup>21</sup> or SPBM modes (for example) without disrupting communication. To avoid creating a region boundary all  
<sup>22</sup> the Bridges have to be configured so they are all using the same new MCID before any other change can be  
<sup>23</sup> made.

## <sup>24</sup> 13.9 Spanning tree priority vectors

<sup>25</sup> Priority vectors permit concise specification of each protocol's computation of the active topology, both in  
<sup>26</sup> terms of the entire network and of the operation of individual Bridges in support of the distributed algorithm.  
<sup>27</sup> MST, RST, and STP Bridges use *spanning tree priority vector* information in Configuration Messages  
<sup>28</sup> (13.14), sent and received from neighboring Bridges, to assign Port Roles that determine each port's  
<sup>29</sup> participation in a fully and simply connected active topology based on one or more spanning trees. SPT

1 Bridges use ISIS-SPB to disseminate the information necessary to calculate Port Roles throughout SPT  
2 Regions, and to perform those calculations, but also use this Configuration Message information for the  
3 CIST to ensure that neighboring Bridges agree on that active topology, and to receive the information if the  
4 CIST Root lies outside their SPT Region.

5 CIST priority vectors comprise the following components:

- 6 a) CIST Root Identifier, the Bridge Identifier of the CIST Root.
- 7 b) CIST External Root Path Cost, the inter-regional cost from the transmitting Bridge to the CIST  
8 Root.
- 9 c) CIST Regional Root Identifier, the Bridge Identifier of the single Bridge in a region whose CIST  
10 Root Port connects to a LAN in a different region, or of the CIST Root if that is within the region.
- 11 d) CIST Internal Root Path Cost, the cost to the CIST Regional Root.
- 12 e) CIST Designated Bridge Identifier, the Bridge Identifier for the transmitting Bridge for the CIST.
- 13 f) CIST Designated Port Identifier, the Port Identifier for the transmitting port for the CIST.
- 14 g) CIST Receiving Port Identifier (not conveyed in Configuration Messages, used as tie-breaker  
15 between otherwise equal priority vectors within a receiving Bridge).

16 The first two components of the CIST priority vector are significant throughout the network. The CIST  
17 External Root Path Cost transmitted by a Bridge is propagated along each path from the CIST Root, is added  
18 to at Bridge Ports that receive the priority vector from a Bridge in a different region, and thus accumulates  
19 costs at the Root Ports of Bridges that are not MST or SPT Bridges or are CIST Regional Roots and is  
20 constant within a region. The CIST Internal Root Path Cost is only significant and defined within a region.  
21 The last three components are used as locally significant tie breakers, not propagated within or between  
22 regions. The set of all CIST spanning tree priority vectors is thus totally ordered.

23 Since RSTP is not aware of regions, RSTP specifications also refer to the CIST Root Identifier and CIST  
24 External Root Path Cost simply as the Root Bridge Identifier and Root Path Cost, respectively, and omit the  
25 CIST Internal Root Path Cost (as does STP). MSTP encodes the CIST Regional Root Identifier in the BPDU  
26 field used by RSTP to convey the Designated Bridge Identifier (14.1.1), so an entire region appears to an  
27 RSTP-capable Bridge as a single Bridge. RSTP's CST use of CIST priority vectors can be conveniently  
28 specified by the use of the zero for the Internal Root Path Cost and the same values for both the Regional  
29 Root Identifier and Designated Bridge Identifier.

30 NOTE 1—The path to the CIST Root from a Bridge with a CIST Root Port within a region always goes to or through the  
31 CIST Regional Root.

32 NOTE 2—STP lacks the fields necessary for MST Bridges to communicate the Designated Bridge Identifier to resolve a  
33 potential priority vector tie, and MSTP BPDUs are not sent on a LAN to which an STP Bridge is attached.

34 Each MSTI priority vector comprises the following components for the particular MSTI in a given region:

- 35 h) MSTI Regional Root Identifier, the Bridge Identifier of the MSTI Regional Root
- 36 i) MSTI Internal Root Path Cost, the path cost to the MSTI Regional Root
- 37 j) MSTI Designated Bridge Identifier, the Bridge Identifier for the transmitting Bridge for this MSTI
- 38 k) MSTI Designated Port Identifier, the Port Identifier for the transmitting port for this MSTI
- 39 l) MSTI Receiving Port Identifier (not conveyed in Configuration Messages)

40 The set of priority vectors for a given MSTI is only defined within a region. Within each region they are  
41 totally and uniquely ordered. A CIST Root Identifier, CIST External Root Path Cost, and CIST Regional  
42 Root Identifier tuple defines the connection of the region to the external CST and is required to be associated  
43 with the source of the MSTI priority vector information when assessing the agreement of information for  
44 rapid transitions to forwarding, but plays no part in priority vector calculations.

1 As each Bridge and Bridge Port receives priority vector information from Bridges and ports closer to the  
2 Root, calculations and comparisons are made to decide which priority vectors to record, and what  
3 information to pass on. Decisions about a given port's role are made by comparing the priority vector  
4 components that could be transmitted with that received by the port. For all components, a lesser numerical  
5 value is better, and earlier components in the above lists are more significant. As each Bridge Port receives  
6 information from ports closer to the Root, additions are made to one or more priority vector components to  
7 yield a worse priority vector for potential transmission through other ports of the same Bridge.

8 NOTE 3—The consistent use of lower numerical values to indicate better information is deliberate as the Designated  
9 Port that is closest to the Root Bridge, i.e., has a numerically lowest path cost component, is selected from among  
10 potential alternatives for any given LAN (13.9). Adopting the conventions that lower numerical values indicate better  
11 information, that where possible more significant priority components are encoded earlier in the octet sequence of a  
12 BPDU (14.1), and that earlier octets in the encoding of individual components are more significant (14.2) allow  
13 concatenated octets that compose a priority vector to be compared as if they were a multiple octet encoding of a single  
14 number, without regard to the boundaries between the encoded components. To reduce the confusion that naturally arises  
15 from having the lesser of two numerical values represent the better of the two, i.e., that chosen all other factors being  
16 equal, this clause uses the following consistent terminology. Relative numeric values are described as “least,” “lesser,”  
17 “equal,” and “greater,” and their comparisons as “less than,” “equal to,” or “greater than,” while relative spanning tree  
18 priorities are described as “best,” “better,” “the same,” “different,” and “worse” and their comparisons as “better than,”  
19 “the same as,” “different from,” and “worse than.” The operators “<” and “=” represent less than and equal to,  
20 respectively. The terms “superior” and “inferior” are used for comparisons that are not simply based on priority but  
21 include the fact that a priority vector can replace an earlier vector transmitted by the same Bridge Port. All of these terms  
22 are defined for priority vectors in terms of the numeric comparison of components below (13.10, 13.11).

23 NOTE 4—To ensure that the CIST and each MSTI's view of the boundaries of each region remain in synchronization at  
24 all times, each BPDU carries priority vector information for the CIST as well as for MSTIs. Associating the CIST Root  
25 Identifier, External Path Cost, and Regional Root Identifier with the priority vector information for each MSTI does not  
26 therefore raise a requirement to transmit these components separately. A single bit per MSTI vector, the Agreement flag,  
27 satisfies the requirement to indicate that the vector beginning with the MSTI Regional Root Identifier for that specific  
28 MSTI has always been associated with the single CIST Root Identifier, etc. transmitted in the BPDU.

29 To allow the active topology to be managed for each tree through adjusting the relative priority of different  
30 Bridges and Bridge Ports for selection as the CIST Root, a CIST or MSTI Regional Root, Designated  
31 Bridge, or Designated Port, the priority component of the Bridge's Bridge Identifier can be independently  
32 chosen for the CIST and for each MSTI. The priority component used by the CIST for its CIST Regional  
33 Root Identifier can also be chosen independently of that used for the CIST Root Identifier. Independent  
34 configuration of Port Path Cost and Port Priority values for the CIST and for each MSTI can also be used to  
35 control selection of the various roles for the CIST and for each MSTI.

36 In principle an SPT priority vector could be defined within an SPT Region, comprising a Regional Root  
37 Identifier and Internal Root Path Cost, and would reflect the construction of each SPT (lowest Internal Root  
38 Path Cost from each Bridge and LAN to the Regional Root). However, the set of such vectors cannot be  
39 totally ordered by the addition of purely local tie-breaker components: as each SPT Set has to be symmetric.  
40 Clause 28 specifies ISIS-SPB's calculation of SPTs.

### 41 13.10 CIST Priority Vector calculations

42 The *port priority vector* is the priority vector held for the port when the reception of BPDUs and any  
43 pending update of information has been completed:

44 
$$\text{port priority vector} = \{ \text{RootID} : \text{ExtRootPathCost} : \\$$
  
45 
$$\text{RRootID} : \text{IntRootPathCost} : \\$$
  
46 
$$\text{DesignatedBridgeID} : \text{DesignatedPortID} : \text{RcvPortID} \}$$

47 The *message priority vector* is the priority vector conveyed in a received Configuration Message. For a  
48 Bridge with Bridge Identifier  $B$  receiving a Configuration Message on a port  $P_B$  from a Designated Port  $P_D$   
49 on Bridge  $D$  claiming a CIST Root Identifier of  $R_D$ , a CIST External Root Path Cost of  $ERC_D$ , a CIST  
50 Regional Root Identifier of  $RR_D$ , and a CIST Internal Root Path Cost of  $IRC_D$ :

51 
$$\text{message priority vector} = \{ R_D : ERC_D : RR_D : IRC_D : D : P_D : P_B \}$$

1 If  $B$  is not in the same region as  $D$ , the Internal Root Path Cost has no meaning to  $B$  and is set to 0.

2 NOTE 1—If a Configuration Message is received in an RST or STP BPDU, both the Regional Root Identifier and the  
3 Designated Bridge Identifier are decoded from the single BPDU field used for the Designated Bridge Parameter (the  
4 MST BPDU field in this position encodes the CIST Regional Root Identifier). An STP or RST Bridge is always treated  
5 by MSTP as being in an region of its own, so the Internal Root Path Cost is decoded as zero.

6 The received CIST message priority vector is the same as  $B$ 's port priority vector if:

7  $(R_D == RootID) \ \&\& \ (ERC_D == ExtRootPathCost) \ \&\& \ (RR_D == RRootID) \ \&\&$   
8  $(IRC_D == IntRootPathCost) \ \&\& \ (D == DesignatedBridgeID) \ \&\& \ (P_D == DesignatedPortID)$

9 and is better if:

10  $((R_D < RootID)) \ ||$   
11  $((R_D == RootID) \ \&\& \ (ERC_D < ExtRootPathCost)) \ ||$   
12  $((R_D == RootID) \ \&\& \ (ERC_D == ExtRootPathCost) \ \&\& \ (RR_D < RRootID)) \ ||$   
13  $((R_D == RootID) \ \&\& \ (ERC_D == ExtRootPathCost) \ \&\& \ (RR_D == RRootID)$   
14  $\ \&\& \ (IRC_D < IntRootPathCost)) \ ||$   
15  $((R_D == RootID) \ \&\& \ (ERC_D == ExtRootPathCost) \ \&\& \ (RR_D == RRootID)$   
16  $\ \&\& \ (IRC_D == IntRootPathCost) \ \&\& \ (D < DesignatedBridgeID)) \ ||$   
17  $((R_D == RootID) \ \&\& \ (ERC_D == ExtRootPathCost) \ \&\& \ (RR_D == RRootID)$   
18  $\ \&\& \ (IRC_D == IntRootPathCost) \ \&\& \ (D == DesignatedBridgeID)$   
19  $\ \&\& \ (P_D < DesignatedPortID))$

20 A received CIST message priority vector is superior to the port priority vector if, and only if, the message  
21 priority vector is better than the port priority vector, or the Designated Bridge Identifier Bridge Address and  
22 Designated Port Identifier Port Number components are the same; in which case, the message has been  
23 transmitted from the same Designated Port as a previously received superior message, i.e., if:

24  $\{R_D : ERC_D : RR_D : IRC_D : D : P_D : P_B\}$   
25 *is better than*  
26  $\{RootID : ExtRootPathCost : RRootID : IntRootPathCost :$   
27  $DesignatedBridgeID : DesignatedPortID : RcvPortID\}$   
28  $\} \ || \ ((D.BridgeAddress == DesignatedBridgeID.BridgeAddress) \ \&\&$   
29  $(P_D.PortNumber == DesignatedPortID.PortNumber))$

30 If the message priority vector received in a Configuration Message from a Designated Port is superior, it will  
31 replace the current port priority vector.

32 A *root path priority vector* for a port can be calculated from a port priority vector that contains information  
33 from a message priority vector, as follows:

34 If the port priority vector was received from a Bridge in a different region (13.29.8), the External Port Path  
35 Cost  $EPC_{PB}$  is added to the External Root Path Cost component, and the Regional Root Identifier is set to  
36 the value of the Bridge Identifier for the receiving Bridge. The Internal Root Path Cost component will have  
37 been set to zero on reception.

38  $root \ path \ priority \ vector = \{R_D : ERC_D + EPC_{PB} : B : 0 : D : P_D : P_B\}$

39 If the port priority vector was received from a Bridge in the same region (13.29.8), the Internal Port Path  
40 Cost  $IPC_{PB}$  is added to the Internal Root Path Cost component.

41  $root \ path \ priority \ vector = \{R_D : ERC_D : RR_D : IRC_D + IPC_{PB} : D : P_D : P_B\}$

1 The *Bridge priority vector* for a Bridge  $B$  is the priority vector that would, with the Designated Port  
2 Identifier set equal to the transmitting Port Identifier, be used as the message priority vector in Configuration  
3 Messages transmitted on Bridge  $B$ 's Designated Ports if  $B$  was selected as the Root Bridge of the CIST.

4 
$$\text{Bridge priority vector} = \{B : 0 : B : 0 : B : 0 : 0\}$$

5 The *root priority vector* for Bridge  $B$  is the best priority vector of the set of priority vectors comprising:

- 6 a) The Bridge priority vector; plus
- 7 b) All root path priority vectors that:
  - 8 1) Have a Designated Bridge Identifier  $D$  that is not equal to  $B$ , and
  - 9 2) Were received from a Bridge Port attached to a LAN that is not in the same SPT Region as  $B$ ;
- 10 plus
- 11 c) The root path priority vector calculated by ISIS-SPB (if SPB is enabled, and the attached LAN is  
12 within the Bridge's SPT Region).

13 NOTE 2—The BPDUs sent and received by all Bridges attached to a LAN allow MST and SPT Bridges to determine  
14 whether each attached LAN is within their region independently of priority vector values. SPT Bridges take advantage of  
15 this fact by using ISIS-SPB to communicate the CST priority vector for each of SPT Region's potential Master Ports  
16 throughout the region, at the same time as ISIS-SPB calculates the Port Roles for each SPT (see Clause 28).

17 If the Bridge priority vector is the best of this set of priority vectors, Bridge  $B$  has been selected as the CIST  
18 Root. Otherwise, the root priority vector will only be that calculated by ISIS-SPB if the Root Bridge or  
19 Regional Root is within the Bridge's SPT Region.

20 The *designated priority vector* for a port  $Q$  on Bridge  $B$  is the root priority vector with  $B$ 's Bridge Identifier  
21  $B$  substituted for the *DesignatedBridgeID* and  $Q$ 's Port Identifier  $Q_B$  substituted for the *DesignatedPortID*  
22 and *RcvPortID* components. If  $Q$  is attached to a LAN that has one or more STP Bridges attached (as  
23 determined by the Port Protocol Migration state machine),  $B$ 's Bridge Identifier  $B$  is also substituted for the  
24 *RRootID* component.

25 If the designated priority vector is better than the port priority vector and the LAN attached to the port is not  
26 within the Bridge's SPT Region (possibly because SPB is not enabled), the port will be the Designated Port  
27 for that LAN and the current port priority vector will be updated. If the attached LAN is within the Bridge's  
28 SPT Region, then the Port Role is as calculated by ISIS-SPB and the port priority vector will be updated  
29 with the designated priority vector if and only if the port is a Designated Port. The message priority vector in  
30 Configuration Messages transmitted by a port always comprises the components of the designated priority  
31 vector for the port, even if the port is a Root Port.

### 32 13.11 MST Priority Vector calculations

33 The *port priority vector* for a given MSTI is the priority vector held for the port per MSTI when the  
34 reception of BPDUs and any pending update of information has been completed:

35 
$$\text{port priority vector} = \{RRootID : IntRootPathCost : \\ 36 \text{DesignatedBridgeID} : \text{DesignatedPortID} : RcvPortID\}$$

37 The *message priority vector* for a given MSTI is the MSTI priority vector conveyed in a received  
38 Configuration Message. For a Bridge with Bridge Identifier  $B$  receiving a Configuration Message on a  
39 Regional Port  $P_B$  from a Designated Port  $P_D$  on Bridge  $D$  belonging to the same MST Region and claiming  
40 an Internal Root Path Cost of  $IRC_D$ :

41 
$$\text{message priority vector} = \{RR_D : IRC_D : D : P_D : P_B\}$$

42 An MSTI message priority vector received from a Bridge not in the same MST Region is discarded.

1 An MSTI message priority vector received from a Bridge Port internal to the region is the same as the port  
2 priority vector if:

3  $((RR_D == RRootID) \&\& (IRC_D == IntRootPathCost) \&\& (D == DesignatedBridgeID)$   
4  $\&\& (P_D == DesignatedPortID))$

5 and is better if:

6  $((RR_D < RRootID)) ||$   
7  $((RR_D == RRootID) \&\& (IRC_D < IntRootPathCost)) ||$   
8  $((RR_D == RRootID) \&\& (IRC_D == IntRootPathCost) \&\& (D < DesignatedBridgeID)) ||$   
9  $((RR_D == RRootID) \&\& (IRC_D == IntRootPathCost) \&\& (D == DesignatedBridgeID)$   
10  $\&\& (P_D < DesignatedPortID))$

11 An MSTI message priority vector is superior to the port priority vector if, and only if, the message priority  
12 vector is better than the port priority vector, or the Designated Bridge Identifier Bridge Address and  
13 Designated Port Identifier Port Number components are the same; in which case, the message has been  
14 transmitted from the same Designated Port as a previously received superior message, i.e., if:

15  $\{RR_D : IRC_D : D : P_D : P_B\}$   
16 *is better than*  
17  $\{RRootID : IntRootPathCost : DesignatedBridgeID : DesignatedPortID : RcvPortID\}$   
18  $) || ((D.BridgeAddress == DesignatedBridgeID.BridgeAddress) \&\&$   
19  $(P_D.PortNumber == DesignatedPortID.PortNumber))$

20 If the message priority vector received in a Configuration Message from a Designated Port for the MSTI is  
21 superior, it will replace the current port priority vector.

22 NOTE 1—The agree flag (13.27.3) for the port and this MSTI will be cleared if the CIST Root Identifier, CIST External  
23 Root Path Cost, and CIST Regional Root Identifier in the received BPDU are not better than or the same as those for the  
24 CIST designated priority vector for the port following processing of the received BPDU.

25 A *root path priority vector* for a given MSTI can be calculated for a port that has received a port priority  
26 vector from a Bridge in the same region by adding the Internal Port Path Cost  $IPC_{PB}$  to the Internal Root  
27 Path Cost component.

28  $root\ path\ priority\ vector = \{RR_D : IRC_D + IPC_{PB} : D : P_D : P_B\}$

29 NOTE 2—Internal Port Path Costs are independently manageable for each MSTI, as are the priority components of the  
30 Bridge and Port Identifiers. The ability to independently manage the topology of each MSTI without transmitting  
31 individual Port Path Costs is a key reason for retaining the use of a Distance Vector protocol for constructing MSTIs. A  
32 simple link state protocol requires transmission (or *a priori* sharing) of all Port Costs for all links.

33 The *Bridge priority vector* for a Bridge  $B$  for a given MSTI is the priority vector that would, with the  
34 Designated Port Identifier set equal to the transmitting Port Identifier, be used as the message priority vector  
35 in Configuration Messages transmitted on Bridge  $B$ 's Designated Ports if  $B$  was selected as the Root Bridge  
36 of a given tree.

37  $Bridge\ priority\ vector = \{B : 0 : B : 0\}$

38 The *root priority vector* for Bridge  $B$  is the best priority vector of the set of priority vectors comprising the  
39 Bridge priority vector plus all root path priority vectors whose Designated Bridge Identifier  $D$  is not equal to  
40  $B$ . If the Bridge priority vector is the best of this set of priority vectors, Bridge  $B$  has been selected as the  
41 Root of the tree.

42 The *designated priority vector* for a port  $Q$  on Bridge  $B$  is the root priority vector with  $B$ 's Bridge Identifier  
43  $B$  substituted for the *DesignatedBridgeID* and  $Q$ 's Port Identifier  $Q_B$  substituted for the *DesignatedPortID*  
44 and *RcvPortID* components.

1 If the designated priority vector is better than the port priority vector, the port will be the Designated Port for  
2 the attached LAN and the current port priority vector will be updated. The message priority vector in MSTP  
3 BPDUs transmitted by a port always comprises the components of the designated priority vector of the port,  
4 even if the port is a Root Port.

5 Figure 13-8 shows the priority vectors and the active topology calculated for an MSTI in a region of the  
6 example network of Figure 13-6.

### 7 **13.12 Port Role assignments**

8 Each Bridge assigns CIST Port Roles (when new information becomes available as specified in this  
9 subclause, 13.12) before assigning MSTI or SPT Port Roles. The calculations specified in 13.10 are used to  
10 assign a role to each Bridge Port that is enabled as follows:

- 11 a) If the Bridge is not the CIST Root, the source of the root priority vector is the Root Port.
- 12 b) Each port whose port priority vector is the designated priority vector is a Designated Port.
- 13 c) Each port, other than the Root Port, with a port priority vector received from another Bridge is a  
14 Alternate Port.
- 15 d) Each port with a port priority vector received from another port on this Bridge is a Backup Port.

16 If the port is not enabled, i.e., its MAC\_Operational status is FALSE or its Administrative Bridge Port state  
17 is Disabled (8.4), it is assigned the Disabled Port role for the CIST, all MSTIs, and all SPTs, to identify it as  
18 having no part in the operation of any of the spanning trees or the active topology of the network.

19 If the Bridge is an MST or SPT Bridge, the calculations specified in 13.11 are used to assign a role to each  
20 enabled Bridge Port for each MSTI as follows:

- 21 e) If the port is the CIST Root Port and the CIST port priority vector was received from a Bridge in  
22 another MST or SPT Region, the port is the Master Port.
- 23 f) If the Bridge is not the MSTI Regional Root, the port that is the source of the MSTI root priority  
24 vector is the Root Port.
- 25 g) Each port whose port priority vector is the designated priority vector derived from the root priority  
26 vector is a Designated Port.
- 27 h) Each port, other than the Master Port or the Root Port, with a port priority vector received from  
28 another Bridge or a CIST port priority vector from a Bridge in another region, is an Alternate Port.
- 29 i) Each port that has a port priority vector that has been received from another port on this Bridge is a  
30 Backup Port.

31 Independently of priority vector values and active topology calculations, each SPT Bridge Port determines  
32 from received BPDUs whether all the Bridges attached to its LAN are in the same SPT Region. If not, the  
33 port is a Boundary Port, and its role for each SPT is determined by its CIST Port Role as follows:

- 34 j) If the port is the CIST Root Port, the port is the Master Port for all SPTs.
- 35 k) If the port is not the CIST Root Port, the port's role is the same as that for the CIST.

36 By excluding Boundary Ports from the physical topology used to calculate SPTs, and adopting CIST  
37 connectivity at those ports, ISIS-SPB ensures that the use of SPVIDs (see Clause 27) is not required on  
38 shared media LANs attached to Bridges in other regions.

39 SPT Bridges use ISIS-SPB to assign Port Roles for each SPT to non-Boundary Ports as follows:

- 40 l) If the Bridge is not the SPT Root Bridge, the port that ISIS-SPB has calculated as providing the path  
41 for frames assigned to the SPT and forwarded to the Bridge from that SPT Root is the Root Port.
- 42 m) Each port, other than the Root Port, that ISIS-SPB has calculated as providing a path for frames  
43 forwarded from the SPT Root to the attached LAN is a Designated Port.
- 44 n) Each port that is attached to the same LAN as another port on that same Bridge that is a Designated  
45 Port for the SPT, is a Backup Port.
- 46 o) Each port not assigned a Root, Designated, or Backup Port role is an Alternate Port.

### 13.13 Stable connectivity

This subclause provides an analysis to show that RSTP, MSTP, and ISIS-SPB meet the goal of providing full and simple connectivity for frames assigned to any given VID in a stable network, i.e., where the physical topology has remained constant for long enough that the spanning tree information communicated and processed by Bridges is not changing.

NOTE 1—The FDB can be configured to prevent connectivity, in particular this analysis assumes that every Bridge Port is a member of every VID's Member Set (8.8.10). Spanning tree protocol controls can also be used to prevent new connectivity (to allow for upgrades), or to disallow certain topologies (restricting the location of the CIST Root, for example). This analysis assumes that those controls are not being used, that all the Bridges are using conformant protocol implementations and that the LANs are providing omnidirectional connectivity.

Every LAN provides connectivity for all frames between all attached Bridge Ports. Every Bridge provides connectivity between and only between its CIST Root and Designated Ports for frames assigned to the CIST; between the Root, Designated, and Master Ports for a given MSTI for frames assigned to that MSTI; and between Root and Designated Ports for a given SPT for frames assigned to that SPT. Any given Bridge does not assign frames to more than one tree and has one Root Port per tree, unless it is the Root of that tree.

Every LAN has one and only one CIST Designated Port, and every Bridge apart from the CIST Root has one and only one CIST Root Port. The CIST spanning tree priority vector of the Designated Port attached to the LAN that is connected to a Bridge's Root Port is better than of any Designated Port of that Bridge. The CIST thus connects all Bridges and LANs (is "spanning") and loop-free (is a "tree").

Each MST or SPT Region is bounded by CST Root and Alternate Ports. At the CST Root Ports connectivity for frames assigned to MSTIs or SPTs within the connected regions is the same as that for the CIST. Every region apart from that containing the CIST Root has a single CST Root Port, identified as the Master Port for each MSTI. The CIST spanning tree priority vector of the LAN attached to the region's CST Root Port is better than that of any CST Designated Port of a Bridge in the region attached to a LAN also attached to the CST Root Port of another region. The CST thus provides loop-free connectivity between all regions.

NOTE 2—The term "Common Spanning Tree (CST)" refers to the CIST connectivity between regions, and the term "Internal Spanning Tree (IST)" to the CIST connectivity within each region. An RST Bridge and the LANs for which it is the Designated Bridge are conveniently considered as forming an MST region of limited extent.

Within each region each frame is consistently assigned to the CIST, an MSTI, or an SPT, and each of these spanning trees provides full loop-free connectivity to each of the Bridges within the region, just as the CIST does for the network as a whole, including connectivity between the CST Root Port (Master Port) and the CST Designated Ports. Since each Bridge or LAN is in one and only one region, and it has already been shown that loop-free connectivity is provided between regions, loop-free connectivity is thus provided between all the Bridges and LANs in the network.

Figure 13-9 illustrates the above connectivity with the simple example of Region 1 from the example network of Figure 13-6 and Figure 13-8. Bridge 0.42 has been selected as the CIST Root and Regional Root, Bridge 0.57 as the Regional Root for MSTI 1, and Bridge 2.83 for MSTI 2 by management of the per MSTI Bridge Identifier priority component. The potential loop through the three Bridges in the region is blocked at different Bridge Ports for the CIST, and each MSTI, but the connectivity across the region and from each LAN and Bridge in the region through the boundaries of the region is the same in all cases.

### 13.14 Communicating spanning tree information

A Spanning Tree Protocol Entity transmits and receives group addressed BPDUs (Clause 14, 8.13.4) through each of its Bridge Ports to communicate with the Spanning Tree Protocol Entities of the other Bridges attached to the same LAN. The group address used is one of a small number of addresses that identify frames that are not directly forwarded by Bridges (8.6.3), but the information in the BPDU can be used by a Bridge in calculating its own BPDUs to transmit and can stimulate that transmission.

**Figure 13-9—CIST and MSTI active topologies in Region 1 of the example network**

1 BPDUs are used to convey the following:

- 2 a) Configuration Messages
- 3 b) Topology Change Notification (TCN) Messages
- 4 c) MCIDs
- 5 d) Agreement parameters to support SPB

6 Designated Ports also transmit BPDUs at intervals to guard against loss and to assist in the detection of  
7 failed components (LANs, Bridges, or Bridge Ports), so all messages are designed to be idempotent.

8 A Configuration Message for the CIST can be encoded in an STP Configuration BPDUs, an RST BPDUs, an  
9 MST BPDUs, or an SPT BPDUs (14.1, 14.5). A TCN Message for the CIST can be encoded in an STP  
10 Topology Change Notification BPDUs (14.2), or an RST, MST, or SPT BPDUs with the [Topology Change](#)  
11 flag set. Configuration and TCN Messages for the CIST and for all MSTIs in an MST Region are encoded in  
12 a single MST or SPT BPDUs, as is the MCID. No more than 64 MSTI Configuration Messages shall be  
13 encoded in an MST BPDUs, and no more than 64 MSTIs shall be supported by an MST Bridge.

1 When SPB is enabled, ISIS-SPB is used to communicate CST priority vectors, IST topology information,  
2 and CST topology change information to and from the other Bridges in the SPT Region and to calculate IST  
3 and SPT Port Roles and designated priority vectors. However, the full CIST priority information is still  
4 conveyed in SPT BPDUs, partly to encode agreement information for the IST, but principally to support  
5 interoperability at the boundaries of each region without having to assess whether the transmitting port is at  
6 a boundary before deciding what to encode in each BPDU.

7 Configuration and Topology Change Notification BPDUs are distinguished from each other and from RST  
8 and MST BPDUs by their BPDU Type (Clause 14). RST and MST BPDUs share the same BPDU Type and  
9 are distinguished by their version identifiers.

10 Bridges implementing STP (Clause 8 of IEEE Std 802.1D, 1998 Edition [B13]) transmit and decode  
11 Configuration and Topology Change Notification BPDUs, and ignore RST and MST BPDUs on receipt.  
12 This ensures that connection of a Bridge Port of such a Bridge to a LAN that is also attached to a Bridge  
13 implementing RSTP or MSTP is detected, as transmission of RSTP or MSTP BPDUs does not suppress  
14 regular transmissions by the STP Bridge. This functionality is provided by the Port Protocol Migration state  
15 machine for RSTP (13.32). The Port Protocol Migration state machines select the BPDU types used to  
16 encode spanning tree messages so that all Bridges attached to the same LAN participate in a spanning tree  
17 protocol, while maximizing the available functionality. If one or more attached Bridges only implement STP,  
18 only Configuration and Topology Change Notification BPDUs will be used and the functionality provided  
19 by the protocol will be constrained.

### 20 **13.15 Changing spanning tree information**

21 Addition, removal, failure, or management of the parameters of Bridges and LAN connectivity can change  
22 spanning tree information and require Port Role changes in all or part of the network (for the CIST) or all or  
23 part of an MST or SPT Region (for an MSTI or SPT Set). A CIST or MSTI configuration message received  
24 in a BPDU is considered superior to, and will replace, that recorded in the reception Port's port priority  
25 vector if its message priority vector is better, or if it was transmitted by the same Designated Bridge and  
26 Designated Port and the message priority vector, timer, or hop count information differ from those recorded.

27 RSTP and MSTP propagate new information rapidly from Bridge to Bridge, superseding prior information  
28 and stimulating further transmissions until it reaches either Designated Ports that have already received the  
29 new information through redundant paths in the network or the leaves of the spanning tree, as defined by the  
30 new configuration. Configuration Message transmissions will then once more occur at regular intervals from  
31 ports selected as Designated Ports.

32 To ensure that old information does not endlessly circulate through redundant paths in the network,  
33 preventing the effective propagation of the new information, MSTP associates a hop count with the  
34 information for each spanning tree. The hop count is assigned by the CIST Regional Root or the MSTI  
35 Regional Root and decremented by each reception Port. Received information is discarded and the port  
36 made a Designated Port if the hop count reaches zero.

37 RSTP and MSTP's CST processing do not use an explicit hop count (for reasons of STP compatibility), but  
38 detect circulating aged information by treating the BPDU Message Age parameter as an incrementing hop  
39 count with Max Age as its maximum value. MSTP increments Message Age for information received at the  
40 boundary of an MST Region, discarding the information if necessary.

1 If a Bridge Port's MAC\_Operational parameter becomes FALSE, the port becomes a Disabled Port and  
2 received information is discarded. Spanning tree information for the tree can be recomputed, the Bridge's  
3 Port Roles changed, and new spanning tree information transmitted if necessary. Not all component failure  
4 conditions can be detected in this way, so each Designated Port transmits BPDUs at regular intervals and a  
5 reception Port will discard information and become a Designated Port if two transmissions are missed.

6 NOTE—Use of a separate hop count and message loss detection timer provides superior reconfiguration performance  
7 compared with the original use of Message Age and Max Age by STP. Connectivity loss detection is not compromised  
8 by the need to allow for the overall diameter of the network, nor does the time allowed extend the number of hops  
9 permitted to aged recirculating information. Management calculation of the necessary parameters for custom topologies  
10 is also facilitated, as no allowance needs to be made for relative timer jitter and accuracy in different Bridges.

11 ISIS-SPB communicates CST, IST, and SPT information throughout an SPT Region using link state  
12 procedures specified in Clause 28. In addition to the normal hop-by-hop distribution of this information,  
13 which is essential to guarantee its dissemination, each link state PDU (LSP) is also broadcast on the SPT  
14 rooted at the originating Bridge, so new information can reach Bridges in the region with the same delay as  
15 data.

## 16 13.16 Changing Port States with RSTP or MSTP

17 The Port State for the CIST and each MSTI for each Bridge Port is controlled by state machines whose goal  
18 is to maximize connectivity without introducing temporary loops in each of these active topologies. Root  
19 Ports, Master Ports, and Designated Ports are transitioned to the Forwarding Port State, and Alternate Ports  
20 and Backup Ports to the Discarding Port State, as rapidly as possible. Transitions to the Discarding Port State  
21 can be simply effected without the risk of data loops. This subclause (13.16) describes the conditions that  
22 RSTP and MSTP use to transition a Port State for a given spanning tree to Forwarding.

23 Starting with the assumption that any connected fragment of a network is composed of Bridges, Bridge  
24 Ports, and connected LANs that form a subtree of a spanning tree, ports with Root Port, Master Port, or  
25 Designated Port roles are transitioned using conditions that ensure that the newly enlarged fragment  
26 continues to form either a subtree or the whole of the spanning tree. Since the conditions are used every time  
27 a fragment is enlarged, it is possible to trace the growth of a fragment from a single Bridge—a consistent, if  
28 small, subtree of a spanning tree—to any sized fragment, thus justifying the initial assumption.

29 Port States in two subtrees, each bounded by ports that are not forwarding or are attached to LANs not  
30 attached to any other Bridge, can be made consistent by waiting for any changes in the priority vector  
31 information used to assign Port Roles to reach all Bridges in the network, thus ensuring that the subtrees are  
32 not, and are not about to be, joined by other Forwarding Ports. However, it can be shown that a newly  
33 selected Root Port can forward frames as soon as prior recent root ports on the same Bridge cease to do so,  
34 without further communication from other Bridges. Rapid transitions of Designated Ports and Master Ports  
35 do require an explicit Agreement from the Bridges in the subtrees to be connected. The Agreement  
36 mechanism is described, together with a Proposal mechanism that forces satisfaction of the conditions if  
37 they have not already been met by blocking Designated Ports connecting lower subtrees that are not yet in  
38 agreement. The same Agreement mechanism is then used to transition the newly blocked ports back to  
39 forwarding, advancing any temporary cut in the active topology toward the edge of the network.

### 40 13.16.1 Subtree connectivity and priority vectors

41 Any given Bridge  $B$ , the LANs connected through its Forwarding Designated Ports, the further Bridges  
42 connected to those LANs through their Root Ports, the LANs connected to their Forwarding Designated  
43 Ports, and so on, recursively, constitute a subtree  $S_B$ . Any LAN  $L$  that is part of  $S_B$  will be connected to  $B$   
44 through a Forwarding Designated Port  $P_{CL}$  on a Bridge  $C$  also in  $S_B$ .  $L$  cannot be directly connected to any  
45 port  $P_B$  on Bridge  $B$  unless  $B$  and  $C$  are one and the same, since the message priority vector for  $P_B$  is better  
46 than that of any port of any other Bridge in  $S_B$ , and prior to Forwarding  $P_{CL}$  will have advertised its spanning

1 port priority vector for long enough for it to receive any better message priority vector (within the design  
2 probabilities of protocol failure due to repeated BPDU loss) or will have engaged in an explicit confirmed  
3 exchange (see below) with all other Bridge Ports attached to that LAN.

4 NOTE—The analysis for the distance vector-based RSTP and MSTP differs from that for the link state-based ISIS-SPB  
5 (see 13.17). In the latter C's priority vector can become better than B's while C remains in  $S_B$ , without B being aware of  
6 the improvement first.

### 7 13.16.2 Root Port transition to Forwarding

8 It follows from the above that B's Root Port can be transitioned to Forwarding immediately whether it is  
9 attached to a LAN in  $S_B$  or in the rest of the network, provided that all prior recent Root Ports on B (that  
10 might be similarly arbitrarily attached) have been transitioned to Discarding and the Root Port was not a  
11 Backup Port recently (B and C the same as above).

### 12 13.16.3 Designated Port transition to Forwarding

13 On any given Bridge A, the Designated Port  $P_{AM}$  connected to a LAN M can be transitioned to Forwarding  
14 provided that the message priority advertised by the Designated Port  $P_{CL}$  on any LAN L in any subtree  $S_{M1}$ ,  
15  $S_{M2}$ , etc. connected to M is worse than that advertised by  $P_{AM}$ ; that any Bridge D attached to L has agreed  
16 that  $P_{CL}$  is the Designated Port; and that only the Root Port and Designated Ports on D are Forwarding. A  
17 sufficient condition for  $P_{AM}$  to transition to Forwarding is that M is a point-to-point link attached to the Root  
18 Port  $P_{BM}$  of a Bridge B, that the port priority of  $P_{BM}$  is the same as or worse than that of  $P_{AM}$ , and any port  
19  $P_{BN}$  on B is Discarding or similarly attached to a Bridge C.  $P_{BM}$  signals this condition to  $P_{AM}$  by setting the  
20 Agreement flag in a Configuration Message carrying  $P_{BM}$ 's designated priority and Port Role.

21 NOTE 1—RSTP and MSTP use adminPointToPointMAC and operPointToPointMAC (IEEE Std 802.1AC) to allow the  
22 point-to-point status of LANs to be managed and used by the Port Role Transition state machines for Designated Ports.  
23 A newly selected Root Port can be transitioned to Forwarding rapidly, even if attached to a shared media LAN.

24 Figure 13-10 illustrates the generation of an Agreement at a Bridge's Root Port from an Agreement received  
25 or a Port State of Discarding at each of its Designated Ports, and a Port State of Discarding at each of its  
26 Alternate and Backup Ports. A Bridge receiving a Proposal transitions any Designated Port not already  
27 synchronized to Discarding so it can send the Agreement, and that port solicits an Agreement by sending a  
28 Proposal in its turn.

29 NOTE 2—Agreements can be generated without prior receipt of a Proposal as soon as the necessary conditions are met.  
30 Subsequent receipt of a Proposal serves to elicit a further Agreement. If all other ports have already been synchronized  
31 (allSynced in Figure 13-10) and the Proposal's priority vector does not convey worse information, synchronization is  
32 maintained and there is no need to transition Designated Ports to Discarding once more, or to transmit further Proposals.

Figure 13-10—Agreements and Proposals

### 13.16.4 Master Port transition to Forwarding

While the connectivity of the CIST from the CIST Regional Root through an MST Region to the rest of the CST comprises a subtree rooted in the CIST Regional Root, the connectivity of the MSTI from the Master Port includes both a subtree below the CIST Regional Root and a subtree rooted in the MSTI Regional Root and connected to the CIST Regional Root by an MSTI Root Port. In the example network of Figure 13-6, this latter subtree continues CST connectivity, from the Master Port on Bridge 86 through to LAN N, for frames allocated to the MSTI within Region 2 (see Figure 13-11). In general either MSTI subtree could be providing CST connectivity through a prior Master Port: the connectivity of both subtrees has to agree with the new CIST Regional Root, before a new Master Port transitions to Forwarding.

**Figure 13-11—CIST and MSTI Active Topologies in Region 2 of Figure 13-6**

NOTE 1—The physical layout shown in the two halves of Figure 13-11 differs in order to reflect the different priorities and logical topologies for the two spanning tree instances. The layout convention is that Designated Ports are shown as horizontal lines, Root Ports as vertical lines, and Alternate Ports as diagonal lines.

Figure 13-12 illustrates the extension of the Agreement mechanism to signal from Designated Ports to Root Ports as well as vice versa. To ensure that an MSTI does not connect alternate Master Ports, an Agreement is only recognized at an MSTI Port when the associated CIST Regional Root information matches that selected

1 by the reception Port. Proposals, eliciting Agreements, necessarily flow from Designated Ports to Root Ports  
2 with the propagation of spanning tree information, so a new CIST Regional Root cannot transmit a Proposal  
3 directly on its MSTI Root Ports. However, updating a CIST Designated Port's port priority vector with a  
4 new Regional Root Identifier forces the port to discard frames for all MSTIs, thus initiating the Proposal  
5 from the first Bridge nearer the MSTI Regional Root that learns of the new Regional Root.

Figure 13-12—Enhanced Agreements

1 When an Agreement  $A_{MR}$  is sent by a Root Port  $P_{MR}$  on a Regional Root  $M$ , it attests that the CIST Root  
2 Identifier and External Root Path Cost components of the message priority advertised on all LANs  
3 connected to the CIST by  $P_{MR}$  through  $M$  are the same as or worse than those accompanying  $A_{MR}$ . The  
4 connectivity provided by each MSTI can be independent of that provided by the CIST within the MST  
5 Region and can therefore connect  $P_{MR}$  and one or more CIST Root Ports external to but attached at the  
6 boundary of the region even as CIST connectivity within the region is interrupted in order to satisfy the  
7 conditions for generating  $A_{MR}$ . The Agreement cannot therefore be generated unless all MSTI subtrees as  
8 well as the CIST subtree internal to the region are in Agreement. To ensure that an MSTI does not connect to  
9 a CIST subtree external to the region that does not meet the constraints on the CST priority vector  
10 components, an Agreement received at an MSTI Designated Port from a Bridge Port not internal to the  
11 region is only recognized if the CIST Root Identifier and External Root Path Cost of the CIST root priority  
12 vector selected by the transmitting Bridge Port are equal to or worse than those selected by the receiver.  
13 Updating of a CIST Designated Port's port priority vector with a worse CIST Root Identifier and External  
14 Root Path Cost forces the port to discard frames for all MSTIs, thus initiating a Proposal that will elicit  
15 agreement.

16 NOTE 2—MSTI Designated Ports are prompted to discard frames, as required above, as follows. The CIST Port  
17 Information state machine sets sync for all MSTIs on a transition into the UPDATE state if updating the port priority with  
18 the designated priority changes the Regional Root Identifier or replaces the CIST Root Identifier or External Path Cost  
19 with a worse tuple. The MSTI's Port Role Transition machine acts on the sync, instructing the port to discard frames, and  
20 setting synced and canceling sync when the port is discarding or an agreement is received.

21 NOTE 3—A "cut" in an MSTI can be transferred to the CST, either at a Designated Port attached to the same LAN as an  
22 STP Bridge or at the Root Port of a Bridge in an adjacent region. If the CST priority components have already been  
23 synced, as is likely if the original cut was caused by changes in physical topology within the region, the cut will terminate  
24 there. Otherwise, the transferred cut precedes a cut in the CIST, and the synced port may terminate the latter. In that way,  
25 cuts in the CST will proceed through an MST Region by the quickest tree that will carry them.

26 NOTE 4—In the important topology where the CIST Root Bridge is within an MST Region, cuts are not transferred  
27 from the region's IST to any MSTI. CIST cuts propagating in the region will not disrupt MSTI connectivity.

### 28 13.17 Changing Port States with SPB

29 While the link state routing protocols are less likely to create temporary loops than distance vector-based  
30 protocols, loops are still possible if (for example) two (or more) links fail about the same time. Any potential  
31 loop is a serious problem for bridged networks, as a frame that is multicast or whose destination has not been  
32 learned and is traveling around a loop is copied to each of the connected subtrees on every circuit,  
33 consuming bandwidth throughout the network. Each SPT Bridge Port uses SPT BPDUs and/or SPB Hello  
34 PDUs (28.2) to ensure that additions to each active topology do not occur unless there is sufficient  
35 agreement between neighboring Bridges (with some ports temporarily transitioned to Discarding if  
36 necessary) to ensure that a temporary loop will not be created.

37 Like RSTP and MSTP, agreements (see 13.16, Figure 13-12) are used to ensure that ports that transition to  
38 forwarding do not create loops. However, IS-IS distributes information in parallel with computation, rather  
39 than computing a new active topology hop-by-hop as priority vector information is passed from the Root  
40 Bridge to members of a potential subtree. Moreover the distribution path is not restricted to the potential  
41 subtree. Arbitrary distribution and parallel computation means that different Bridges can complete topology  
42 calculations at quite different times, with two major consequences as follows.

43 First, each Bridge is not necessarily aware of priority vector changes passed to any subtree connected  
44 through one of its Designated Ports before any other Bridge in that subtree. A forwarding Designated Port  
45 on a given Bridge can only provide connectivity to another Bridge through the latter's Root Port; and new  
46 connectivity is only allowed if the Designated Port has received an agreement showing that the Root Port's  
47 designated priority is worse than its own. When RSTP (or MSTP) is used priority vectors propagate down  
48 the tree: so each Bridge knows that its forwarding parents (connected through its Root Port) either have a  
49 better *designated priority* or have discarded any agreement previously received. None of those parents can  
50 therefore provide an agreement allowing connectivity through their Root Port to one of the given Bridge's

1 Designated Ports (potentially creating a loop), unless one of the Designated Ports between the parent and the  
2 given Bridge becomes Discarding—allowing an agreement to be sent but interrupting the potential loop.  
3 When the CIST or an SPT is supported by ISIS-SPB, a Bridge Port needs to receive an explicit message  
4 from its neighbors discarding any outstanding agreement before it can start forwarding as a Designated Port  
5 or (if it is the Root Port) before the Bridge's Designated Ports can use an improved designated priority to  
6 transition to forwarding. A given port cannot discard outstanding agreements until all the other ports of the  
7 Bridge have either received suitable agreements or stopped forwarding, or until the given port itself is  
8 Discarding.

9 The second major consequence of arbitrary distribution and parallel computation is that received  
10 Agreements that appear to contradict the results of the last local link state computation can become useful  
11 after a future computation completes. Agreements received after the last computation can be retained until  
12 they prove useful (following a further link state update) or are superseded by the receipt of a further  
13 agreement or a changed Port Role. The Bridge transmitting the agreement will not create any connectivity  
14 that is inconsistent with the agreement until it has been explicitly discarded. For example, two Designated  
15 Ports attached to the same LAN cannot both transition to forwarding, each using an old Agreement with a  
16 Root Port role from the other. To minimize the number of messages needed to create new connectivity,  
17 unsatisfactory received Agreements are voluntarily discarded when a link state topology calculation  
18 completes. In addition to the Agreement Digest, the Agreement Protocol (13.16, 13.17) uses a two-bit  
19 Agreement Number and a Discarded Agreement Number (in SPT BPDUs and SPB Hello PDUs) to allow for  
20 message delay, loss, duplication, and misordering. Once an Agreement has been sent it is considered  
21 outstanding until the Agreement Protocol declares a new topology match.

22 Agreements for the IST use CIST information present in MST and SPT BPDUs. This minimizes active  
23 topology disruption while allowing parallel adoption of a new topology since neighboring Bridges can  
24 communicate IST priority vectors, propagate agreements, and signal the need for temporary cuts to speed  
25 transitions to forwarding: even while those neighbors' views of the entire active topology differ as a  
26 consequence of differences in their knowledge of the latest physical topology. A single BPDUs or SPB Hello  
27 PDU cannot convey the same per-tree state for all possible SPTs, so the input to their link state calculation is  
28 summarized in a Agreement Digest (28.4). If a received digest matches the Bridge's own digest, the Bridge  
29 can compute the implied received Agreements. Using a digest means neighboring Bridges cannot  
30 synchronize their local views of any SPT's active topology until they have synchronized their views of the  
31 physical topology of the entire SPT Region, but reducing the number of messages is worthwhile.

32 NOTE 1—Management VLANs with modest bandwidth needs should be allocated to the IST in SPT Regions.

33 The per-port per-tree state machine variable agreed (see Figure 13-12) is recomputed after ISIS-SPB  
34 completes a link state calculation, including the calculation of each port's designated priority vector, and  
35 after each BPDUs is received: agreed is TRUE if and only if the port is a Root or Alternate Port with no  
36 outstanding agreements worse than its designated priority vector, or a Designated Port with no outstanding  
37 agreements and a received agreement that is worse than its designated priority vector and any outstanding  
38 agreement for the Bridge's Root Port. As in Figure 13-12 each port is synced if it is either agreed or  
39 Discarding for the tree, and agree is TRUE for a given port when all other ports are synced. Unused  
40 outstanding agreements are discarded, by their recipient, only when agree is TRUE, since any continued  
41 connectivity has to be supported by continued agreement if loops are to be prevented.

42 To avoid delays that might otherwise occur waiting for Agreements to percolate up the tree, sync is set for  
43 all Designated Ports to force those that are not agreed to Discarding, so that the Root Port can transmit an  
44 Agreement to its neighbor. However, it is an implementation issue about how long sync requires to take  
45 effect: the likelihood of receiving an Agreement for the CIST from the Designated Port's neighbor before  
46 the port can be transitioned to Discarding and then to Forwarding again can be taken into account. Each  
47 BPDUs CIST Proposal flag should be set when a Designated Port is Discarding, thus providing a prompt  
48 for the return of an Agreement just as described above (13.16) for RSTP and MSTP.

1 The Agreement Digest conveys fresh Agreements for all SPTs (all identified by the same Agreement  
2 Number used for the CIST) and discards those received for prior topologies (identified by the Discarded  
3 Agreement Number). Since different trees will have different Root Ports (in the same Bridge), if all Bridges  
4 waited for agreed to be set for all other ports for all other trees before transmitting a fresh digest the protocol  
5 would deadlock. If the Root Port is not agreed but all other ports are synced, then agree is also set for any  
6 port that is Discarding, thus avoiding the potential deadlock. When a link state computation completes, each  
7 Bridge transitions any Designated Port that is not agreed for an SPT to Discarding as rapidly as possible so  
8 that it can send the fresh digest to its neighbors, and does not attempt to optimize Port State transitions by  
9 waiting to receive a matching digest.

10 NOTE 2—In all comparisons between SPT priority vectors, the specified comparisons take place within the CST  
11 context, and agreed is only set if the CST Root and External Path Cost match exactly. This allow the Port Role Transition  
12 state machine for the Master Port at the SPT Region boundary, where the IST and each SPT are connected into the CST,  
13 to function just as for MSTP.

14 The considerations and state machine conditions detailed in this subclause (13.17) can be summarized (for  
15 an SPT Bridge with all ports providing connectivity within an SPT Region) as follows:

16 A Root Port satisfies the conditions for Forwarding if and only if:

- 17 a) The Agreement Protocol has declared a topology match; and
- 18 b) Since (and including) that topology match, no outstanding Agreement Digest sent through the port is  
19 for a topology where:
  - 20 1) This Bridge is or was farther from the SPT's Root Bridge than in the current topology; or
  - 21 2) The port was a Designated Port or Backup Port.

22 A Designated Port satisfies the conditions for Forwarding if and only if:

- 23 c) The Agreement Protocol has declared a topology match; and
- 24 d) Since (and including) that topology match, no outstanding Agreement Digest sent through the port is  
25 for a topology where:
  - 26 1) Any other Bridge attached to the same LAN is or was as close or closer to the SPT's Root  
27 Bridge than this Bridge is in the current topology; or
  - 28 2) The port was a Root Port or Alternate Port.

29 Note that a Root Port can only become Forwarding following receipt of a fresh Agreement Digest if all  
30 Designated Ports either satisfy the conditions for Forwarding or are made Discarding. A Designated Port can  
31 only become Forwarding if the Root Port also satisfies the conditions for Forwarding, or is made Discarding.

32 An Agreement Digest is sent on all ports as soon as possible after ISIS-SPB completes a link state  
33 calculation, but is only sent if (for every SPT)

- 34 e) The port sending the Agreement Digest is Discarding; or
- 35 f) The port is a Root Port or a Designated Port, that satisfies the necessary conditions for Forwarding  
36 [item a) to item d) above], and every other port of the Bridge is either Discarding or is a Root or  
37 Designated Port that also satisfies those conditions.

### 38 13.17.1 Agreement Digest

39 The Agreement Digest is calculated as specified in 28.4.

40 The purpose of the Agreement Digest is to prevent temporary loops and its use as an input to the Port Role  
41 Transition and Port State Transition state machines is specified in 13.29, 13.37, and 13.38. Successful  
42 operation of ISIS-SPB relies on the fact that SPT Bridges attached to the same LAN will, in the absence of  
43 continual physical topology changes in the network or continual loss of ISIS-SPB frames, advertise the same  
44 Agreement Digest in transmitted BPDUs and SPB Hello PDUs. Conditions that would result in permanent  
45 disagreement, and consequent failure to provide SPB, are captured in the MCID (13.8). Differences in the  
46 MCID result in both MST and SPT Bridge Ports attached to the LAN being identified as bounding a region,  
47 so connectivity can be provided using the CST.

## 1 13.18 Managing spanning tree topologies

2 The active topology of the CIST, and the topologies that can result after the failure or addition of network  
3 components, may be managed by assigning values to some or all of the following:

- 4 — The Bridge Priority component of the CIST Bridge Identifier for one or more Bridges
- 5 — The External Port Path Cost (also referred to as the Port Path Cost for RSTP) for some Bridge Ports
- 6 — Components of the MCID for Bridges with the same Configuration Digest
- 7 — The CIST Internal Port Path Cost Port (for MSTP and ISIS-SPB) for some Bridge Ports
- 8 — The Port Priority component of the Port Identifier for some Bridge Ports

9 Within an MST Region, the active topology of each MSTI may be managed by assigning values to some or  
10 all of the following:

- 11 — The Bridge Priority component of the MSTI Regional Root Identifier
- 12 — The Internal Port Path Cost for the MSTI for some Bridge Ports
- 13 — The Port Priority component of the MSTI's Port Identifier for some Bridge Ports

14 In general topology management objectives can be met by modifying only a few parameter values in a few  
15 Bridges in the network. Table 13-3 specifies default values and ranges for Bridge Priorities and Port  
16 Priorities. If these parameters can be updated by management, the Bridge shall have the capability to use the  
17 full range of values with the granularity specified.

**Table 13-3—Bridge and Port Priority values**

| Parameter       | Recommended or default value | Range                     |
|-----------------|------------------------------|---------------------------|
| Bridge Priority | 32 768                       | 0–61 440 in steps of 4096 |
| Port Priority   | 128                          | 0–240 in steps of 16      |

18 NOTE 1—The stated ranges and granularities for Bridge Priority and Port Priority differ from those in IEEE Std 802.1D,  
19 1998 Edition [B13], and earlier revisions of that standard. Expressing these values in steps of 4096 and 16 allows  
20 consistent management of old and new implementations of this standard; the steps chosen ensure that bits that have been  
21 re-assigned are not modified, but priority values can be directly compared.

22 Table 13-4 recommends defaults and ranges for Port Path Cost and Internal Port Path Cost values, chosen  
23 according to the speed of the attached LAN, to minimize the administrative effort required to provide  
24 reasonable active topologies. If these values can be set by management, the Bridge shall be able to use the  
25 full range of values in the parameter ranges specified, with a granularity of 1.

26 When two or more links are aggregated (see IEEE Std 802.1AX), Port Path Cost and Internal Port Path Cost  
27 values can be modified to reflect the actual throughput. However, as the primary purpose of Path Cost is to  
28 select active topologies, it can be inappropriate to track throughput too closely, as the resultant active  
29 topology could fluctuate or differ from that intended by the network administrator. For example, if the  
30 network administrator had chosen aggregated links for resilience (rather than for increased data rate), it  
31 would be inappropriate to change topology as a result of one of the links in an aggregation failing. Similarly,  
32 with links that can autonegotiate their data rate, reflecting such changes of data rate in changes to Path Cost  
33 is not necessarily appropriate. As a default behavior, dynamic changes of data rate should not automatically  
34 cause changes in Port Path Cost.

**Table 13-4—Port Path Cost values**

| Link Speed | Recommended value | Recommended range      | Range         |
|------------|-------------------|------------------------|---------------|
| <=100 kb/s | 200 000 000       | 20 000 000–200 000 000 | 1–200 000 000 |
| 1 Mb/s     | 20 000 000        | 2 000 000–200 000 000  | 1–200 000 000 |
| 10 Mb/s    | 2 000 000         | 200 000–20 000 000     | 1–200 000 000 |
| 100 Mb/s   | 200 000           | 20 000–2 000 000       | 1–200 000 000 |
| 1 Gb/s     | 20 000            | 2000–200 000           | 1–200 000 000 |
| 10 Gb/s    | 2000              | 200–20 000             | 1–200 000 000 |
| 100 Gb/s   | 200               | 20–2000                | 1–200 000 000 |
| 1 Tb/s     | 20                | 2–200                  | 1–200 000 000 |
| 10 Tb/s    | 2                 | 1–20                   | 1–200 000 000 |

1 NOTE 2—BPDUs are capable of carrying 32 bits of Root Path Cost information, though IEEE Std 802.1D, 1998 Edition  
2 [B13], and its earlier revisions limited the range of the Port Path Cost parameter to a 16-bit unsigned integer value.  
3 Table 13-4 uses the full 32-bit range to extend the range of supported link speeds. Additional recommended values can  
4 be calculated as 20 000 000 000/(Link Speed in kb/s). Limiting the range of the Path Cost parameter to 1–200 000 000  
5 ensures that the accumulated Path Cost cannot exceed 32 bits over a concatenation of 20 hops. Where Bridges using the  
6 IEEE Std 802.1D, 1998 Edition [B13], recommendations and others using Table 13-4 are mixed in the same Bridged  
7 Network, explicit configuration is likely to be necessary to obtain reasonable CST topologies.

8 There exist media for which it is difficult to define a Link Speed. This includes, for example,  
9 Ethernet-over-packet-network technologies, where the frames are carried over a layer 3 best-effort network.  
10 Another example is IEEE 802.11 wireless media, where the effective bandwidth is shared among stations  
11 operating at different speeds, all varying on short timescales. Individual media specifications provide values  
12 for Link Speed suitable for use with Table 13-4 to determine a Port Path Cost.

### 13 13.19 Updating learned station location information

14 In normal stable operation, learned station location information held in the FDB need only change as a  
15 consequence of the physical relocation of stations. It is therefore desirable to employ a long ageing time for  
16 Dynamic Filtering Entries (8.8.3), especially as many end stations transmit frames following power-up  
17 causing the information to be relearned.

18 However, when the active topology reconfigures, stations can appear to move from the point of view of any  
19 given Bridge even if that Bridge's Port States have not changed. If a Bridge Port is no longer part of an  
20 active topology, stations are no longer reachable through that port, and its Dynamic Filtering Entries are  
21 removed from that Bridge's FDB. Conversely, stations formerly reachable through other ports might be  
22 reachable through a newly active port. Dynamic Filtering Entries for the other ports are removed, and RSTP  
23 and MSTP transmit Topology Change Notification Messages both through the newly active Port and  
24 through the other active Ports on that Bridge. TCNs signal additional connectivity, not just changes in  
25 connectivity, as relearning a station's location is only possible if it can be reached, and if that is possible  
26 when a port is removed from the active topology another port will be added. A TCN is sent when a Bridge  
27 Port joins the active topology, and not before, so that Bridges can relearn removed station location  
28 information and minimize unnecessary flooding of frames. A Bridge that receives a TCN on an active port  
29 removes Dynamic Filtering Entries for their other active ports and propagates the TCN through those ports.

1 NOTE 1—STP allowed for the presence of LAN repeaters that could partition a shared media LAN, thus causing  
2 stations to appear to move when the partition was repaired later—with the only Bridge Port changing Port Role or Port  
3 State transitioning to Discarding at that time. This scenario does not occur with current technology, and its future  
4 likelihood does not justify the use of TCNs to signal connectivity loss. Bridge Ports that participate in the MAC status  
5 propagation protocol (Clause 23) should be capable of originating TCNs when that protocol signals additional  
6 connectivity.

7 The Topology Change state machine (13.39) avoids removing learned information when ports temporarily  
8 revert to Discarding to suppress loops. It treats a port as joining the active topology when it becomes  
9 forwarding, and no longer active when it becomes an Alternate, Backup, or Disabled Port and stops  
10 forwarding and learning. TCNs are not generated following Edge Port (operEdge, 13.27.44) Port State  
11 changes, as these do not affect connectivity or station location information in the rest of the network, nor are  
12 Dynamic Filtering Entries for Edge Ports removed when TCNs are received.

13 Dynamic Filtering Entries for MAC addresses previously learned on a Root Port may be modified to move  
14 those addresses to an Alternate Port that becomes the new Root Port and a TCN sent only through the new  
15 Root Port (and not through other active ports), reducing the need to flood frames. This optimization is  
16 possible because a retiring Root Port that becomes Discarding temporarily partitions the active topology into  
17 two subtrees, one including all Bridges and LANs hitherto reachable through the retiring Root Port, and the  
18 other including all the others. If the new Root Port simply provides a new path to the first of these subtrees,  
19 its stations will not appear to move from the point of view of Bridges in the other subtree. Alternatively if a  
20 the tree reconfiguration is more complex one or more newly Designated Port will become active and will  
21 transmit the necessary TCNs.

22 NOTE 2—The rules described require removal of potentially invalid learned information for a minimum set of ports on  
23 each Bridge. A Bridge implementation can flush information from more ports than strictly necessary, removing (for  
24 example) all Dynamic Filtering Entries rather than just those for the specified ports. This does not result in incorrect  
25 operation, but will result in more flooding of frames with unknown destination addresses.

26 Changes in the active topology of any given MSTI or SPT do not change Dynamic Filtering Entries for the  
27 CIST or any other MSTI or SPT, unless the underlying changes in the physical topology that gave rise to the  
28 reconfiguration also cause those trees to reconfigure. Changes to the CST, i.e., the connectivity provided  
29 between regions, can cause end station location changes for all trees. Changes to an IST can cause CST end  
30 station location changes but do not affect MSTIs in that region unless those trees also reconfigure.

31 On receipt of a CIST TCN Message from a Bridge Port not internal to the region, or on a change in Port Role  
32 for a Bridge Port at the region boundary, TCN Messages are transmitted through each of the other ports of  
33 the receiving Bridge for each MSTI and the Dynamic Filtering Entries for those ports are removed.

34 NOTE 3—The port receiving the CIST TCN Message can be a Master Port, a Designated Port attached to the same LAN  
35 as an STP Bridge, or a Designated Port attached to the same LAN as the Root Ports of Bridges in other regions.

36 TCN Messages for the CIST are always encoded in the same way, irrespective of whether they are perceived  
37 to have originated from topology changes internal to the region or outside it. This allows RST Bridges  
38 whose Root Ports attach to a LAN within an MST Region to receive these TCN Messages correctly.

39 Since each SPT is rooted at the source of the frames assigned to that SPT, or at the point where those frames  
40 enter the SPT Region, entries are only learned for the Root Port of an SPT. Any apparent changes in station  
41 location due to changes in an SPT's active topology only occur when a Bridge changes the Root Port for that  
42 SPT, and are accommodated by removing the Dynamic Filtering Entries for the prior Root Port and FID  
43 associated with the SPT Set. If the same new Root Port is chosen for all SPTs, in the SPT set, with that prior  
44 Root Port, the entries can be moved to the new Root Port rather than simply being deleted.

45 NOTE 4—Dynamic Filtering Entries created by ISIS-SPB as a result of that protocol's direct knowledge of the location  
46 of some stations are not removed when a TCN is received, but can be changed by ISIS-SPB as result of its calculations.

47 NOTE 5—Topology changes for the IST are always propagated by TCNs received and transmitted in BPDUs, and are  
48 not injected as a result of ISIS-SPB calculations as the latter complete prior to new connectivity being established.

## 1 13.20 Managing reconfiguration

2 The priority component of the Bridge Identifier can be managed for the CIST, and independently for each  
3 MSTI, to allow preferential selection of the first choice Root Bridge and of alternate Roots that will be used  
4 if the better choices have failed or lack connectivity. The Port Path Cost of each Bridge Port can also be  
5 managed to allow preferential selection of the path from each Bridge to the Root, with the priority  
6 component of each Bridge's Bridge Identifier providing a manageable tie-breaker between equal cost paths.

7 In the event of LAN or Bridge failure, fastest reconfiguration (and thus highest service availability) can  
8 usually be provided by a Bridge that can substitute a prior Alternate Port for a Root Port that now lacks or  
9 provides inferior connectivity to the Root. Figure 13-2 illustrates a simple topology where most failures can  
10 be handled in this way. Configuration to place a backup Root Bridge adjacent to the primary (Bridges 222  
11 and 111 in the figure, respectively) enables Alternate Port to Root Port failover in the other Bridges. If the  
12 original Root Port and its replacement Alternate Port have the same Root Port Path Cost, Bridges further  
13 from the Root will not see a topology change. Figure 13-5 illustrates a ring topology, where simple failover  
14 copes with few failures. However, locating a backup Root Bridge adjacent to the preferred Root remains  
15 effective in reducing the effect of any change.

16 RSTP and MSTP are distance vector protocols: following the failure of a Root Bridge (or selection of a  
17 costlier path to the Root) spanning tree priority vectors conveying the prior Root can circulate in the network  
18 until that information ages out (i.e., until Message Age exceeds Max Age, or the remainingHops parameter  
19 is decremented to zero). To accommodate a wide range of networks, the default setting of these parameters  
20 permit 20 hops. However, if the preferred and alternate Roots are located at the center of the network, many  
21 networks can be configured with minimal values (6 hops, Table 13-5) so each message can only be received  
22 by any node at most twice. In larger networks, for example ring backbones with other Bridges redundantly  
23 attached to adjacent Bridges in the ring, the unwanted effects of recirculating information can be prevented  
24 by configuring the restrictedRole parameter (13.27.64). This parameter prevents information from being  
25 propagated through ports that should never provide connectivity toward the Root. In Figure 13-3, for  
26 example, restrictedRole could be configured for any or all of the Designated Ports.

27 Other potentially disruptive effects of reconfiguration can be prevented or mitigated by setting the  
28 restrictedTcn parameter (13.27.65) for a port.

29 The configuration of a subtree of a spanning tree defined by the connectivity provided by a given Bridge *B*  
30 (say) can be made independent of the rest of the tree by configuring *B*'s Root Port as a Layer 2 Gateway Port  
31 (L2GP). An L2GP Port behaves as if it is in continual receipt of a fixed, manageable, spanning tree priority  
32 vector. Provided that this fixed priority vector is worse than the actual priority vector transmitted by the  
33 Designated Port for the LAN attached to *B*'s Root Port, there is no potential for a loop. Each port in the  
34 subtree will transmit a worse priority vector. If a received message priority vector is worse than the fixed  
35 value the disputed flag is set, causing the L2GP port to transition to Discarding. Thus stability of the  
36 spanning tree priority vector information in the subtree is maintained, at the possible expense of the  
37 connectivity between the subtree and the rest of the tree. Alternatively, if another Bridge within *B*'s subtree  
38 becomes the source of better priority information, causing *B*'s L2GP port to assume a Designated Port Role,  
39 a dispute will exist between the newly propagated spanning tree information and the fixed information for  
40 the L2GP port, and will also cause that port to become Discarding.

41 The L2GP capability is optional, and is primarily intended to be used for service access protection (25.9)  
42 when a single customer's Bridged Network is connected to a PBBN or a PBN. Two or more Bridge Ports on  
43 one or more of the Bridges within the customer's network, are connected to a single service instance  
44 supported by the provider's network, and are configured as L2GP ports. The L2GP ports' fixed priority  
45 vectors are each defined by a different, configured pseudoRootId (13.27.51). Only the L2GP port with the  
46 best pseudoRootId can provide connectivity to the provider's network. Spanning tree information from that  
47 port will be disseminated throughout the customer's network and will be disputed by the other L2GP port,  
48 causing the latter to become Discarding. If all the customer network's ports that are bridged to other

networks (such as PBNs or PBBNs) are configured as L2GP ports, those ports neither have to transmit or receive BPDUs to prevent loops—though connectivity through providers' networks to other networks will not be protected. Enabling BPDU reception for each L2GP port prevents loops that might otherwise be caused by attaching another of the customer's network's ports to the provider network.

### 13.21 Partial and disputed connectivity

It is possible for the connectivity between Bridge Ports attached to the same LAN to fail, in system or media access method-dependent ways, so that BPDUs and data frames are transmitted in one direction only. As a result it is possible for more than one port attached to the same LAN to believe itself to be the Designated Port. To ensure that the active topology remains loop-free, a Designated Port will recognize that a dispute is in progress and stop learning from or forwarding frames, if it receives a BPDU with a worse message priority and the Learning flag set from another port that claims to be Designated.

If two (Designated) ports attached to the same shared media LAN cannot communicate with each other at all, but can each communicate with a third (Root) port, a potential loop exists if one of the Designated Ports has a priority vector that is worse than that of the Root Port. To ensure that such loop does not occur, a Root Port that receives an inferior message from a Designated Port detects a dispute if the Learning flag is set, and transitions to Discarding.

### 13.22 In-service upgrades

It can be desirable to upgrade the control plane software of a bridging system, without interrupting existing data connectivity, while the Spanning Tree Protocol Entity is not operating. This can be done, without the risk of creating data loops, providing that the other Bridges in the network are suitably configured. However, the failure of a network component (Bridge or LAN) while the upgrade is in progress can result in a loss of connectivity, as the ways in which the network can reconfigure are restricted. This subclause (13.22) describes the necessary configuration of the other Bridges in the network; the behavior of the upgrading system is assumed to be system dependent and is not specified in detail, except as follows:

- a) Frames can be received from and transmitted to ports that were forwarding prior to beginning the upgrade, and are not forwarded to or from any other port.
- b) Frames received on ports that were learning prior to beginning the upgrade can be submitted to the Learning Process, while frames received on other ports are not.
- c) BPDUs are not transmitted, and received BPDUs are discarded, while the upgrade is in progress.
- d) If there is to be no interruption in connectivity when the upgrade is complete, the parameters of BPDUs received prior to beginning the upgrade are retained, or recovered using ISIS-SPB.

NOTE 1—If received BPDU information is not retained, the spanning tree protocol variables and state machines are reinitialized by asserting BEGIN, and there will be a brief interruption in connectivity.

The need for a control plane software upgrade can result from the need to change any component of that software, and rarely from upgrades to the Spanning Tree Protocol Entity itself. The in-service upgrade procedures described here depend on the operation of specifically identified features of the RSTP, MSTP, and ISIS-SPB specified in this standard (Clause 13), and do not ensure loop-free operation if the necessary criteria are not met by all Bridges in the network. In particular, safe upgrades are not supported in networks including Bridges operating STP as specified in the IEEE Std 802.1D, 1998 Edition [B13], and earlier revisions. It is essential for the network administrator to base-line the network, i.e., verify its configuration and the configuration of its components, prior to attempting an in-service upgrade. It is recommended that a single system be upgraded at a time, and its subsequent correct operation verified prior to making further changes.

1 If all the LANs that connect the Bridges in the network provide point-to-point connectivity, connecting at  
2 most two Bridges, and each Bridge Port thus connecting to another Bridge meets the following conditions:

- 3 e) operPointToPointMAC (13.28.16) is TRUE and
- 4 f) operEdge (13.27.44) is FALSE,

5 NOTE 2—Apart from the requirement for a point-to-point physical topology, these conditions can be ensured by setting  
6 adminPointToPointMAC (IEEE Std 802.1AC) TRUE, and both AdminEdge and AutoEdge FALSE.

7 then a Designated Port will not transition from Discarding to Learning or Forwarding without receiving an  
8 Agreement from its immediate neighbor (see 13.37). This prevents the introduction of data loops while one  
9 or more Bridges are being upgraded, even if other Bridges or LANs fail or are added to the network. To  
10 prevent existing connectivity being disrupted (provided no other network additions or failures occur) the  
11 following are also necessary:

- 12 g) Prior to the upgrade, each of the upgrading Bridge's immediately neighboring ports that is a Root  
13 Port (for a given tree) has to be configured as an Layer 2 Gateway Port (13.20) (for that tree), with  
14 the same information that it was previously receiving from the upgrading Bridge.
- 15 h) After the upgrade, each of the ports thus temporarily configured as an Layer 2 Gateway Port needs  
16 to have its normal configuration restored.

17 NOTE 3—If the upgrading Bridge is capable of sending periodic 'canned BPDUs' containing the same information as  
18 immediately prior to the upgrade, there is no requirement for neighbor L2GP configuration, or for the point-to-point and  
19 operEdge conditions. Attempts by neighboring Bridges to operate outside the parameters dictated by the 'canned  
20 BPDUs' will result in disputes, preventing new connectivity.

21 On the SPB ports within an SPT Region, the functions of the Layer 2 Gateway Port described in item g) and  
22 item h) above are replaced by those of "Restart Signaling for IS-IS" (IETF RFC 5306 [B37]), which allows  
23 the forwarding state across an adjacency to be maintained while an IS-IS element is restarted. When the  
24 neighbor (running) shortest path Bridge receives a restart request, it performs the procedures of IETF  
25 RFC 5306, and for as long as it maintains the state of the IS-IS adjacency as "UP" it also maintains its  
26 received Agreement Digest at the last value received from the restarting Bridge before it requested restart. If  
27 the adjacency is successfully reacquired by the procedures of IETF RFC 5306, as signaled by the restarting  
28 Bridge clearing the Restart Request bit in an SPB Hello PDU, its running neighbor shall include its current  
29 Agreement Digest value in its SPB Hello response [and update it as required thereafter according to the  
30 Agreement Protocol (13.17)].

31 Once the restarting Bridge has achieved LSP Database Synchronization according to the procedures of IETF  
32 RFC 5306 [B37], it shall compute its local value of the Agreement Digest prior to making any changes to its  
33 FDB. On ports for which a Digest match is achieved with a neighbor, full installation of unicast and  
34 multicast state may be performed immediately. On ports that do not have a Digest match (caused for  
35 example by a propagating topology change), the restarting Bridge shall assume when computing allowed  
36 forwarding entries that Digest Agreement has never been achieved on the affected adjacency (where  
37 "allowed" is determined by the value of the Agreement Digest Convention Identifier; see 28.4.3). In either  
38 event, a Digest Agreement shall be sent to the neighbor as soon as possible, as specified by the Agreement  
39 Protocol.

40 SPB ports on the boundary of an SPT Region use the procedures of a) to h) unaltered.

### 41 13.23 Fragile Bridges

42 Some, nonconformant, bridging systems are known to be "fragile," i.e., they can suffer from unpredictable  
43 interruptions to Spanning Tree Protocol Entity operation and will forward data frames while no longer  
44 sending or receiving BPDUs, on some or all ports. If the spanning tree protocol implementations of the other  
45 Bridges in the network conform to prior revisions of this standard and IEEE Std 802.1D-2004 [B14], these  
46 interruptions can result data loops even in networks of point-to-point LANs. This revision of this standard  
47 allows a Bridge Port attached to point-to-point LAN to ensure that its neighbor remains capable of receiving

1 and transmitting BPDUs, even if that neighbor's RSTP or MSTP implementation conforms to a prior  
2 revision of this standard, and to block connectivity (by transitioning to Discarding) otherwise. The CIST  
3 Proposal flag is set in all BPDUs transmitted by a Designated Port, and used to solicit an Agreement from  
4 the neighbor (which might otherwise not transmit). This capability is controlled by the AutoIsolate  
5 (13.27.19) variable, is disabled by default to allow for in-service upgrades, and is only effective if the  
6 neighboring Bridge is capable of RSTP or MSTP operation.

## 7 **13.24 Spanning tree protocol state machines**

8 Each Spanning Tree Protocol Entity's operation of the protocols specified in this clause (Clause 13) is  
9 specified by the following state machines:

10 a) Port Role Selection (PRS, 13.36)

11 for the CIST and for each MSTI, with the following state machines for each Bridge Port:

12 b) Port Timers (PTI, 13.30)

13 c) Port Protocol Migration (PPM, 13.32)

14 d) Port Receive (PRX, 13.31)

15 e) Port Transmit (PRT, 13.34)

16 f) Bridge Detection (BDM, 13.33)

17 and the following optional state machine for each Bridge Port:

18 g) Layer 2 Gateway Port Receive (L2GPRX, 13.40)

19 and the following state machines for each Bridge Port for the CIST and for each MSTI:

20 h) Port Information (PIM, 13.35)

21 i) Topology Change (TCM, 13.39)

22 and the following state machines for each Bridge Port for the CIST, for each MSTI, and for each SPT:

23 j) Port Role Transitions (PRT, 13.37)

24 k) Port State Transition (PST, 13.38)

25 Each state machine and its associated variable and procedural definitions are specified in detail in 13.25  
26 through 13.40. The state machine notation is specified in Annex E. Figure 13-13 is not itself a state machine  
27 but provides an overview of the state machines, their state variables, and communication between machines.  
28 Figure 13-14 describes its notation.

## 29 **13.25 State machine timers**

30 The timer variables declared in this subclause are part of the specification. The accompanying descriptions  
31 are provided to aid in the comprehension of the protocol only, and are not part of the specification. Each  
32 timer variable represents an integral number of seconds before timer expiry.

33 One instance of the following shall be implemented per port:

34 a) edgeDelayWhile (13.25.1)

35 b) helloWhen (13.25.3)

36 c) mdelayWhile (13.25.4)

37 One instance of the following shall be implemented per port when L2GP functionality is provided:

38 d) pseudoInfoHelloWhen (13.25.10)

**Figure 13-13—Spanning tree protocol state machines—overview and relationships**

**NOTATION:**

Variables are shown both within the machine where they are principally used and between machines where they are used to communicate information. In the latter case they are shown with a variety of arrow styles, running from one machine to another, that provide an overview of how the variables are typically used:

→ Not changed by the target machine. Where the state machines are both per Port, this variable communicates between machine instances for the same port.

⇨ Set (or cleared) by the originating machine, cleared (or set) by the target machine. Where the state machines are both per Port, this variable communicates between machine instances for the same port.

⇨⇨ As above except that the originating per port machine instance communicates with multiple port machine instances (by setting or clearing variables owned by those Ports).

⇨⇨⇨ As above except that multiple per Port instances communicate with (an) other instance(s) (by setting or clearing variables owned by the originating Ports).

**ABBREVIATIONS:**

BDM: Bridge Detection Machine  
PIM: Port Information Machine  
PPM: Port Protocol Migration Machine  
PRS: Port Role Selection Machine  
PRT: Port Role Transitions Machine  
PRX: Port Receive Machine  
PST: Port State Transitions Machine  
PTI: Port Timers Machine  
PTX: Port Transmit Machine  
TCM: Topology Change Machine

**Figure 13-14—MSTP overview notation**

1 One instance per port of the following shall be implemented for the CIST and one per port for each MSTI:

- 2 e) fdWhile (13.25.2)
- 3 f) rrWhile (13.25.7)
- 4 g) rbWhile (13.25.5)
- 5 h) tcWhile (13.25.9)
- 6 i) rcvdInfoWhile (13.25.6)
- 7 j) tcDetected (13.25.8)

8 Table 13-5 specifies values and ranges for the initial values of timers and for transmission rate limiting  
9 performance parameters. Default values are specified to avoid the need to set values prior to operation in  
10 most cases, and are widely applicable to networks using the spanning tree protocols specified in this  
11 standard. The table recommends Bridge Hello Time, Bridge Max Age, and Bridge Forward Delay values  
12 that maximize interoperability in networks that include Bridges using STP as specified in IEEE Std 802.1D,  
13 1998 Edition [B13]. Ranges are specified to ensure that the protocols operate correctly.

**Table 13-5—Timer and related parameter values**

| Parameter            | Default | Permitted range | Interoperability recommendations |
|----------------------|---------|-----------------|----------------------------------|
| Migrate Time         | 3.0     | — <sup>a</sup>  | — <sup>a</sup>                   |
| (Bridge) Hello Time  | 2.0     | — <sup>a</sup>  | — <sup>a</sup>                   |
| Bridge Max Age       | 20.0    | 6.0–40.0        | 20.0                             |
| Bridge Forward Delay | 15.0    | 4.0–30.0        | 15.0                             |
| Transmit Hold Count  | 6       | 1–10            | 6                                |
| Max Hops             | 20      | 6–100           | —                                |

All times are in seconds. —<sup>a</sup> Not applicable, value is fixed.

14 NOTE—Changes to Bridge Forward Delay do not affect reconfiguration times, unless the network includes Bridges that  
15 do not conform to this revision of this standard. Changes to Bridge Max Age can have an effect, as it is possible for old  
16 information to persist in loops in the physical topology for a number of “hops” equal to the value of Max Age in seconds,  
17 and thus exhaust the Transmit Hold Count in small loops. The IEEE Std 802.1Qdy amendment to this standard increased  
18 the permitted range of Max Hops to allow a spanning tree to provide initial and remedial connectivity in extended ring  
19 topologies whenever physical connectivity is possible. Once configured such networks are not expected to depend on  
20 spanning tree for failure protection.

1 Bridge Max Age, Bridge Forward Delay, and Transmit Hold Count may be set by management, if this  
2 capability is provided the Bridge shall have the capability to use the full range of values in the parameter  
3 ranges specified in the “Permitted range” column of Table 13-5, with a timer resolution of  $r$  seconds, where  
4  $0 < r \leq 1$ . To support interoperability with previous revisions of this standard and IEEE Std 802.1D-2004  
5 [B14], a Bridge shall enforce the following relationships:

$$6 \quad 2 \times (\text{Bridge\_Forward\_Delay} - 1.0 \text{ seconds}) \geq \text{Bridge\_Max\_Age}$$

$$7 \quad \text{Bridge\_Max\_Age} \geq 2 \times (\text{Bridge\_Hello\_Time} + 1.0 \text{ seconds})$$

### 8 **13.25.1 edgeDelayWhile**

9 The Edge Delay timer. The time remaining, in the absence of a received BPDU, before this port is identified  
10 as an operEdgePort.

### 11 **13.25.2 fdWhile**

12 The Forward Delay timer. Used to delay Port State transitions until other Bridges have received spanning  
13 tree information.

### 14 **13.25.3 helloWhen**

15 The Hello timer. Used to ensure that at least one BPDU is transmitted by a Designated Port in each  
16 HelloTime period.

### 17 **13.25.4 mdelayWhile**

18 The Migration Delay timer. Used by the Port Protocol Migration state machine to allow time for another  
19 RST Bridge on the same LAN to synchronize its migration state with this port before the receipt of a BPDU  
20 can cause this port to change the BPDU types it transmits. Initialized to MigrateTime (13.26.6).

### 21 **13.25.5 rbWhile**

22 The Recent Backup timer. Maintained at its initial value, twice HelloTime, while the port is a Backup Port.

### 23 **13.25.6 rcvdInfoWhile**

24 The Received Info timer. The time remaining before information, i.e., portPriority (13.27.47) and portTimes  
25 (13.27.48), received in a Configuration Message is aged out if a further message is not received.

### 26 **13.25.7 rrWhile**

27 The Recent Root timer.

### 28 **13.25.8 tcDetected**

29 The Topology Change timer for MRP application usage. ‘New’ messages are sent while this timer is running  
30 (see 10.2).

### 31 **13.25.9 tcWhile**

32 The Topology Change timer. TCN Messages are sent while this timer is running.

### 33 **13.25.10 pseudoInfoHelloWhen**

34 The Pseudo Info Hello When timer. Used by the Layer 2 Gateway Port Receive (L2GPRX, 13.40) state  
35 machine to prompt the simulated reception at HelloTime intervals of a BPDU (see 13.29.11).

## 1 **13.26 Per Bridge variables**

2 The variables declared in this subclause (13.26) are part of the specification. The accompanying descriptions  
3 are provided to aid in the comprehension of the protocol only, and are not part of the specification.

4 There is one instance per Bridge component of the following variable(s):

- 5 a) ForceProtocolVersion (13.26.5)
- 6 b) TxHoldCount (13.26.12)
- 7 c) MigrateTime (13.26.6)

8 One instance of the following shall be implemented per Bridge component if MSTP or ISIS-SPB is  
9 implemented:

- 10 d) MstConfigId (13.26.7)

11 The above parameters [item a) through item d)] are not modified by the operation of the spanning tree  
12 protocols, but are treated as constants by the state machines. If ForceProtocolVersion or MstConfigId are  
13 modified by management, BEGIN shall be asserted for all state machines.

14 There is one instance per Bridge of each of the following for the CIST and one for each MSTI.

- 15 e) BridgeIdentifier (13.26.2)
- 16 f) BridgePriority (13.26.3)
- 17 g) BridgeTimes (13.26.4)
- 18 h) rootPortId (13.26.9)
- 19 i) rootPriority (13.26.10)
- 20 j) rootTimes (13.26.11)

21 BridgeIdentifier, BridgePriority, and BridgeTimes are not modified by the operation of the spanning tree  
22 protocols but are treated as constants by the state machines. If they are modified by management, spanning  
23 tree priority vectors and Port Role assignments for all trees shall be recomputed, as specified by the  
24 operation of the Port Role Selection state machine (13.36) by clearing selected (13.27.67) and setting  
25 reselect (13.27.62) for all Bridge Ports for the relevant MSTI and for all trees if the CIST parameter is  
26 changed.

27 If the ISIS-SPB is implemented there is one instance per Bridge component, of the following variable(s),  
28 with that single instance supporting all SPTs:

- 29 k) agreementDigest (13.26.1)
- 30 l) AuxMstConfigId (13.26.8)

### 31 **13.26.1 agreementDigest**

32 The Agreement Digest calculated by ISIS-SPB (28.4), and updated with other calculated parameters (see  
33 13.36).

### 34 **13.26.2 BridgeIdentifier**

35 The unique Bridge Identifier assigned to this Bridge for this tree (CIST or MSTI).

36 The 12-bit system ID extension component of a Bridge Identifier (14.2.5) shall be set to zero for the CIST  
37 and to the value of the MSTID for an MSTI, thus allocating distinct Bridge Identifiers to the CIST and each  
38 MSTI—all based on the use of a single Bridge Address component value for the MST Bridge as a whole.

39 NOTE—This convention is used to convey the MSTID for each MSTI Configuration Message in an MST BPDU.

1 The most significant 4 bits of the Bridge Identifier (the settable Priority component) for the CIST and for  
2 each MSTI can be modified independently of the setting of those bits for all other trees, as a part of allowing  
3 full and independent configuration control to be exerted over each spanning tree instance.

#### 4 **13.26.3 BridgePriority**

5 For the CIST, the value of the CIST Bridge priority vector, as defined in 13.10. The CIST Root Identifier,  
6 CIST Regional Root Identifier, and Designated Bridge Identifier components are all equal to the value of the  
7 CIST Bridge Identifier. The remaining components (External Root Path Cost, Internal Root Path Cost, and  
8 Designated Port Identifier) are set to zero.

9 For a given MSTI, the value of the MSTI Bridge priority vector, as defined in 13.11. The MSTI Regional  
10 Root Identifier and Designated Bridge Identifier components are equal to the value of the MSTI Bridge  
11 Identifier (13.26.2). The remaining components (MSTI Internal Root Path Cost, Designated Port Identifier)  
12 are set to zero.

13 BridgePriority is used by updtRolesTree() in determining the value of the rootPriority variable (see 13.26.10).

#### 14 **13.26.4 BridgeTimes**

15 For the CIST, BridgeTimes comprises:

- 16 a) The current values of Bridge Forward Delay and Bridge Max Age (13.25, Table 13-5).
- 17 b) A Message Age value of zero.
- 18 c) The current value of Max Hops (13.25, Table 13-5). This parameter value is determined only by  
19 management.

20 For a given MSTI, BridgeTimes comprises:

- 21 d) The current value of MaxHops (Max Hops in Table 13-5), the initial value of remainingHops for  
22 MSTI information generated at the boundary of an MSTI region (see 13.26.11).

23 BridgeTimes is used by updtRolesTree() in determining the value of the rootTimes variable (13.26.11).

#### 24 **13.26.5 ForceProtocolVersion**

25 The Force Protocol Version parameter for the Bridge (13.7.2).

#### 26 **13.26.6 MigrateTime**

27 The value of the Migrate Time parameter as specified in Table 13-5. This value shall not be changed.

#### 28 **13.26.7 MstConfigId**

29 The current value of the Bridge's MCID (13.8). Changes in this parameter cause BEGIN to be asserted for  
30 the state machines for the Bridge, for all trees, and for each port.

#### 31 **13.26.8 AuxMstConfigId**

32 The previous value of the Bridge's MCID (13.8). This value is saved in nonvolatile memory when certain  
33 non-critical configuration is made if the Bridge supports the ISIS-SPB non critical changes (27.4.1).

#### 34 **13.26.9 rootPortId**

35 For the CIST, the Port Identifier of the Root Port, and a component of the CIST root priority vector (13.10).

36 For a given MSTI, the Port Identifier of the Root Port, and a component of the MSTI root priority vector  
37 (13.11).

### 1 **13.26.10 rootPriority**

2 For the CIST: the Root Identifier, External Root Path Cost, Regional Root Identifier, Internal Root Path  
3 Cost, Designated Bridge Identifier, and Designated Port Identifier components of the Bridge's CIST root  
4 priority vector (13.10).

5 For a given MSTI: the MSTI Regional Root Identifier, Internal Root Path Cost, Designated Bridge  
6 Identifier, and Designated Port Identifier components of the Bridge's MSTI root priority vector (13.11).

### 7 **13.26.11 rootTimes**

8 For the CIST, the Bridge's timer parameter values (Message Age, Max Age, Forward Delay, and  
9 remainingHops). The values of these timers are derived (see 13.29.34) from the values stored in the CIST's  
10 portTimes parameter (13.27.48) for the Root Port or from BridgeTimes (13.26.4).

11 For a given MSTI, the value of remainingHops derived (13.29.34) from the value stored in the MSTI's  
12 portTimes parameter (13.27.48) for the Root Port or from BridgeTimes (13.26.4).

### 13 **13.26.12 TxHoldCount**

14 The value of Transmit Hold Count (Table 13-5) for the Bridge. If this is modified, the value of txCount  
15 (13.27) for all ports shall be set to zero.

## 16 **13.27 Per port variables**

17 The variables declared in this subclause (13.27) are part of the specification. The accompanying descriptions  
18 are provided to aid in the comprehension of the protocol only, and are not part of the specification.

19 There is one instance per port of each of the following variables:

- 20 a) AdminEdge (13.27.1)
- 21 b) ageingTime (13.27.2)
- 22 c) AutoEdge (13.27.18)
- 23 d) Autololate (13.27.19)
- 24 e) enableBPDURx (13.27.23)
- 25 f) enableBPDUTx (13.27.24)
- 26 g) ExternalPortPathCost (13.27.25)
- 27 h) isL2gp (13.27.26)
- 28 i) isolate (13.27.27)
- 29 j) mcheck (13.27.38)
- 30 k) newInfo (13.27.42)
- 31 l) operEdge (13.27.44)
- 32 m) portEnabled (13.27.45)
- 33 n) rcvdBpdu (13.27.52)
- 34 o) rcvdRSTP (13.27.56)
- 35 p) rcvdSTP (13.27.57)
- 36 q) rcvdTcAck (13.27.59)
- 37 r) rcvdTcn (13.27.60)
- 38 s) restrictedRole (13.27.64)
- 39 t) restrictedTcn (13.27.65)
- 40 u) sendRSTP (13.27.69)
- 41 v) tcAck (13.27.72)
- 42 w) tick (13.27.74)
- 43 x) txCount (13.27.75)

1 If MSTP or the ISIS-SPB is implemented, there is one instance per port, applicable to the CIST and to all  
2 MSTIs and SPTs, of the following variable(s):

- 3 y) rcvdInternal (13.27.54)
- 4 z) restrictedDomainRole (13.27.63)

5 If MSTP or the ISIS-SPB is implemented, there is one instance per port of each of the following variables  
6 for the CIST:

- 7 aa) infoInternal (13.27.31)
- 8 ab) master (13.27.36)
- 9 ac) mastered (13.27.37)

10 A single per port instance of the following variable(s) applies to all MSTIs:

- 11 ad) newInfoMsti (13.27.43)

12 If the Layer 2 Gateway Port Receive state machine (13.20, 13.40) is implemented for a port, there is one  
13 instance for the CIST, and one instance for each MSTI, for that port of the following variable:

- 14 ae) pseudoRootId (13.27.51)

15 If the ISIS-SPB is implemented, there is one instance per port of the following variable(s):

- 16 af) agreedMisorder (13.27.10)
- 17 ag) agreedN (13.27.11)
- 18 ah) agreedND (13.27.12)
- 19 ai) agreeN (13.27.16)
- 20 aj) agreeND (13.27.17)

21 If the ISIS-SPB is implemented, there is one instance per port of the following variable(s), with that single  
22 instance supporting all SPTs:

- 23 ak) agreedDigest (13.27.6)
- 24 al) agreedDigestValid (13.27.7)
- 25 am) agreeDigest (13.27.8)
- 26 an) agreeDigestValid (13.27.9)
- 27 ao) agreedTopology (13.27.14)

28 There is one instance per port of each of the following variables for the CIST, one per port for each MSTI  
29 and one per port for each SPT:

- 30 ap) agree (13.27.3)
- 31 aq) agreed (13.27.4)
- 32 ar) designatedPriority (13.27.20)
- 33 as) designatedTimes (13.27.21)
- 34 at) disputed (13.27.22)
- 35 au) fdbFlush (13.27.28)
- 36 av) forward (13.27.29)
- 37 aw) forwarding (13.27.30)
- 38 ax) infols (13.27.32)
- 39 ay) InternalPortPathCost (13.27.33)
- 40 az) learn (13.27.34)
- 41 ba) learning (13.27.35)
- 42 bb) msgPriority (13.27.39)
- 43 bc) msgTimes (13.27.40)
- 44 bd) portId (13.27.46)
- 45 be) portPriority (13.27.47)

- 1 bf) portTimes (13.27.48)
- 2 bg) proposed (13.27.49)
- 3 bh) proposing (13.27.50)
- 4 bi) rcvdInfo (13.27.53)
- 5 bj) rcvdMsg (13.27.55)
- 6 bk) rcvdTc (13.27.58)
- 7 bl) reRoot (13.27.61)
- 8 bm) reselect (13.27.62)
- 9 bn) role (13.27.66)
- 10 bo) selected (13.27.67)
- 11 bp) selectedRole (13.27.68)
- 12 bq) sync (13.27.70)
- 13 br) synced (13.27.71)
- 14 bs) tcProp (13.27.73)
- 15 bt) updtInfo (13.27.76)

16 If the ISIS-SPB is implemented, there is one instance per port of the following variable(s) for the CIST and  
17 one per port for each SPT:

- 18 bu) agreedPriority (13.27.13)
- 19 bv) agreementOutstanding (13.27.15)

20 If the ISIS-SPB is implemented, there is one instance per port of the following variables for each SPT:

- 21 bw) agreedAbove (13.27.5)
- 22 bx) neighbourPriority (13.27.41)

### 23 13.27.1 AdminEdge

24 A Boolean. Set by management if the port is to be identified as operEdge immediately on initialization,  
25 without a delay to detect other Bridges attached to the LAN. The recommended default value is FALSE.

### 26 13.27.2 ageingTime

27 FDB entries for this port are aged out after ageingTime has elapsed since they were first created or refreshed  
28 by the Learning Process. The value of this parameter is normally Ageing Time (8.8.3, Table 8-9), and is  
29 changed to FwdDelay (13.28.10) for a period of FwdDelay after fdbFlush (13.27.28) is set by the topology  
30 change state machine if stpVersion (13.28.23) is TRUE.

### 31 13.27.3 agree

32 A Boolean. See 13.16 and Figure 13-12.

### 33 13.27.4 agreed

34 A Boolean. Set, for the CIST or an MSTI, if an Agreement has been received indicating that the Port States  
35 and transmitted priority vectors for the other Bridge attached to this LAN are (and, in the absence of further  
36 communication with this Bridge and within the design probabilities of protocol failure due to repeated  
37 BPDU loss, will remain) compatible with a loop-free active topology determined by this port's priority  
38 vectors (13.16, 13.24).

### 39 13.27.5 agreedAbove

40 A Boolean controlled by the updtAgreement() procedure to indicate agreement on the neighbor(s) superior  
41 priority vector.

1 **13.27.6 agreedDigest**

2 The Agreement Digest conveyed in the last BPDU received, if the port is internal to an SPT Region.

3 **13.27.7 agreedDigestValid**

4 A Boolean. TRUE if the Agreement Valid flag was set in the last BPDU or SPB Hello PDU that conveyed an  
5 Agreement Digest.

6 **13.27.8 agreeDigest**

7 The Agreement Digest currently encoded in SPT BPDUs transmitted from the port.

8 **13.27.9 agreeDigestValid**

9 A Boolean. TRUE if the Agreement Valid flag is to be set in transmitted SPT BPDUs and SPB Hello PDUs.

10 **13.27.10 agreedMisorder**

11 A Boolean. TRUE if the Agreement Protocol (13.16, 13.17) has received an out of order message as  
12 indicated by the received Agreement Number (13.27.16), reset when an in order message is received.

13 **13.27.11 agreedN**

14 The Agreement Number associated with the last BPDU received, if the port is within an SPT Region.  
15 It takes values 0, 1, 2, or 3, and all arithmetic using this variable is modulo 4, e.g.,  $1 + 1 = 2$ ,  $3 + 1 = 0$ ,  $0 - 1$   
16  $= 3$ .

17 **13.27.12 agreedND**

18 The Discarded Agreement Number (see 13.17) to be included in SPT BPDUs transmitted from the port. The  
19 variable values 0, 1, 2, or 3, are encoded in a two-bit field and all arithmetic using this variable is modulo 4.

20 **13.27.13 agreedPriority**

21 The priority vector associated with the worst priority received by a CIST or SPT Designated Port from an  
22 SPT Region in SPT BPDUs that are sent by Root Ports, zero if there is no such agreement.

23 **13.27.14 agreedTopology**

24 A Boolean. TRUE if the Agreement Protocol has declared a topology match for agreeDigest (13.27.8), and  
25 agreeDigest has the same value as the last calculated agreementDigest (13.26.1). Reset to FALSE whenever  
26 agreementDigest is recalculated by ISIS-SPB, and set TRUE by updtDigest().

27 **13.27.15 agreementOutstanding**

28 The priority vector for the worst priority associated with outstanding Agreements made by a CIST or SPT  
29 Root Port, Alternate Port, or Backup Port within an SPT Region. in SPT BPDUs. When an SPT BPDU, from  
30 the same SPT Region, is received with a Discarded Agreement Number that is the immediate precursor of  
31 the current agreeN (13.27.16), the CIST's agreementOutstanding is set to the port's designatedPriority. On  
32 reception of a BPDU that is either not an SPT BPDU or is from a different SPT Region, the agreeND  
33 (13.27.17) is set to the value of the agreeN (13.27.16), so there is no outstanding Agreement.

34 **13.27.16 agreeN**

35 The Agreement Number (see 13.17) transmitted in SPT BPDUs. The variable values 0, 1, 2, or 3, are  
36 encoded in a two-bit field and arithmetic using this variable is modulo 4.

### 1 **13.27.17 agreeND**

2 The last Discarded Agreement Number (see 13.17) received in an SPT BPDU. It takes values 0, 1, 2, or 3,  
3 and arithmetic using this variable is modulo 4. If agreeND matches agreeN, there is no outstanding  
4 agreement.

### 5 **13.27.18 AutoEdge**

6 A Boolean. Set by management if the Bridge detection state machine (BDM, 13.33) is to detect other  
7 Bridges attached to the LAN, and set operEdge automatically. The recommended default is TRUE.

### 8 **13.27.19 Autolsolate**

9 A Boolean. Set by management if isolate (13.27.27) is to be set, causing a Designated Port to transition to  
10 Discarding if both AdminEdge (13.27.1) and AutoEdge (13.27.18) are FALSE and the other Bridge  
11 presumed to be attached to the same point-to-point LAN does not transmit periodic BPDUs—either as a  
12 Designated Port or in response to BPDUs with the Proposal flag set (see 13.23). The recommended default  
13 of this parameter is FALSE. AdminEdge and AutoEdge are both reset only on ports that are known to  
14 connect to other Bridges.

### 15 **13.27.20 designatedPriority**

16 For the CIST and a given port, the CIST Root Identifier, External Root Path Cost, Regional Root Identifier,  
17 Internal Root Path Cost, Designated Bridge Identifier, and Designated Port Identifier components of the  
18 port's CIST designated priority vector, as defined in 13.10.

19 For a given MSTI and port, the Regional Root Identifier, Internal Root Path Cost, Designated Bridge  
20 Identifier, and Designated Port Identifier components of the designated priority vector, as defined in 13.11.

### 21 **13.27.21 designatedTimes**

22 For the CIST and a given port, the set of timer parameter values (Message Age, Max Age, Forward Delay,  
23 and remainingHops) that are used to update Port Times when updtnfo is set. These timer parameter values  
24 are used in BPDUs transmitted from the port. The value of designatedTimes is copied from the CIST  
25 rootTimes Parameter (13.26.11) by the operation of the updRolesTree() procedure.

26 For a given MSTI and port, the value of remainingHops used to update this MSTI's portTimes parameter  
27 when updtnfo is set. This timer parameter value is used in BPDUs transmitted from the port. The  
28 updRolesTree() procedure (13.29.34) copies designatedTimes from the MSTI's rootTimes (13.26.11).

### 29 **13.27.22 disputed**

30 A Boolean. See 13.21, 13.20, Figure 13-20, 13.29.16, Figure 13-24, and Figure 13-25.

### 31 **13.27.23 enableBPDURx**

32 A Boolean. This per port management parameter is set by default, and should not be clear unless the port is  
33 configured as a Layer Two Gateway Port (i.e., isL2gp is set). When clear it can allow loops to be created, or  
34 can result in no connectivity. When cleared, BPDUs received on the port are discarded and not processed.

### 35 **13.27.24 enableBPDUTx**

36 A Boolean. This per port management parameter is set by default, and should not be clear unless the port is  
37 configured as a Layer Two Gateway Port (i.e., isL2gp is set). When clear it can allow loops to be created, or  
38 can result in no connectivity. When cleared, no BPDUs are transmitted by this port.

### 1 **13.27.25 ExternalPortPathCost**

2 The port's contribution, when it is the CIST Master Port (for MSTP and ISIS-SPB) or the CST Root Port  
3 (for RSTP and MSTP), to the External Root Path Cost (13.9) for the Bridge.

### 4 **13.27.26 isL2gp**

5 A Boolean. Set by management to identify a port configured to be a Layer Two Gateway Port. This  
6 parameter is set to FALSE by default. When set, enableBPDUTx should be cleared.

### 7 **13.27.27 isolate**

8 A Boolean. Set by the Bridge detection state machine (BDM, 13.33) when the Spanning Tree Protocol  
9 Entity of a neighboring Bridge has apparently failed (see 13.23, 13.27.19).

### 10 **13.27.28 fdbFlush**

11 A Boolean. Set by the topology change state machine to instruct the FDB to remove entries for this port,  
12 immediately if rstpVersion (13.28.21) is TRUE, or by rapid ageing (13.27.2) if stpVersion (13.28.23) is  
13 TRUE. Reset by the FDB once the entries are removed if rstpVersion is TRUE, and immediately if  
14 stpVersion is TRUE. Setting the fdbFlush variable does not result in removal of FDB entries in the case that  
15 the port is an Edge Port (i.e., operEdge is TRUE). The FDB removes entries only for those VIDs that have a  
16 fixed registration (see 10.7.2) on any port of the Bridge that is not an Edge Port.

17 NOTE—If MVRP or MIRP is in use, the topology change notification and flushing mechanisms defined in MRP  
18 (Clause 10) and MVRP (11.2.5) are responsible for filtering entries in the FDB for VIDs that are dynamically registered  
19 using MVRP or MIRP (i.e., for which there is no fixed registration in the Bridge on non-Edge Ports).

### 20 **13.27.29 forward**

21 A Boolean. Set or cleared by the Port Role Transitions state machine (13.37) to instruct the Port State  
22 Transitions state machine (13.38) to enable or disable forwarding.

### 23 **13.27.30 forwarding**

24 A Boolean. Set or cleared by the Port State Transitions state machine (13.38) to indicate that forwarding has  
25 been enabled or disabled.

### 26 **13.27.31 infoInternal**

27 If infoIs Received, indicating that the port has received current information from the Designated Bridge for  
28 the attached LAN, infoInternal is set if that Designated Bridge is in the same MST Region as the receiving  
29 Bridge and reset otherwise.

### 30 **13.27.32 infoIs**

31 A variable that takes the values Mine, Aged, Received, or Disabled, to indicate the origin/state of the port's  
32 Spanning Tree information (portInfo) held for the port, as follows:

- 33 a) If infoIs Received, the port has received current (not aged out) information from the Designated  
34 Bridge for the attached LAN (a point-to-point Bridge link being a special case of a LAN).
- 35 b) If infoIs Mine, information for the port has been derived from the Root Port for the Bridge (with  
36 the addition of root port cost information). This includes the possibility that the Root Port is  
37 "Port 0," i.e., the Bridge is the Root Bridge for the Bridged Network.
- 38 c) If infoIs Aged, information from the Root Bridge has been aged out. Just as for reselect (13.27.62),  
39 the state machine does not formally allow the Aged state to persist. However, if there is a delay in  
40 recomputing the new root port, correct processing of a received BPDU is specified.
- 41 d) Finally if the port is disabled, infoIs is Disabled.

### 1 **13.27.33 InternalPortPathCost**

2 The port's contribution, when it is an IST or SPT Root Port (for MSTP and ISIS-SPB) to the Internal Root  
3 Path Cost (13.9) for the Bridge.

### 4 **13.27.34 learn**

5 A Boolean. Set or cleared by the Port Role Transitions state machine (13.37) to instruct the Port State  
6 Transitions state machine (13.38) to enable or disable learning.

### 7 **13.27.35 learning**

8 A Boolean. Set or cleared by the Port State Transitions state machine (13.38) to indicate that learning has  
9 been enabled or disabled.

### 10 **13.27.36 master**

11 A Boolean. Used to determine the value of the Master flag for a given MSTI and port in transmitted MST  
12 BPDUs.

13 Set TRUE if the Port Role for the MSTI and Port is Root Port or Designated Port, and the Bridge has  
14 selected one of its ports as the Master Port for this MSTI or the mastered flag is set for this MSTI for any  
15 other Bridge Port with a Root Port or Designated Port Role. Set FALSE otherwise.

### 16 **13.27.37 mastered**

17 A Boolean. Used to record the value of the Master flag for a given MSTI and port in MST BPDUs received  
18 from the attached LAN.

19 NOTE—master and mastered signal the connection of the MSTI to the CST via the Master Port throughout the MSTI.  
20 These variables and their supporting procedures do not affect the connectivity provided by this standard but permit  
21 future enhancements to MSTP providing increased flexibility in the choice of Master Port without abandoning  
22 plug-and-play network migration. They are therefore omitted from the overviews of protocol operation, including  
23 Figure 13-13.

### 24 **13.27.38 mcheck**

25 A Boolean. May be set by management to force the Port Protocol Migration state machine to transmit RST  
26 (or MST or SPT) BPDUs for a MigrateTime (13.26.6, Table 13-5) period, to test whether all STP Bridges on  
27 the attached LAN have been removed and the port can continue to transmit RST BPDUs. Setting mcheck  
28 has no effect if stpVersion (13.28.23) is TRUE.

### 29 **13.27.39 msgPriority**

30 For the CIST and a given port, the CIST Root Identifier, External Root Path Cost, Regional Root Identifier,  
31 Internal Root Path Cost, Designated Bridge Identifier, and Designated Port Identifier components of the  
32 CIST message priority vector conveyed in a received BPDU, as defined in 13.10.

33 For a given MSTI and port, the Regional Root Identifier, Internal Root Path Cost, Designated Bridge  
34 Identifier, and Designated Port Identifier components of the MSTI message priority vector, as defined in  
35 13.11 and conveyed in a received BPDU for this MSTI.

### 36 **13.27.40 msgTimes**

37 For the CIST and a given port, the timer parameter values (Message Age, Max Age, Forward Delay, Hello  
38 Time, and remainingHops) conveyed in a received BPDU. If the BPDU is an STP or RST BPDU without  
39 MSTP parameters, remainingHops is set to the value of the MaxHops component of BridgeTimes (13.26.4).

40 For a given MSTI and port, the value of remainingHops received in the same BPDU as the message priority  
41 components of this MSTI's msgPriority parameter.

#### 1 **13.27.41 neighbourPriority**

2 For a port attached to a point-to-point LAN within the same SPT Region, the designated priority of the other  
3 Bridge attached to that LAN as calculated by ISIS-SPB for a given SPT. Receipt of an Agreement Digest  
4 matching the Bridge component's agreementDigest implies receipt of an Agreement, with agreedPriority ==  
5 neighbourPriority, for each SPT for which the port's selectedRole is DesignatedPort.

6 If the port is attached to a shared media LAN that is within the same SPT Region, i.e., all Bridges attached to  
7 that LAN are within the Region, then neighbourPriority is the best (13.9) of all the neighbor's calculated  
8 designated priority vectors, and an SPT BPDUs with a matching digest has to be received from all the  
9 neighbors before agreedPriority is updated.

#### 10 **13.27.42 newInfo**

11 A Boolean. Set TRUE if a BPDUs conveying changed CIST information is to be transmitted. It is set FALSE  
12 by the Port Transmit state machine.

#### 13 **13.27.43 newInfoMsti**

14 A Boolean. Set TRUE if a BPDUs conveying changed MSTI information is to be transmitted. It is set FALSE  
15 by the Port Transmit state machine.

#### 16 **13.27.44 operEdge**

17 A Boolean. The value of the operEdgePort parameter [item l) in 12.18.2.1.3], as determined by the operation  
18 of the Bridge Detection state machine (13.33).

#### 19 **13.27.45 portEnabled**

20 A Boolean. Set if the Bridge's MAC Relay Entity and Spanning Tree Protocol Entity can use the MAC  
21 Service provided by the Bridge Port's MAC entity to transmit and receive frames to and from the attached  
22 LAN, i.e., portEnabled is TRUE if and only if:

- 23 a) MAC\_Operational (IEEE Std 802.1AC) is TRUE; and
- 24 b) Administrative Bridge Port State (8.4, 13.12) for the port is Enabled.

#### 25 **13.27.46 portId**

26 The Port Identifier for this port. This variable forms a component of the port priority and designated priority  
27 vectors (13.10, 13.11).

28 The most significant 4 bits of the Port Identifier (the settable Priority component) for the CIST and for each  
29 MSTI can be modified independently of the setting of those bits for all other trees, as a part of allowing full  
30 and independent configuration control to be exerted over each spanning tree instance.

#### 31 **13.27.47 portPriority**

32 For the CIST and a given port, the CIST Root Identifier, External Root Path Cost, Regional Root Identifier,  
33 Internal Root Path Cost, Designated Bridge Identifier, and Designated Port Identifier components of the  
34 port's port priority vector (13.10).

35 For a given MSTI and port, the Regional Root Identifier, Internal Root Path Cost, Designated Bridge  
36 Identifier, and Designated Port Identifier components of the port's MSTI port priority vector (13.11).

#### 37 **13.27.48 portTimes**

38 For the CIST and a given port, the port's timer parameter values (Message Age, Max Age, Forward Delay,  
39 Hello Time, and remainingHops). The Hello Time timer parameter value is used in transmitted BPDUs.

40 For a given MSTI and port, the value of remainingHops for this MSTI in transmitted BPDUs.

1 **13.27.49 proposed**

2 A Boolean. See 13.16, Figure 13-10, Figure 13-12, 13.29.14, 13.29.19, 13.37, and Figure 13-24.

3 **13.27.50 proposing**

4 A Boolean. See 13.16, Figure 13-10, Figure 13-12, 13.29.14, 13.29.15, 13.33, and Figure 13-25.

5 **13.27.51 pseudoRootId**

6 A Bridge Identifier configured by management for L2GP operation. By default, it is set to the  
7 BridgeIdentifier (13.26.2).

8 **13.27.52 rcvdBPDU**

9 A Boolean. Set by system-dependent processes, this variable notifies the Port Receive state machine (13.31)  
10 when a valid (Clause 14) Configuration, TCN, RST, MST, or SPT BPDU (14.3) is received on the port.  
11 Reset by the Port Receive state machine.

12 **13.27.53 rcvdInfo**

13 Set to the result of the rcvInfo() procedure (13.29.12).

14 **13.27.54 rcvdInternal**

15 A Boolean. Set TRUE by the Receive Machine if the BPDU received was transmitted by a Bridge in the  
16 same MST Region as the receiving Bridge.

17 **13.27.55 rcvdMsg**

18 A Boolean. See 13.29.13 and 13.31.

19 **13.27.56 rcvdRSTP**

20 A Boolean. See 13.31, 13.29.31, and 13.32.

21 **13.27.57 rcvdSTP**

22 A Boolean. See 13.31, 13.29.31, and 13.32.

23 **13.27.58 rcvdTc**

24 A Boolean. See 13.29.13, 13.29.24, and 13.39.

25 **13.27.59 rcvdTcAck**

26 A Boolean. See 13.29.24 and 13.39.

27 **13.27.60 rcvdTcn**

28 A Boolean. See 13.29.13, 13.29.24, and 13.39.

29 **13.27.61 reRoot**

30 A Boolean. Set by a newly selected Root Port to force prior Root Ports to Discarding, before it becomes  
31 forwarding. See Figure 13-24, 13.29.21, Figure 13-23, Figure 13-25, and Figure 13-26.

32 **13.27.62 reselect**

33 A Boolean. Set to prompt recomputation of the CIST or an MSTI. See 13.35 and 13.36.

1 **13.27.63 restrictedDomainRole**

2 A Boolean. Set by management. If TRUE, causes a port that is a Boundary Port of an SPT Region not to be  
3 selected as Root Port for the CIST, any MSTI, or any SPT, even it has the best spanning tree priority vector.  
4 See 13.20, 27.7, and restrictedRole (13.27.64).

5 **13.27.64 restrictedRole**

6 A Boolean. Set by management. If TRUE causes the port not to be selected as Root Port for the CIST or any  
7 MSTI, even it has the best spanning tree priority vector. Such a port will be selected as an Alternate Port  
8 after the Root Port has been selected. This parameter should be FALSE by default. If set, it can cause lack of  
9 spanning tree connectivity. It is set by a network administrator to prevent Bridges external to a core region of  
10 the network influencing the spanning tree active topology, possibly because those Bridges are not under the  
11 full control of the administrator.

12 **13.27.65 restrictedTcn**

13 A Boolean. Set by management. If TRUE causes the port not to propagate received topology change  
14 notifications and topology changes to other ports. This parameter should be FALSE by default. If set it can  
15 cause temporary loss of connectivity after changes in a spanning trees active topology as a result of  
16 persistent incorrectly learned station location information. It is set by a network administrator to prevent  
17 Bridges external to a core region of the network, causing address flushing in that region, possibly because  
18 those Bridges are not under the full control of the administrator or MAC\_Operational for the attached LANs  
19 transitions frequently.

20 **13.27.66 role**

21 The current Port Role. DisabledPort, RootPort, DesignatedPort, AlternatePort, BackupPort, or MasterPort.  
22 NOTE—The MasterPort role applies to each MSTI when the CIST Port Role is RootPort and connects to another MST  
23 Region. An MSTI Master Port is part of the stable active topology for frames assigned to that MSTI, just as the CIST  
24 Root Port forwards frames for the IST. The Port State for each MSTI may differ as required to suppress temporary loops.

25 **13.27.67 selected**

26 A Boolean. See 13.36 and 13.29.22.

27 **13.27.68 selectedRole**

28 A newly computed role for the port.

29 **13.27.69 sendRSTP**

30 A Boolean. See 13.32 and 13.34.

31 **13.27.70 sync**

32 A Boolean. Set to force the Port State to be compatible with the loop-free active topology determined by the  
33 priority vectors held by this Bridge (13.16, 13.24) for this tree (CIST or MSTI), transitioning the Port State  
34 to Discarding, and soliciting an Agreement if possible, if the port is not already synchronized (13.27.71).

35 **13.27.71 synced**

36 A Boolean. TRUE only if the Port State is compatible with the loop-free active topology determined by the  
37 priority vectors held by this Bridge for this tree (13.16, 13.24).

38 **13.27.72 tcAck**

39 A Boolean. Set to transmit a Configuration Message with a topology change acknowledge flag set.

1 **13.27.73 tcProp**

2 A Boolean. Set by the Topology Change state machine of any other port, to indicate that a topology change  
3 should be propagated through this port.

4 **13.27.74 tick**

5 A Boolean. See the Port Timers state machine (13.30).

6 **13.27.75 txCount**

7 A counter. Incremented by the Port Transmission (13.34) state machine on every BPDU transmission, and  
8 decremented used by the Port Timers state machine (13.30) once a second. Transmissions are delayed if  
9 txCount reaches TxHoldCount (13.26.12).

10 **13.27.76 updtInfo**

11 A Boolean. Set by the Port Role Selection state machine (13.36, 13.29.34) to tell the Port Information state  
12 machine that it should copy designatedPriority to portPriority and designatedTimes to portTimes.

13 **13.28 State machine conditions and parameters**

14 The following variable evaluations are defined for notational convenience in the state machines:

- 15 a) allSptAgree (13.28.1)
- 16 b) allSynced (13.28.2)
- 17 c) allTransmitReady (13.28.3)
- 18 d) BestAgreementPriority (13.28.4)
- 19 e) cist (13.28.5)
- 20 f) cistRootPort (13.28.6)
- 21 g) cistDesignatedPort (13.28.7)
- 22 h) EdgeDelay (13.28.8)
- 23 i) forwardDelay (13.28.9)
- 24 j) FwdDelay (13.28.10)
- 25 k) HelloTime (13.28.11)
- 26 l) MaxAge (13.28.12)
- 27 m) msti (13.28.13)
- 28 n) mstiDesignatedOrTCpropagatingRootPort (13.28.14)
- 29 o) mstiMasterPort (13.28.15)
- 30 p) operPointToPointMAC (13.28.16)
- 31 q) rcvdAnyMsg (13.28.17)
- 32 r) rcvdCistMsg (13.28.18)
- 33 s) rcvdMstiMsg (13.28.19)
- 34 t) reRooted (13.28.20)
- 35 u) rstpVersion (13.28.21)
- 36 v) spt (13.28.22)
- 37 w) stpVersion (13.28.23)
- 38 x) updtCistInfo (13.28.24)
- 39 y) updtMstiInfo (13.28.25)

40 **13.28.1 allSptAgree**

41 TRUE, if and only if, agree is TRUE for the given port for all SPTs.

1 **13.28.2 allSynced**

2 The condition allSynced is TRUE for a given port, for a given tree, if and only if:

- 3 a) For all ports for the given tree, selected is TRUE, the port's role is the same as its selectedRole, and  
4 updtInfo is FALSE; and
- 5 b) The role of the given port is:
  - 6 1) Root Port or Alternate Port and synced is TRUE for all ports for the given tree other than the  
7 Root Port; or
  - 8 2) Designated Port and synced is TRUE for all ports for the given tree other than the given port; or
  - 9 3) Designated Port, and the tree is an SPT or the IST, and the Root Port of the tree and the given  
10 port are both within the Bridge's SPT Region, and both learning and forwarding are FALSE for  
11 the given port; or
  - 12 4) Master Port and synced is TRUE for all ports for the given tree other than the given port.

13 **13.28.3 allTransmitReady**

14 TRUE, if and only if, for the given port for all trees:

- 15 a) selected is TRUE; and
- 16 b) updtInfo is FALSE.

17 **13.28.4 BestAgreementPriority**

18 The best of all possible priority vectors, i.e., numerically the lowest.

19 **13.28.5 cist**

20 TRUE only for CIST state machines; i.e., FALSE for MSTI or SPT state machine instances.

21 **13.28.6 cistRootPort**

22 TRUE if the CIST role for the given port is RootPort.

23 **13.28.7 cistDesignatedPort**

24 TRUE if the CIST role for the given port is DesignatedPort.

25 **13.28.8 EdgeDelay**

26 Returns the value of MigrateTime if operPointToPointMAC is TRUE, and the value of MaxAge otherwise.

27 **13.28.9 forwardDelay**

28 Returns the value of HelloTime if sendRSTP is TRUE, and the value of FwdDelay otherwise.

29 **13.28.10 FwdDelay**

30 The Forward Delay component of the CIST's designatedTimes parameter (13.27.21).

31 **13.28.11 HelloTime**

32 The Hello Time component of the CIST's portTimes parameter (13.27.48) with the recommended default  
33 value given in Table 13-5.

34 **13.28.12 MaxAge**

35 The Max Age component of the CIST's designatedTimes parameter (13.27.21).

1 **13.28.13 msti**

2 TRUE only for MSTI state machines; i.e., FALSE for CIST or SPT state machine instances.

3 **13.28.14 mstiDesignatedOrTCpropagatingRootPort**

4 TRUE if the role for any MSTI for the given port is either:

- 5 a) DesignatedPort or
- 6 b) RootPort, and the instance for the given MSTI and port of the tcWhile timer is not zero.

7 **13.28.15 mstiMasterPort**

8 TRUE if the role for any MSTI for the given port is MasterPort.

9 **13.28.16 operPointToPoint**

10 TRUE if operPointToPointMAC (IEEE Std 802.1AC) is TRUE for the Bridge Port.

11 **13.28.17 rcvdAnyMsg**

12 TRUE for a given port if rcvdMsg is TRUE for the CIST or any MSTI for that port.

13 **13.28.18 rcvdCistMsg**

14 TRUE for a given port if and only if rcvdMsg is TRUE for the CIST for that port.

15 **13.28.19 rcvdMstiMsg**

16 TRUE for a given port and MSTI if and only if rcvdMsg is FALSE for the CIST for that port and rcvdMsg is

17 TRUE for the MSTI for that port.

18 **13.28.20 reRooted**

19 TRUE if the rrWhile timer is clear (zero) for all Ports for the given tree other than the given Port.

20 **13.28.21 rstpVersion**

21 TRUE if ForceProtocolVersion (13.7.2) is greater than or equal to 2.

22 **13.28.22 spt**

23 TRUE only for SPT state machines, in an SPT Bridge; i.e., FALSE for CIST and MSTI state machine  
24 instances.

25 **13.28.23 stpVersion**

26 TRUE if Force Protocol Version (13.7.2) is less than 2.

27 **13.28.24 updtCistInfo**

28 TRUE for a given port if and only if updtInfo is TRUE for the CIST for that port.

29 **13.28.25 updtMstiInfo**

30 TRUE for a given port and MSTI if and only if updtInfo is TRUE for the MSTI for that port or updtInfo is

31 TRUE for the CIST for that port.

32 NOTE—The dependency of rcvdMstiMsg and updtMstiInfo on CIST variables for the port reflects the fact that MSTIs  
33 exist in a context of CST parameters. The state machines ensure that the CIST parameters from received BPDUs are  
34 processed and updated prior to processing MSTI information.

## 1 13.29 State machine procedures

2 The following procedures perform the functions specified for both the state machines for all trees, or  
3 specifically for the CIST, a given MSTI, or a given SPT:

- 4 a) betterorsameInfo(newInfos) (13.29.1)
- 5 b) clearAllRcvdMsgs() (13.29.2)
- 6 c) clearReselectTree() (13.29.3)
- 7 d) disableForwarding() (13.29.4)
- 8 e) disableLearning() (13.29.5)
- 9 f) enableForwarding() (13.29.6)
- 10 g) enableLearning() (13.29.7)
- 11 h) fromSameRegion() (13.29.8)
- 12 i) newTcDetected() (13.29.9)
- 13 j) newTcWhile() (13.29.10)
- 14 k) pseudoRcvMsgs() (13.29.11)
- 15 l) rcvInfo() (13.29.12)
- 16 m) rcvMsgs() (13.29.13)
- 17 n) recordAgreement() (13.29.15)
- 18 o) recordDispute() (13.29.16)
- 19 p) recordMastered() (13.29.17)
- 20 q) recordPriority() (13.29.18)
- 21 r) recordProposal() (13.29.19)
- 22 s) recordTimes() (13.29.20)
- 23 t) setReRootTree() (13.29.21)
- 24 u) setSelectedTree() (13.29.22)
- 25 v) setSyncTree() (13.29.23)
- 26 w) setTcFlags() (13.29.24)
- 27 x) setTcPropTree() (13.29.25)
- 28 y) syncMaster() (13.29.26)
- 29 z) txConfig() (13.29.27)
- 30 aa) txRstp() (13.29.28)
- 31 ab) txTcn() (13.29.29)
- 32 ac) updtBPDUVersion() (13.29.31)
- 33 ad) updtRcvdInfoWhile() (13.29.33)
- 34 ae) updtRolesTree() (13.29.34)
- 35 af) updtRolesDisabledTree() (13.29.35)

36 The following procedures perform the functions specified for all SPTs, or for a given SPT or the CIST when  
37 ISIS-SPB is implemented:

- 38 ag) rcvAgreements() (13.29.14)
- 39 ah) updtAgreement() (13.29.30)
- 40 ai) updtDigest() (13.29.32)

41 All references to named variables in the specification of procedures are to instances of the variables  
42 corresponding to the instance of the state machine using the function, i.e., to the CIST or the given MSTI or  
43 the given SPT as appropriate. References to forwarding and learning apply to frames assigned to the  
44 specified tree.

1 **13.29.1 betterorsameInfo(newInfoIs)**

2 Returns TRUE if, for a given port and tree (CIST or MSTI), either:

- 3 a) The procedure's parameter newInfoIs is Received, and infoIs is Received and the msgPriority vector  
4 is better than or the same as (13.10) the portPriority vector; or
- 5 b) The procedure's parameter newInfoIs is Mine, and infoIs is Mine and the designatedPriority vector is  
6 better than or the same as (13.10) the portPriority vector.

7 Returns False otherwise.

8 NOTE—This procedure is not invoked (in the case of a MSTI) if the received BPDU carrying the MSTI information was  
9 received from another MST Region. In that event, the Port Receive Machine (using rcvMsgs()) does not set rcvdMsg  
10 for any MSTI, and the Port Information Machine's SUPERIOR\_DESIGNATED state is not entered.

11 **13.29.2 clearAllRcvdMsgs()**

12 Clears rcvdMsg for the CIST and all MSTIs, for this port.

13 **13.29.3 clearReselectTree()**

14 Clears reselect for the tree (the CIST or a given MSTI) for all ports of the Bridge.

15 **13.29.4 disableForwarding()**

16 An implementation-dependent procedure that causes the Forwarding Process (8.6) to stop forwarding frames  
17 through the port. The procedure does not complete until forwarding has stopped.

18 **13.29.5 disableLearning()**

19 An implementation-dependent procedure that causes the Learning Process (8.7) to stop learning from the  
20 source address of frames received on the port. The procedure does not complete until learning has stopped.

21 **13.29.6 enableForwarding()**

22 An implementation-dependent procedure that causes the Forwarding Process (8.6) to start forwarding  
23 frames through the port. The procedure does not complete until forwarding has been enabled.

24 **13.29.7 enableLearning()**

25 An implementation-dependent procedure that causes the Learning Process (8.7) to start learning from frames  
26 received on the port. The procedure does not complete until learning has been enabled.

27 **13.29.8 fromSameRegion()**

28 Returns TRUE if rcvdRSTP is TRUE, and the received BPDU conveys a MCID that matches that held for  
29 the Bridge. Returns FALSE otherwise. If SPB protocols are implemented, fromSameRegion() returns TRUE  
30 if the Bridge detects that either its MCID (13.26.7) or its Auxiliary MCID (13.26.8) match either the MCID  
31 or Auxiliary MCID carried by the received SPT BPDU.

32 **13.29.9 newTcDetected()**

33 If the value of tcDetected is zero and sendRSTP is TRUE, this procedure sets the value of tcDetected to  
34 HelloTime plus one second. The value of HelloTime is taken from the CIST's portTimes parameter (13.27.48)  
35 for this port.

36 If the value of tcDetected is zero and sendRSTP is FALSE, this procedure sets the value of tcDetected to the  
37 sum of the Max Age and Forward Delay components of rootTimes.

38 Otherwise, the procedure takes no action.

### 1 **13.29.10 newTcWhile()**

2 If the value of tcWhile is zero and sendRSTP is TRUE, this procedure sets the value of tcWhile to HelloTime  
3 plus one second and sets either newInfo TRUE for the CIST or newInfoMsti TRUE for a given MSTI. The  
4 value of HelloTime is taken from the CIST's portTimes parameter (13.27.48) for this port.

5 If the value of tcWhile is zero and sendRSTP is FALSE, this procedure sets the value of tcWhile to the sum  
6 of the Max Age and Forward Delay components of rootTimes and does not change the value of either  
7 newInfo or newInfoMsti.

8 Otherwise, the procedure takes no action.

### 9 **13.29.11 pseudoRcvMsgs()**

10 Using local parameters, this procedure simulates the processing that would be applied by rcvInfo() and  
11 rcvMsgs() to a BPDU received on the port, from the same region and with the following parameters:

- 12 a) Message Age, Max Age, Hello Time, and Forward Delay are derived from BridgeTimes (13.26.4).
- 13 b) The CIST information carries the message priority vector (13.10) with a value of {pseudoRootId, 0,  
14 pseudoRootId, 0, 0, 0}.
- 15 c) A CIST Port Role of Designated Port, with the Learning and Forwarding flags set.
- 16 d) The Version 1 Length is 0 and Version 3 Length calculated appropriately.
- 17 e) For each MSTI configured on the Bridge, the corresponding MSTI Configuration Message carries  
18 the following:
  - 19 1) A message priority vector with a value of {pseudoRootId, 0, 0, 0}
  - 20 2) A Port Role of Designated Port, with the Learning and Forwarding flags set
  - 21 3) MSTI Remaining Hops set to the value of the MaxHops component of BridgeTimes (13.26.4)

22 NOTE—If two L2GP ports are configured with the same CIST pseudoRootId then the IST may partition within the MST  
23 Region, but either of the L2GP ports can be selected to provide connectivity from the Region/customer network to a  
24 provider's network on an MSTI by MSTI basis.

### 25 **13.29.12 rcvInfo()**

26 Returns SuperiorDesignatedInfo if, for a given port and tree (CIST or MSTI),

- 27 a) The received CIST or MSTI message conveys a Designated Port Role and
  - 28 1) The message priority (msgPriority—13.27.39) is superior (13.10 or 13.11) to the port's port  
29 priority vector; or
  - 30 2) The message priority is the same as the port's port priority vector, and any of the received timer  
31 parameter values (msgTimes—13.27.40) differ from those already held for the port  
32 (portTimes—13.27.48).

33 Otherwise, returns RepeatedDesignatedInfo if, for a given port and tree (CIST or MSTI),

- 34 b) The received CIST or MSTI message conveys a Designated Port Role and
  - 35 1) A message priority vector and timer parameters that are the same as the port's port priority  
36 vector and timer values and
  - 37 2) infols is Received.

38 Otherwise, returns InferiorDesignatedInfo if, for a given port and tree (CIST or MSTI),

- 39 c) The received CIST or MSTI message conveys a Designated Port Role.

40 Otherwise, returns InferiorRootAlternateInfo if, for a given port and tree (CIST or MSTI),

- 41 d) The received CIST or MSTI message conveys a Root Port, Alternate Port, or Backup Port Role and  
42 a CIST or MSTI message priority that is the same as or worse than the CIST or MSTI port priority  
43 vector.

44 Otherwise, returns OtherInfo.

45 NOTE—A Configuration BPDU implicitly conveys a Designated Port Role.

### 1 **13.29.13 rcvMsgs()**

2 This procedure is invoked by the Port Receive state machine (13.31) to decode a received BPDU. Sets  
3 rcvdTcn and rcvdTc for each and every MSTI if a TCN BPDU has been received, and extracts the message  
4 priority and timer values from the received BPDU storing them in the msgPriority and msgTimes variables.

5 If ISIS-SPB is implemented, ForceProtocolVersion is 4 (or greater), the BPDU is an SPT BPDU, and has  
6 been received on a Bridge Port that is internal to the SPT Region (i.e., is not a Boundary Port, see 13.12),  
7 then the rcvAgreements() procedure processes the CIST and SPT information conveyed by the BPDU.

8 Otherwise (i.e., if rcvAgreements() is not used), this procedure sets rcvdMsg for the CIST and makes the  
9 received CST or CIST message available to the CIST Port Information state machines.

10 If and only if rcvdInternal is set, this procedure sets rcvdMsg for each and every MSTI for which a MSTI  
11 message is conveyed in the BPDU, and makes available each MSTI message and the common parts of the  
12 CIST message priority (the CIST Root Identifier, External Root Path Cost, and Regional Root Identifier) to  
13 the Port Information state machine for that MSTI.

### 14 **13.29.14 rcvAgreements()**

15 This procedure is used to process agreements received in SPT BPDUs and in SPB Hello PDUs. The same  
16 variables are used in both cases. In the case of SPT BPDUs, this procedure is invoked by the rcvMsgs()  
17 procedure that decodes received BPDUs.

18 If the received Agreement Number is equal to the value of agreedN plus three, agreedMisorder is set TRUE.

19 The variables agreedN and agreeND are set to the values of the received Agreement Number and Discard  
20 Agreement Number, respectively. The variables agreedDigest and agreedDigestValid are updated with the  
21 values of the received Agreement Digest and Agreement Digest flag, respectively.

22 The CIST proposed flag is set to the value of the Proposal flag for the CIST in the received BPDU.

23 The updtDigest() procedure is invoked. The updtAgreement() procedure is invoked for the port, for the  
24 CIST and for each SPT.

### 25 **13.29.15 recordAgreement()**

26 For the CIST and a given port, if rstpVersion is TRUE, operPointToPointMAC (IEEE Std 802.1AC) is  
27 TRUE, and the received CIST Message has the Agreement flag set, then the CIST agreed flag is set and the  
28 CIST proposing flag is cleared. Otherwise, the CIST agreed flag is cleared. Additionally, if the CIST  
29 message was received from a Bridge in a different MST Region, i.e., the rcvdInternal flag is clear, the agreed  
30 and proposing flags for this port for all MSTIs are set or cleared to the same value as the CIST agreed and  
31 proposing flags. If the CIST message was received from a Bridge in the same MST Region, the MSTI  
32 agreed and proposing flags are not changed.

33 For a given MSTI and port, if operPointToPointMAC (IEEE Std 802.1AC) is TRUE, and:

- 34 a) The message priority vector of the CIST Message accompanying the received MSTI Message (i.e.,  
35 received in the same BPDU) has the same CIST Root Identifier, CIST External Root Path Cost, and  
36 Regional Root Identifier as the CIST port priority vector, and
- 37 b) The received MSTI Message has the Agreement flag set,

38 the MSTI agreed flag is set and the MSTI proposing flag is cleared. Otherwise, the MSTI agreed flag is  
39 cleared.

40 NOTE—MSTI Messages received from Bridges external to the MST Region are discarded and not processed by  
41 recordAgreement() or recordProposal().

1 **13.29.16 recordDispute()**

2 For the CIST and a given port, if the CIST message has the learning flag set:

- 3 a) The disputed variable is set, and
- 4 b) The agreed variable is cleared.

5 Additionally, if the CIST message was received from a Bridge in a different MST region (i.e., if the  
6 rcvdInternal flag is clear), then for all the MSTIs:

- 7 c) The disputed variable is set, and
- 8 d) The agreed variable is cleared.

9 For a given MSTI and port, if the received MSTI message has the learning flag set:

- 10 e) The disputed variable is set, and
- 11 f) The agreed variable is cleared.

12 **13.29.17 recordMastered()**

13 For the CIST and a given port, if the CIST message was received from a Bridge in a different MST Region,  
14 i.e., the rcvdInternal flag is clear, the mastered variable for this port is cleared for all MSTIs.

15 For a given MSTI and port, if the MSTI message was received on a point-to-point link and the MSTI  
16 Message has the Master flag set, set the mastered variable for this MSTI. Otherwise, reset the mastered  
17 variable.

18 **13.29.18 recordPriority()**

19 Sets the components of the portPriority variable to the values of the corresponding msgPriority components.

20 **13.29.19 recordProposal()**

21 For the CIST and a given port, if the received CIST Message conveys a Designated Port Role, and has the  
22 Proposal flag set, the CIST proposed flag is set. Otherwise, the CIST proposed flag is not changed.  
23 Additionally, if the CIST Message was received from a Bridge in a different MST Region, i.e., the  
24 rcvdInternal flag is clear, the proposed flags for this port for all MSTIs are set or cleared to the same value as  
25 the CIST proposed flag. If the CIST message was received from a Bridge in the same MST Region, the  
26 MSTI proposed flags are not changed.

27 For a given MSTI and port, if the received MSTI Message conveys a Designated Port Role, and has the  
28 Proposal flag set, the MSTI proposed flag is set. Otherwise, the MSTI proposed flag is not changed.

29 **13.29.20 recordTimes()**

30 For the CIST and a given port, sets portTimes' Message Age, Max Age, Forward Delay, and remainingHops  
31 to the received values held in msgTimes and portTimes' Hello Time to the default specified in Table 13-5.

32 For a given MSTI and port, sets portTime's remainingHops to the received value held in msgTimes.

33 **13.29.21 setReRootTree()**

34 Sets reRoot TRUE for this tree (the CIST or a given MSTI) for all ports of the Bridge.

35 **13.29.22 setSelectedTree()**

36 Sets selected TRUE for this tree (the CIST or a given MSTI) for all ports of the Bridge if reselect is FALSE  
37 for all ports in this tree. If reselect is TRUE for any port in this tree, this procedure takes no action.

38 **13.29.23 setSyncTree()**

39 Sets sync TRUE for this tree (the CIST or a given MSTI) for all ports of the Bridge.

1 **13.29.24 setTcFlags()**

2 For the CIST and a given port:

- 3 a) If the Topology Change Acknowledgment flag is set for the CIST in the received BPDU, sets  
4 rcvdTcAck TRUE.
- 5 b) If rcvdInternal is clear and the Topology Change flag is set for the CIST in the received BPDU, sets  
6 rcvdTc TRUE for the CIST and for each and every MSTI.
- 7 c) If rcvdInternal is set, sets rcvdTc for the CIST if the Topology Change flag is set for the CIST in the  
8 received BPDU.

9 For a given MSTI and port, sets rcvdTc for this MSTI if the Topology Change flag is set in the corresponding  
10 MSTI message.

11 **13.29.25 setTcPropTree()**

12 If and only if restrictedTcn is FALSE for the port that invoked the procedure, sets tcProp TRUE for the given  
13 tree (the CIST or a given MSTI) for all other ports.

14 **13.29.26 syncMaster()**

15 For all MSTIs, for each port that has infoInternal set:

- 16 a) Clears the agree, agreed, and synced variables; and
- 17 b) Sets the sync variable.

18 **13.29.27 txConfig()**

19 Transmits a Configuration BPDU. The first four components of the message priority vector (13.27.39)  
20 conveyed in the BPDU are set to the value of the CIST Root Identifier, External Root Path Cost, Bridge  
21 Identifier, and Port Identifier components of the CIST's designatedPriority parameter (13.27.20) for this  
22 port. The topology change flag is set if (tcWhile != 0) for the port. The topology change acknowledgment flag  
23 is set to the value of tcAck for the port. The remaining flags are set to zero. The value of the Message Age,  
24 Max Age, and Fwd Delay parameters conveyed in the BPDU are set to the values held in the CIST's  
25 designatedTimes parameter (13.27.21) for the port. The value of the Hello Time parameter conveyed in the  
26 BPDU is set to the value held in the CIST's portTimes parameter (13.27.48) for the port.

27 **13.29.28 txRstp()**

28 Transmits a RST BPDU, MST BPDU, or SPT BPDU as determined by the value of ForceProtocolVersion  
29 (13.7.2), and encoded as specified by Clause 14. All per port variables referenced in this subclause  
30 (13.29.28) are those for the transmitting port.

31 The first six components of the CIST message priority vector (13.27.39) conveyed in the BPDU are set to  
32 the value of the CIST's designatedPriority parameter (13.27.20). The Port Role in the BPDU (14.2.9) is set to  
33 the current value of the CIST's role (13.27.66). The Agreement and Proposal flags in the BPDU are set to  
34 the values of agree (13.27.3) and proposing (13.27.50), respectively. The CIST topology change flag is set if  
35 (tcWhile != 0) for the port. The topology change acknowledge flag in the BPDU is never used and is set to  
36 zero. The Learning and Forwarding flags in the BPDU are set to the values of learning (13.27.35) and  
37 forwarding (13.27.30) for the CIST, respectively. The value of the Message Age, Max Age, and Fwd Delay  
38 parameters conveyed in the BPDU are set to the values held in the CIST's designatedTimes parameter  
39 (13.27.21). The value of the Hello Time parameter conveyed in the BPDU is set to the value held in the  
40 CIST's portTimes parameter (13.27.48).

1 If the value of the Force Protocol Version parameter is less than 3, no further parameters are encoded in the  
2 BPDU and the protocol version parameter is set to 2 (denoting a RST BPDU). Otherwise, MST BPDU  
3 parameters are encoded as follows:

- 4 a) The version 3 length.
- 5 b) The MST Configuration Identifier parameter of the BPDU is the value of MstConfigId (13.26.7).
- 6 c) The CIST Internal Root Path Cost (13.27.20).
- 7 d) The CIST Bridge Identifier (CIST Designated Bridge Identifier—13.27.20).
- 8 e) The CIST Remaining Hops (13.27.21).
- 9 f) The parameters of each MSTI message, encoded in MSTID order.

10 NOTE—No more than 64 MSTIs may be supported. The parameter sets for all of these can be encoded in a  
11 standard-sized Ethernet frame. The number of MSTIs supported can be zero: an SPT Bridge, for example, is not obliged  
12 to have MSTIs configured in order to support SPB.

13 If the value of the Force Protocol Version parameter is less than 3, no further parameters are encoded in the  
14 BPDU and the protocol version parameter is set to 3 (denoting a MST BPDU). Otherwise, SPT BPDU  
15 parameters are encoded, and the protocol version parameter is set to 4 (denoting an SPT BPDU):

- 16 g) agreeN (13.27.16) is encoded in the Agreement Number field.
- 17 h) agreedND (13.27.17) is encoded in the Discarded Agreement Number field.
- 18 i) agreeDigest (13.27.8) is encoded in the Agreement Digest field.

### 19 **13.29.29 txTcn()**

20 Transmits a TCN BPDU.

### 21 **13.29.30 updtAgreement()**

22 If ISIS-SPB is implemented, this procedure is invoked for a given port, for the CIST or a given SPT, by the  
23 updtRolesTree() procedure used by the Port Role Selection machine (13.36), and by the rcvAgreements()  
24 procedure. The Port Role Selection machine itself could have been invoked following receipt of a BPDU on  
25 a port that is at the boundary of the SPT Region, possibly changing the context for the link state calculation,  
26 or following a link state update computed by ISIS-SPB following receipt of an IS-IS PDU.

27 If the procedure has been invoked for the CIST:

- 28 a) If the port's selectedRole is DesignatedPort, agreed is TRUE if and only if:
  - 29 1) agreedTopology is TRUE; and
  - 30 2) designatedPriority is the same or better (13.9) than agreedPriority.
- 31 b) If the port's selectedRole is not DesignatedPort, agreed is TRUE if and only if:
  - 32 1) agreementOutstanding is the same or better than designatedPriority.

33 If the procedure has been invoked for an SPT, and the port's selectedRole is DesignatedPort:

- 34 c) agreedAbove is reset to FALSE;
- 35 d) if agreedTopology is TRUE:
  - 36 1) agreementOutstanding (13.27.15) is set to BestAgreementPriority (13.28.4); and
  - 37 2) agreedPriority (13.27.13) is set to the sum of neighbourPriority (13.27.41) and  
38 InternalPortPathCost.
- 39 e) if agreedTopology is FALSE and agreedPriority is less than the sum of neighbourPriority and  
40 InternalPortPathCost:
  - 41 1) agreedPriority (13.27.13) is set to the sum of neighbourPriority (13.27.41) and  
42 InternalPortPathCost.
- 43 f) agreed (13.27.4) is TRUE if and only if:
  - 44 1) designatedPriority is better than agreedPriority.

1 If the procedure has been invoked for an SPT and the port's selectedRole is not DesignatedPort:

- 2 g) agreedPriority is set to BestAgreementPriority;
- 3 h) if agreedTopology is TRUE:
  - 4 1) agreedAbove is set TRUE, and
  - 5 2) agreementOutstanding (13.27.15) is set to the sum of neighbourPriority (13.27.41) and
  - 6 InternalPortPathCost.
- 7 i) if agreedTopology is FALSE and agreementOutstanding is better than the sum of neighbourPriority
- 8 and InternalPortPathCost:
  - 9 1) agreementOutstanding is set to the sum of neighbourPriority (13.27.41) and
  - 10 InternalPortPathCost.
- 11 j) agreed is TRUE if and only if:
  - 12 1) agreedAbove is TRUE, and
  - 13 2) agreementOutstanding is the same as or better than designatedPriority.

14 Independently of whether the procedure was invoked for the CIST or an SPT:

- 15 k) if agreed is FALSE, then the sync variable is set TRUE.

#### 16 **13.29.31 updtBPDUVersion()**

17 Sets rcvdSTP TRUE if the BPDU received is a version 0 or version 1 TCN or a Config BPDU. Sets  
18 rcvdRSTP TRUE if the received BPDU is a RST BPDU or a MST BPDU.

#### 19 **13.29.32 updtDigest()**

20 Updates agreeDigest and agreeN, following calculation of a new topology or topologies by ISIS-SPB, and  
21 checks for a topology match with the updated values of those variables, as follows.

22 If agreeDigest is not equal to agreementDigest and:

- 23 a) agreeN is equal to agreeND, or
- 24 b) agreeN plus one is equal to agreeND:

25 then

- 26 c) agreeDigest is set equal to agreementDigest, and
- 27 d) agreeDigestValid is reset to FALSE, and
- 28 e) agreeN is set equal to agreeN plus one.

29 Additionally, if agreeDigest is now equal to agreementDigest and:

- 30 f) agreeDigest equals agreedDigest, and
- 31 g) agreedDigestValid is TRUE:

32 then

- 33 h) if agreedND is not equal to agreedN plus one, then
  - 34 1) agreedND is set equal to agreedN plus one, and
  - 35 2) newInfoMsti is set.

36 and

- 37 i) if agreeND is equal to agreeN and agreedMisorder is FALSE, or
- 38 j) if agreeND is set equal to agreeN plus one, then
  - 39 1) agreedTopology is set TRUE, and
  - 40 2) agreedMisorder is set FALSE;

41 otherwise, i.e., if (f) and (g) above are not both TRUE:

- 1 k) if `agreedND` is not equal to `agreedN`, then:
- 2     1) `agreedND` is set equal to `agreedN`, and
- 3     2) `newInfoMsti` is set.

4 The `agreeDigest`, `agreeN`, and `agreedND` variables determine the values of the Agreement Digest,  
5 Agreement Number (AN), and Discarded Agreement Number (DAN), transmitted in SPT BPDU and SPB  
6 Hello PDUs. This procedure is used by `updtRolesTree()` before using `updtAgreement()` for each SPT, and  
7 also by `rcvAgreements()`, since the latter can rotate the AN sequence window number and thus allow  
8 `agreeDigest` to be updated with `agreementDigest`.

9 Wherever `newInfoMsti` is set in this procedure, transmission of an SPB Hello PDU to convey the updated  
10 digest and sequence number information is also requested. SPT BPDUs and SPB Hello PDUs perform  
11 additional functions and are subject to different rate limiters, but both convey the Agreement Digest and  
12 related information.

### 13 13.29.33 `updtRcvdInfoWhile()`

14 Updates `rcvdInfoWhile` (13.25). The value assigned to `rcvdInfoWhile` is three times the Hello Time, if either:

- 15 a) Message Age, incremented by 1 second and rounded to the nearest whole second, does not exceed  
16 Max Age and the information was received from a Bridge external to the MST Region (`rcvdInternal`  
17 `FALSE`); or
- 18 b) `remainingHops`, decremented by one, is greater than zero and the information was received from a  
19 Bridge internal to the MST Region (`rcvdInternal TRUE`);

20 and is zero otherwise.

21 The values of Message Age, Max Age, `remainingHops`, and Hello Time used in these calculations are taken  
22 from the CIST's `portTimes` parameter (13.27.48) and are not changed by this procedure.

### 23 13.29.34 `updtRolesTree()`

24 This procedure calculates the following priority vectors (13.9, 13.10 for the CIST, 13.11 for a MSTI) and  
25 timer values, for the CIST or a given MSTI:

- 26 a) The *root path priority* vector for each Bridge Port that is not Disabled and has a *port priority* vector  
27 (`portPriority` plus `portId`—see 13.27.47 and 13.27.46) that has been recorded from a received message  
28 and not aged out (`infoIs == Received`).
- 29 b) The *root path priority* vector propagated and calculated by ISIS-SPB (if ISIS-SPB is implemented  
30 and `ForceProtocolVersion` is 4).
- 31 c) The Bridge's *root priority vector* (`rootPortId`, `rootPriority`—13.26.9, 13.26.10), chosen as the best of  
32 the set of priority vectors comprising the Bridge's own *Bridge priority vector*  
33 (`BridgePriority`—13.26.3) plus all calculated root path priority vectors whose:
  - 34 1) DesignatedBridgeID Bridge Address component is not equal to that component of the Bridge's  
35 own Bridge priority vector (13.10) and
  - 36 2) Port's `restrictedRole` parameter is `FALSE` and
  - 37 3) Port's `restrictedDomainRole` parameter is `FALSE` or the port is not a Boundary Port of the SPT  
38 Region (13.12).

39 NOTE 1—If ISIS-SPB is being used but did not provide the selected *root priority vector* for the CIST, that priority  
40 vector will be associated with the Master Port of the SPT Region (a Boundary Port of, and not internal to, the Region)  
41 and will be used by ISIS-SPB to propagate the CST component of the priority vector throughout the Region.

- 1 d) The Bridge's *root times*, (*rootTimes*—13.26.11), set equal to:
- 2 1) *BridgeTimes* (13.26.4), if the chosen root priority vector is the Bridge priority vector, or was  
3 calculated by ISIS-SPB; otherwise,
- 4 2) *portTimes* (13.27.48) for the port associated with the selected root priority vector, with the  
5 Message Age component incremented by 1 second and rounded to the nearest whole second if  
6 the information was received from a Bridge external to the MST Region (*rcvdInternal* FALSE),  
7 and with *remainingHops* decremented by one if the information was received from a Bridge  
8 internal to the MST Region (*rcvdInternal* TRUE).
- 9 e) The *designated priority vector* (*designatedPriority*—13.27.20) for each port that is not internal an  
10 SPT Region.
- 11 f) The *designated times* (*designatedTimes*—13.27.21) for each port set equal to the value of *root times*.

12 If the root priority vector for the CIST is recalculated, and has a different Regional Root Identifier than that  
13 previously selected, and has or had a nonzero CIST External Root Path Cost, the *syncMaster()* procedure  
14 (13.29.26) is invoked.

15 NOTE 2—Changes in Regional Root Identifier will not cause loops if the Regional Root is within an MST Region, as is  
16 the case if and only if the MST Region is the Root of the CST. This important optimization allows the MSTIs to be fully  
17 independent of each other in the case where they compose the core of a network.

18 The CIST, MSTI, or SPT Port Role for each port is assigned, and its port priority vector and timer  
19 information are updated as specified in the remainder of this subclause (13.41.2).

20 If the port is Disabled (*infols* == Disabled), *selectedRole* is set to DisabledPort.

21 Otherwise, if this procedure was invoked for an MSTI or an SPT, for a port that is not Disabled, and that has  
22 CIST port priority information that was received from a Bridge external to its Bridge's Region  
23 (*infols* == Received and *infolInternal* == FALSE), then:

- 24 g) If the selected CIST Port Role (calculated for the CIST prior to invoking this procedure for an MSTI  
25 or SPT) is RootPort, *selectedRole* is set to MasterPort.
- 26 h) If selected CIST Port Role is AlternatePort, *selectedRole* is set to AlternatePort.
- 27 i) Additionally, *updtInfo* is set if the port priority vector differs from the designated priority vector or  
28 the port's associated timer parameter differs from the one for the Root Port.

29 Otherwise, for the CIST for a port that is not Disabled and not internal to an SPT Region, or for an MSTI for  
30 a port of that is not Disabled and whose CIST port priority information was not received from a Bridge  
31 external to the Region (*infols* != Received or *infolInternal* == TRUE), the CIST or MSTI port role is assigned,  
32 and the port priority vector and timer information updated as follows:

- 33 j) If the port priority vector information was aged (*infols* = Aged), *updtInfo* is set and *selectedRole* is  
34 set to DesignatedPort.
- 35 k) If the port priority vector was derived from another port on the Bridge or from the Bridge itself as  
36 the Root Bridge (*infols* = Mine), *selectedRole* is set to DesignatedPort. Additionally, *updtInfo* is set if  
37 the port priority vector differs from the designated priority vector or the port's associated timer  
38 parameter(s) differ(s) from the Root Port's associated timer parameters.
- 39 l) If the port priority vector was received in a Configuration Message and is not aged  
40 (*infols* == Received), and the root priority vector is now derived from it, *selectedRole* is set to  
41 RootPort, and *updtInfo* is reset.
- 42 m) If the port priority vector was received in a Configuration Message and is not aged  
43 (*infols* == Received), the root priority vector is not now derived from it, the designated priority  
44 vector is not better than the port priority vector, and the designated Bridge and designated port  
45 components of the port priority vector do not reflect another port on this Bridge, *selectedRole* is set  
46 to AlternatePort, and *updtInfo* is reset.

- 1 n) If the port priority vector was received in a Configuration Message and is not aged  
2 (infols == Received), the root priority vector is not now derived from it, the designated priority  
3 vector is not better than the port priority vector, and the designated Bridge and designated port  
4 components of the port priority vector reflect another port on this Bridge, selectedRole is set to  
5 BackupPort, and updtInfo is reset.
- 6 o) If the port priority vector was received in a Configuration Message and is not aged  
7 (infols == Received), the root priority vector is not now derived from it, the designated priority  
8 vector is better than the port priority vector, selectedRole is set to DesignatedPort, and updtInfo is  
9 set.

10 Otherwise, for the CIST or an SPT, for a port that is not Disabled and is internal to an SPT Region, ISIS-SPB  
11 determines the selectedRole (and other parameters, see 13.36), and uses updtAgreement() (13.29.30).

### 12 13.29.35 updtRolesDisabledTree()

13 This procedure sets selectedRole to DisabledPort for all ports of the Bridge for a given tree (CIST, or MSTI,  
14 or SPT).

## 15 13.30 The Port Timers state machine

16 The Port Timers state machine shall implement the function specified by the state diagram in Figure 13-15  
17 and the attendant definitions in 13.25 through 13.29.

Figure 13-15—Port Timers state machine

18 The state machine uses tick (13.27), a signal set by an implementation-specific system clock function at one  
19 second intervals, to decrement the timer variables for the CIST and all MSTIs for the port. The state machine  
20 that uses a given timer variable is responsible for setting its initial value.

### 1 13.31 Port Receive state machine

2 The Port Receive state machine shall implement the function specified by the state diagram in Figure 13-16  
3 and the attendant definitions in 13.25 through 13.29.

**Figure 13-16—Port Receive state machine**

4 This state machine receives and decodes validated BPDUs. The rcvdMsg flag is set for the CIST and for  
5 each MSTI supported by the receiving Bridge if the received BPDU is from the same MST or SPT Region.  
6 The next BPDU is not processed until all rcvdMsg flags have been cleared by the per-tree state machines.  
7 NOTE—This standard does not specify or constrain the means used by the rcvMsgs() procedure to identify or extract  
8 per-tree information from a BPDU for processing by rcvInfo() in the Port Information Machine RECEIVE state.

### 1 13.32 Port Protocol Migration state machine

2 The Port Protocol Migration state machine shall implement the function specified by the state diagram in  
3 Figure 13-17 and the attendant definitions in 13.25 through 13.29.

Figure 13-17—Port Protocol Migration state machine

### 4 13.33 Bridge Detection state machine

5 The Bridge Detection state machine shall implement the function specified by the state diagram in  
6 Figure 13-18 and the attendant definitions in 13.25 through 13.29.

Figure 13-18—Bridge Detection state machine

### 1 13.34 Port Transmit state machine

2 The Port Transmit state machine shall implement the function specified by the state diagram in Figure 13-19  
3 and the attendant definitions in 13.25 through 13.29.

Figure 13-19—Port Transmit state machine

4 This state machine is responsible for transmitting BPDUs. It also determines when the Agreement Digest in  
5 SPT BPDUs can be updated, and prompts transmission when that has been done.

6 NOTE 1—Any single received BPDU that changes the CIST Root Identifier, CIST External Root Path Cost, or CIST  
7 Regional Root associated with MSTIs should be processed entirely, or not at all, before encoding BPDUs for  
8 transmission. This recommendation minimizes the number of BPDUs to be transmitted following receipt of a BPDU with  
9 new information. It is not required for correctness and has not therefore been incorporated into the state machines.

10 NOTE 2—If a CIST state machine sets **newInfo**, this machine will ensure that a BPDU is transmitted conveying the new  
11 CIST information. If MST BPDUs can be transmitted through the port, this BPDU will also convey new MSTI  
12 information for all MSTIs. If a MSTI state machine sets **newInfoMsti**, and MST BPDUs can be transmitted through the  
13 port, this machine will ensure that a BPDU is transmitted conveying information for the CIST and all MSTIs. Separate  
14 **newInfo** and **newInfoMsti** variables are provided to avoid requiring useless transmission of a BPDU through a port that  
15 can only transmit STP BPDUs (as required by the Force Protocol Version parameter or Port Protocol Migration  
16 machine) following a change in MSTI information without any change to the CIST.

### 13.35 Port Information state machine

The Port Information state machine for each tree shall implement the function specified by the state diagram in Figure 13-20 and the attendant definitions in 13.25 through 13.29.

Figure 13-20—Port Information state machine

This state machine is responsible for recording the spanning tree information currently in use by the CIST or a given MSTI for a given port, ageing that information out if it was derived from an incoming BPDU, and recording the origin of the information in the infols variable. The selected variable is cleared and reselect set to signal to the Port Role Selection machine that port roles need to be recomputed. The infols and portPriority variables from all ports are used in that computation and, together with portTimes, determine new values of designatedPriority and designatedTimes. The selected variable is set by the Port Role Selection machine once the computation is complete.

### 13.36 Port Role Selection state machine

The Port Role Selection state machine shall implement the function specified by the state diagram in Figure 13-21 and the attendant definitions in 13.25 through 13.29.

Figure 13-21—Port Role Selection state machine

When ISIS-SPB finishes a link state calculation, it clears the selected variable for each port for each SPT before updating agreementDigest (13.26.1) for the Bridge component, the root priority vector (rootPortId, rootPriority—13.26.9, 13.26.10) for each SPT and the selectedRole (13.12, 13.27.68), designated priority vector (designatedPriority—13.27.20), and neighbourPriority for each port for each SPT. ISIS-SPB then sets reselect for each SPT.

### 13.37 Port Role Transitions state machine

The Port Role Transitions state machine shall implement the function specified by the state diagram in the following figures:

- Part 1: Figure 13-22 for both the initialization of this state machine and the states associated with the DisabledPort role
- Part 2: Figure 13-23 for the states associated with the MasterPort role
- Part 3: Figure 13-24 for the states associated with the RootPort role
- Part 4: Figure 13-25 for the states associated with the DesignatedPort role
- Part 5: Figure 13-26 for the states associated with the AlternatePort and BackupPort roles

and the attendant definitions in 13.25 through 13.29.

1 As Figure 13-22, Figure 13-23, Figure 13-24, Figure 13-25, and Figure 13-26 are component parts of the  
2 same state machine, the global transitions associated with these diagrams are possible exit transitions from  
3 the states shown in any of the diagrams.

4 Figure 13-22 and Figure 13-26 show the Port Roles for ports that do not form part of the active topology of  
5 the given tree.

6 Figure 13-23, Figure 13-24, and Figure 13-25 show the Port Roles that form part of the active topology.

7

**Figure 13-22—Disabled Port role transitions**

Figure 13-23—Port Role Transitions state machine—MasterPort

Figure 13-24—Port Role Transitions state machine—RootPort

All transitions, except UCT, are qualified by "&& selected && !updtInfo".

**Figure 13-25—Port Role Transitions state machine—DesignatedPort**

**Figure 13-26—Port Role Transitions state machine—AlternatePort and BackupPort**

### 1 13.38 Port State Transition state machine

- 2 The Port State Transition state machine shall implement the function specified by the state diagram in  
3 Figure 13-27 and the attendant definitions in 13.25 through 13.29.

**Figure 13-27—Port State Transition state machine**

- 4 NOTE—A small system-dependent delay may occur on each of the transitions shown in the referenced state machine.

5 This state machine operates independently of the type of tree (CIST, MSTI, or SPT) and whether backbone  
6 bridging is being supported. However, the way in which the Bridge supports the learn and forward variables  
7 and the `disableForwarding()`, `disableLearning()`, `enableForwarding()`, and `enableLearning()` procedures are  
8 supported does vary (see 8.4, 8.6, 8.6.1). The forwarding and learning variables provide  
9 implementation-independent reporting of the current state.

### 1 **13.38.1 Port State transitions for the CIST and MSTIs**

2 The CIST and each MSTI are always supported by an explicit Port State, enforced by Bridge's  
3 implementation of the Forwarding Process, and the procedures prompt that implementation to take the  
4 necessary action to forward and/or learn from received frames (as requested).

### 5 **13.38.2 Port State transitions for SPTs**

6 The `enableLearning()` and `disableLearning()` procedures return without taking an action: for SPBV mode  
7 learning does not occur until forwarding is enabled (8.6.1); for SPBM mode the Learning Process (8.7)  
8 neither creates or deletes Dynamic Filtering Entries.

9 When a VLAN is supported by an SPT Bridge using SPBV mode, a Dynamic VLAN Registration Entry is  
10 created for each SPVID and Enable Ingress Filtering (8.6.2) enabled on each port. Connectivity is provided,  
11 and loops prevented, by adding and removing ports from the Dynamic VLAN Registration Entry (27.13).

12 The `enableForwarding()` procedure adds the port to the Dynamic VLAN Registration Entry for each SPVID  
13 that is associated with the SPT (provided the VLAN topology extends through the port, see 27.13). Similarly  
14 `disableForwarding()` removes the port from the registration entry.

15 When frames with a given VID are supported by SPBM mode, MAC address-based ingress filtering is used  
16 to discard a received frame if there is no corresponding Dynamic Filtering Entry (8.8, 8.6.1, 27.14) for that  
17 VID and the frame's source MAC address with the receiving port in the Port Map.

18 ISIS-SPB identifies the port that provides the shortest path to a given Bridge: this is the Root Port for the  
19 SPT rooted at that Bridge. The individual MAC addresses (there can be more than one) known to ISIS-SPB  
20 as identifying sources for which that given Bridge first transmits frames within the SPT Region (entering the  
21 region from an attached Bridge or station, or from a protocol entity within the Bridge) or as identifying  
22 destinations for which that Bridge is the last recipient within the region (delivering frames to an attached  
23 Bridge or station, or to a protocol entity within the Bridge) are associated with that Root Port. If loop  
24 mitigation (6.5.4.2) is used for unicast frames, a Dynamic Filtering Entry is created for those addresses and  
25 VID, permitting forwarding through that port and no others, without reference to the state machines  
26 specified in this clause (Clause 13), and the setting or clearing of the forward variable for any port. The  
27 `enableForwarding()` procedure creates or modifies these Dynamic Filtering Entries, so that forwarding to  
28 and from a given port is permitted, if and only if loop prevention (6.5.4.1) is used for both unicast and  
29 multicast frames and the port's role is RootPort, and has no effect otherwise. Similarly if loop prevention is  
30 being used, `disableForwarding()` modifies or removes any existing Dynamic Filtering Entry so that  
31 forwarding to or from the port is not permitted.

32 NOTE—The Port Role Transition machine allows an SPT to transition a Root Port to Discarding in support of  
33 `enableForwarding()` and `disableForwarding()` as specified in this subclause (13.38.2). The need to specify that  
34 transition could have been avoided by specifying that the Dynamic Filtering Entry would only permit forwarding  
35 through a given port if `forward` was TRUE for the port for every other SPT for which it was a Designated Port. While  
36 equivalent, such a specification approach would have been obscure and many implementors would have failed to spot  
37 the way to avoid checking variables for all SPTs when processing a change for a single tree.

38 An SPT Bridge using SPBM mode uses source-specific multicast addresses, so that the destination address  
39 alone can be used to identify the SPT (Clause 27) on egress, and a Static Filtering Entry (8.8.1) is created for  
40 that multicast address and the B-VIDs supported by the SPT. If `enableForwarding()` is invoked for a  
41 Designated Port, the Static Filtering Entry's control element for that port is updated to specify that frames  
42 should be Forwarded through the port. The control element is modified to specify Filtered if  
43 `enableForwarding()` is invoked and the port's role is not Designated Port, or if `disabledForwarding()` is used.

### 1 13.39 Topology Change state machine

2 The Topology Change state machine for each tree shall implement the function specified by the state  
3 diagram in Figure 13-28 and the attendant definitions in 13.25 through 13.29.

Figure 13-28—Topology Change state machine

4 NOTE—MRP (Clause 10) uses the `tcDetected` variable maintained by this state machine.

## 1 13.40 Layer 2 Gateway Port Receive state machine

2 If implemented, the Layer 2 Gateway Port state machine for each port shall implement the function specified  
3 by the state diagram in Figure 13-29 and the attendant definitions in 13.25 through 13.29.

Figure 13-29—L2 Gateway Port Receive state machine

4 NOTE—The functionality provided by this state machine is discussed in 13.20, 25.9.2, 26.4.3, and 13.29.11.

## 5 13.41 CEP spanning tree operation

6 This clause specifies the operation of the Spanning Tree Protocol Entity within a C-VLAN component that  
7 supports a CEP (Figure 15-4) of a Provider Edge Bridge. The CEP and each PEP are treated as separate  
8 Bridge Ports by the spanning tree protocol.

9 If the C-VLAN component connects to the S-VLAN component with a single PEP, and the associated  
10 service instance supports no more than two customer interfaces, then all frames (including ST BPDUs)  
11 addressed to the Bridge Group Address may be relayed between the two ports of the C-VLAN component  
12 without modification. Otherwise, the Spanning Tree Protocol Entity shall execute RSTP, as modified by the  
13 provisions of this subclause (13.41).

14 The RSTP enhancements specified do not reduce PBN connectivity between CEPs to a single spanning tree  
15 of service instances but ensure that connectivity for frames assigned to any given C-VLAN is loop-free. In  
16 this respect, the C-VLAN component's spanning tree protocol operation is equivalent to, but simpler to  
17 manage than, the operation of MSTP.

### 18 13.41.1 PEP operPointToPointMAC and operEdge

19 The value of the adminPointToPointMAC parameter for a PEP is always Auto, and no management control  
20 over its setting is provided. The value of the operPointToPointMAC parameter, used by the RSTP state  
21 machines, shall be TRUE if the service instance corresponding to the PEP connects at most two customer  
22 interfaces, and FALSE otherwise.

1 The value of the AdminEdge, AutoEdge, and operEdge parameters for a PEP are always FALSE, TRUE, and  
2 FALSE, respectively. No management control over their setting is provided.

### 3 **13.41.2 updtRolesTree()**

4 The spanning tree priority vectors timer values are calculated, and the port role for each port, its port priority  
5 vector, and timer information updated as specified in 13.29.34, with one exception. If selectedRole was to be  
6 set to AlternatePort, the port is a PEP, and the root priority vector was derived from another PEP, then the  
7 selectedRole shall be set to RootPort.

8 NOTE—The effect of this enhancement is to allow the C-VLAN component to have multiple Root Ports (just as if  
9 separate per S-VLAN trees were being provided), if they are all PEPs. As the C-VLAN component assigns each frame to  
10 a single C-VLAN and maps any given C-VLAN to and from at most one PEP, no loop is created.

### 11 **13.41.3 setReRootTree(), setSyncTree(), setTcPropTree()**

12 The setReRootTree() and setSyncTree() procedures specified in 13.29.21 and 13.29.23 set the reRoot and  
13 sync variables for all ports of the Bridge, and the setTcPropTree() as specified in 13.29.25 sets the tcProp  
14 variable for all ports other than the port that invoked the procedure. If the port invoking the procedure is a  
15 CEP, then this behavior is unchanged; if it is a PEP, then the behavior of each procedure shall be as follows:

- 16 — The setReRootTree() procedure sets reRoot for the port invoking the procedure and for the CEP.
- 17 — The setSyncTree() procedure sets sync for the port invoking the procedure and for the CEP.
- 18 — The setTcPropTree() procedure sets tcProp for the CEP.

### 19 **13.41.4 allSynced, reRooted**

20 RSTP specifies a single value of the allSynced and reRooted state machine conditions for all Bridge Ports.  
21 This specification requires an independent value of each of these conditions for each port of the C-VLAN  
22 component. If that port is the CEP, then allSynced shall be TRUE if and only if synced is TRUE for all PEPs,  
23 and reRooted shall be TRUE if and only if rrWhile is zero for all PEPs. If the port for which the condition is  
24 being evaluated is a PEP, then allSynced shall take the value of synced for the CEP, and reRooted shall be  
25 TRUE if and only if rrWhile is zero for the CEP.

### 26 **13.41.5 Configuration parameters**

27 All configuration parameters for RSTP should be set to their recommended defaults, with the exception of  
28 the following, which are chosen to minimize the chance of interfering with the customer's configuration  
29 (e.g., by the C-VLAN component becoming the root of the customer spanning tree), as follows:

- 30 a) The Bridge Priority (13.18, Table 13-3, 13.26.2) should be set to 61 440. This sets the priority part  
31 of the Bridge Identifier (the most significant 4 bits) to hex F.
- 32 b) The following 12 bits (the Bridge Identifier system ID extension) should be set to hex FFF.
- 33 c) The Port Priority (13.18, Table 13-3, 13.27.47) should be set to 32. This sets the priority part of the  
34 Port Identifier (the most significant 4 bits) to hex 2, a higher priority than the default (128, or hex 8).
- 35 d) The Port Path Cost values for PEPs should be set to 128.

36 All BPDUs generated by the Spanning Tree Protocol Entity within a C-VLAN component use the MAC  
37 address of the CEP as a source address and as the Bridge address portion of the Bridge Identifier. For each  
38 internal PEP, the protocol uses the S-VID associated with the corresponding internal CNP on the S-VLAN  
39 component as a port number. For the CEP, the value 0xFFFF is used as the port number.

## 1 **13.42 Virtual Instance Port (VIP) spanning tree operation**

2 This subclause specifies the operation of the Spanning Tree Protocol Entity within an I-component in a  
3 BEB. The CNPs and VIPs are treated as separate Bridge Ports by the spanning tree protocol.

4 If the I-component has a single CNP and a single VIP supported by a point-to-point backbone service  
5 instance, then all frames (including ST BPDUs) addressed to the Provider Bridge Group address may be  
6 relayed between the two ports of the I-component without modification. Otherwise, the Spanning Tree  
7 Protocol Entity shall execute RSTP, as modified by the provisions of this subclause.

8 The RSTP enhancements specified ensure that connectivity for frames assigned to any given S-VLAN is  
9 loop-free.

10 The parameters and functions of the RSTP used on the VIPs get the same values and functionality as defined  
11 for PEPs of a C-VLAN component as defined in 13.41. The Bridge Identifier Priority and system ID  
12 extension get the values specified in 13.41.5. These changes in RSTP ensure that no VIP is blocked due to  
13 the operation of RSTP and the I-component will never be elected as root.

14 NOTE—The effect of not blocking any VIP in the I-component (never set the port role alternate to a VIP) will not cause  
15 a loop since the I-component maps any given S-VID to at most one VIP.

16

## 14. Encoding of Bridge Protocol Data Units (BPDUs)

This clause specifies formats, and the encoding, decoding, and validation of BPDUs exchanged by protocol entities operating RSTP, MSTP, and other protocols enhancing or designed to interoperate with STP, RSTP, or MSTP (Clause 13).

Interoperability with STP, as specified in IEEE Std 802.1D, 1998 Edition [B13], and prior revisions, is provided as specified by the state machines and procedures in Clause 13 of this standard. Parameter type encodings for STP BPDUs are a subset of those used for RSTP, MSTP, and SPT BPDUs, and the fields encoded in STP Configuration BPDUs are a subset of those used in RST BPDUs.

The format of MST BPDUs is compatible with that specified for RST BPDUs, with the addition of fields to convey information for the IST and each MSTI, and is shown in Figure 14-1.

The format of SPT BPDUs comprises the fields specified for MST BPDUs, with the addition of fields that communicate the Agreement Number, Discarded Agreement Number, and Agreement Digest (13.17).

The Protocol Version Identifier encoded in all BPDUs serves to distinguish RST BPDUs, MST BPDUs, and SPT BPDUs. A BPDU Type is also encoded in all BPDUs, and distinguishes the Configuration and TCN BPDUs used by STP and by the spanning tree protocols specified in this standard when interoperating with STP implementations.

Figure 14-1 shows the overall format of RST, MST, SPT, and STP Configuration BPDUs. Figure 14-2 shows the format of STP TCN BPDUs.

### 14.1 BPDU Structure

#### 14.1.1 Transmission and representation of octets

All BPDUs shall contain an integral number of octets. The octets in a BPDU are numbered starting from 1 and increasing in the order they are put into a Data Link Service Data Unit (DLSDU). When bit positions in an octet or a sequence of octets encode a number, the number is encoded as an unsigned binary numeral with bit positions in lower octet numbers having more significance. Within an octet the bits are numbered from 8 to 1, where 1 is the low-order bit. Where sequences of bits are represented, high order bits are shown to the left of lower order bits in the same octet, and bits in lower octet numbers are shown to the left of bits in higher octet numbers.

#### 14.1.2 Common BPDU fields

A Protocol Identifier is encoded in the initial octets of all BPDUs. The single Protocol Identifier value of 0000 0000 0000 0000 identifies the spanning tree family of protocols (STP, RSTP, and MSTP) and BPDUs whose formats are compatible with:

- a) STP BPDUs, as specified in this clause and in IEEE Std 802.1D, 1998 Edition [B13]
- b) RST BPDUs, as specified in this clause and Clause 9 of IEEE Std 802.1D-2004 [B14]
- c) The BPDUs specified in IEEE Std 802.1G, now withdrawn
- d) MST BPDUs, as specified in this clause
- e) SPT BPDUs, as specified in this clause

NOTE—ISIS-SPB (Clause 27, Clause 28) sends and receives its own PDUs to support the distributed computation of symmetric SPTs.

A Protocol Version Identifier and BPDU Type are also encoded in all BPDUs.

|                                                                                              | Octet                                                                                             |
|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| Protocol Identifier                                                                          | 1–2                                                                                               |
| Protocol Version Identifier                                                                  | 3                                                                                                 |
| BPDU Type                                                                                    | 4                                                                                                 |
| CIST Flags                                                                                   | 5                                                                                                 |
| CIST Root Identifier                                                                         | 6–13                                                                                              |
| CIST External Path Cost                                                                      | 14–17                                                                                             |
| CIST Regional Root Identifier                                                                | 18–25                                                                                             |
| CIST Port Identifier                                                                         | 26–27                                                                                             |
| Message Age                                                                                  | 28–29                                                                                             |
| Max Age                                                                                      | 30–31                                                                                             |
| Hello Time                                                                                   | 32–33                                                                                             |
| Forward Delay                                                                                | 34–35                                                                                             |
| Version 1 Length = 0<br>(RST, MST, SPT BPDUs only)                                           | 36                                                                                                |
| Version 3 Length<br>(MST, SPT BPDUs only)                                                    | 37–38                                                                                             |
| MST Configuration Identifier                                                                 | 39–89                                                                                             |
| CIST Internal Root Path Cost                                                                 | 90–93                                                                                             |
| CIST Bridge Identifier                                                                       | 94–101                                                                                            |
| CIST Remaining Hops                                                                          | 102                                                                                               |
| MSTI Configuration Messages<br>(may be absent)                                               | 103–39 + <i>Version 3 Length</i>                                                                  |
| Version 4 Length<br>(SPT BPDUs only)                                                         | (40 + <i>Version 3 Length</i> )<br>– (41 + <i>Version 3 Length</i> )                              |
| Auxiliary MCID<br>(SPT BPDUs only)                                                           | (42 + <i>Version 3 Length</i> )<br>– (92 + <i>Version 3 Length</i> )                              |
| SPT Agreement Number,<br>Discarded Agreement Number,<br>Agreement Digest<br>(SPT BPDUs only) | (93 + <i>Version 3 Length</i> )<br>– (41 + <i>Version 3 Length</i><br>+ <i>Version 4 Length</i> ) |

NOTE—BPDUs are encoded in LLC Type 1 frames following the DSAP, LSAP, and UI fields, so if that frame is received from directly an IEEE 802.3 MAC with the MAC addresses aligned on an even octet boundaries then the BPDU octet pairs 6 and 7, 14 and 15, 18 and 19, etc. will also be aligned on those boundaries.

**Figure 14-1—RST, MST, SPT, and STP Configuration BPDU format**

|                             | Octet |
|-----------------------------|-------|
| Protocol Identifier         | 1–2   |
| Protocol Version Identifier | 3     |
| BPDU Type                   | 4     |

**Figure 14-2—STP TCN BPDU format**

## 1 14.2 Encoding of parameter types

### 2 14.2.1 Encoding of Protocol Identifiers

3 A Protocol Identifier shall be encoded in two octets.

### 4 14.2.2 Encoding of Protocol Version Identifiers

5 A Protocol Version Identifier shall be encoded in one octet. If two Protocol Version Identifiers are  
6 interpreted as unsigned binary numbers, the greater identifies the more recently defined Protocol Version.

### 7 14.2.3 Encoding of BPDUs types

8 The type of the BPDUs shall be encoded as a single octet. The bit pattern contained in the octet merely serves  
9 to distinguish the type; no ordering relationship between BPDUs of different types is implied.

### 10 14.2.4 Encoding of flags

11 A flag shall be encoded as a bit in a single octet. A flag is set if the bit takes the value 1. A number of flags  
12 may be encoded in a single octet. Bits in the octet that do not correspond to flags defined for the BPDUs  
13 type are reset, i.e., shall take the value 0. No additional flags will be defined for a BPDUs of given protocol  
14 version and type.

### 15 14.2.5 Encoding of Bridge Identifiers

16 A Bridge Identifier is a 64-bit unsigned integer. If two Bridge Identifiers are numerically compared, the  
17 lesser number denotes the Bridge of the better priority.

18 NOTE 1—Use of the terms “higher” and “lower” to describe both the relative numerical values and the relative priority  
19 of Spanning Tree information can cause confusion, as lesser numbers convey better priorities. In this clause and in  
20 Clause 13, relative numeric values are described as “least,” “lesser,” “equal,” and “greater,” and their comparisons as  
21 “less than,” “equal to,” or “greater than,” while relative spanning tree priorities are described as “best,” “better,” “the  
22 same,” “different,” and “worse” and their comparisons as “better than,” “the same as,” “different from,” and “worse  
23 than.” The terms “superior” and “inferior” describe comparisons not simply based on strict ordered comparison of  
24 priority components.

25 The most significant 4 bits of a Bridge Identifier comprise a settable priority component (13.20, 13.26.2),  
26 and can be modified for the CIST or for an MSTI independently of those for other MSTIs (or for the CIST),  
27 allowing the Bridge Identifier priority to be used to provide full and independent control over the  
28 configuration of each of those trees. Each SPT uses the same Bridge Identifier as the CIST, so SPT Bridge  
29 Identifiers are not separately encoded.

30 NOTE 2—To maintain management compatibility with implementations of revisions of this standard prior to the  
31 IEEE Std 802.1s-2002 amendment, and of IEEE Std 802.1D, 1998 Edition [B13] and prior revisions, the priority  
32 component is considered to be a 16-bit value for management purposes, but the values that it can be set to are restricted  
33 to only those values where the least significant 12 bits are zero (i.e., only the most significant 4 bits are settable).

34 The next most significant 12 bits of a Bridge Identifier (when encoded, the least significant 4 bits of the most  
35 significant octet plus the second most significant octet) comprise a locally assigned system ID extension,  
36 that provides a distinct Bridge Identifier for each MSTI. The CIST is identified by the system ID extension  
37 of zero. Each MSTI has a system ID extension value equal to its MSTID, a convention used to convey the  
38 MSTID for each MSTI parameter set in an MST BPDUs.

39 The least significant 48 bits of the Bridge Identifier ensure its uniqueness and are derived from the globally  
40 unique Bridge Address (8.13.8) and are encoded in the third through eighth most significant octets of the  
41 encoded identifier according to the following procedure.

1 The third most significant octet is derived from the initial octet of the MAC address; the LSB of the octet  
2 (Bit 1) is assigned the value of the first bit of the Bridge Address, the next most significant bit is assigned the  
3 value of the second bit of the Bridge Address, and so on. The fourth through eighth octets are similarly  
4 assigned the values of the second to the sixth octets of the Bridge Address.

#### 5 **14.2.6 Encoding of External Root Path Cost and Internal Root Path Cost**

6 The External Root Path Cost shall be encoded in four octets as a number of arbitrary cost units. The Internal  
7 Root Path Cost is similarly encoded in four octets. Subclause 13.18 recommends Port Path Cost values so  
8 that a common interpretation can be placed on path cost values, and reasonable spanning tree configurations  
9 obtained without explicit management.

10 NOTE—IEEE Std 802.1D-2004 [B14] refers to the External Root Path Cost as Root Path Cost and does not use Internal  
11 Root Path Cost.

#### 12 **14.2.7 Encoding of Port Identifiers**

13 A Port Identifier is a 16-bit unsigned integer. If two Port Identifiers are numerically compared, the lesser  
14 number denotes the port of better priority. The most significant 4 bits of a Port Identifier is a settable priority  
15 component that permits the relative priority of ports on the same Bridge to be managed (13.27.46), and can  
16 be modified independently for the CIST and each MSTI. The less significant 12 bits is the Port Number  
17 expressed as an unsigned binary number, and is same for the CIST and all MSTIs. The value 0 is not used as  
18 a Port Number.

19 The Port Identifier for the CIST is encoded in two octets, comprising both the CIST's priority component  
20 and the Port Number used for all spanning trees. The 4-bit priority component for each MSTI is encoded as  
21 a binary number, in the MSTI Configuration Message for that MSTI. Each SPT uses the same Port Identifier  
22 as the CIST, so SPT Port Identifiers are not separately encoded.

23 NOTE—IEEE Std 802.1D, 1998 Edition [B13], and prior revisions specified a priority component of 8 bits and a Port  
24 Number of 8 bits. To maintain management compatibility with prior implementations the priority component is still  
25 considered to be an 8-bit value, but its values are restricted to those where the least significant 4 bits are zero (and hence  
26 ignored in encoding).

#### 27 **14.2.8 Encoding of Timer Values**

28 Timer Values shall be encoded in two octets, taken to represent an unsigned binary number multiplied by a  
29 unit of time of 1/256 of a second. This permits times in the range 0 to, but not including, 256 s to be  
30 represented.

#### 31 **14.2.9 Encoding of Port Role values**

32 Port Role values shall be encoded in two consecutive flag bits, taken to represent an unsigned integer, as  
33 follows:

- 34 a) A value of 0 indicates Master Port
- 35 b) A value of 1 indicates Alternate or Backup
- 36 c) A value of 2 indicates Root
- 37 d) A value of 3 indicates Designated

38 NOTE—IEEE Std 802.1D-2004 [B14] identified the Port Role value of 0 as Unknown, as it not used as a CIST Port  
39 Role in transmitted BPDUs. A received BPDU with a CIST Port Role value of 0 is identified as a Configuration BPDU.

#### 40 **14.2.10 Encoding of Length Values**

41 Version 1 Length Values are encoded in one octet, taken to represent an unsigned binary number. No further  
42 length values are encoded for Version 2. Length Values for Version 3 and 4 are encoded in two octets.

#### 43 **14.2.11 Encoding of Hop Counts**

44 The number of remaining Hops parameter shall be encoded in a single octet.

## 14.3 Transmission of BPDUs

A Bridge Protocol Entity shall encode 0000 0000 0000 0000 in Octets 1 and 2 (conveying the Protocol Identifier), the remaining fields shall be encoded to convey an STP Configuration BPDUs, an STP TCN BPDUs, an RST BPDUs, or an MST BDU as required by the Force Protocol Version parameter, the Port Protocol Migration state machine, and other protocol parameters, all as specified in Clause 13.

- a) If transmission of an STP Configuration BPDUs is required, the Protocol Version Identifier shall be 0, and the BPDUs Type shall be 0000 0000.
- b) If transmission of an STP TCN BPDUs is required, the Protocol Version Identifier shall be 0, and the BPDUs Type shall be 1000 0000.
- c) If transmission of an RST BPDUs is required, the Protocol Version Identifier shall be 2, and the BPDUs Type shall be 0000 0010.
- d) If transmission of an MST BPDUs is required, the Protocol Version Identifier shall be 3, and the BPDUs Type shall be 0000 0010.
- e) If transmission of an SPT BPDUs is required, the Protocol Version Identifier shall be 4, and the BPDUs Type shall be 0000 0010.

The remaining parameters for STP Configuration, RST, MST, and SPT BPDUs shall be encoded as specified below (14.4).

## 14.4 Encoding and decoding of STP Configuration, RST, MST, and SPT BPDUs

STP Configuration, RST, MST, and SPT BPDUs protocol parameters are encoded for transmission, and decoded, checked, or ignored on receipt as follows:

- a) Bit 1 of Octet 5 conveys the CIST Topology Change flag.
- b) Bit 2 of Octet 5 conveys the CIST Proposal flag in RST, MST, and SPT BPDUs. It is unused in STP Configuration BPDUs, and shall be transmitted as 0 and ignored on receipt.
- c) Bits 3 and 4 of Octet 5 conveys the CIST Port Role in RST, MST, and SPT BPDUs. It is unused in STP Configuration BPDUs, and shall be transmitted as 0 and ignored on receipt.
- d) Bit 5 of Octet 5 conveys the CIST Learning flag in RST, MST, and SPT BPDUs. It is unused in STP Configuration BPDUs, and shall be transmitted as 0 and ignored on receipt.
- e) Bit 6 of Octet 5 conveys the CIST Forwarding flag in RST, MST, and SPT BPDUs. It is unused in STP Configuration BPDUs, and shall be transmitted as 0 and ignored on receipt.
- f) Bit 7 of Octet 5 conveys the CIST Agreement flag in RST, MST, and SPT BPDUs. It is unused in STP Configuration BPDUs, and shall be transmitted as 0 and ignored on receipt.
- g) Bit 8 of Octet 5 conveys the Topology Change Acknowledge Flag in STP Configuration BPDUs. It is unused in RST, MST, and SPT BPDUs, and shall be transmitted as 0 and ignored on receipt.
- h) Octets 6 through 13 convey the CIST Root Identifier.  
NOTE 1—The 12-bit system ID extension component of the CIST Root Identifier can be received and subsequently transmitted as an arbitrary value, even in MST BPDUs, since the CIST Root may be an STP Bridge.
- i) Octets 14 through 17 convey the CIST External Root Path Cost.
- j) Octets 18 through 25 shall take the value of the CIST Regional Root Identifier when transmitted in RST and MST BPDUs, and the value of the CIST Bridge Identifier of the transmitting Bridge when transmitted in STP Configuration BPDUs. On receipt of an STP Configuration or RST BPDUs both the CIST Regional Root Identifier and the CIST Designated Bridge Identifier shall be decoded from this field. On receipt of an MST BPDUs the CIST Regional Root Identifier shall be decoded from this field.
- k) Octets 26 and 27 convey the CIST Port Identifier of the transmitting Bridge Port.

- 1 l) Octets 28 and 29 convey the Message Age timer value.
- 2 m) Octets 30 and 31 convey the Max Age timer value.
- 3 n) Octets 32 and 33 convey the Hello Time timer value used by the transmitting Bridge Port.
- 4 o) Octets 34 and 35 convey the Forward Delay timer value.

5 No further octets shall be encoded in STP Configuration BPDUs. Additional octets in received BPDUs  
6 identified by the validation procedure (14.5) as STP Configuration BPDUs shall be ignored. The  
7 specification of encoding or decoding of further octets in this subclause refers only to RST, MST, and SPT  
8 BPDUs.

- 9 p) Octet 36 conveys the Version 1 Length. This shall be transmitted as 0. It is checked on receipt by the  
10 validation procedure (14.5).

11 No further octets shall be encoded in RST BPDUs. Additional octets in received BPDUs identified by the  
12 validation procedure (14.5) as RST BPDUs shall be ignored. The specification of encoding or decoding of  
13 further octets in this subclause refers only to MST and SPT BPDUs.

14 NOTE 2—As Version 2 does not specify any additional fields beyond the end of the Version 0 information, there is no  
15 Version 2 Length field specified in Version 2 of the protocol and therefore no need for a Version 2 length field here.

- 16 q) Octets 37 and 38 convey the Version 3 Length. Its value is the number of octets taken by the  
17 parameters that follow in the BPDU. It is checked on receipt by the validation procedure (14.5).

- 18 r) Octets 39 through 89 convey the elements of the MCID (13.8):

- 19 1) The Configuration Identifier Format Selector is encoded in octet 39 and shall take the value  
20 0000 0000.
- 21 2) The Configuration Name is encoded in octets 40 through 71.
- 22 3) The Revision Level is encoded as a number in octets 72 through 73.
- 23 4) The Configuration Digest is encoded in octets 74 through 89.

- 24 s) Octets 90 through 93 convey the CIST Internal Root Path Cost.

- 25 t) Octets 94 through 101 convey the CIST Bridge Identifier of the transmitting Bridge. The 12-bit  
26 system ID extension component of the CIST Bridge Identifier shall be transmitted as 0. The  
27 behavior on receipt is unspecified if it is nonzero.

28 NOTE 3—The most significant 4 bits of the Bridge Identifier constitute the manageable priority component for  
29 each MSTI and are separately encoded in MSTI Configuration Messages in the BPDU.

- 30 u) Octet 102 encodes the value of remaining Hops for the CIST.

- 31 v) A sequence of zero or more, up to a maximum of 64, MSTI Configuration Messages follows, each  
32 encoded as specified in 14.4.1.

33 No further octets shall be encoded in MST Configuration BPDUs. Additional octets in received BPDUs  
34 identified by the validation procedure (14.5) as MST Configuration BPDUs shall be ignored. The  
35 specification of encoding or decoding of further octets in this subclause refers only to SPT BPDUs.

- 36 w) Octets 1 and 2 following the Version 3 information convey the Version 4 Length. Its value is the  
37 number of octets that follow the Version 4 Length in the BPDU, up to but not including octets added  
38 by subsequent revisions of this standard and associated with Versions 5 or greater. It is checked on  
39 receipt by the validation procedure (14.5).

- 40 x) Octets 1 through 51 following the Version 4 Length encode the Auxiliary MCID (if present) as  
41 follows:

- 42 1) The Configuration Identifier Format Selector is encoded in octet 1 and shall take the value  
43 0000 0000.
- 44 2) The Configuration Name is encoded in octets 2 through 33.
- 45 3) The Revision Level is encoded as a number in octets 34 through 35.
- 46 4) The Configuration Digest is encoded in octets 36 through 51.

- 1 y) Octets 1 and 2 following the Auxiliary MCID are encoded (if present) as follows:
- 2 1) Bits 1 and 2 of Octet 1 convey the Agreement Number (13.27.11, 13.27.16).
- 3 2) Bits 3 and 4 of Octet 1 convey the Discarded Agreement Number (13.27.12, 13.27.17).
- 4 3) Bit 5 of Octet 1 conveys the Agreement Valid flag (13.27.7, 13.27.9).
- 5 4) Bit 6 of Octet 1 conveys the Restricted Role flag (13.27.63, 27.20).
- 6 5) Bits 7 through 8 of Octet 1 are unused, and shall be transmitted as 0 and ignored on receipt.
- 7 6) Octet 2 is unused, and shall be transmitted as 0 and ignored on receipt.
- 8 z) The remaining Octets following the Version 4 Length and covered by that length comprise the
- 9 Agreement Digest (13.17.1, 28.4).

10 No further octets shall be encoded in BPDUs. Additional octets in received BPDUs shall be ignored.

#### 11 14.4.1 MSTI Configuration Messages

12 A single instance of the following set of parameters is encoded for each MSTI supported by the transmitting

13 Bridge.

- 14 a) Bits 1, 2, 3 and 4, 5, 6, 7, and 8, respectively, of Octet 1 convey the Topology Change flag, Proposal
- 15 flag, Port Role, Learning flag, Forwarding flag, Agreement flag, and Master flag for this MSTI.
- 16 b) Octets 2 through 9 convey the Regional Root Identifier (13.27.20) as illustrated in Figure 14-3. This
- 17 includes the value of the MSTID for this Configuration Message encoded in bits 4 through 1 of
- 18 Octet 1, and bits 8 through 1 of Octet 2.
- 19 NOTE—The most significant 4 bits of each MSTI's Regional Root Identifier constitute a manageable priority
- 20 component.
- 21 c) Octets 10 through 13 convey the Internal Root Path Cost.
- 22 d) Bits 5 through 8 of Octet 14 convey the value of the Bridge Identifier Priority for this MSTI. Bits 1
- 23 through 4 of Octet 14 shall be transmitted as 0, and ignored on receipt.
- 24 e) Bits 5 through 8 of Octet 15 convey the value of the Port Identifier Priority for this MSTI. Bits 1
- 25 through 4 of Octet 15 shall be transmitted as 0, and ignored on receipt.
- 26 f) Octet 16 conveys the value of remainingHops for this MSTI (13.27.21).

|                               | Octet |
|-------------------------------|-------|
| MSTI Flags                    | 1     |
| MSTI Regional Root Identifier | 2–9   |
| MSTI Internal Root Path Cost  | 10–13 |
| MSTI Bridge Priority          | 14    |
| MSTI Port Priority            | 15    |
| MSTI Remaining Hops           | 16    |

**Figure 14-3—MSTI Configuration Message parameters and format**

## 1 14.5 Validation of received BPDUs

2 The receiving protocol entity shall examine Octets 1 and 2 (conveying the Protocol Identifier), Octet 3  
3 (conveying the Protocol Version Identifier encoded as a number), Octet 4 (conveying the BPDU Type) and  
4 the total length of the received BPDU (including the preceding fields, but none prior to the Protocol  
5 Identifier) to determine the further processing required as follows:

- 6 a) If the Protocol Identifier is 0000 0000 0000 0000, the BPDU Type is 0000 0000, and the BPDU  
7 contains 35 or more octets, it shall be decoded as an STP Configuration BPDU.
- 8 b) If the Protocol Identifier is 0000 0000 0000 0000, the BPDU Type is 1000 0000 (where bit 8 is  
9 shown at the left of the sequence), and the BPDU contains 4 or more octets, it shall be decoded as an  
10 STP TCN BPDU (9.3.2 of IEEE Std 802.1D-2004 [B14]).
- 11 c) If the Protocol Identifier is 0000 0000 0000 0000, the Protocol Version Identifier is 2, and the BPDU  
12 Type is 0000 0010 (where bit 8 is shown at the left of the sequence), and the BPDU contains 36 or  
13 more octets, it shall be decoded as an RST BPDU.
- 14 d) If the Protocol Identifier is 0000 0000 0000 0000, the Protocol Version Identifier is 3 or greater, the  
15 BPDU Type is 0000 0010, the Bridge is configured as an MST Bridge or an SPT Bridge or  
16 according to a future revision of this standard that intends to provide interoperability with prior  
17 revisions, and the BPDU:
  - 18 1) Contains 35 or more but less than 103 octets, or
  - 19 2) Contains a Version 1 Length that is not 0, or
  - 20 3) Contains a Version 3 length that does not represent an integral number, from 0 to 64 inclusive,  
21 of MSTI Configuration Messages,22 it shall be decoded as an RST BPDU.
- 23 e) If the Protocol Identifier is 0000 0000 0000 0000, the Protocol Version Identifier is 3 or greater and  
24 the Bridge is configured as an MST Bridge or the Protocol Version Identifier is 3 and the Bridge is  
25 configured as an SPT Bridge or according to a future revision of this standard that intends to provide  
26 interoperability with prior revisions, the BPDU Type is 0000 0010, and the BPDU:
  - 27 1) Contains 102 or more octets, and
  - 28 2) Contains a Version 1 Length of 0, and
  - 29 3) Contains a Version 3 length representing an integral number, from 0 to 64 inclusive, of MSTI  
30 Configuration Messages,31 it shall be decoded as an MST BPDU.
- 32 f) If the Protocol Identifier is 0000 0000 0000 0000, the Protocol Version Identifier is 3 or greater, the  
33 BPDU Type is 0000 0010, the Bridge is configured as an SPT Bridge or according to a future  
34 revision of this standard that intends to provide interoperability with prior revisions, and the BPDU:
  - 35 1) Contains 102 or more octets, and
  - 36 2) Contains a Version 1 Length of 0, and
  - 37 3) Contains a Version 3 length representing an integral number, from 0 to 64 inclusive, of MSTI  
38 Configuration Messages, and
  - 39 4) Is not a well-formed an SPT BPDU, i.e.,
    - 40 i) Contains less than 6 octets following the octets specified by the Version 3 length,
    - 41 ii) Has a Version 4 length that is less than 55,
    - 42 iii) Does not contain an MCID Format Selector of 1,43 it shall be decoded as an MST BPDU.
- 44 g) If the Protocol Identifier is 0000 0000 0000 0000, the Protocol Version Identifier is 4 or greater, the  
45 BPDU Type is 0000 0010, the Bridge is configured as an MST Bridge or an SPT Bridge or  
46 according to a future revision of this standard that intends to provide interoperability with prior  
47 revisions, and the BPDU:
  - 48 1) Contains 106 or more octets, and
  - 49 2) Contains a Version 1 Length of 0, and

- 1) Contains a Version 3 length representing an integral number, from 0 to 64 inclusive, of MSTI Configuration Messages, and
- 2) Is a well-formed an SPT BPDUs, i.e., contains
  - i) At least 6 octets following the octets specified by the Version 3 length,
  - ii) A Version 4 length of 55 or greater,
  - iii) An MCID Format Selector of 1,it shall be decoded as an SPT BPDUs.
- h) Otherwise, the BPDUs shall be discarded and not processed.

NOTE 1—The LLC LSAP that identifies BPDUs is reserved for standard protocols, no other protocols using that LSAP have been standardized though they may be at some future time. At that time, BPDUs with different PIDs may be processed according to the rules of those protocols but will still be discarded from the point of view of MSTP.

NOTE 2—These validation rules do not contain a loopback check of the form specified for use with STP Configuration BPDUs in 9.3.4 of IEEE Std 802.1D-2004 [B14].

## 14.6 Validation and interoperability

The validation rules above (14.5) follow a consistent general approach that allows future version enhancements to be made while retaining backwards compatibility. In particular, tests (a) and (b) in 14.5 above do not check the Protocol Version Identifier.

In general, for an implementation that supports version A of a given protocol, a received PDU of a given type that carries a protocol version number B is interpreted as follows:

- a) Where B is greater than or equal to A, the PDU shall be interpreted as if it carried the supported version number, A. Specifically,
  - 1) All PDU types, parameters, and flags that are defined in version A shall be interpreted in the manner specified for version A of the protocol for the given BPDUs type.
  - 2) All PDU types, parameters, and flags that are undefined in version A for the given BPDUs type shall be ignored.
  - 3) All octets that appear in the PDU beyond the largest numbered octet defined for version A for the given BPDUs type shall be ignored.
- b) Where B is less than A, the PDU shall be interpreted as specified for the version number, B, carried in the BPDUs. Specifically,
  - 1) All PDU parameters and flags shall be interpreted in the manner specified for version B of the protocol for the given PDU type.
  - 2) All PDU parameters and flags that are undefined in version B for the given BPDUs type shall be ignored.
  - 3) All octets that appear in the PDU beyond the largest numbered octet defined for version B for the given BPDUs type shall be ignored.

NOTE—In other words, if the protocol version implemented differs from the protocol version number carried in the PDU, then only those PDU types, parameters, and flags that are specified within the lesser numbered protocol version are interpreted by the implementation (in accordance with the lesser numbered protocol version's specification), and no attempt is made to interpret any additional PDU types, parameters, and flags that may be specified within the greater numbered protocol version. In the specific case of STP (version 0) and RSTP (version 2), as there is only a single RST BPDUs type defined in version 2, and as the RST BPDUs type is undefined in version 0, a version 0 implementation will ignore all RST BPDUs. Version 2 implementations, however, recognize and process both version 0 and version 2 BPDUs. As version 2 makes no changes to the BPDUs types defined for version 0 (and always transmits such BPDUs types with 0 as the version identifier), version 0 BPDUs are always interpreted by version 2 implementations according to their version 0 definition.

2 Provider Bridges interconnect the separate MACs of the IEEE 802 LANs that compose a PBN, relaying  
3 frames to provide connectivity between all LANs that provide customer interfaces for each service instance.  
4 The position of the Provider Bridge S-VLAN component bridging function within the MAC Sublayer is  
5 shown in Figure 15-1.

- 7 a) Service transparency
- 8 b) Customer service interfaces
- 9 c) Service instance segregation
- 10 d) Service instance selection and identification
- 11 e) Service priority selection
- 12 f) Service access protection

## 24 15.1 Service transparency

30 The service is not transparent to the operation of media access method-dependent convergence functions,  
31 specified in IEEE Std 802.1AC, or to the operation of the media access method-specific functions specified  
32 by standards for each media access method. Media access method-dependent and -specific functions operate

1 between Bridges, whether Customer Bridges or Provider Bridges, attached to the same LAN. Where these  
2 functions make use of standard group MAC addresses, those addresses are included in the Reserved  
3 Addresses that are always filtered by Customer Bridges (Table 8-1) and by Provider Bridges (Table 8-2).

4 Frames transmitted and received by media access method-independent functions particular to PBN  
5 operation are not forwarded by Customer Bridges between provider networks. Where these frames are  
6 addressed using standard group MAC addresses, those addresses are included in the Reserved Addresses  
7 that are always filtered by Customer Bridges (Table 8-1). In addition, such frames may be filtered from  
8 PEPs.

## 9 15.2 Customer service interfaces

10 A service provider can offer a customer one or more types of service interfaces, each providing different  
11 capabilities for service selection, priority selection, and service access protection (15.8, 15.9, and 15.10).  
12 Some service interfaces are provided by the service provider operating systems that include C-VLAN  
13 components, or by customer operating systems that include S-VLAN components. In all cases, segregation  
14 of different service instances is achieved at an interface wholly under the control of the service provider by  
15 authentication and authorization of the attached customer systems, and by verification of customer provided  
16 parameters that provide service instance selection.

17 NOTE—The term “service access protection” describes provision of service access over multiple access LANs with  
18 redundancy and rapid failover in case of failure of an access LAN or attached equipment.

19 Access to a given service instance can be provided through different types of customer interface.

## 20 15.3 Port-based service interface

21 The customer service interfaces that can be provided by a provider network are specified by reference to a  
22 CNP provided by the S-VLAN component of a Provider Bridge. The CNP provides a single service  
23 instance, as illustrated in Figure 15-2 and Figure 15-3. The attached customer system can be a Bridge, a  
24 router, or an end station.

**Figure 15-2—Port-based service interface to a PBN**

1 This interface is Port-based; i.e., customers select and identify different service instances by associating each  
2 with a different CNP. Frames transmitted to a CNP by a C-VLAN-aware customer system do not include an  
3 S-VID but can be priority-tagged with an S-TAG (6.13).

**Figure 15-3—Port-based service interface to a PBN**

4 NOTE—The terms “Customer Network Port,” “Customer Edge Port,” “Provider Network Port,” and “Provider Edge  
5 Port,” do not refer to the ownership of equipment, or necessarily to differently implemented Ports, but to Ports that are  
6 configured to fulfill the requirements of precise roles within a structured provider network design. These requirements  
7 are described in 15.6 through 15.10 and in Clause 16. All “Network” Ports are part of S-VLAN components, and all  
8 “Edge” Ports are part of C-VLAN components, whereas all “Customer” Ports receive data from a single customer  
9 inbound to the network and transmit data outbound from the network to a single customer. See Clause 3 for definitions.

#### 10 15.4 C-tagged service interface

11 A C-tagged service interface can be provided by a Provider Edge Bridge comprising one or more C-VLAN  
12 components attached to Port-based service interfaces provided by a single S-VLAN component, as  
13 illustrated by Figure 15-4 and Figure 15-5.

**Figure 15-4—C-tagged service interface to a PBN**

14 The C-tagged service interface allows service instance selection and identification by C-VID. Each frame  
15 from the customer system is assigned to a C-VLAN and presented at zero or one internal Port-based service  
16 interfaces, each supporting a single service instance that the customer desires to carry that C-VLAN.

17 NOTE—The restriction that each C-VLAN map to a single service instance allows the customer equipment receiving  
18 frames to correctly identify the service instance used, supports mechanisms that guard against accidental creation of data  
19 loops, and prevents configuration of the C-VLAN component to create a multi-point service from point-to-point service  
20 instances. The service provider can offer a multi-point service through appropriate configuration of the S-VLAN  
21 component.

**Figure 15-5—C-tagged service interface to a PBN**

1 Similarly frames from the provider network are assigned to an internal interface or “LAN” on the basis of  
2 the S-VID. As each internal interface supports a single service instance, no S-TAG is used at this interface. If  
3 multiple C-VLANs are supported by this service instance, the frames will have C-TAGs with the possible  
4 exception of frames for a single C-VLAN. The C-VLAN component applies a PVID to untagged frames  
5 received on each internal “LAN,” allowing full control over the delivery of frames for each C-VLAN  
6 through the CEP.

7 Each Provider Edge Bridge can support multiple CEPs for the same customer or for multiple customers.  
8 Each CEP is supported by a dedicated C-VLAN component as illustrated in Figure 15-6.

**Figure 15-6—Customer Edge Ports (CEPs)**

## 9 15.5 S-tagged service interface

10 An S-tagged service interface can be provided to an S-VLAN Bridge operated by a customer as illustrated  
11 by Figure 15-7 and Figure 15-8, or to a customer-operated Provider Edge Bridge that in turn provides  
12 C-tagged service interfaces within the customer’s own network as described in 15.4.

## 13 15.6 Remote customer service interfaces (RCSIs)

14 An RCSI provides a C-tagged or Port-based service interface to a customer attached via an access PBN as  
15 depicted in Figure 16-2 (16.2). Multiple RCSIs can be provided over a LAN interconnecting two PBNs  
16 through the use of a Port-mapping S-VLAN component as shown in Figure 15-2. The Port-mapping

**Figure 15-7—S-tagged service interface to a PBN**

**Figure 15-8—S-tagged interface to a PBN**

1 S-VLAN component has one external port (RCAP) and one or more internal Ports (PAPs) that each support  
2 one RCSI. The Port-mapping S-VLAN component also can have an internal PNP for service instances that  
3 do not require an RCSI.

4 The Port-mapping S-VLAN component is configured to associate a unique S-VID with each PAP.  
5 Furthermore, each S-VID configured in the Port-mapping S-VLAN component has the RCAP and exactly  
6 one other Port in its member set. This ensures that each external service instance is mapped to only one  
7 internal port. See Figure 15-9.

**Figure 15-9—RCSIs to a PBN**

8 Each RCSI supported by a RCAP is associated with a PAP connected via an internal LAN to either a CNP,  
9 providing a Port-based service interface (15.3), or a CEP, providing a C-tagged service interface (15.4). The  
10 external S-VID mapped to an RCSI identifies a service instance originating at a remote customer interface  
11 LAN attached to an access PBN (16.2). To provide separation between the external S-VID space used by the

1 access PBN and the internal S-VID space for this PBN, frames on an RCSI do not carry an S-TAG. When  
2 frames transit an RCSI the internal S-VID is set by the PVID of the CNP and the external S-VID by the  
3 PVID of the PAP.

4 NOTE—If two CNPs associated with different RCSIs on the same RCAP belong to the same internal S-VLAN, frames  
5 received on the RCAP with one S-VID can be transmitted on that same external port with a different S-VID. This is  
6 sometimes referred to as “Hairpin Switching” and is described in 16.2.

7 In addition to the RCSIs, a PNP on the Port-mapping S-VLAN component is connected via an internal LAN  
8 to a PNP on the primary S-VLAN component. External service instances that are not associated with an  
9 RCSI can be mapped to this Port. This allows multiple service instances to be passed between the PBNs  
10 without requiring a separate Port for each service instance. On this interface service frames carry S-TAGs  
11 and the VID translation table of the PNP on the S-VLAN component is used to provide independence  
12 between internal and external S-VID spaces.

13 A Provider Edge Bridge can support multiple RCAPs connected to other PBNs. Each RCAP can support  
14 multiple RCSIs for one or more customers. Each RCAP is supported by a Port-mapping S-VLAN  
15 component as illustrated in Figure 15-10. As shown in the figure, each Port-mapping S-VLAN component  
16 with a RCAP can have one PNP and multiple PAPs providing either Port-based or C-tagged RCSIs.

**Figure 15-10—Remote Customer Access Ports (RCAPs)**

1 Figure 15-11 shows a C-tagged RCSI. Since S-VLAN components are transparent to C-VLAN control  
2 PDUs, i.e., PDUs using addresses in Table 8-1 but not in Table 8-2, these control PDUs exchanged via the  
3 CEP reach the next (e.g., customer controlled) C-VLAN component across the access PBN. S-VLAN  
4 control PDUs, using addresses in Table 8-2, exchanged on the RCAP will normally reach the neighboring  
5 Provider Bridge in the adjacent PBN.

**Figure 15-11—C-tagged RCSI to a PBN**

6 Frames traversing the internal LAN between the Port-mapping S-VLAN component and the C-VLAN  
7 component do not contain an S-TAG. The S-VID for frames received on this interface by the Port-mapping  
8 S-VLAN component is provided by the PAP's PVID.

9 Figure 15-12 shows a Port-based RCSI. In this case the PAP is connected to a CNP on the S-VLAN  
10 component. Frames carried over the internal LAN between the PAP and CNP do not contain an S-TAG. An  
11 S-VID is provided at each Port by the respective Port's PVID. These S-VIDs are not required to have the  
12 same value.

**Figure 15-12—Port-based RCSI to a PBN**

1 Figure 15-13 shows the PNP on the Port-mapping S-VLAN component connected to a PNP on the S-VLAN  
2 component. Service frames carried over this interface have S-TAGs and S-VID translation can be  
3 performed.

**Figure 15-13—Provider Network Port (PNP) interface**

## 4 15.7 Service instance segregation

5 Segregation of data frames associated with different MAC Service instances is achieved by supporting each  
6 service instance with a separate S-VLAN and ensuring that:

- 7 a) Provider Bridges are configured such that no customer data frames are transmitted through a PNP  
8 untagged, i.e., without an S-TAG.
- 9 b) No frames are accepted, i.e., received and relayed, from any customer system without first being  
10 subject to service instance selection.
- 11 c) No frames are delivered to any customer system without explicit service instance identification.
- 12 d) Prior to transmission through a PNP, customer data frames are received through a CNP within the  
13 provider network that is exclusively accessed by a single customer. The S-VIDs of all frames  
14 received through that CNP correspond to service instances that the customer is permitted to access.
- 15 e) Provider Bridges and the S-VLAN component of each Provider Edge Bridge within the provider  
16 network can only be directly controlled by the service provider. Customer equipment, including  
17 customer-owned Provider Bridges, are not within the provider network and are controlled by the  
18 customer.
- 19 f) Only frames that have been transmitted through a PNP can be received through other PNPs within  
20 the provider network.

## 21 15.8 Service instance selection and identification

22 Service instance selection is provided for Port-based service interfaces by configuring a CNP with a PVID  
23 value corresponding to the S-VID used to identify the service instance and an Acceptable Frame Types value  
24 of *Admit Only Untagged and Priority-tagged frames*.

25 Service instance selection is provided for C-tagged service interfaces by a C-VLAN component internal to a  
26 Provider Edge Bridge. The C-VLAN component uses the C-VID to direct frames to an internal PEP  
27 supporting a specific service instance. Frames for at most one C-VLAN can be conveyed untagged over a  
28 single service instance. Management control of associating C-VIDs with PEPs is accomplished using the  
29 C-VID Registration Table (12.13.2), which provides equivalent functionality to configuring the PVID of the  
30 internal CNP with the S-VID of the service instance, and adding the PEP to the Member Set, and possibly

1 Untagged Set, of the C-VLAN. No management control is provided for Protocol-based VID assignment on  
2 internal CNPs.

3 NOTE 1—A Provider Edge Bridge can configure the C-VLAN component associated with a CEP to select the same  
4 service instance for all frames. This creates a service interface similar, but not identical, to a Port-based service interface.  
5 The C-VLAN component allows modification of the C-TAG (insertion of a C-TAG with the PVID value in untagged  
6 frames, assigning the PVID value to priority-tagged frames, or stripping the C-TAG from frames forwarded through the  
7 PEP) but never forwards a frame with a null C-VID. A Port-based service interface does not modify the C-TAG of  
8 received frames in any way. A Provider Edge Bridge may offer a Port-based service interface by configuring the Port to  
9 be a CNP rather than a CEP; in which case, there is no associated C-VLAN component.

10 Service instance selection is provided by the attached customer system for S-tagged service interfaces. The  
11 CNP is configured with Enable Ingress Filtering (8.6.2), and the Port is only included in the Member Set for  
12 S-VLANs corresponding to service instances that the customer is permitted to use.

13 For all service interfaces described, the CNP determines the S-VID for each customer data frame as  
14 specified in 6.9.1 for an EISS instance using an S-TAG type.

15 The VID Translation Table for the Port (6.9.1) allows a service provider to assign S-VIDs independently  
16 from those used by a customer (or other service provider) to identify service instances on an S-tagged  
17 service interface (15.5). The table also allows customers to identify the same service instance by different  
18 VIDs at different interfaces.

19 NOTE 2—The means used by a service provider and a customer to determine the VIDs used by the customer to select  
20 and identify a given service instance are outside the scope of this standard.

21 The service instance for each frame received by the attached customer system is identified in the same way  
22 as frames transmitted using the same interface, but not necessarily in the same way that the service instance  
23 is selected or identified at other interfaces. A single service instance can support Port-based, C-tagged, and  
24 S-tagged service interfaces.

## 25 **15.9 Service priority selection**

26 For all service interface types, the service priority is selected using the received priority for each frame,  
27 possible regenerated using the Priority Regeneration Table (6.9.4). The mechanism for determining the  
28 received priority varies with the type of service interface.

29 Service priority selection is provided for Port-based service interfaces using the received priority signaled  
30 from the media access method of the port. If the media access method used to attach to the interface does not  
31 directly support priority, this will result in the selection of a single value for all frames. A customer system  
32 may also signal priority to a Port-based service interface on a per-frame basis by priority-tagging each frame  
33 with an S-TAG with a null VID. Subclause 6.13 specifies a function to support priority-tagging with an  
34 S-TAG on Customer Bridges.

35 Service priority selection is provided by C-tagged service interfaces using the priority conveyed in the  
36 C-TAG of each frame. A C-tagged service interface can provide a single service instance for all C-VIDs  
37 received and in this way function much as a Port-based service interface with the addition of the capability  
38 of the customer to independently signal priority with each frame.

39 Service priority selection is provided by S-tagged interfaces using the received priority decoded from the  
40 PCP field in the S-TAG.

## 41 **15.10 Service access protection**

42 A customer system or systems at a single location can attach to two or more service interfaces using separate  
43 LANs for attachment, thus providing fault tolerance through redundancy of the interface components.

## 16. Principles of Provider Bridged Network (PBN) operation

This clause establishes the principles and a model of PBN operation. It provides the context necessary to understand how the:

- a) Operation of individual Provider Bridges (Clause 8),
- b) Configuration and management of individual Provider Bridges (Clause 12), and
- c) Management of spanning tree and VLAN topologies within a provider network (Clause 7, Clause 11, Clause 13)

support, preserve, and maintain the quality of each instance of the MAC Service offered to the customers of the provider network (Clause 6, Clause 15), including:

- d) Independence of each service instance supported by a service provider from other service instances (Clause 15).
- e) Identification of service instances within the provider network (Clause 15, 8.8).
- f) Maintenance of service availability in the event of the failure, restoration, removal, or insertion of LAN components connecting a customer network to a provider network (Clause 6, Clause 11, Clause 13, 16.2).

A PBN is a Virtual Bridged Network that comprises Provider Bridges (S-VLAN Bridges and Provider Edge Bridges) and attached LANs, under the administrative control of a single service provider. The principal elements of provider network operation are those specified in Clause 7 for Virtual Bridged Networks in general, as amended by this clause.

NOTE 1—Unless explicitly stated, the term “provider network” in this standard refers to a PBN. The term “Provider Bridged Network (PBN)” is used exclusively to refer to networks configured and managed as specified by this clause and comprising only (a) Provider Bridges and Provider Edge Bridges and (b) communications media and equipment providing the ISS (IEEE Std 802.1AC). Although the requirements of Clause 15 are generally applicable to similar services, a generalized framework for all network designs that could support these requirements, while useful in the context of other equipment and services, is outside the scope of this standard. This clause describes specific best practice for PBNs to ensure that the requirements for Bridge functionality are clear. Conformance of a Provider Bridge implementation to this standard does not require that the implementation be used as specified in this clause, merely that it is capable of being so used.

NOTE 2—Within a provider network, an instance or instances of the MAC Service are reserved for the service provider’s own use to configure and manage the network. All frames associated with such service instances, and that are not confined to an individual LAN, are subject to service instance selection, segregation, and identification as specified in 16.1.

### 16.1 PBN overview

The principal elements of PBN operation comprise:

- a) Service instance segregation within the provider network for customer frames (15.6).
- b) Service instance selection on ingress, and service instance identification on egress, for each customer frame (15.8).
- c) Resource allocation and configuration to provide service instance connectivity (16.3).

The principal elements of PBN operation may also include:

- d) Management of customer end station address learning (16.4).
- e) Prevention of connectivity loops formed through attached networks (16.5).

### 16.2 Provider Bridged Network (PBN)

An example PBN is illustrated by Figure 16-1.

**Figure 16-1—PBN with interface examples**

1 Customer equipment attaches, via one or more customer interface LANs, to equipment that provides the  
2 service interfaces specified in Clause 15. That interface equipment can be located in the core of the provider  
3 network, such that both the equipment and the attached LANs are secure against direct addition of frames  
4 either by the customer or by others. More commonly the interface equipment connects to the network core  
5 using one or more access LANs, which can be subject to external interference. Figure 16-1 provides  
6 examples. Within the network core, Provider Bridges and LANs are secured so that only the service provider  
7 can manage the reception, transmission, and relay of frames between Provider Bridges.

8 The arbitrary physical network topology of the network core and the connectivity that it provides to support  
9 segregated instances (15.6) of the MAC Service is designed and managed (16.3) by the service provider to  
10 meet bandwidth and service availability requirements at the PNP. Application of the S-VLAN ingress and  
11 egress rules at these Ports in support of service instance selection and identification (15.8) ensures that  
12 frames cannot be transmitted or received on any service instance by any customer's equipment without prior  
13 agreement with the service provider.

1 Although the application of the ingress and egress rules, together with the use of the MSTP restrictedRole  
2 and restrictedTcn (13.27.64, 13.27.65) parameters and MVRP registration controls (16.3), permit service  
3 providers to allow direct attachment of customer-operated equipment to access LANs, there are commonly  
4 other reasons, such as Operations, Administration, and Maintenance (OAM) support of access LANs, why  
5 interface equipment is mandated. The interface equipment, as illustrated by, but not limited to, the examples  
6 in Figure 16-1 can be used to partition and enhance network access functionality to provide:

- 7 a) Service instance multiplexing on a single access LAN
- 8 b) Provision of resilient, and optionally physically route diverse, access
- 9 c) Reduced management of customer use of multiple service instances
- 10 d) Selective multiplexing of C-VLANs onto service instances
- 11 e) Reliable identification of the customer point of attachment

12 without requiring customer systems to understand the internal details of the provider network.

13 Provider Bridge A in Figure 16-1 uses physically separate customer interface LANs to provide separate  
14 Port-based service interfaces to the customer equipment and uses S-TAGs to multiplex the corresponding  
15 service instances over a single access LAN. The interface equipment can be managed by the service  
16 provider to use S-VIDs that do not require use of a VID Translation Table at the edge of the core network.  
17 Alternatively, the latter can translate S-VIDs to remove the need for such management, with all interface  
18 equipment using the same S-VIDs in the same way.

19 Provider Bridge B in Figure 16-1 uses a single customer interface LAN to provide a Port-based service  
20 interface to the customer equipment and uses two access LANs to provide resilient connectivity to distinct  
21 Provider Bridges in the core network. Receipt of Provider Bridge BPDUs by Bridge B protects against the  
22 failure of an access LAN, of one of the core Bridges, or of some internal physical connectivity within the  
23 provider network. Use of the MSTP restrictedRole and restrictedTcn parameters by PNP ensures that  
24 receipt of frames from the access LANs cannot disrupt the active topology or address learning within the  
25 core network. Where multiple service instances are provided at a single customer point of attachment, both  
26 access links can be used.

27 Provider Edge Bridge C in Figure 16-1 provides a C-tagged service interface to the customer equipment and  
28 uses C-TAGs on the customer interface LAN to select between multiple S-VLAN-tagged service instances  
29 on the access LAN. Individual C-VLANs can be conveyed on any service instance, and this distribution of  
30 C-VLANs can be changed in response to changes in the connectivity offered by the service instances  
31 through customer systems at other points of customer attachment. The traffic for a particular C-VLAN can  
32 be the majority of that carried on a specific service instance; specifying that frames for that C-VLAN are  
33 untagged on the internal LAN that corresponds to that service instance within the Provider Edge Bridge  
34 allows those frames to be carried through the provider network without a C-VID following the S-VID if the  
35 overhead of conveying the additional octets is a concern.

36 NOTE 1—In the scenario where a customer network has multiple service interfaces to a provider network, and the  
37 customer network VLAN topology is such that frames sent from a single MAC source on different C-VLANs will enter  
38 the provider network on different service interfaces and be mapped to the same service instance (same S-VLAN), then  
39 the C-MAC address will appear to be duplicated and potentially cause oscillation in the learning process within the  
40 Provider Network. This scenario can be avoided by restricting a MAC address to enter the provider network at the same  
41 service interface for all C-VLANs, or by mapping the different C-VLANs to different service instances (different  
42 S-VLANs), or by restricting the service instance to be point-to-point so the provider Bridges do not need to learn  
43 the C-MAC addresses.

44 In some cases a service provider needs to reach a customer interface LAN that is not directly attached to the  
45 service provider's network but is attached instead to another PBN. Figure 16-2 shows some examples in  
46 which a customer interface LAN is connected to an access PBN that is not the PBN providing service to the  
47 customer.

48 NOTE 2—The PBN providing access to the customer interface LANs in these examples can provide other services to its  
49 own customers as well.

**Figure 16-2—Examples of remote customer service access via a second PBN**

1 In these examples the service provider uses a Port-based service provided by the access PBN to reach the  
2 customer interface LANs. Each such access service is identified by a distinct S-VID at the network-to-  
3 network interface LAN. The service PBN uses this S-VID to select an RCSI that provides either a  
4 Port-based or C-tagged service interface as specified in Clause 15. An RCSI provides service instance  
5 selection and identification (15.3) and service management for each customer interface LAN. Each RCSI  
6 carries frames to/from a single customer interface LAN.

7 PEB A in Figure 16-2 receives traffic from two customer interface LANs attached to the access PBN. The  
8 traffic from each customer interface LAN is carried over a separate RCSI. In the example shown each RCSI  
9 is connected to a Port-based service interface (CNP). If the two customer interface LANs participate in the  
10 same service instance (i.e., their RCSI CNPs belong to the same S-VLAN) a frame received from one RCSI  
11 CNP can be transmitted on the other RCSI CNP. Thus a frame received on the network-to-network LAN  
12 with one S-VID can be subsequently transmitted on that same external LAN with a different S-VID. This  
13 behavior is sometimes called “Hairpin Switching”.<sup>27</sup>

14 The structure allowing a frame to be received and subsequently transmitted on the same external interface  
15 while avoiding loops and misdelivery of multicast frames is illustrated in Figure 16-3. Frames from/to CE<sub>1</sub>  
16 have S-VID A and frames from/to CE<sub>2</sub> have S-VID B. Thus the two customer interface LANs cannot  
17 exchange traffic within the access PBN. In PEB A external S-VIDs A and B select or identify different RCSI  
18 PAPs.

<sup>27</sup> For example, this behavior is called “Hairpin Switching” in MEF 26 [B55].

**Figure 16-3—Access service separation and “Hairpin Switching”**

1 In this example, both RCSI CNPs belong to the same internal S-VLAN in the service provider’s network  
2 identified by S-VID X. Frames can be relayed between all Ports belonging to S-VID X, including between  
3 the two RCSIs. When a frame is received on one RCSI and subsequently transmitted on the other RCSI the  
4 frame is received and transmitted on the same external RCAP. However, in this case the external S-VIDs in  
5 the received and transmitted frames are different. If the sets of endpoints in the access PBN associated with  
6 each external S-VID are disjoint there is no possibility of looping or misdelivery of multicast frames.

7 PEB B in Figure 16-2 receives traffic from a customer interface LAN and provides a C-tagged RCSI (CEP).  
8 The capabilities of a C-tagged RCSI are the same as those provided by an external CEP as described above.

## 9 16.3 Service instance connectivity

10 The VLAN Topology of each S-VLAN is established by the mechanisms introduced in 7.1 and Figure 7-1.  
11 The service provider can use and configure MSTP to provide a number of independent spanning tree active  
12 topologies and can assign each S-VLAN independently to one of these to best use the resources in the  
13 network. MVRP running in the context of each spanning tree active topology configures the extent of each  
14 S-VLAN to the subset of that active topology necessary to support connectivity between the customer points  
15 of attachment to the MAC Service instance provided, and it can reconfigure that connectivity as required if  
16 the spanning tree active topology changes.

17 NOTE 1—Autoconfiguration of the extent of each S-VLAN is accomplished by the service provider configuring the  
18 MVRP Administrative Control “Registration Fixed (New ignored)” for the S-VLAN on each CNP where the  
19 corresponding MAC Service Instance can be selected. The Enable Ingress Filtering parameter is not typically used  
20 within an individual provider network, as it limits the ability of the network to carry service instances following changes  
21 in the active topology. However, it can be used to limit the reachability of service instances used by the service provider  
22 for network management and to restrict service instances carried from one provider network domain to another.

23 The operation of MSTP within a provider network is independent of the operation of any spanning tree  
24 protocol within attached customer networks. This independence is achieved by using the Provider Bridge  
25 Group Address (Table 8-1) as the destination address of all MSTP BPDUs transmitted on all Provider  
26 Bridge Ports and by setting the restrictedRole and restrictedTcn parameters (13.27.64, 13.27.65) for CNPs.  
27 Frames received by CNPs and addressed to the Bridge Group Address are subject to service instance  
28 selection and relay in the same way as customer data frames.

29 NOTE 2—Customer BPDUs addressed to the Bridge Group Address are conveyed transparently, allowing the customer  
30 to use an instance of MSTP or RSTP that is completely independent of the provider network to establish and maintain  
31 full and loop-free connectivity of the customer connected networks and services. A customer can also use MVRP to  
32 limit the transmission of frames assigned to C-VLANs to the service instances required for C-VLAN connectivity.

1 The operation of MVRP within a provider network is independent of the operation of any configuration  
2 protocol within attached customer networks. The Provider Bridge MVRP Address (Table 8-1) is used as the  
3 destination address of all MVRPDUs transmitted in support of the MVRP Application. Frames received by  
4 CNPs and addressed to an MRP Application Address (Table 10-1) not in use by the S-VLAN component are  
5 subject to service instance selection and relay in the same way as customer data frames. The MVRP  
6 Administrative Control for each S-VLAN is either “Registration Fixed (New ignored)” or “Registration  
7 Forbidden” on all CNPs, so no information is received from any Provider Bridge MVRPDU that has been  
8 erroneously transmitted by a customer system.

## 9 **16.4 Service provider learning of customer end station addresses**

10 Customer data frames for any given MAC Service instance are restricted to that part of the provider network  
11 that supports the VLAN topology of the associated S-VLAN as described in 16.3 and are further restricted  
12 by learning the source addresses of frames as described in Clause 7 and Clause 8.

13 In a PBN that commonly provides interfaces to each customer at a small fraction of the total number of  
14 customer interfaces provided, the requirement for learning customer end station addresses can be much  
15 reduced by applying enhanced filtering utility criteria (8.7). In particular, learning can be restricted to the  
16 ingress and egress Provider Bridge Ports of each S-VLAN that connects only two customer points of  
17 attachment, or to the customer systems attached to those Ports.

18 The “new” flag in MVRP can be used to flush learned addresses on a specific service instance in a PBN in  
19 response to a topology change in the Customer Network.

## 20 **16.5 Detection of connectivity loops through attached networks**

21 The transmission and reception of MSTP BPDUs through CNPs will detect accidental direct connection of  
22 those ports, or their interconnection by a network that is transparent to frames with the Provider Bridge  
23 Group Address as the destination MAC address. However, a service provider cannot rely on any customer  
24 network relaying such frames and should develop a policy and mechanisms to deal with potential data loops  
25 that can arise if the attached customer systems do not correctly operate their own instance or instances of a  
26 spanning tree protocol.

27 NOTE 1—Use of the restrictedRole parameter at ingress ports ensures that receipt of BPDUs addressed to the Provider  
28 Bridge Group Address cannot disrupt internal connectivity within the provider network.

29 NOTE 2—Specification of service provider policies, mechanisms, and heuristics used to detect or minimize the impact  
30 of data loops created by customer systems is not addressed by this standard. They can include, but are not limited to,  
31 bandwidth limitation, charging policies, detection of the repetitive movement of the apparent location of customer  
32 stations, and customer agreement to allow the use of service provider loop detection protocols by not filtering the  
33 associated frames.

34 NOTE 3—A data loop is not the only possible cause of excess bandwidth consumption by a given customer of a  
35 provider network, and the service provider is usually required to meet service guarantees to other customers irrespective  
36 of the cause of the excess bandwidth demand. Data loops are not a unique threat to satisfactory overall network  
37 performance. Their distinct characteristic is consumption of discretionary bandwidth without benefiting any customer.  
38 The customer that creates the loop can suffer particularly serious network degradation or excess cost as the service  
39 provider limits the total bandwidth consumed by that customer. It is therefore in the interests of each customer and the  
40 service provider to raise service satisfaction by preventing and detecting loops.

41 Each C-VLAN component within a Provider Edge Bridge implements RSTP, with the enhancements to  
42 support loop-free connectivity between CEPs, as specified in 13.41, thus interoperating with customer  
43 equipment and spanning tree configurations to support reliable and deterministic prevention of loops, and  
44 supporting provision of redundant connectivity.

## **1 16.6 Network management**

2 Management of a Provider Bridge is directly under the control of the service provider. Provider network  
3 customers shall not have access to managed objects related to elements of Provider Bridges within the  
4 provider network.

## 17. Management Information Base (MIB)

This clause (Clause 17) contains a complete SMIV2 MIB set for all features of this standard.

### 17.1 Internet Standard Management Framework

For a detailed overview of the documents that describe the Internet Standard Management Framework, refer to section 7 of IETF RFC 3410 (2002).

Managed objects are accessed via a virtual information store, termed the *Management Information Base* or *MIB*. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This clause specifies a MIB module that is compliant to the SMIV2, which is described in IETF STD 58, IETF RFC 2578, IETF RFC 2579, and IETF RFC 2580.

Control of the transmission of Fault Alarms, which are Notifications in SNMP, are described by IETF STD 62, IETF RFC 3413, IETF RFC 3417, and IETF RFC 4789. As a consequence of the concentration of control of the reporting of SNMP Notifications in the SNMP-TARGET-MIB and SNMP-NOTIFICATION-MIB of IETF RFC 3413, the variables controlling Fault Alarm notifications require no specific objects in the MIB modules defined in this standard.

### 17.2 Structure of the MIB

The IEEE 802.1Q MIB set comprises a number of modules. These are summarized in Table 17-1 with the name of each module and references to its specification in this clause (Clause 17) and to the clause that specifies the managed functionality. The table also identifies the amendment or amendment project that introduced that functionality<sup>28</sup> (and unless otherwise noted) the MIB module for its management. The definitive specification of both functionality and MIB module is provided by this standard, not by any prior amendment.

Prior revisions of this standard relied on MIB modules defined by the IETF Bridge Working Group. IETF RFC 4663 [B35] describes more details of the IETF transition of responsibility for bridging-related MIB modules from the IETF Bridge MIB Working Group to the IEEE 802.1 Working Group.

The REVISION statements in each MIB module describe its history and development.

**Table 17-1—IEEE 802.1Q MIB modules**

| Module                     | Structure, relationships, security considerations, module definition | Managed functionality | Initial functionality and MIB specification                                             |
|----------------------------|----------------------------------------------------------------------|-----------------------|-----------------------------------------------------------------------------------------|
| IEEE8021-TC-MIB            | 17.2.1, 17.3.1, 17.4.1, 17.7.1                                       | Textual conventions   | IEEE Std 802.1ap                                                                        |
| IEEE8021-BRIDGE-MIB        | 17.2.2, 17.3.2, 17.4.2, 17.7.2                                       | Clause 8              | IEEE Std 802.1D, 802.1p, IEEE Std 802.1t. MIB adapted from IETF RFC 4188, IETF RFC 4363 |
| IEEE8021-SPANNING-TREE-MIB | 17.2.3, 17.3.3, 17.4.3, 17.7.3                                       | Clause 13             | IEEE Std 802.1w. MIB adapted from IETF RFC 4318                                         |

<sup>28</sup> Functionality added to an IEEE standard is often referred to using an amendment or amendment project designation long after it has been incorporated in a revision of the standard, even if the amendment was not independently published and the functionality has since been revised. This table column is provided as an aid to identifying this standard's specification of that functionality and MIB module.

**Table 17-1—IEEE 802.1Q MIB modules (*continued*)**

| Module                             | Structure, relationships, security considerations, module definition | Managed functionality           | Initial functionality and MIB specification                                        |
|------------------------------------|----------------------------------------------------------------------|---------------------------------|------------------------------------------------------------------------------------|
| IEEE8021-Q-BRIDGE-MIB              | 17.2.4, 17.3.4, 17.4.4, 17.7.4                                       | Clause 8                        | IEEE Std 802.1Q, IEEE Std 802.1u, IEEE Std 802.1v. MIB adapted from IETF RFC 4363. |
| IEEE8021-PB-MIB                    | 17.2.5, 17.3.5, 17.4.5, 17.7.5                                       | Clause 16                       | IEEE Std 802.1ad. MIB in IEEE Std 802.1ap                                          |
| IEEE8021-MSTP-MIB                  | 17.2.6, 17.3.6, 17.4.6, 17.7.6                                       | Clause 13                       | IEEE Std 802.1s. MIB in IEEE Std 802.1ap                                           |
| IEEE8021-CFM-MIB                   | 17.2.7, 17.3.7, 17.4.7, 17.7.7.1                                     | Clause 20                       | IEEE Std 802.1ag                                                                   |
| IEEE8021-CFM-V2-MIB                | 17.2.7, 17.3.7, 17.4.7, 17.7.7.2                                     | Clause 20                       | IEEE Std 802.1ag. MIB updated in IEEE Std 802.1ap                                  |
| IEEE8021-PBB-MIB                   | 17.2.8, 17.3.8, 17.4.8, 17.7.8                                       | Clause 26                       | IEEE Std 802.1ah. MIB updated in IEEE Std 802.1ap                                  |
| IEEE8021-DDCFM-MIB                 | 17.2.9, 17.3.9, 17.4.9, 17.7.9                                       | Clause 29                       | IEEE Std 802.1Qaw                                                                  |
| IEEE8021-PBBTE-MIB                 | 17.2.10, 17.3.10, 17.4.10, 17.7.10                                   | 25.10                           | IEEE Std 802.1Qay                                                                  |
