36 same manner that the first-level PBBN carries the customer S-VLANs as services. In this model an S-VLAN  
37 is presented to a level  $n$  PBBN for transport. The PBBN transports the S-VLAN as an instance of MAC  
38 Service within a B-VLAN generated by the  $n$ -level PBBN. The  $n$ -level PBBN is connected to an  
39 ( $n + 1$ )-level PBBN over a hierarchal E-NNI interface. The ( $n + 1$ )-level PBBN carries B-VLANs from the  
40 attached  $n$ -level PBBN as service instances in ( $n + 1$ )-level B-VLANs through the ( $n + 1$ )-level PBBN.

41 Since each hierarchal level requires an additional encapsulation, the nesting depth is limited by the  
42 maximum defined frame length for the MAC type used.

## 1 26.6.2 Peer PBBNs

2 The peer interconnect between PBBNs results in a flat service space that does not increase the encapsulation  
3 nesting depth. The network scales the number of services over the combined PBBNs by service localization.  
4 Further localization and scaling of services is supported by the I-SID filtering functions in addition to the  
5 optional I-SID translation functions of the CBP interfaces on each side of the peer E-NNI (6.11). Services  
6 that are limited in extent to a single PBBN do not consume any resources within the other connected  
7 PBBNs.

8 The peer interconnect will extend backbone service instances across the peer connected PBBNs. In the peer  
9 interconnect a service instance in PBBN A is connected to a service instance in PBBN B by the peer E-NNI  
10 between the PBBNs. The peer E-NNI is formed by an I-tagged Service Interface between two CBPs (6.11),  
11 one in each of the peer PBBNs. The I-SID used over the E-NNI must be agreed to mutually by both  
12 providers. At each end of the E-NNI the CBP may optionally translate the I-SID (and the B-DA if it is the  
13 default multicast address generated from the I-SID) used over the E-NNI to a new I-SID for use within the  
14 PBBN. The CBPs also map the I-SID to a B-VLAN within the PBBN, as no B-TAGs are transmitted across  
15 the peer interconnect.

## 16 26.7 Network management

17 Management of a PBB is directly under the control of the backbone provider. PBB customers shall not have  
18 access to managed objects related to elements of PBBs within the PBBN.

19 In SNMP management systems, this can be realized by implementing one management entity acting as an  
20 agent in the Provider Bridge and separating the management views that include customer networks  
21 information from the management views that include provider networks information using the mechanisms  
22 defined by the SNMP management framework in IETF RFC 3411.

## 23 26.8 CFM in PBBs

24 CFM (Clause 18 through Clause 22) may operate over LANs, C-VLANs, S-VLANs, B-VLANs, and  
25 backbone service instances identified by I-SIDs. CFM Maintenance domain Endpoints (MEPs) and  
26 Maintenance domain Intermediate Points (MIPs) may be inserted at any of the EISS service interfaces  
27 described by 6.9, 6.10, and 6.11, at the ISS service interface described in IEEE Std 802.1AC, and within the  
28 EISS and Backbone Service Instance Multiplex Entity described in 6.17 and 6.18.

29 Within a PBBN, the encapsulation performed by PIPs also encapsulates CFM frames sourced by customers  
30 attached to CNPs. Encapsulation of S-VLAN and C-VLAN CFM frames hides them from the PBBN  
31 enabling a new set of independent MD levels to be defined in the PBBN for CFM, which may be used for  
32 managing B-VLANs spanning between the B-components and BCBs of the PBBN, and over LANs that  
33 span between PBB ports. In addition, the backbone may support MAs per backbone service instance that are  
34 identified by I-SIDs and span between the PIPs and CBPs of I-components and B-components of the PBBN.  
35 A full set of eight maintenance levels exists within each PBBN for use by B-VLAN CFM frames. The  
36 Backbone Service Instance CFM frames may extend over a E-NNI, therefore providing eight levels of  
37 Backbone Service Instance CFM for the extended backbone, which includes all peer connected PBBNs. All  
38 eight levels of CFM frames generated in customer networks are carried over the backbone as encapsulated  
39 data and may be used by customer networks. Another eight maintenance levels exist for the LANs for which  
40 no frames are untagged. This may be the case for the PNP-PNP LAN links. The CFM stacks for the PIP and  
41 CBP are depicted in Figure 26-2. The stacks for the CNP and PNP are as depicted in 22.1.1.

1

Figure 26-2—CFM shim model

2 Figure 26-3 and Figure 26-4 show possible MAs at the three types of PBBN service interfaces described in  
3 25.3, 25.4, and 25.5, respectively. These three interfaces are depicted in Figure 26-1, where they are  
4 labeled 1, 2, and 3. Figure 26-5 and Figure 26-6 show possible MAs at the two types of PBBN E-NNI  
5 interfaces, which are described in 26.6.1 and 26.6.2, respectively. These two types of E-NNIs are depicted in  
6 Figure 26-1, where they are labeled 4 and 5. The MAs indicated in Figure 26-3 through Figure 26-6 are  
7 example MAs for each PBBN service interface type and PBBN E-NNI type. Typically not all these MAs  
8 would be supported within any given PBBN since some MAs illustrated provide redundant capabilities and  
9 since the selection of MAs will depend on the service-level agreements used for a particular service, on the  
10 operational environment of a particular PBBN and on the equipment used in the particular PBBN. In these  
11 figures, four distinct categories of MAs are depicted. These are the S-VLAN and C-VLAN MAs, the  
12 Backbone Service Instance MAs, the B-VLAN MAs, and the LAN MAs. Each of these four classes of MAs  
13 is associated with independent sets of MDs introducing four independent sets of eight maintenance levels.  
14 The selection of which levels for each of these MDs to use in a particular network depends on the specific  
15 network implementation. The S-VLAN MAs are only visible within the I-component where customer  
16 frames are un-encapsulated. Customer CFM frames are encapsulated along with the other customer frames  
17 at the VIPs within the I-component. Once the S-VLAN CFM frames are encapsulated, they appear just like  
18 any data frame within the PBBN; therefore, they do not activate any CFM functions within the PBBN past  
19 the VIPs. The Backbone Service Instance CFM frames may optionally be generated at the Backbone Service  
20 Instance Multiplex Entity within the PIP or CBP. These CFM frames are only visible within the PBBN  
21 where the I-TAG is being processed, that is at the CBP and at the PIP. Each Backbone Service Instance MD  
22 may be assigned to one of eight maintenance levels. Since the Backbone Service Instance CFM maintenance  
23 domain may extend over E-NNI boundaries, these eight levels extend over all interconnected PBBNs until  
24 they are terminated at a VIP. B-VLAN MAs manage the B-VLANs within a single PBBN. The B-VLAN  
25 MDs have a new set of eight maintenance levels, which are separate for each PBBN and never extend out of

1 the PBBN. Finally, the LAN links within a PBBN (PIP to CBP, PNP to PNP), between two PBBNs (CBP to  
2 CBP, PIP to CBP) and entering/egressing the PBBN (to/from CNP) may optionally be monitored by LAN  
3 link MAs, generated/terminated within the PIP, CBP, PNP, and CNP. LAN link MAs are typically confined  
4 to the LAN link.

## 26.8.1 CFM over Port-based and S-tagged service interfaces

Figure 26-3 shows example MAs for the Port-based or S-tagged service interface described in 25.3 and 25.4 and depicted in Figure 26-1 labeled 1 and 2.

MAs (a) and (b) illustrated in Figure 26-3 through Figure 26-6 are used to monitor the PBBN core. Each PBBN has an independent backbone MD-level space. MAs (a) and (b) are assigned Backbone Maintenance Levels from the backbone MD-level space of their PBBN in the same manner used to assign S-VLAN MAs described in Clause 22. The MAs (a) are used to monitor each individual LAN that interconnects PNPs. The MAs (b) monitor specific B-VLANs. The B-VLAN monitoring, illustrated in the example, begins at the up MEP located at the top of the CBP. A given B-VLAN may exit a B-component on multiple PNPs, each of which may have a MIP on MA (b) if desired.

1 MAs (i) and (j) illustrated in Figure 26-3 through Figure 26-6 are two possible customer MAs. Attached  
2 customers have an independent customer MD-level space. MAs (i) and (j) are assigned Customer  
3 Maintenance Domain Levels from their customer MD-level space in the manner used for S-VLAN MAs  
4 described in Clause 22. The MAs (i) monitor the links between the customer equipment and the CNP or the  
5 PBBN. At the Port-based or the S-tagged service interface, MAs (i) may be terminated by the provider by an  
6 MEP at the CNP and used to monitor the customer's access link. The MAs (j) monitor the service instance  
7 from the customer over the PBBN. MAs (j) extend between all the customer attachments of the extended  
8 PBBN, passing through any PBBN E-NNI interfaces. At the VIPs located at the edge of the extended PBBN,  
9 the CFM frames for MA(j) will be mapped to/from an I-SID and carried over the extended PBBN as  
10 encapsulated frames. These CFM frames are encapsulated by the PBBN in the same manner as data frames.  
11 The encapsulation makes them invisible to any MPs within the extended PBBN.

12 In the case of a Port-based service interface, the MA(j) CFM frames are untagged or C-tagged over the  
13 interface formed between the CNP and the customer equipment. In this case, the MA(j) CFM frames have an  
14 S-VID assigned from the PVID at the CNP, which will be carried to the VIP within the I-component. In the  
15 case of an S-tagged service interface, the MA(j) CFM frames are untagged, C-tagged, or S-tagged over the  
16 interface formed between the CNP and the customer equipment. In this case, the MA(j) CFM frames have  
17 the S-VID carried over the service interface or, if the CFM frame is not S-tagged, it will have an S-VID  
18 assigned from the PVID of the CNP.

19 MA (f) depicted in Figure 26-3 through Figure 26-6 is used for backbone service instance management.  
20 MAs (f) are within the Backbone Service Instance MD-level space, which is shared over the entire extended  
21 PBBN. MAs (f) are assigned Service Maintenance Domain Levels from this Backbone Service Instance  
22 MD-level space. The MEPs for MA(f) are formed at the PIP within the Backbone Service Instance  
23 Multiplex Entity (6.18) as seen in Figure 26-2. MA(f) may have MIPs located in the CBP also formed by a  
24 Backbone Service Instance Multiplex Entity as depicted in Figure 26-2.

## 25 26.8.2 CFM over I-tagged Service Interfaces

26 Figure 26-4 shows possible MAs for the I-tagged service interface described in 25.5 and depicted in  
27 Figure 26-1 labeled 3. The MAs (a) and (b) in Figure 26-4 are used for PBBN core monitoring as described  
28 in 26.8.1.

29 MAs (c) in Figure 26-4, Figure 26-5, and Figure 26-6 are used to monitor the link between the PIP and CBP.  
30 The MAs (c) CFM frames are unique among the other CFM frames because they are transmitted without an  
31 I-TAG over the CBP to PIP LAN.

32 MAs (f) depicted in Figure 26-4 are used for service management as described in 26.8.1. In an I-tagged  
33 service interface, MAs (f) have an MEP in the customer network located at the Backbone Service Instance  
34 Multiplex Entities (6.18) of the customer PIP and may have MIP within the extended provider network  
35 located at the Backbone Service Instance Multiplex Entities of the CBPs. The provider may use MAs (e) to  
36 monitor each service instance by placing a MEP at the Backbone Service Instance Multiplex Entities of the  
37 CBP. The backbone service instance-level space is shared between the customer and provider who must  
38 agree on the levels used for provider and customer Backbone Service Instance CFM messages.

39 Customer S-VLAN MAs (j) are encapsulated by the customer equipment and are indistinguishable from  
40 data within the PBBN.

## 41 26.8.3 CFM over hierarchal E-NNI

42 Figure 26-5 shows possible MAs for the hierarchal E-NNI described in 26.6.1. In Figure 26-1 the hierarchal  
43 E-NNI labeled 4 depicts an E-NNI with the demarcation point between the CBP and PIP. Example MAs for  
44 a hierarchal E-NNI with demarcation between CBP and PIP are illustrated in Figure 26-5. The MAs (a) and  
45 (b) in Figure 26-5 are used for PBBN core monitoring as described in 26.8.1.

1 The operation of the backbone service instance and LAN MAs (f), (e), and (c) are as described in 26.8.2.  
2 Since each PBBN-A B-VLAN MA (j) is mapped into a PBBN-B backbone service instance monitored by  
3 MAs (f) and/or (e) the MAs (f) and (e) may be used to monitor the extended B-VLAN from PBBN-A.

4 MAs (j) are not visible to PBBN-B as described in 26.8.2. The per PBBN-A Backbone Service Instance  
5 MAs (l) illustrated in Figure 26-5 are never visible to PBBN-B since they are encapsulated along with the  
6 B-VLAN.

#### 7 **26.8.4 CFM over peer E-NNI**

8 Figure 26-6 shows possible MAs for the peer E-NNI described in 26.6.2 and depicted in Figure 26-1 labeled  
9 5. The MAs (a) and (b) in Figure 26-6 are used for PBBN core monitoring as described in 26.8.1. The LAN  
10 MAs (c) and Backbone Service Instance MAs (e) and (f) in Figure 26-6 are as described in 26.8.2.

11 The MAs (f), (g), (d), and (c) extend over the demarcation point between PBBN-A and PBBN-B, while the  
12 MAs (e) are within PBBN-A and PBBN-B and do not extend over the demarcation point. The MA (f) is a  
13 Backbone Service Instance MA that extends through both PBBN-A and PBBN-B providing monitoring for  
14 the service from VIP to VIP. MAs (f) may have a MIP on each side of the demarcation point to allow  
15 isolation of a fault to an individual PBBN. The MAs (g) also are Backbone Service Instance MAs that  
16 extend over the demarcation point. MAs (g) are launched by PBBN-B at the CBP facing the E-NNI rather  
17 than at the service originating VIP and extend to the far edge of PBBN-A. MAs (g) may be used by PBBN-B  
18 to monitor the backbone service instance over PBBN-A, but only provides information to PBBN-A on the  
19 operation of the backbone service instance over the demarcation point to PBBN-B. The MA (d) is a  
20 Backbone Service Instance MA that monitors the service over the demarcation point, but does not provide  
21 any monitoring deeper in PBBN-A or PBBN-B. MAs (e) provide internal monitoring of the backbone  
22 service instance within PBBN-A and PBBN-B, respectively.

#### 23 **26.9 CFM in a PBB-TE Region**

24 CFM as specified in Clause 18 through Clause 22, provides capabilities useful in detecting, isolating, and  
25 reporting connectivity faults in VID-based service instances, backbone service instances, TESIS, and  
26 Infrastructure Segments. The list of features that are specifically related to TESIS and Infrastructure  
27 Segments is summarized here.

28 NOTE—MIP function is not supported for an Infrastructure Segment MA. Loopback is supported on Infrastructure  
29 Segment MEPs. It is not useful to apply the Linktrace operation to an Infrastructure Segment MA. No extension is made  
30 to the Loopback or Linktrace operations supporting their use for an Infrastructure Segment MA. This does not preclude  
31 the use of MIPs associated with a PBB-TE MA.

32 In particular, this subclause summarizes PBB-TE considerations related to the following:

- 33 a) Addressing PBB-TE MEPs (26.9.1)
- 34 b) TESI identification (26.9.2)
- 35 c) PBB-TE MEP placement in a Bridge Port (26.9.3)
- 36 d) PBB-TE MIP placement in a Bridge Port (26.9.4)
- 37 e) TESI Maintenance Domains (26.9.5)
- 38 f) PBB-TE enhancements of the CFM protocols (26.9.6)
- 39 g) Addressing Infrastructure Segment MEPs (26.9.7)
- 40 h) Infrastructure Segment identification (26.9.8)
- 41 i) Infrastructure Segment MEP placement in a Bridge Port (26.9.9)
- 42 j) Infrastructure Segment Maintenance Domains (26.9.10)
- 43 k) IPS extensions to Continuity Check operation (26.9.11)

## 26.9.1 Addressing PBB-TE MEPs

The configuration of an MA requires a parameter (or a list of parameters) that associates it with the monitored service. A TESI is identified by the list of ESPs supporting it. Correspondingly, the configuration of a PBB-TE MA, requires the list of the monitored TESI's ESPs, each identified by the 3-tuple <ESP-DA, ESP-SA, ESP-VID> or collectively by the TE-SID (12.14.5.3.2).

The MEPs related to a TESI require the same set of parameters as a VID-based MEP requires, with the following changes:

- a) The Primary VID is not writable but is always set to the value of the ESP-VID parameter that corresponds to the MA's ESP that has the MEP's MAC address in its ESP-SA field [item d) in 12.14.7.1.3, 20.9.7].
- b) The MAC address of the MEP is the MAC address of the CBP upon which the MEP is operating [item i) in 12.14.7.1.3].

## 26.9.2 TESI identification

In contrast to VID-based services where the `vlan_identifier` is used to identify the service, independent ESPs could have the same VID value in their ESP-VID field if some other parameters in their identifying 3-tuples are different. Figure 26-7 depicts such a case where the two ESPs are distinguished by their source addresses. The TESI Multiplex Entity (6.19) allows shims defined for PBB-TE to be instantiated per TESI at a SAP that supports multiple TESIs.

Figure 26-7—Independent ESPs using the same ESP-DAs and ESP-VIDs

## 26.9.3 PBB-TE MEP placement in a Bridge Port

PBB-TE MEPs are always Up MEPs and can only be placed on CBPs as these correspond to the demarcation points of the ESPs supporting the PBB-TE service. The PBB-TE MEPs are placed between the Frame filtering entity (8.6.3) and the Port filtering entities (8.6.1, 8.6.2, and 8.6.4) in the ESP-VID space identified by the EISS Multiplex Entity (6.17). Since the ESP MAC addresses can be reused by different ESPs, the PBB-TE MEPs need to be further differentiated by the TESI Multiplex Entity (6.19). In principle, separately for each TESI, there can be from zero to eight Up MEPs, ordered by increasing MD Level, from Frame filtering toward Port filtering, even though not more than one MD Level is expected for PBB-TE MAs. Figure 26-8 depicts an example of PBB-TE MEPs on a CBP.

Figure 26-8—PBB-TE MEP placement in a CBP

1 26.9.4 PBB-TE MIP placement in a Bridge Port

2 PBB-TE MIPs creation is based on the algorithm described in 22.2.3. PBB-TE MIPs are created per  
3 identified ESP-VIDs on PNPs. Figure 22-9 depicts an example of a pair of PBB-TE MHFs on a PNP.

4 26.9.5 TESI Maintenance Domains

5 A PBB that is capable of providing TESIS supports a new set of TESI MDs in addition to those described in  
6 26.8. In particular the CFM stacks in Figure 26-2 will need to have TESI MD levels in parallel to the  
7 depicted Backbone MD levels for CBPs initiating TESIS while TESI MDs will have to be present in parallel  
8 to the Backbone MD levels depicted in Figure 26-3.

## 1 26.9.6 PBB-TE enhancements of the CFM protocols

### 2 26.9.6.1 Continuity Check protocol in a PBB-TE MA

3 The Continuity Check protocol is described in 20.1 and the corresponding state machines in Clause 20. The  
4 only enhancement required by the PBB-TE MA is in the procedure that is responsible for constructing and  
5 transmitting a CCM (20.11.1):

- 6 a) The `destination_address` parameter is set to the MAC address indicated by the value of the ESP-DA  
7 field of the ESP having as ESP-SA the MAC address of the MEP emitting the CCM.

8 PBB-TE MAs may also implement the following enhancements to the Continuity Check protocol:

- 9 b) The procedure `MEPprocessEqualCCM()` on PBB-TE MEPs does not include the check of the MAID  
10 on received CCMs [item b) in 20.17.1].
- 11 c) PBB-TE MEP's may:
- 12 1) Set the Traffic field (21.6.1.4) bit on transmitted CCMs based on information from the  
13 Backbone Service Instance table associated with the CBP upon which the MEP is configured.  
14 In particular, the procedure `xmitCCM()` (20.11.1) is performing the additional action to fill the  
15 Traffic field with the `presentTraffic` variable (20.9.8); and
- 16 2) Check the Traffic field bit on received CCMs (20.16.13); and
- 17 3) Implement the MEP Mismatch state machines (20.26).

18 All other Continuity Check processes are the same as those for a VID-based MA.

### 19 26.9.6.2 Loopback protocol in a PBB-TE MA

20 The Loopback protocol is described in 20.2 and the corresponding state machines in Clause 20. The  
21 enhancements required by the PBB-TE MA are summarized below:

- 22 a) The LBMs transmitted by a MEP associated with a PBB-TE MA use as the `destination_address`  
23 parameter, the MAC address indicated by the value of the ESP-DA field of the MA's ESP that has  
24 the MEP's MAC address indicated in its ESP-SA field [item a) in 20.31.1]. To enable MIPs to  
25 selectively intercept LBMs that are targeting them, the PBB-TE MIP TLV (21.7.5) is inserted as the  
26 first TLV [item f) in 20.31.1] in an LBM. The PBB-TE MIP TLV is not included if the LBM  
27 destination address in 12.14.7.3.2 is associated with any of the values in the ESP-DA field of the  
28 monitored MA's ESPs. The format of the PBB-TE MIP TLV is described in 21.7.5 and is  
29 constructed as follows:
- 30 1) The MIP MAC address field contains the MAC address of the MIP to which the LBM is  
31 targeted [item b) in 12.14.7.3.2].
- 32 2) The Reverse VID field contains the parameter provided in item f) in 12.14.7.3.2, which it uses  
33 as the `vlan_identifier` in the replied LBR.
- 34 3) The Reverse MAC field is only included if the MEP is associated with a point-to-multipoint  
35 TESI. If the MEP is the root MEP, the Reverse MAC field contains the ESP-SA value of any of  
36 the point-to-point ESPs in the TESI. If the MEP is a leaf MEP, the Reverse MAC field contains  
37 the ESP-DA of the point-to-multipoint ESP in the TESI.
- 38 b) LBMs received by PBB-TE MEPs are not processed and are discarded if the received LBM carries a  
39 PBB-TE MIP TLV. A PBB-TE MHF forwards all received LBMs except those carrying a PBB-TE  
40 MIP TLV containing in their MIP MAC address field the MAC address of the MIP associated with  
41 that PBB-TE MHF [item f) in 20.28.1].
- 42 c) The `destination_address` parameter used by LBRs transmitted by PBB-TE MEPs is the value of the  
43 ESP-DA of the MA's ESP that has the MEP's own address in its ESP-SA field. In the case of a  
44 PBB-TE MHF, the `destination_address` parameter for the transmitted LBR is:

- 1) The value carried in the Reverse MAC field contained in the PBB-TE MIP TLV of the received LBM, if this is a group MAC address; otherwise,
- 2) The value of the source\_address of the received LBM.
- d) The source\_address of LBRs transmitted by PBB-TE MHFs is set to:
  - 1) The destination\_address of the received LBM if this destination address is an individual MAC address; otherwise,
  - 2) The value carried in the Reverse MAC field contained in the PBB-TE MIP TLV if the received LBM's destination address is a group MAC address.
- e) The vlan\_identifier used by LBRs transmitted by PBB-TE MEPs is set to the value of its Primary VID [item d) in 12.14.7.1.3]. The vlan\_identifier used by LBRs transmitted by PBB-TE MHFs is set to the value carried in the Reverse VID field contained in the PBB-TE MIP TLV of the received LBM.

All other Loopback processes are the same as those for a VID-based MA.

### 26.9.6.3 Linktrace protocol in a PBB-TE MA

The Linktrace protocol is described in 20.3 and the corresponding state machines in Clause 20. The enhancements required by the PBB-TE MA are summarized as follows:

- a) The LTM's transmitted by a MEP associated with a PBB-TE MA use as the destination\_address parameter, the MAC address indicated by the value of the ESP-DA field of the MA's ESP that has the MEP's MAC address indicated in its ESP-SA field [item a) in 20.42.1]. LTM's carry the PBB-TE MIP TLV constructed as follows:
  - 1) The MIP MAC address field is null.
  - 2) The Reverse VID field contains the parameter provided in item e) in 12.14.7.4.2, which is used as the vlan\_identifier of the replied LTR.
  - 3) The Reverse MAC field is only included if the MEP is associated with a point-to-multipoint TESI. If the MEP is the root MEP, the Reverse MAC field contains the ESP-SA value of any of the point-to-point ESPs in the TESI. If the MEP is a leaf MEP, the Reverse MAC field contains the ESP-DA of the point-to-multipoint ESP in TESI.
- b) No special destination\_address validation tests are performed by the ProcessLTM() procedure in the case of PBB-TE MAs [item c) in 20.47.1].
- c) The process to identify a possible egress port by an intermediate device that implements a MIP associated with a PBB-TE MA, queries the FDB of the corresponding Bridge, using the destination\_address, and the vlan\_identifier of the LTM as the parameters for the lookup (20.47.1.2). The LTM's can be further forwarded by PBB-TE MIPs even if the lookup identifies more than one Egress port.
- d) Finally an LTR issued by a PBB-TE MP:
  - 1) Uses as destination\_address: the value carried in the Reverse MAC field contained in the PBB-TE MIP TLV of the received LTM, if this is a group MAC address; otherwise, the source\_address of the received LTM [item a) in 20.47.4].
  - 2) Uses as source\_address: its MAC address if the LTR is issued by a PBB-TE MEP; otherwise, the destination\_address of the received LTM if this is destination address is an individual MAC address; otherwise, the value carried in the Reverse MAC field contained in the PBB-TE MIP TLV of the received LTM [item b) in 20.47.4].
  - 3) Sets the vlan\_identifier parameter to the value carried in the Reverse VID field contained in the PBB-TE MIP TLV of the received LTM [item c) in 20.47.4].

All other Linktrace processes are the same as those for a VID-based MA.

## 26.9.7 Addressing Infrastructure Segment MEPs

The configuration of an Infrastructure Segment MA requires a parameter identifying the associated Infrastructure Segment. An Infrastructure Segment is composed of a pair of counterdirectional and co-routed Segment Monitoring Paths (SMPs) (26.11.1). Each SMP is identified by an SMP Identifier (SMP-ID). Thus, an Infrastructure Segment is identified by a pair of SMP-IDs that is known as an Infrastructure Segment Identifier (SEG-ID). The SEG-ID is specified on configuration of the associated Infrastructure Segment MA (12.14.5.3.2).

A MEP associated with an Infrastructure Segment requires the same set of parameters required by a VID-based MEP, with the following changes:

- a) The Primary VID is not writable but is always set to the value of the SMP-VID parameter that corresponds to the MA's SMP that has the MEP's MAC address in its SMP-SA field [item d) in 12.14.7.1.3].
- b) The MAC address of the MEP is the MAC address of the PNP upon which the MEP is operating [item i) in 12.14.2.1.2].

## 26.9.8 Infrastructure Segment identification

Two SMPs are distinct if their corresponding SMP-ID values (3-tuples) differ in at least one parameter. Thus, independent Infrastructure Segments can be associated with SMPs having identical values of SMP-DA and SMP-VID. Figure 26-9 depicts a case in which two SMPs, having identical values of SMP-DA and SMP-VID, are distinguished by their SMP-SA values. The Infrastructure Segment Multiplex Entity (6.21) allows shims defined for PBB-TE IPS to be instantiated per Infrastructure Segment at a SAP that supports multiple Infrastructure Segments.

Figure 26-9—Independent Infrastructure Segments distinguished by SMP-SA

## 26.9.9 Infrastructure Segment MEP placement in a Bridge Port

Infrastructure Segment MEPs are always Down MEPs and are placed only on PNPs as these correspond to the demarcation points of the Infrastructure Segment. The Infrastructure Segment MEPs are placed between the Port filtering entities (8.6.1, 8.6.2, and 8.6.4) and the Queuing entities (8.6.5, 8.6.6, 8.6.7, and 8.6.8) in the SMP-VID space identified by the EISS Multiplex Entity (6.17). Since the Infrastructure Segment MAC addresses can be reused by different Infrastructure Segments, the Infrastructure Segment MEPs need to be further differentiated by the Infrastructure Segment Multiplex Entity (6.21). In principle, separately for each

- 1 Infrastructure Segment, there can be from zero to eight Down MEPs, ordered by increasing MD Level, from
- 2 Frame filtering towards Port filtering, even though not more than one MD Level is expected for
- 3 Infrastructure Segment MAs. Figure 26-10 depicts an example of Infrastructure Segment MEPs on a PNP.

**Figure 26-10—Infrastructure Segment MEP placement in a PNP**

## 26.9.10 Infrastructure Segment Maintenance Domains

A PBB deploying IPS specifies a set of Infrastructure Segment MDs independent of those described in 26.8 and 26.9.5. In particular the CFM stacks in Figure 26-2 have Infrastructure Segment MD levels in parallel to the depicted Backbone MD levels for Ports instantiating Infrastructure Segments while Infrastructure Segment MDs will be present in parallel to the Backbone MD levels depicted in Figure 26-3.

## 26.9.11 IPS extensions to Continuity Check operation

The Continuity Check protocol is described in 20.1 and the corresponding state machines in Clause 20. The only enhancement required by the Infrastructure Segment MA is in the procedure that is responsible for constructing and transmitting a CCM (20.11.1):

- a) The destination\_address parameter is set to the MAC address indicated by the value of the SMP-DA field of the SMP-ID having as SMP-SA the MAC address of the MEP emitting the CCM.

All other Continuity Check processes are the same as those for a VID-based MA.

## 26.10 Protection switching for point-to-point TESI

### 26.10.1 Introduction

In contrast to PBB, spanning tree protocols and broadcasting/flooding are not used in PBB-TE. FDBs are populated using a network management system or a control plane, allowing ESPs to be engineered and provisioned across the network. PBB-TE provides end-to-end linear protection for point-to-point TESI, where a dedicated protection point-to-point TESI is established for one particular working point-to-point TESI, and the traffic is automatically switched from the working TESI to the protection TESI when a failure occurs on the working entity. The protection entity is preestablished, ensuring the availability of those resources when a defect is detected on the working entity, and allowing for a corresponding sub-50 ms switchover.

Figure 26-11 depicts the essential elements of the PBB-TE protection scheme and its arrangement. In this, 1:1 (i.e., 1 for 1) arrangement, traffic is sent on only one of the paths at any point in time based on information from OAM processes or network operators.

**Figure 26-11—Protection switching architecture**

Protection switching may be triggered by manual operation or by CFM information arising from, periodic monitoring of the working and protection paths, or from physical layer monitoring, such as loss of signal or other defects detected through CFM.

1 The PBB-TE protection switching mechanism aims to offer the capability to switch completely (both ends)  
2 in less than 50 ms following the detection of the fault.

3 NOTE 1—The capability of supporting the above switchover requirement on TESIs, is provided by configuring the  
4 interval of CCMs on the MAs associated these TESIs to be equal to or lower than 10 ms enabling the detection of the  
5 fault and the signaling of the coordination information end to end in less than 50 ms.

6 The PBB-TE protection scheme may be configurable to be “revertive” or “nonrevertive,” where traffic  
7 transmission reverts, or not, to the working path automatically once CFM indicates the fault or defect has  
8 been cleared. The protection switching mechanism may also incorporate hold-off and wait to restore timers,  
9 the first to allow the fault to be protected by a lower layer protection switching mechanism for instance,  
10 while the latter ensures the performance of the working path is fully restored before switching back to it. The  
11 hold-off timer obviously slows the overall recovery time for a fault within the protected domain.

12 NOTE 2—A complete discussion on the various protection switching mechanisms and terminology is provided by  
13 ITU-T G.8031 [B50]. As a caution it should be noted that ITU-T uses the term “Bridge” for the logical entity that selects  
14 either or both of the transmit paths at the sending end of a protected domain. This is not to be confused with the term  
15 Bridge used in this standard.

16 The description herein, defines and provides a scalable end-to-end resiliency mechanism that offers  
17 end-to-end 1:1 bidirectional linear protection switching capable of load sharing for point-to-point TESIs in a  
18 PBB-TE Region.

19 NOTE 3—Some scenarios exist where multiple input events may cause the protection switching state machines in a  
20 protection group to select diverse TESIs on which to send traffic. The Mismatch defect informs the operator of such an  
21 occurrence thereby allowing the appropriate corrective action to be taken.

22 Protection for point-to-multipoint TESIs may be provided by external mechanisms or agents, which are out  
23 of scope for this specification.

## 24 **26.10.2 1:1 point-to-point TESI protection switching**

25 In a PBB-TE Region, IB-BEBs constitute the demarcation between the PBBN of interest and the networks  
26 attached to it. The protected domain is defined to be the area between the CBPs on the different  
27 B-Components of the involved IB-BEBs.

28 The starting point in providing protection switching is the creation and configuration of a TE protection  
29 group. A TE protection group is a group of two point-to-point TESIs between a pair of CBPs, which carries  
30 an assigned set of backbone service instances, and continues to carry these backbone service instances if any  
31 one of the TESIs in the group is failed or disabled. The creation of the TE protection group requires the  
32 assignment of one TESI as a working entity and a second TESI with the same terminating points as a  
33 protection entity providing a different bidirectional connectivity path (12.14.1.2). The configuration of the  
34 TE protection group is completed with the assignment of the list of the backbone service instances that are to  
35 be protected by the TE protection group [item b) in 12.18.2.1.3].

36 The protection switching mechanism is capable of load sharing as the TESIs that are assigned to a TE  
37 protection group can be reused in a number of TE protection groups enabling a list of I-SIDs to be  
38 distributed among a set of interdependent TE protection groups [item c) in 12.18.2.1.3]. A set of  
39 interdependent TE protection groups forms a coordinated protection group. Protection switching requests to  
40 interdependent TE protection groups must be coordinated for an operator to manage the TESIs in a coherent  
41 manner and to avoid potentially competing requests for each TESI. For example, to unconditionally remove  
42 traffic from a TESI, one request to Lock Out the TESI results in a request to each TE protection group to  
43 which the TESI belongs, either LoP or FS according the role of the TESI in each group. Similarly, to  
44 conditionally remove traffic from a TESI, one Manual Switch request for the TESI results in the appropriate  
45 Manual Switch request to each TE protection group to which the TESI belongs. Allowing a single operator  
46 request per coordinated protection group and coordinating the resulting requests to each TE protection group

1 reduces the operational complexity of the set of interrelated TE protection groups. Using a coordinated  
2 protection group, the service traffic (backbone service instance) load can be shared across a set of TESIs and  
3 at the same time be protected against single faults by 1:1 protection.

4 NOTE 1—If the operator initiates switching of an individual load shared TE protection group the mmCCMdefect may  
5 not detect a switch mismatch.

6 NOTE 2—The load sharing mode of operation corresponds to 1:1 ETH Sub Network Connection Group protection with  
7 Inherent monitoring (ETH SNCG/I) in the ITU-T protection switching terminology.

8 The following description of the PBB-TE protection switching mechanism is an example provided for  
9 illustrative purposes. Figure 26-12 depicts a network where two point-to-point TESIs have been  
10 provisioned. The TE-1 service instance on the top of the figure consists of two ESPs each identified by a  
11 3-tuple: <CBP-B, CBP-A, VID-1> is depicted in black and <CBP-A, CBP-B, VID-2> in gray. The TE-2  
12 service instance below consists of two other ESPs identified by the 3-tuples <CBP-B, CBP-A, VID-3> and  
13 <CBP-A, CBP-B, VID-3> which are depicted in white. The use of the same ESP-VID on the TE-2 ESPs is  
14 only for illustrative purposes. There are no explicit requirements on using the same or different ESP-VIDs  
15 on the ESPs comprising the TESIs that are assigned to a TE protection group. One set of backbone service  
16 instances, shown by the black arrows just outside the two CBPs, has TE-1 assigned as its working TESI and  
17 TE-2 assigned as its protecting TESI.

**Figure 26-12—PBB-TE point-to-point protection switching**

18 The ESPs are provided by configuring entries in the FDBs on all the Bridges that these ESPs need to pass  
19 through. On the terminating IB-BEBs, the VLAN membership of each participating port has to be  
20 configured for the B-components. In Figure 26-12, this is depicted by the color of the boxes that are placed  
21 inside each of the B-Component boxes. For example, the upper right PNP-1 port on the West B-component  
22 is a member of the VID-1 (black), while the CBP on the same component is a member of VID-2 (gray) and  
23 VID-3 (white). Only frames tagged with the appropriate VID parameter can egress these ports.

24 NOTE 3—The PNPs are shown for illustrative purposes only and that there is no explicit requirement to diversify PNPs  
25 on the terminating IB-BEBs.

26 Each of the TESIs is monitored by an independent MA. One MA is set to monitor the top (TE-1) TESI and a  
27 second to monitor the bottom (TE-2) TESI. Each of these two MAs is associated with a pair of ESPs and  
28 identified by their corresponding 3-tuples. Two Up MEPs, associated with the MA monitoring the TE-1  
29 service instance, are configured on the CBPs that terminate the TE-1 service instance. Each of these MEPs  
30 has its own primary VID, VID-1 (black) for the MEP on the West B-component associated with the TE-1  
31 service instance, and VID-2 (gray) for the MEP on the East B-component. In this configuration each MEP  
32 receives frames that are tagged with the ESP-VID corresponding to the primary VID of the associated  
33 remote MEP and can only send frames that are tagged with its own primary VID. In particular, in the  
34 depicted example the MEP for the top entity on the West B-component can send only CCMs tagged with  
35 VID-1 (black) and receive CCMs tagged with VID-2 (gray), while the corresponding MEP on the East  
36 component can only send CCMs tagged with VID-2 (gray) and receive CCMs tagged with VID-1 (black).

1 The primary VID of each MEP is depicted by the color of the MEP. It should be also noted that all the  
2 depicted ports in Figure 26-12 have their Enable Ingress Filtering parameter (8.6.2) reset to its default value,  
3 i.e., Disable Ingress Filtering.

4 Data traffic is mapped to a TESI by configuring the CBP parameters (6.11). In particular, the CBP I-SID is  
5 used to allow specific service instances to be carried by the TESI while the entries of the B-VID column in  
6 the Backbone Service Instance table are indicating how to map the identified service instances to a specific  
7 ESP. The CBP's B-VID value is depicted in Figure 26-12 by the color of the vertical bars (black for CBP-A,  
8 gray for CBP-B) placed at the tips of the arrows representing the set of backbone service instances.

9 As a result customer frames that need to be transported by a TESI and are identified by a specific I-SID and  
10 reach the CBP on the West B-component from the left can be mapped to the black ESP or the white ESP  
11 while frames on the same service that reach the CBP on the East B-component from the right will be mapped  
12 to the gray ESP or the white ESP based on the CBP's configured B-VID value. If all the services are  
13 normally mapped to the black ESP and gray ESP, then TE-1 would correspond to the working entity and  
14 TE-2 to a stand-by protection entity. Irrespective of how the data traffic is mapped to the TESIs, CCM  
15 frames are exchanged on both TESIs in order to regularly check the provided connectivity.

16 If a fault occurs on any of the ESPs, the MEP on the receiving end will be notified. In particular if a fault on  
17 the black ESP occurs, as shown in Figure 26-13, the MEP on the East B-component will declare a remote  
18 MEP defect by setting the rMEPCCMdefect parameter (20.19.1). The timer counter for timing out CCMs  
19 has a granularity finer than or equal to  $1/4$  of the time represented by the CCMinterval variable (20.8.1). A  
20 Bridge does not set rMEPCCMdefect within  $(3.25 \times \text{CCMinterval})$  seconds of the receipt of a CCM, and  
21 sets rMEPCCMdefect within  $(3.5 \times \text{CCMinterval})$  seconds after the receipt of the last CCM. The setting of  
22 the rMEPCCMdefect parameter will result in a change of the appropriate B-VID entries in the Backbone  
23 Service Instance table, of the east CBP from the gray VID-2 to the white VID-3, which is the ESP-VID of  
24 the associated ESP on the protection TESI.

25 NOTE 4—The B-VID parameter will also change when the xConCCMdefect (20.23.3) or the errorCCMdefect (20.21.3)  
26 parameters are set as these indicate a very serious misconfiguration problem.

27 All subsequent CCMs sent by the east gray MEP on TE-1 will have the RDI field set for as long as proper  
28 CCMs are not received by the MEP. A reception of a CCM frame with the RDI field set (or an event that  
29 causes setting of the someRMEPCCMdefect, xConCCMdefect, or errorCCMdefect) by the MEP associated  
30 with TE-1 on CBP-A will cause a change of the appropriate B-VID entries in the Backbone Service Instance  
31 table of the CBP-A on the West B-component, to the pre-configured value of the protection ESP. The  
32 result will be to move the affected service instances to the protection TE-2 service instance as depicted  
33 Figure 26-13. Consequently, the approximate maximum time before a bidirectional switch occurs following

1 a unidirectional failure would be approximately equal to  $(3.5 \times \text{CCMinterval})$  + the time required for a CCM  
2 PDU to travel between the MEPs monitoring the TESI + the time to update the associated Backbone Service  
3 Instance table entries.

Figure 26-13—Mapping data traffic to the protection entity

#### 26.10.3 Protection Switching state machines

5 The local protection commands and protection behavior specified here follow the architectural model used  
6 in ITU-T G.8031 [B50]. The relationships among the protection switching state machines are illustrated in  
7 Figure 26-14. That figure uses conventions similar to those of 13.24, and of Figure 13-13: open arrows  
8 denote variables that are set by one state machine and both read and set by another; closed arrows denote  
9 variables that are set by the owning state machine, and only read by other state machines.

Figure 26-14—Relationships of the Protection switching state machines—overview

10 There is one set of Protection Switching state machines per protection group on each Bridge that terminates  
11 the protection group. The protection group consists of the working and the protection entities. The  
12 Protection Switching state machine reuses the defect variables that are presented in Table 20-1. Variables

1 and procedures that are preceded with “w.” refer to the working entity while those that are preceded with  
2 “p.” refer to the protection entity. These internal prefix/entity associations remain the same following a  
3 protection switch to the protection entity.

#### 4 **26.10.3.1 Notational conventions used in state diagrams**

5 The Protection Switching state machines are specified using the notational conventions defined in Annex E.

#### 6 **26.10.3.2 State machine timers**

7 The timer variables declared in this subclause are part of the specification of the operation of Protection  
8 Switching. The accompanying descriptions of their meaning and use are provided to aid in the  
9 comprehension of the protocol only, and are not part of the specification.

10 One instance of the following may be implemented per Service Mapping state machine:

11 a) WTRwhile (26.10.3.2.1)

12 One instance of the following may be implemented per Hold-off state machine:

13 b) HoldOffWhile (26.10.3.2.2)

##### 14 **26.10.3.2.1 WTRwhile**

15 A timer to be used to prevent frequent operation of the protection switch due to an intermittent defect. This  
16 timer allows for a fixed period of time to elapse before data traffic is mapped from the protection entity to  
17 the working entity when in revertive mode.

##### 18 **26.10.3.2.2 HoldOffWhile**

19 In order to coordinate timing of protection switches at multiple layers or across cascaded protected domains,  
20 a hold-off timer may be required. The purpose is either to allow a server layer protection switch to have a  
21 chance to fix the problem before switching at a client layer, to allow an upstream protected domain to switch  
22 before a downstream domain, or to allow the inner protected domain to switch before the outer protected  
23 domain in the case of IPS nested protection domains.

#### 24 **26.10.3.3 Protection Switching variables**

25 The following variables are defined for the Protection Switching state machines:

- 26 a) BEGIN (26.10.3.3.1)
- 27 b) SF (26.10.3.3.2)
- 28 c) SFH (26.10.3.3.3)
- 29 d) LoP (26.10.3.3.4)
- 30 e) FS (26.10.3.3.5)
- 31 f) MStoProtection (26.10.3.3.6)
- 32 g) MStoWorking (26.10.3.3.7)
- 33 h) WTRTime (26.10.3.3.8)
- 34 i) HoldOffTime (26.10.3.3.9)

35 Table 26-2 illustrates the inherent priority of each protection request.

36 NOTE—The priorities associated with the various requests in this table are in general alignment with the corresponding  
37 priorities in ITU-T G.8031 [B50]. The only difference is that the precedence of p.SF and FS are inverted since ITU-T  
38 G.8031 relies on an APS protocol to be running on the protection path.

**Table 26-2—Protection Requests Hierarchy**

| Priority | Request                        |
|----------|--------------------------------|
| highest  | LoP                            |
|          | FS                             |
|          | p.SF                           |
|          | w.SF                           |
|          | MStoProtection,<br>MStoWorking |
|          | WTR                            |
| lowest   | NoRequest                      |

### 1 26.10.3.3.1 BEGIN

2 This is a Boolean variable controlled by the system initialization process. A value of TRUE causes all  
3 Protection Switching state machines per protection group to continuously execute their initial state. A value  
4 of FALSE allows these state machines to perform transitions out of their initial state, in accordance with the  
5 relevant state machine definitions.

### 6 26.10.3.3.2 SF

7 SF is the logical OR of someRMEPCCMdefect (20.35.5), someRDId defect (20.35.7), xConCCMdefect  
8 (20.23.3), and errorCCMdefect (20.21.3).

9 NOTE—Locally detected MAC/PHY faults may also be components of SF (e.g., to enable potentially faster fault  
10 detection), but are outside the scope of this standard.

### 11 26.10.3.3.3 SFH

12 A Boolean flag set and cleared by the Hold-off state machine to indicate that SF is set for a period that is  
13 equal to, or larger than, the HoldOffTime. The variable will be set equal to SF if the Hold-Off timer is not  
14 supported.

### 15 26.10.3.3.4 LoP

16 A Boolean flag indicating the administrative state of the protection entity. If set, it prohibits the use of the  
17 protection entity. Its value can only be controlled by an administrator action [item b2) in 12.18.2.3.2].

### 18 26.10.3.3.5 FS

19 A Boolean flag indicating the presence of an administrative command to force switch the data traffic to the  
20 protection entity. Its value is set to 1 by an administrator action [item b3) in 12.18.2.3.2 or 12.24.2.3.2]. It  
21 can be reset by an administrator action that corresponds to a request of the same or higher priority according  
22 to Table 26-2.

### 1 **26.10.3.3.6 MStoProtection**

2 A Boolean flag indicating the presence of an administrative command to manually switch the data traffic to  
3 the protection entity, in the absence of a failure of the working or the protection entity. Its value is set to 1 by  
4 an administrator action [item b4) in 12.18.2.3.2 or 12.24.2.3.2]. It can be reset by an administrator action  
5 that corresponds to a request of the same or higher priority according to Table 26-2 and by the operation of  
6 the Clear Manual Switch state machine.

### 7 **26.10.3.3.7 MStoWorking**

8 A Boolean flag indicating the presence of an administrative command to manually switch the data traffic to  
9 the working entity in the absence of a failure of the working or the protection entity. Its value is set to 1 by an  
10 administrator action [item b5) in 12.18.2.3.2 or 12.24.2.3.2]. It can be reset by an administrator action that  
11 corresponds to a request of the same or higher priority according to Table 26-2 and by the operation of the  
12 Clear Manual Switch state machine.

### 13 **26.10.3.3.8 WTRTime**

14 The wait-to-restore (WTR) period, as provided by the corresponding managed object item e) in 12.18.2.1.3  
15 or item h) in 12.24.2.1.3]. May be configured by the operator in 1 min steps between 5 and 12 min; the  
16 default value is 5 min. A value of 0 indicates nonrevertive mode. The overall accuracy of the WTR timer  
17 (e.g.,  $\pm 25$  ms) should be sufficient to allow both ports at the protection domain termination to revert to the  
18 working entity in less than 50 ms.

### 19 **26.10.3.3.9 HoldOffTime**

20 The Hold-Off period as provided by the corresponding managed object [item f) in 12.14.6.1.3 or item i) in  
21 12.24.2.1.3]. The suggested range of the hold-off timer is 0 to 10 s in steps of 100 ms (accuracy of  $\pm 5$  ms);  
22 the default value is 0.

## 23 **26.10.3.4 Protection Switching procedures for PBB-TE TESI Protection**

24 The following procedures are defined for the Service Mapping state machine:

- 25 a) mapDataToWorking() (26.10.3.4.1)
- 26 b) mapDataToProtection() (26.10.3.4.2)

27 NOTE 1—Since a merging selector is used, there is the potential for misordered frames at egress due to differential  
28 delay between the working and protection TESIS following a protection switch. If this is a concern, then briefly  
29 discarding frames prior to executing either mapDataToX() processes described in 26.10.3.4.1 or 26.10.3.4.2 will avoid  
30 the issue (e.g., 1 ms is equivalent to a 20% differential delay across 1000 km of fiber).

31 NOTE 2—The procedure descriptions in this subclause are specific to PBB-TE TESI Protection. A description of the  
32 corresponding procedures for IPS can be found in 26.11.4.1.1 and 26.11.4.1.2.

### 33 **26.10.3.4.1 mapDataToWorking()**

34 Maps the customer service(s) that are to be transported by a TE protection group [item b) in 12.18.2.1.3], to  
35 the working TESI identified by the 3-tuples <remote CBP MAC, local CBP MAC, ESP-VID(w)>, <local  
36 CBP MAC, remote CBP MAC, ESP-VID(w')>, by setting the VID values of the corresponding I-SID  
37 entry(-ies) in the Backbone Service Instance table to the ESP-VID(w).

### 38 **26.10.3.4.2 mapDataToProtection()**

39 Maps the customer service(s) that are to be transported by a TE protection group [item b) in 12.18.2.1.3],  
40 to the protection TESI identified by the 3-tuples <remote CBP MAC, local CBP MAC, ESP-VID(p)>,  
41 <local CBP MAC, remote CBP MAC, ESP-VID(p')>, by setting the VID values of the corresponding I-SID  
42 entry(ies) in the Backbone Service Instance table to the ESP-VID(p).

### 26.10.3.5 Protection Switching state machine diagram

- The Protection Switching state machines implement the function specified by the state diagrams in Figure 26-15, Figure 26-16, and Figure 26-17, the variables in 26.10.3.3, and the procedures in 26.10.3.4.
- The Hold-off state machine shall be present only when the Hold-off timer is supported.
- The current state of the Service Mapping state machine is available as a managed object [item c) in 12.18.2.1.3].

Figure 26-15—Hold-off state machine

Figure 26-16—Clear Manual Switch state machine

**Figure 26-17—Service Mapping state machine**

## 26.11 IPS in PBB-TE Region

In addition to supporting end-to-end linear protection for TESIs (26.10), PBB-TE supports localized protection of selected TESIs traversing a common sequence of PNPs. Such a sequence of PNPs, together with the intervening MAC relay entities and LANs, is called an Infrastructure Segment. The group of TESIs associated with the Infrastructure Segment is protected from the failure of one or more components (i.e., port, LAN, or MAC Relay Entity) of the Infrastructure Segment. The method of providing such protection is called Infrastructure Protection Switching (IPS). 1:1 IPS and M:1 IPS are described by this standard. Support for IPS is optional. If IPS is supported, 1:1 IPS is required, and M:1 IPS is optional. IPS may be triggered automatically by a change in the operational state of an Infrastructure Segment or manually by administrative command.

NOTE—A complete discussion on the various protection switching mechanisms and terminology is provided by ITU-T G.8031 [B50]. The ITU-T uses the term “bridge” for the logical entity that selects either or both of the transmit paths at the sending end of a protected domain. This is not to be confused with the term “Bridge” used in this standard.

As illustrated in Figure 26-18, a Bridge supporting IPS is a PBB. Definitions of entities associated with an Infrastructure Segment and properties of such entities are as follows:

- a) A PBB terminating the Infrastructure Segment is a Segment Endpoint Bridge (SEB).
- b) A PBB in the interior of the Infrastructure Segment is a Segment Intermediate Bridge (SIB).
- c) A PNP terminating the Infrastructure Segment is called a Segment Endpoint Port (SEP).
- d) A PNP in the interior of the Infrastructure Segment is called a Segment Intermediate Port (SIP).
- e) A SEB contains one SEP and does not contain a SIP.
- f) A SIB contains exactly two SIPs and, by definition, cannot contain a SEP.
- g) A SEP is connected to a single SIP or SEP in a neighboring PBB via a LAN.
- h) A SIP is connected to one other SIP within the SIB via the MAC Relay Entity and is connected to a single SEP or SIP in a neighboring PBB via a LAN.

The role of SEB or SIB is assigned to a PBB only with respect to a particular Infrastructure Segment. Similarly, the role of SEP or SIP is assigned to a Port only with respect to a particular Infrastructure Segment.

Figure 26-18—Segment terminology and properties

## 26.11.1 Infrastructure Segment monitoring

As illustrated in Figure 26-19, each Infrastructure Segment is associated with an MA for purposes of determining the connectivity state of that Infrastructure Segment. The Infrastructure Segment MA is associated with a pair of co-routed counterdirectional Infrastructure Segment Monitoring Paths (SMPs). Each SMP is identified by an <SMP-DA, SMP-SA, SMP-VID> 3-tuple that is known as an SMP-ID. The SMP-SA takes the value of the MAC address of the SEP from which the SMP originates. The SMP-DA takes the value of the MAC address of the SEP in which the SMP terminates. It follows from the co-routed and counterdirectional properties of the pair of SMPs that the SMP-DA value of one SMP in the pair of SMPs is equal to the SMP-SA value of the other SMP of the pair. The SMP-VID is a VID associated with a special value of the Multiple Spanning Tree Instance Identifier (MSTID) in the MST Configuration Table, the TE-MSTID, indicating that the VID is under the control of an external agent (8.9). The pair of SMP-IDs associated with an Infrastructure Segment is known as an Infrastructure Segment Identifier (SEG-ID). The MA managed object (12.14.6) associated with an Infrastructure Segment specifies the SEG-ID identifying that Infrastructure Segment. The value of the SEG-ID is inherited by the MEP associated with the Infrastructure Segment MA.

**Figure 26-19—Infrastructure Segment monitoring**

The operational state of the Infrastructure Segment is indicated by the Signal Fail (SF) variable (26.10.3.3.2) of the Protection Switching state machines (26.10.3). A value of TRUE indicates that the associated Infrastructure Segment is not operational. A value of FALSE indicates that the associated Infrastructure Segment is operational.

NOTE—For proper network operation, each SMP, of the pair of SMPs identifying an Infrastructure Segment MA, is represented by a Static Filtering Entry configured via the Create Filtering Entry operation (12.7.7.1) in each SIB along the path of the Infrastructure Segment. The SMP-ID <SMP-DA, SMP-SA, SMP-VID> would be represented by the Static Filtering Entry <SMP-DA, SMP-VID, outbound port value>. The outbound port value is the port number of the port by which the SMP exits the SIB. Proper operation further includes the creation, at each SEP, of a Maintenance Domain managed object (12.14.5), a Maintenance Association managed object (12.14.6), and a Maintenance association Endpoint managed object (12.14.7) associated with the Infrastructure Segment MA.

## 1 26.11.2 1:1 IPS

2 Figure 26-20 depicts two Infrastructure Segments with a TESI that has been provisioned to fully traverse the  
3 upper Infrastructure Segment. The Infrastructure Segment traversed by the provisioned TESI is known as  
4 the Working Segment with respect to that TESI. The lower Infrastructure Segment terminates in the same  
5 pair of SEBs that terminates the Working Segment but is otherwise diverse from the Working Segment. The  
6 lower Infrastructure Segment is known as the Protection Segment with respect to the TESI that traverses the  
7 Working Segment.

**Figure 26-20—Working Segment and Protection Segment**

### 8 26.11.2.1 Infrastructure Protection Group (IPG)

9 The associated Working and Protection Segments depicted in Figure 26-20 are said to form an IPG. The  
10 Working and Protection Segments are fully disjoint except for the common SEBs in which they terminate;  
11 that is, they share no common SEP, SIB, SIP, LAN, or MAC Relay Entity. One or more TESI, each  
12 identified by a TE-SID are associated with an IPG at the SEB by which the TESI enters that IPG. A TESI is  
13 associated with the IPG via the Write IPG managed object (12.24.2.2.) Multiple TESI may be associated  
14 with an IPG. TESI associated with an IPG may have diverse end-to-end paths, but they follow a common  
15 path traversing the IPG. Two or more TESI may be associated with ESPs having the same <ESP-DA,  
16 ESP-VID> 2-tuple. In particular this can occur if the TESI are distinguished only by different values of  
17 ESP-SA. In such cases where TESI share a common value of <ESP-DA, ESP-VID>, the association of one  
18 such TESI with an IPG at a SEB implies that all such TESI are associated with that IPG. In other words, all  
19 such TESI are protected by the IPG, or no such TESI are protected by the IPG.

20 NOTE—An Infrastructure Segment can be associated with more than one IPG. For example, the operator can designate  
21 Infrastructure Segment 1 as the Working Segment of IPG1 and Infrastructure Segment 2 as the Protection Segment of  
22 IPG1. The operator can concurrently designate Infrastructure Segment 2 as the Working Segment of IPG2 and  
23 Infrastructure Segment 1 as an Protection Segment of IPG2. This property can be utilized as a method of load sharing  
24 across multiple Infrastructure Segments during normal operation.

### 26.11.2.1.1 Nested IPGs

IPGs are said to be nested with respect to a TESI if:

- a) The TESI is associated with both IPGs, and
- b) The set of SEPs and SIPs comprising the Working Segment of one IPG, the inner IPG, is identical to a contiguous sequence of SIPs contained within the Working Segment of the other IPG, the outer IPG.

In Figure 26-21, IPG2 (dashed) is nested within IPG1 (solid). IPG1 is the outer IPG, and IPG2 is the inner IPG. The Working Segment of the inner IPG is fully contained within the Working Segment of the outer IPG. The SEBs associated with the outer IPG are different from those associated with the inner IPG. Each nested IPG deploys an independent set of MAs for the purpose of monitoring the operational state of Infrastructure Segments associated with that IPG.

Figure 26-21—Nested IPGs

NOTE—Two IPGs are said to overlap with respect to a TESI if (a) the TESI is associated with both IPGs and (b) the IPGs share a sequence of PNPs. Designing networks having IPGs that overlap, but are not nested, requires careful study of issues not specifically identified in this standard.

### 26.11.2.2 Protection Switching method

When a TESI is assigned to an IPG by provisioning, traffic associated with that TESI transits the IPG via the Working Segment or the Protection Segment as directed by the Protection Switching state machines (26.10.3). In the absence of faults or outstanding administrative commands, TESI traffic transits the IPG via the Working Segment. The Protection Switching state machines can cause the TESI traffic to transit the IPG via the Protection Segment by invoking the Protection Switching procedure `mapDataToProtection()` (26.11.4.1.2). This procedure causes the value of the outbound Port field of the FDB entry corresponding to the  $\langle \text{ESP}_{\text{in}}\text{-DA}, \text{ESP}_{\text{in}}\text{-VID} \rangle$  2-tuple of each TESI associated with the IPG to be assigned the Port Number associated with the Protection Segment. The notation “ $\text{ESP}_{\text{in}}$ ” denotes the ESP, of the pair of ESPs associated with the TESI, that enters the IPG via the SEB. The Protection Switching state machines can cause the traffic to transit the IPG via the Working Segment by invoking the Protection Switching procedure `mapDataToWorking()` (26.11.4.1.1) (26.11.4.1.2). This procedure causes the value of the outbound Port field of the FDB entry corresponding to each  $\langle \text{ESP}_{\text{in}}\text{-DA}, \text{ESP}_{\text{in}}\text{-VID} \rangle$  2-tuple of each TESI associated with the IPG to be assigned the Port Number associated with Working Segment. The two SEBs associated with the IPG perform protection activities independently. At any point in time, traffic associated with an IPG is carried on either the Working Segment or the Protection Segment. The Infrastructure Segment carrying the TESI traffic is known as the active Infrastructure Segment.

NOTE—Proper operation of the network requires that the FDB entry provisioned in a SIB to forward traffic along an Infrastructure Segment associated with the IPG identify only a single outbound Port. In other words, the portion of a TESI transiting an IPG is provisioned as point-to-point, without regard to whether the TESI is point-to-point or point-to-multipoint from an end-to-end perspective.

### 1 26.11.2.3 Hold-off timer

2 An IPG is provisioned with a “hold-off timer” value. The hold-off timer delays protection action associated  
3 with the failure of an Infrastructure Segment. The delay provides a lower layer with the opportunity to take  
4 corrective action before IPS is performed. Use of the hold-off timer can increase the total time required to  
5 recover from a failure.

6 In the case of nested IPGs, proper operation of the network requires that the outer IPG be provisioned with a  
7 “hold-off timer” value greater than that of the inner IPG. The outer IPG Working Segment is provisioned to  
8 coincide with the path of the inner IPG Working Segment. CCM traffic monitoring the outer IPG Working  
9 Segment traverses the Active Segment of the Inner IPG. The TESI list associated with the Inner IPG  
10 Endpoint Bridge is provisioned to include the SEG-ID associated with the CCM on the outer IPG Working  
11 Segment MA that ingresses the Inner IPG SEB. Thus, on a failure of the inner IPG Working Segment, traffic  
12 associated with the outer IPG Working Segment, including the CCM traffic associated with the outer IPG  
13 Working Segment MA, is protected. The outer IPG will not be aware of the protection switch of the inner  
14 IPG and will not perform protection switching activities.

### 15 26.11.2.4 Reversion

16 An IPG is provisioned to operate in revertive mode or nonrevertive mode. In revertive mode, traffic is  
17 switched from the Protection Segment to the Working Segment when the Working Segment becomes  
18 operational. In nonrevertive mode, traffic remains associated with the Protection Segment when the Working  
19 Segment becomes operational unless:

- 20 a) The Protection Segment fails, or
- 21 b) Traffic is switched to the Working Segment by administrative command.

22 An IPG operates in revertive mode if that IPG is provisioned to support M:1 IPS.

#### 23 26.11.2.4.1 Wait-to-restore timer

24 An IPG operating in revertive mode is provisioned with a “wait-to-restore (WTR) timer” value. The WTR  
25 timer delays reversion from the Protection Segment to the Working Segment on recovery of the Working  
26 Segment. Use of the WTR timer reduces the severity of “flapping,” or rapid oscillation, that may occur if the  
27 Working Segment is experiencing intermittent connectivity failure. Setting the WTR time to zero indicates  
28 that the IPG is operating in nonrevertive mode.

### 29 26.11.2.5 Administrative commands

30 IPS supports the following administrative commands:

- 31 — **Lockout of Protection (LoP)** allows the operator to suppress automatic switching from Working  
32 Segment to Protection Segment.
- 33 — **Forced Switch (FS)** allows the operator to force traffic to the Protection Segment as if a  
34 connectivity failure exists on the Working Segment. The behavior persists until the command is  
35 withdrawn.
- 36 — **Manual Switch to Protection (MStoProtection)** switches traffic to the Protection Segment, but  
37 does not force traffic to remain associated with the Protection Segment.
- 38 — **Manual Switch to Working (MStoWorking)** switches traffic to the Working Segment, but does not  
39 force traffic to remain associated with the Working Segment.

### 26.11.3 IPS Control entity

The IPS Control entity contains the 1:1 IPS state machines (26.11.4) and, if M:1 IPS (26.11.5) is supported, the M:1 IPS state machines (26.11.5.1). There is an instance of the IPS Control entity for each SEB.

As shown in Figure 26-22, the operation of the IPS state machines depends upon input from Bridge Management and from each Infrastructure Segment MA associated with the IPG. The input from Bridge Management includes the list of TESIs [item e) in 12.14.2.1.2] associated with the IPG and Administrative commands (26.11.2.5) associated with the IPG. The outbound Port field of a Static Filtering Entry associated with an IPG can be modified by IPS Control. When a Static Filtering Entry is no longer associated with an IPG, the Outbound Port value of that Static Filtering Entry is restored by IPS control to the Port associated with the Working Segment of the IPG and IPS Control cannot subsequently modify the Outbound Port value. While the Outbound Port value can be modified by IPS Control, addition and deletion of FDB entries remains under the control of Bridge Management.

**Figure 26-22—IPS Control entity**

IPS Control maintains the following entities associated with the IPG:

- a) The SEG-ID identifying the Working Segment MA
- b) The SEG-ID identifying the Protection Segment MA
- c) The 1:1 IPS state machines
- d) The list of the TESIs describing traffic protected by the IPG

When an IPG is associated with optional M:1 IPS, the following additional entities are maintained:

- e) The list of SEG-IDs identifying the MAs of candidate Protection Segments
- f) The M:1 IPS state machines

## 1 **26.11.4 1:1 IPS state machines**

2 Protection switching for point-to-point TESI (26.10) and 1:1 IPS (26.11.2) both utilize Protection Switching  
3 state machines (26.10.3). In the case of 1:1 IPS, the “Protection Group” is an “IPG,” the “working entity” is  
4 the “Working Segment,” and the “protection entity” is the “Protection Segment.” One set of Protection  
5 Switching state machines is instantiated per IPG per SEB.

### 6 **26.11.4.1 Procedures referenced by the 1:1 IPS state machines**

7 The procedures `mapDataToWorking()` and `mapDataToProtection()` referenced by the 1:1 IPS state machines  
8 and described in the subclauses that follow, differ from the procedures of the same name (26.10.3.4)  
9 referenced by the TESI Protection state machines.

#### 10 **26.11.4.1.1 `mapDataToWorking()`**

11 This procedure changes the value of the outbound Port field of each Static Filtering Entry identified by the  
12  $\langle \text{ESP}_{\text{in}}\text{-DA}, \text{ESP}_{\text{in}}\text{-VID} \rangle$  2-tuple associated with each TESI on the list of TESI associated with an IPG to  
13 the port Number associated with the Working Segment of the IPG.

#### 14 **26.11.4.1.2 `mapDataToProtection()`**

15 This procedure changes the value of the outbound Port field of each Static Filtering Entry identified by the  
16  $\langle \text{ESP}_{\text{in}}\text{-DA}, \text{ESP}_{\text{in}}\text{-VID} \rangle$  2-tuple associated with each TESI on the list of TESI associated with an IPG to  
17 the port Number associated with the Protection Segment of the IPG.

## 26.11.5 M:1 IPS

This subclause describes extensions to 1:1 IPS (26.11.2) supporting M:1 IPS when this optional feature is implemented. An IPG is constrained to operate in 1:1 revertive mode when that IPG supports M:1 IPS.

As illustrated in Figure 26-23, a list of candidate Protection Segments, ordered by priority value, is provisioned for each IPG. deploying M:1 IPS. The list contains at least one candidate Protection Segment. Candidate Protection Segments are mutually disjoint and disjoint from the Working Segment. The candidate Protection Segment having the highest (lowest numeric) priority among the operational candidate Protection Segments is the Protection Segment referenced by the 1:1 IPS state machine. This selected candidate Protection Segment is called the “current” Protection Segment. In the absence of any operational candidate Protection Segments, the current Protection Segment retains the value it had prior to the failure of the last candidate Protection Segment. In this case, the 1:1 IPS Protection Segment is declared to have failed. If the 1:1 IPS Protection Segment is not operational and a candidate Protection Segment becomes operational, that candidate Protection Segment assumes the role of 1:1 IPS Protection Segment, and the 1:1 IPS Protection Segment becomes operational. If a candidate Protection Segment of higher priority than the current Protection Segment becomes operational, then that candidate Protection Segment assumes the role of the 1:1 IPS Protection Segment following expiration of the M:1 wait-to-restore timer. If the current Protection Segment has changed and the 1:1 IPS Protection Segment is the active Infrastructure Segment, then Static Filtering Entries associated with TESIs protected by the IPG are updated with the Port number of the current Protection Segment as described in 26.11.2.2. Thus, M:1 IPS is deployed using an extension of 1:1 IPS that allows the current Protection Segment to be replaced by a candidate Protection Segment of higher priority, provided that such a candidate exists and is operational.

Figure 26-23—M:1 IPS

## 26.11.5.1 M:1 IPS state machines

There is one set of M:1 IPS state machines per IPG.

The M:1 IPS state machines comprise one M:1 Hold-off state machine (26.11.5.6) per candidate Protection Segment and one Protection Segment Selection state machine (26.11.5.7) per IPG, in addition to the 1:1 IPS state machines (26.11.4). The relationship between the M:1 IPS state machines and the 1:1 IPS state machines is illustrated in Figure 26-24.

Figure 26-24—M:1 IPS state machines

## 26.11.5.2 Notational conventions used in state diagrams

The Protection Switching state machines are specified using the notational conventions defined in Annex E. Additionally, in cases of multiple instances of a state variable, each instance is represented by adding the suffix “[n]” to indicate the n<sup>th</sup> instance. If instances of a state variable may be associated with either the Working Segment or the Protection Segment, the references can be distinguished by prefixing “w.” or “p.” to distinguish the two cases.

## 26.11.5.3 State machine timers

The timer variables declared in this subclause are part of the specification of the operation of Protection Switching. The accompanying descriptions of their meaning and use are provided to aid in the comprehension of the protocol only and are not part of the specification. Timer variables deployed by the M:1 IPS state machines are as follows:

- a) HoldOffWhile (26.10.3.2.2): one instance per M:1 Hold-off state machine
- b) MWTRwhile (26.11.5.3.1): one instance per M:1 Hold-off state machine

### 1 **26.11.5.3.1 MWTRwhile**

2 A timer to be used to prevent frequent operation of the protection switch among candidate Protection  
3 Segments due to an intermittent defect. This timer allows for a fixed period of time to elapse before data  
4 traffic is mapped from a lower priority Protection Segment to a higher priority Protection Segment when in  
5 M:1 revertive mode.

### 6 **26.11.5.4 Variables referenced by M:1 IPS state machines**

7 The following variables are referenced by the M:1 IPS state machines:

- 8 a) BEGIN (26.11.5.4.1)
- 9 b) SF (26.11.5.4.2)
- 10 c) SFH (26.11.5.4.3)
- 11 d) stateChange (26.11.5.4.4)
- 12 e) pri (26.11.5.4.5)
- 13 f) allPsSFH (26.11.5.4.8)
- 14 g) crntPs (26.11.5.4.6)
- 15 h) WTRTime (26.10.3.3.8)
- 16 i) MWTRTime (26.11.5.4.7)
- 17 j) HoldOffTime (26.10.3.3.9)

### 18 **26.11.5.4.1 BEGIN**

19 This is a Boolean variable controlled by the system initialization process. A value of TRUE causes all M:1  
20 IPS state machines per IPG to continuously execute their initial state. A value of FALSE allows these state  
21 machines to perform transitions out of their initial state, in accordance with the relevant state machine  
22 definitions.

### 23 **26.11.5.4.2 SF**

24 SF is the logical OR of someRMEPCCMdefect (20.35.5), someRDId defect (20.35.7), xConCCMdefect  
25 (20.23.3), and errorCCMdefect (20.21.3). An instance of this variable, identified by the notation SF[n], is  
26 specified per candidate Protection Segment.

### 27 **26.11.5.4.3 SFH**

28 A Boolean flag set and cleared by the M:1 Hold-off state machine to indicate that SF is set for a period that  
29 is equal to, or larger than, the HoldOffTime. The variable is set equal to SF if the hold-off timer is not  
30 supported. An instance of this variable, identified by the notation SFH[n], is specified per candidate  
31 Protection Segment.

### 32 **26.11.5.4.4 stateChange**

33 A Boolean flag set by the M:1 Hold-off state machine and cleared by the Protection Segment Selection state  
34 machine indicating the value of SFH associated with a candidate Protection Segment has changed. An  
35 instance of the variable, identified by the notation stateChange[n], is specified per candidate Protection  
36 Segment.

#### 1 **26.11.5.4.5 pri**

2 An integer value associated with each candidate Protection Segment and unique within the IPG indicating  
3 the selection priority of a candidate Protection Segment. Lower numeric values are associated with higher  
4 priority. An instance of the variable, identified by the notation pri[n], is specified per candidate Protection  
5 Segment.

#### 6 **26.11.5.4.6 crntPs**

7 An integer value identifying the operational candidate Protection Segment having the highest (lowest  
8 numeric) selection priority. In the event that no candidate Protection Segment is available, the value is that  
9 of the last candidate Protection Segment to be available.

#### 10 **26.11.5.4.7 MWTRTime**

11 The M:1 wait-to-restore (MWTR) period associated with reverting from a lower priority to a higher priority  
12 candidate Protection Segment, as provided by the corresponding managed object [item k] in 12.24.2.1.3].  
13 May be configured by the operator in 1 min steps between 5 and 12 min; the default value is 5 min. A value  
14 of 0 indicates M:1 nonrevertive mode. The overall accuracy of the MWTR timer (e.g.,  $<\pm 25$  ms) should be  
15 sufficient to allow both SEBs at the termination of the IPG to revert to the same value of the Protection  
16 Segment in less than 50 ms.

#### 17 **26.11.5.4.8 allPsSFH**

18 The logical AND of the value of SFH[n] over the M candidate Protection Segments.

#### 19 **26.11.5.5 Procedures referenced by M:1 IPS state machines**

20 The following procedures are referenced by the M:1 IPS state machines:

- 21 a) highestPriOperPs() (26.11.5.5.1)
- 22 b) setPs(n) (26.11.5.5.2) (26.11.5.5.2)
- 23 c) mapDataToProtection() (26.10.3.4.2)

#### 24 **26.11.5.5.1 highestPriOperPs()**

25 Returns the identity of the highest priority candidate Protection Segment for which SFH[n] == FALSE or, in  
26 the event that SFH[n] == TRUE for all candidate Protection Segments, the value NULL.

#### 27 **26.11.5.5.2 setPs(n)**

28 Establishes the n<sup>th</sup> candidate Protection Segment as the Protection Segment referenced by the Service  
29 Mapping state machine.

#### 30 **26.11.5.6 M:1 Hold-off state machine**

31 The M:1 Hold-off state machine is specified by the state diagram in Figure 26-25 and the variables in  
32 26.11.5.4.

1

Figure 26-25—M:1 Hold-off state machine

2 NOTE—The state NO\_SF\_H\_WTR is entered only in the case that M:1 reversion has been provisioned (i.e., MWTRTime  
3 != 0) and the candidate Protection Segment “n” is operational (i.e., !SF[n]). The state allows the machine to wait a period  
4 of time (i.e., MWTRTime) before permitting the candidate Protection Segment “n” to become available for selection as  
5 the Protection Segment, thus increasing stability. If, during this time, it is determined that no candidate Protection  
6 Segments are available for selection (i.e., allPsSFH), but candidate Protection Segment “n” is operational, then it is  
7 prudent not to wait MWTRTime but instead to proceed directly to the selection of candidate Protection Segment “n” as  
8 the current Protection Segment. In other words, when no candidate Protection Segment has met the criterion for  
9 availability (i.e., allPsSFH), but there is a candidate Protection Segment that is operational (i.e., !SF[n]), then it is not  
10 necessary to wait MWTRTime before proceeding with selection.

### 26.11.5.7 Protection Segment Selection state machine

The Protection Segment Selection state machine is specified by the state diagram in Figure 26-26 and the variables in 26.11.5.4.

Figure 26-26—Protection Segment Selection state machine

### 26.12 Mismatch defect

Under equipment malfunction conditions and/or incorrect configuration, a mismatch between the mappings of the backbone service instances to the appropriate TESI at the terminating CBPs can happen. Similarly, a mismatch can occur in the mapping of a TESI to the appropriate Infrastructure Segment at the terminating PNP. To maintain the proper operation of the network, such a mismatch should be detected and reported. There can be two types of mismatch. They are as follows:

- a) Protection switching incomplete
- b) Working/protection configuration mismatch

An example of protection switching incomplete mismatch is when, due to equipment malfunction, the near end (East B-Component in Figure 26-13) fails to switch over but it sends a CCM with the RDI field set to the far end (West B-Component in Figure 26-13). The far end transmits to the protection TESI while the near end is still transmitting in the working TESI. Similarly a mismatch can also happen when the near end transmits to the protection TESI but the far end fails to start transmitting to the protection TESI when it receives a CCM with the RDI field set.

1 The mismatch can also happen because of incorrect configuration. For example, one end is configured to  
2 send traffic on working TESI while the other end is configured to send traffic on protection TESI. Or one  
3 end is configured as revertive mode while the other end is configured as nonrevertive mode. The mismatch  
4 occurs when a failure is cleared.

5 NOTE—Since a merging selector is used, in the case of TESI protection, there is not necessarily a traffic loss in all  
6 mismatch cases.

7 PBB-TE MEPs and Infrastructure Segment MEPs that support the Traffic field (21.6.1.4) can detect such a  
8 mismatch. The Mismatch state machine in 20.26 provides this capability.

## 9 **26.13 Signaling VLAN registrations among I-components**

10 A VIP is a Bridge Port. MVRP can therefore be enabled in an I-component and used to convey dynamic  
11 VLAN Registrations from I-component to I-component across a PBBN.

12 In the particular case of VIPs that do not emit an S-TAG, and thus use only the I-TAG to differentiate among  
13 service instances, the Multiple I-SID Registration Protocol (MIRP, Clause 39) can be enabled instead of  
14 MVRP (11.2) to signal the need to flush learned C-MAC address information from one Icomponent to  
15 another. The network administrator can select between using MVRP or MIRP to perform this signaling  
16 according to the need to minimize the number of control frames sent (MIRP) or the number of remote  
17 I-components affected by any given control frame (MVRP).

## 1 27. Shortest Path Bridging (SPB)

2 SPB provides shortest path communication for user data frames in SPT regions (Clause 3). ISIS-SPB  
3 interoperates with MSTP and RSTP (Clause 13) and STP (Clause 8 of IEEE Std 802.1D, 1998 Edition  
4 [B13]), exchanging BPDUs to determine the extent of each SPT Region and to configure full, simple, and  
5 symmetric connectivity throughout a network comprising arbitrarily interconnected Bridges and individual  
6 point-to-point LANs (13.6, 13.7). IS-IS supports point-to-point links and shared LANs; however, only point-  
7 to-point is considered for ISIS-SPB in this specification. A future revision may add shared media. The  
8 Clause 13 SPB description allows for both point-to-point links and shared media.

9 Within an SPT Region (7.4, 13.6), the active topology that supports the frames for any given Base VID can  
10 be chosen (27.4) by the network administrator to be one of the following:

- 11 — The Internal Spanning Tree (IST).
- 12 — A Multiple Spanning Tree Instance (MSTI).
- 13 — A set of Traffic Engineering service instances (TESIs).
- 14 — A set of shortest path trees (SPT Set), one SPT rooted at each SPT Bridge and supporting frames  
15 transmitted into the region through that Bridge.
- 16 — Multiple equal cost unicast paths and multicast trees that spread traffic rooted at each SPT Bridge  
17 over multiple SPTs. This ECMP connectivity is only supported by SPT Bridges using SPBM mode.
- 18 — A set of Explicit Trees (ETs).

19 Clause 28 specifies the use of ISIS-SPB to calculate the IST and multiple SPT Sets (supporting different  
20 ECTs) within an SPT Region. Clause 13 specifies the use of MSTP to calculate MSTIs, and state machines  
21 that use the results provided by ISIS-SPB for each SPT to prevent loops within and between regions while  
22 maintaining or recovering connectivity as the network reconfigures (13.12, 13.14–13.40, 27.5). The  
23 umbrella term ISIS-SPB refers to the coordinated use of the protocols and algorithms specified in Clause 28  
24 and Clause 13 to support SPB.

25 Clause 45 specifies the use of IS-IS to establish explicit trees within an SPT Region. These trees can differ  
26 from the SPTs.

27 To allow SPB to support plug-and-play operation for some VLANs, while providing the administrative  
28 controls and scalability required for large scale operations, this standard specifies two complementary  
29 modes of SPT Bridges (SPBV and SPBM) for assigning each shortest path bridged frame to the correct SPT.  
30 All the Bridges in a given SPT Region agree on the method to be used to support any given VLAN.  
31 Subclause 27.19 describes network scenarios that use one or both of these methods.

32 If a VLAN is supported by an SPT Bridge using SPBV mode, Shortest Path VIDs (SPVIDs) are  
33 automatically allocated by ISIS-SPB and used in VLAN tags within an SPT Region. Each SPVID identifies  
34 both the VLAN and the SPT supporting transmission of a tagged frame, and Dynamic VLAN Registration  
35 Entries are created to provide connectivity while preventing loops (13.38.2). The SPVIDs for a given VLAN  
36 use a single FID that is associated with the Base VID for that VLAN (Shared VLAN Learning (SVL), 7.5,  
37 8.8.8). VID translation (6.9) at the region boundary (7.4, 13.5, 13.12) maps SPVIDs to and from the  
38 associated Base VID.

39 If a VLAN is supported by an SPT Bridge in SPBM mode without ECMP, the Base VID is used in each  
40 frame's VLAN tag within the SPT Region and identifies the VLAN and the SPT Set. Each Bridge mitigates  
41 and prevents loops (6.5.4, 13.38.2) by using the source and destination MAC address of each frame with  
42 Dynamic Filtering Entries for the Base VID, MAC address tuples. The source MAC address identifies the  
43 particular SPT from the SPT Set, and supports active topology enforcement (13.38.2, 8.6.1). When  
44 forwarding unicast frames it is not necessary to consider the particular SPT since all the SPTs in a given set  
45 transiting a given Bridge en route to a destination take the same path from that given Bridge to the

1 destination (in other words, they are all reverse path congruent with the SPT rooted at that destination).  
2 Therefore, for unicast frames the destination MAC address is used for egress filtering as normal. SPT  
3 Bridging using SPBM mode requires the use of SPT-specific destination group MAC addresses, so loop-free  
4 multicast forwarding is also supported without requiring the source MAC address or source Bridge Port to  
5 be part of the FDB query. ISIS-SPB automatically allocates SPSourceIDs (27.10) that are used as part of  
6 each group address. Since an SPT Bridge using SPBM mode inspects source MAC addresses as a loop  
7 mitigation mechanism, those addresses have to be known before forwarding can take place and are  
8 advertised using ISIS-SPB. Learning of B-MAC addresses is not enabled when SPBM mode is used, and  
9 frames destined for unknown addresses are discarded and not flooded. The individual MAC addresses used  
10 are those of the SPT Bridges themselves, or are associated with functions provided by Provider Bridges or  
11 BEB functions that include an SPT Bridge component. SPBM group multicast addresses are local to the SPT  
12 Bridge domain [using the Locally administered (U/L) address MAC address flag (IEEE Std 802)], so the use  
13 of SPT-specific group MAC addresses does not intrude on the well known global multicast space.

14 With ECMP (Clause 44), ISIS-SPB can configure multiple potential forwarding Ports for each individual  
15 MAC address, and forwarding port selection is performed dynamically. Forwarding Port selection is  
16 controlled by a deterministic hash function whose inputs are the SPB System Identifier and the Flow Hash  
17 carried in an F-TAG. This tends to spread traffic flows over the set of equal cost paths between the source  
18 Bridge and destination Bridge in the SPT Region while preserving frame ordering of individual flows. As a  
19 substitute for the loop prevention and mitigation techniques mentioned above, an alternative loop quenching  
20 mechanism for ECMP is realized with a TTL field included in the F-TAG. With ECMP, bidirectional and  
21 unicast-multicast congruence is no longer guaranteed (since there is no longer a single path in use between a  
22 source and destination). This enables each Backbone Service Instance group address to be independently  
23 routed and multicast traffic to be spread over a set of equal cost SPTs.

24 ISIS-SPB uses the same mechanism to allocate SPVIDs (for SPBV) and SPSourceIDs (for SPBM) (27.10).  
25 The MST Configuration Identifier (MCID) (8.9, 13.8) is used to ensure that all the Bridges in an SPT  
26 Region agree on the method used to support each shortest path VLAN and on the pool of SPVIDs, as well as  
27 on the other uses of VIDs (27.4). An SPSourceID is allocated to each Bridge in an SPT Region,  
28 independently of SPBM mode VLANs, while an SPVID for a given SPBV VLAN is only allocated to the  
29 SPT rooted at a given Bridge if VLAN Registration Entries and controls allow that Bridge to transmit frames  
30 assigned to that VLAN into the region (8.8, 13.6).

31 An SPT Bridge using SPBV mode is typically used to support a C-VLAN or S-VLAN for a single customer.  
32 An SPT Bridge using SPBM mode is typically used to support B-VLANs in PBBNs (Clause 25). Each  
33 B-VLAN can support many backbone service instances, each requiring connectivity between a subset of  
34 the BEBs participating in the B-VLAN, and each identified by an I-SID that is not processed by BCBs. An  
35 SPT Bridge using SPBM mode does not use source address learning, so unicast B-MAC frames  
36 conveying customer data are never flooded throughout the B-VLAN. Multicast frames and flooding of  
37 unknown unicast frames for a given backbone service instance are confined to paths that reach the BEBs  
38 supporting that service instance by including the I-SID in the SPT-specific destination group MAC addresses  
39 (Figure 27-3). The destination address filtering in each BCB prunes transmission of the encapsulated  
40 customer multicast frames as well as preventing loops.

41 MVRP (11.2) is not used within SPT Regions, as ISIS-SPB communicates VLAN registration information  
42 for VLANs supported by SPB from the SPT Bridges that provide ingress to and egress from the region to the  
43 other Bridges, thus allowing SPT Bridges using SPBV and SPBM to configure Dynamic VLAN  
44 Registration Entries for Bridge Ports within the region to provide correct VLAN connectivity when SPTs are  
45 recalculated—instead of waiting for registration information to propagate on those SPTs. SPT Bridges can  
46 use the registration information communicated within the SPT Region to participate in MVRP with Bridges  
47 outside the region (27.13) by supporting MVRP interfaces on the Region boundaries.

1 This clause specifies the following:

- 2 a) Protocol design and support requirements (27.1, 27.2) and design goals (27.3).

3 This clause further specifies how:

- 4 b) Each Bridge's configuration mechanisms specify the supporting method (SPBV, SPBM, MSTI,  
5 CIST, or PBB-TE) and SPT Set (for SPBV and SPBM) for each VLAN (27.4).  
6 c) The boundaries of each SPT Region and ISIS-SPB adjacencies are determined dynamically by ISIS-  
7 SPB (Clause 28).  
8 d) The information exchanged by ISIS-SPB is used (27.5), including CIST calculation (27.6, 27.7),  
9 SPT calculations (27.8), allocating SPVIDs and SPSourceIDs (27.10), and controlling the  
10 connectivity supporting each VLAN (27.13) and backbone service instance (27.15, 27.16).  
11 e) The results of ISIS-SPB's CIST and SPT calculations are used by the Clause 13 state machines to  
12 determine when to discard frames to ensure the calculated trees are loop-free (27.9).  
13 f) SPVIDs are allocated to FIDs (27.11) and translated to and from Base VIDs at the boundary of an  
14 SPT Region (6.9, 13.6).  
15 g) VLAN Registration Entries are used to forward or discard frames for each VLAN (27.13).  
16 h) FDB entries for individual addresses are used to prevent or mitigate loops for VLANs supported by  
17 SPBM (27.14).  
18 i) SPBM Group Addresses are assigned, and FDB entries for those addresses used to forward or  
19 discard frames for each backbone service instance for B-VLANs supported by SPBM (27.15,  
20 27.16).  
21 j) The SPT calculations choose between Equal Cost Trees (ECTs), making different choices for  
22 different SPT Sets, each associated with a different VLAN, enabling load spreading (27.17, 28.9.2).

23 This clause also:

- 24 k) Provides examples of when and how SPT Bridges using SPBV and SPBM modes can be used  
25 (27.19).

## 26 **27.1 Protocol design requirements**

27 ISIS-SPB configures entries in each SPT Bridge's FDB (8.8) to meet the following requirements:

- 28 a) The active topology will fully connect all physically connected LANs and Bridges, and stabilize  
29 (with high probability) within a short, known bounded interval after any change in the physical  
30 topology, maximising service availability (8.4).  
31 b) Except in the case of ECMP, the active topology for any given frame remains simply connected at all  
32 times (6.5.3, 6.5.4).  
33 c) The same symmetric active topology is used, in a stable network, for all frames for the same VLAN,  
34 i.e., between any two individual LANs those frames are forwarded through the same Bridge Ports.  
35 d) The active topology supporting a given VLAN within an SPT Region can be chosen by the network  
36 administrator to be shortest path, the IST, an MSTI, or an ET.  
37 e) Each active topology is predictable and reproducible, and may be influenced by management, thus  
38 allowing the application of Configuration Management following traffic analysis, to meet the goals  
39 of Performance Management (6.5 and 6.5.10).  
40 f) The configured network can support VLAN-unaware end stations, such that they are unaware of  
41 their attachment to a single LAN or a bridged network, or their use of a VLAN (6.3).  
42 g) The SPB mode, SPBV or SPBM, can be chosen by the network administrator independently for  
43 each VLAN using shortest paths.

1 SPBV mode meets the following requirements:

- 2 h) No additional constraint is placed on the values of the Individual or group MAC addresses used, and  
3 those addresses do not have to be known before being used in data frames.
- 4 i) SPVIDs are allocated to every SPT Bridge that is a potential source of frames on VLANs supported  
5 by SPBV.
- 6 j) FDB entries for a given SPVID will only be populated if they are on the shortest path to a  
7 participating boundary node.

8 SPBM mode meets the following requirements:

- 9 k) Multicast flooding for each backbone service instance supported by a PBBN is restricted to paths  
10 necessary to reach BEBs supporting that service instance.
  - 11 l) ECMP operation enables multiple equal cost paths in the SPT Region to carry a share of unicast and  
12 multicast traffic.
- 13 NOTE—The ECMP ECT Algorithm supports multicast load spreading over up to 16 source trees per node and  
14 up to 16 shared trees.

15 Additionally, SPB algorithms and protocols meet the following goals, which limit the complexity of Bridges  
16 and their configuration:

- 17 m) The memory requirements associated with each Bridge Port are either a constant or a linear function  
18 of the number of Bridges and LANs in the network.
- 19 n) The communications bandwidth consumed by ISIS-SPB on any particular LAN is always a small  
20 fraction of the total available bandwidth (6.5.10).
- 21 o) Bridges do not have to be individually configured before being added to a network, other than  
22 having their MAC addresses assigned through normal procedures.

## 23 27.2 Protocol support

24 ISIS-SPB is configured to use one of the Group addresses from Table 8-16 to establish adjacencies and  
25 exchange PDUs. SPB running on C-VLAN components use the Customer Bridge address. SPB running on  
26 S-VLAN components use the Provider Bridge address. SPB running on B-VLAN components may use the  
27 Provider Bridge Address or one of the existing IS-IS addresses.

28 The use of the ISIS-SPB adjacency between Bridges is contingent on the Bridges inclusion within the same  
29 SPT Region, and thus requires they have an MCID and Auxiliary MCID (13.8, 28.12.2) where at least one  
30 matches on every adjacency in the Region (8.9.4, 13.8). MCID and Auxiliary MCID enable migration of the  
31 MCID definition allowing these Bridges to operate as one SPT Region under certain small changes. The  
32 operational set of Base VLANs and SPVIDs must be consistent during migration. This standard specifies  
33 default configurations resulting in a MCID that enables plug-and-play support of both the CIST and SPB  
34 using SPT Bridges using SPBV mode. No default recommendations are made for SPT Bridges using SPBM  
35 mode, since it is only expected to be used in managed environments.

36 This standard recommends defaults for Bridge and Bridge Port priorities and path costs to support the  
37 calculation of active topologies without further configuration. To allow management of those active  
38 topologies, a means of assigning values to the following are required:

- 39 a) The relative priority of each Bridge in the network (13.26.3)
- 40 b) The relative priority of each Port of a Bridge (13.27.47)
- 41 c) A Port Path Cost for each Port (13.27.25, 13.27.33)

1 Management of SPT topologies and of the use of SPBV or SPBM mode to support particular VLANs, also  
2 requires the following:

- 3 d) Management of the SPB objects (12.25)
- 4 e) Administrative agreement on the MCID Configuration Name and Revision Level (Clause 28)

### 5 **27.3 Protocol design goals**

6 It is highly desirable that the operation of ISIS-SPB allows the following:

- 7 a) Addition of Bridges to an existing SPT Region without disrupting existing communication
- 8 b) SPB support for additional VLANs without disrupting existing communication
- 9 c) Enabling or disabling SPB support for individual VLANs with minimum frame loss

### 10 **27.4 ISIS-SPB VLAN configuration**

11 The configuration mechanisms used by MST Bridges to allocate each VLAN to a specified MSTI or the IST  
12 within an MST Region and used to allocate VIDs for PBB-TE (25.10) can be summarized as follows:

- 13 a) The VID to FID allocation table (8.8.8, 12.12.2) is used to allocate each VID to a FID.
- 14 b) The FID to MSTID Allocation Table is used to associate an MSTID with a FID (8.9.3, 12.12.2):
  - 15 1) The IST is identified by the reserved MSTID value 0.
  - 16 2) The use of PBB-TE is identified by the reserved MSTID value TE-MSTID (0xFFE)
  - 17 3) Each MSTID in the MSTI List identifies an MSTI.
  - 18 The reserved MSTID values 0 and TE-MSTID, SPBV-MSTID, SPBM-MSTID, and SPVID-
  - 19 Pool-MSTID are never used in the MSTI List.

20 SPT Bridges extend these configuration mechanisms as follows:

- 21 c) The VID to FID allocation table is used to allocate Base VIDs to FIDs, and to allocate VIDs for use  
22 as SPVIDs. SPVIDs are allocated to the reserved FID value 0xFFFF. SPVIDs in use are reported by  
23 management as allocated to a FID supported by the implementation (27.11).
- 24 d) The reserved FID value SPVID-Pool-MSTID is allocated to the reserved MSTID value 0xFFFF.
- 25 e) The following MSTID values identify the SPT Bridge mode used by SPB:
  - 26 1) 0xFFC—SPBM
  - 27 2) 0xFFD—SPBV

28 This standard recommends default VID to FID and FID to MSTID allocations (27.2, 8.9.3) for SPT Bridges  
29 that enable plug-and-play support of both the CIST and SPB using SPBV mode.

30 Table 27-1 shows the VID to FID and the FID to MSTID allocation tables in a single table for the  
31 configuration example shown in Figure 27-1 for an SPT Region.

32 Base VID 1 is allocated to the IST and VIDs from 0x100 to 0x1FF form the SPVID Pool. Base VIDs 0x002,  
33 0x003, and 0x004 are configured to operate in SPBM mode. Base VIDs 0x005, 0x006, and 0x007 operate in  
34 SPBV mode in the example.

**Table 27-1—Allocation of VIDs to FIDs and FIDs to MSTIDs in an SPT Region (example)**

| VID         | FID   | MSTID |
|-------------|-------|-------|
| 0x001       | 0x001 | 0x000 |
| 0x002       | 0x002 | 0xFFC |
| 0x003       | 0x003 | 0xFFC |
| 0x004       |       |       |
| 0x005       | 0x005 | 0xFFD |
| 0x006       | 0x006 | 0xFFD |
| 0x007       |       |       |
| 0x100–0x1FF | 0xFFF | 0xFFF |

**Figure 27-1—Configuring VLAN support in an SPT Region (example)**

## 27.4.1 SPT Region and ISIS-SPB adjacency determination

It is essential that all Bridges within an SPT Region agree on the allocation of VIDs to spanning trees prior to transmission and reception of frames tagged with those VIDs. This configuration requirement is common to both SPB (13.6) and MSTP operation (13.5), and MSTP can coexist with ISIS-SPB within an SPT Region, supporting different VLANs with different VIDs. ISIS-SPB uses and extends MSTP's configuration mechanisms and use of the MCID (8.9, 13.5, 13.8). Note the MCID (13.8) includes a digest derived from the mapping of VIDs to MSTIDs. To allow dynamic manipulation of SPVIDs without impacting the MCIDs, the mapping of SPVIDs to the FID associated with the supported Base VID is not captured in this table.

1 SPB configuration is highly automated. An SPT Region is created by configuring at least two adjacent  
2 Bridges with compatible information. The region grows dynamically as more SPT Bridges with the same  
3 region configuration are introduced. Once a region has been created, other VLANs can also be created. ISIS-  
4 SPB will populate forwarding only between Bridges that support the same services. The SPT region is an  
5 interconnected set of Bridges supporting the Region configuration [MCID (13.8), ISIS-SPB Configuration  
6 (27.4)] but the forwarding for any one VLAN is simply the Bridges configured to support services on that  
7 VLAN or the Bridges that lie on the shortest path between those Bridges.

8 The same is true of SPT Bridges operating in SPBM mode that can be added to support new VLANs on a  
9 Bridge by Bridge basis. One common operation for SPT Bridges operating in SPBM mode is to create a new  
10 ECT for a new VLAN. To support a graceful migration of services to a new Base VID, SPB allows the  
11 configuration of the Base VID before configuring services on those Base VIDs. The new Base VIDs in SPT  
12 Bridges need to be configured on all Bridges where the services reside. The U-bit (28.12.5) and Use-flag  
13 (28.12.4) are used to identify configured Base VIDs that do not have active services associated with them.

14 In the cases where the allocation of Base VIDs is insufficient a graceful way to support an increase in the  
15 number of Base VIDs is supported by a second (auxiliary) MCID (13.26.8, 28.12.2). Two such Bridges  
16 consider themselves to be in the same MST Region provided that at least one of their MCIDs matches with  
17 one of their SPB neighbor's MCIDs. Non critical changes in the MCID, can be made while maintaining  
18 forwarding on the previous configuration. This is done by configuring a Bridge with a revised VID  
19 allocation that is compatible with the current allocation in use for SPB forwarding. The Bridge advertises  
20 this new MCID and continues to advertise the previous MCID as the Auxiliary MCID, maintaining its  
21 adjacencies.

22 When an adjacent Bridge is similarly configured, it also advertises the new MCID as its MCID to its  
23 adjacencies. The Auxiliary MCID is always the outgoing MCID. Bridges that have not been updated will  
24 continue to match their updated neighbors' Auxiliary MCID until they have been updated, whereupon their  
25 MCID values will match again. When a Bridge sees that all its adjacencies are advertising the value of its  
26 own new MCID as their MCID, then the Bridge shall start advertising the value of its new MCID as its  
27 Auxiliary MCID also. When all Bridges have been verified to have installed the new configuration, the  
28 transfer of services to use the new VLAN allocations may be administratively initiated.

29 NOTE 1—The MCID verifies that each Bridge in the region agrees how each and every Base VID is to be assigned to  
30 the IST, to an MSTI, for use by PBB-TE, for support by SPBV mode, for use as an SPVID, or for support by SPBM  
31 mode. The MCID does not specify the SPT Set for VLANs supported by SPB, or preallocate SPVIDs to SPT Sets as  
32 disagreement on the former or temporary differences in the latter will not cause permanent loss of connectivity, loops, or  
33 protracted flooding. ISIS-SPB verifies that SPT Bridges agree on the SPT Set to be used to support any given SPB  
34 supported VLAN, and the Agreement Digest ensures that new connectivity is not created until that agreement has been  
35 reached.

36 NOTE 2—The MCID and the Agreement Digest (13.8, 28.4) can both influence the connectivity provided, and their  
37 respective roles need to be clear. MCID differences identify configuration mismatches that could cause network  
38 malfunction (e.g., data loops) if connectivity were to be created, and that are not amenable to timely resolution by  
39 normal protocol operation. MCID differences act as a fail-safe mechanism, forcing lowest common denominator  
40 connectivity (to a single spanning tree, the CST) so at least some connectivity is provided, albeit with lower throughput.  
41 The fallback connectivity can be used to investigate or correct configuration issues. The Agreement Digest and related  
42 mechanisms simply verify that delays in propagating and using protocol information do not cause loops in permitted  
43 connectivity.

44 SPT Regions are similar to MST Regions, and can also be modeled as single Bridges (13.5.3). They do not  
45 overlap, superset, or subset other regions but participate in the same active topology solely through the CST.  
46 Each region can be identified by its Master Port, i.e., the Bridge Port that provides connectivity from the  
47 region to a CIST Root that lies outside the region, or, in the case where the CIST Root lies within the region,  
48 by the CIST Root Bridge itself. The Master Port is uniquely and globally identified by its Bridge Identifier  
49 and Port Identifier on an SPT Bridge, and is communicated by the CIST Regional Root Identifier and its  
50 associated CIST Port Identifier fields in SPT BPDUs.

1 IS-IS adjacencies are formed according to IS-IS protocol rules independent of ISIS-SPB. ISIS-SPB  
2 forwarding is only allowed on a more strict basis when the MCID, Base VID, and ECT Algorithm  
3 information lines up in the SPB Hello PDUs.

4 When two SPT Bridge Ports attached to the same LAN have no match between their primary or Auxiliary  
5 MCIDs in transmitted SPT BPDUs, each is a Boundary Port (13.12) for its SPT Region, and forwards user  
6 data frames only if it is a CST Root Port or Designated Port. Such a network configuration is usually  
7 temporary and infrequent, a result of as yet incomplete administrative action, or simply a configuration error  
8 (13.6). To minimize network disruption during such administrative episodes, ISIS-SPB communicates  
9 information throughout an SPT Domain comprising a transitive closure of SPT Bridges attached to  
10 individual LANs.

11 Each SPT Bridge Port uses BPDUs and/or SPB Hello PDUs to transmit and receive MCIDs and  
12 Agreements. BPDUs also carry currently calculated CIST Information, so that all the Bridges (not just SPT  
13 Bridges) attached to each individual LAN can be detected and can participate in the information exchange  
14 required at SPT Region boundaries. SPT BPDUs or SPB Hello PDUs also convey the CIST Agreement and  
15 Agreement Digest information that SPB uses to prevent temporary loops (28.4). This Agreement  
16 information can only be sent after the Bridge's ISIS-SPB calculations have been used to modify its FDB  
17 entries, and is thus not naturally tied to the transmission of the ISIS-SPB Link State PDUs (LSPs) that  
18 convey the adjacency information that makes those calculations possible (LSPs can be disseminated  
19 throughout the SPT Domain without waiting for any single Bridge to complete its calculations—each  
20 proceeding in parallel). Including the Agreement information in the SPT BPDUs helps determine the SPT  
21 Region's extent, ensuring backwards compatibility to non SPT Bridges. Exchanging SPB Hello PDUs (to  
22 establish adjacencies) and transmitting ISIS-SPB LSPs (to propagate information for SPT Identifier  
23 allocation and SPT calculation throughout the SPT Domain) as soon each Bridge Port is MAC\_Operational  
24 is supported in parallel with BPDUs. Bridges that are not SPB-capable will not support SPB Hello PDUs  
25 and it is up to the SPT BPDU logic to determine what type of spanning tree protocol the non-SPT Bridges  
26 support. In most networks the SPT Region's boundary will coincide with that of the SPT Domain, in other  
27 cases LSPs for those Bridge Ports that bound a region but lie within the domain might have to be  
28 transmitted.

29 NOTE 3—Clause 13 specifies the state machines and procedures that determine each SPT's region boundaries,  
30 including interoperability with Bridges implementing STP (Clause 8 of IEEE Std 802.1D, 1998 Edition [B13]), RSTP, or  
31 MSTP as well as the use of SPT BPDUs to address other error conditions that can occur (e.g., disputes with other  
32 Bridges due to one-way connectivity).

### 33 27.5 ISIS-SPB information

34 ISIS-SPB can be viewed primarily as a means of sharing information between nodes in a network, providing  
35 each node with a copy of a common database of information contributed by each and every node, and  
36 ensuring (with high probability) that the copies are kept up to date though not necessarily in lock step  
37 synchronization. Each node can then execute its own independent copy of one or more previously agreed  
38 algorithms that use that node's copy of the database to compute results that are common to all the nodes, or  
39 that are part of a common or complementary set. The result is a set of forwarding tables for each node. ISIS-  
40 SPB shares information throughout an SPT Domain so that any given SPT Bridge in the domain can  
41 calculate or identify the following:

- 42 a) The CIST connectivity provided to each SPT Bridge in the domain (27.6, 27.7). This calculation  
43 identifies each of the SPT Regions within the domain (if more than one, 8.9, 13.6), the Bridges in  
44 each region, and the CST connectivity between regions.
- 45 b) The SPB connectivity provided by each SPT Set between Bridges in the given Bridge's region  
46 (27.8).
- 47 c) The SPVIDs (for SPBV mode) and SPSourceIDs (for SPBM mode) used to support SPB  
48 connectivity (27.10).
- 49 d) The VLAN connectivity provided for each Base VID over the calculated tree(s) (27.13).
- 50 e) The connectivity provided for each I-SID by the SPT Bridge over the calculated tree(s) (27.16).

## 1 27.6 Calculating CIST connectivity

2 ISIS-SPB calculates CIST connectivity (13.4.1, 13.5.3) using the following information from each Bridge in  
3 the SPT Domain:

- 4 a) The Bridge Identifier and, if the Bridge has currently selected its CST Root Port using information  
5 received from a Bridge that is not in the SPT Domain:
  - 6 1) The CIST Root Identifier and CIST External Root Path Cost.
- 7 b) The Port Identifier and the following information for each of the Bridge's Ports:
  - 8 1) Its IS-IS adjacencies, i.e., a list of the Bridge Identifier, Port Identifier tuples that identify each  
9 of the other SPT Bridges attached to the same LAN.
  - 10 2) Whether the Bridge Port is or is not a Boundary Port (13.12).
- 11 c) For each of the Bridge's Ports that is not a Boundary Port:
  - 12 1) The Internal Port Path Cost.
- 13 d) For each of the Bridge's Ports that is a Boundary Port:
  - 14 1) The External Port Path Cost.

15 If the `restrictedDomainRole` (13.27.63) parameter is set for an SPT Bridge Port, then that port will not be  
16 selected as a CIST Root Port if the Designated Bridge for the attached LAN is not in the SPT Domain. Used  
17 arbitrarily `restrictedDomainRole` and `restrictedRole` (13.27.64) can cause lack of connectivity. If used to  
18 support the network design these parameters can speed network convergence and protect against disruption  
19 if inappropriately configured Bridges are attached. If configured for all SPT Bridge Ports,  
20 `restrictedDomainRole` ensures that the CIST Root and all connectivity to and from that CIST Root will be  
21 provided solely by Bridges within the SPT Domain, thus simplifying CIST calculation. An SPT Bridge  
22 implementation may choose to always set `restrictedDomainRole`, managing it as a read only parameter. This  
23 choice restricts network design, but can include all scenarios intended for the implementation (27.19).

24 The CIST calculation uses the Dijkstra algorithm to compute the same active topology that would be  
25 produced by the distributed distance vector calculation specified in 13.10. Computation begins with the best  
26 priority CIST Bridge priority vector from those that represent each of the Bridges within the domain as a  
27 potential root and from those reported as received from a Bridge outside the domain [item a1) above]. If the  
28 External Path Cost accumulated during the computation would exceed that for a Bridge selecting its CST  
29 Root Port using information from a Bridge outside the domain, then that Bridge is also marked as having  
30 been reached in spreading computation and can be the best path to further Bridges, indicating that the CST  
31 path between SPT Regions lies outside the domain (not always a temporary or undesirable result, 27.19).

32 NOTE 1—The purpose of defining *priority vectors* (13.9) is to allow all the components that contribute to the choice of  
33 one path or another to reach a given Bridge or LAN from the CIST Root to form part of a single metric.

34 Each Bridge in the SPT Domain performs the CIST calculation independently, computing and retaining the  
35 following information for use by the state machines specified in Clause 13 (13.10, 13.17, 13.36, 13.29.34):

- 36 e) The CIST root path priority vector for every Bridge Port on the Bridge and the CIST root priority  
37 vector for the Bridge.
- 38 f) The IST Port Role for each of the Bridge's Bridge Ports that is not a Boundary Port.
- 39 g) The CIST designated priority vector for each of the Bridge's Bridge Ports.

40 Each Bridge's CIST calculation also identifies the following:

- 41 h) The SPT Region for itself, and for each of the other Bridges in the domain.
- 42 i) The CST Port Role for each Bridge Port that is a Boundary Port for a region.

43 NOTE 2—Each SPT Region can be identified by the region's Master Port. Connectivity from all Bridges in a given  
44 region,  $R_1$  say, passes through the same Boundary Port  $BP_{12}$ , to reach any Bridge in a region  $R_2$ . Recording the region  
45 and boundary port information during CIST calculation facilitates identification of the boundary Bridges.

## 1 27.7 Connectivity between regions in the same domain

2 If the SPT Domain has been found to comprise more than one region, then, prior to computing shortest  
3 paths, each Bridge uses the SPT Region and CST Port Role information [item h) and item i) in 27.6]  
4 computed for each Boundary Port together with the adjacency information for those ports to determine the  
5 following:

- 6 a) For each of the regions ( $R_2, R_3, \dots$  say) other than the computing Bridge's own region ( $R_1$ , say), the  
7 Boundary Bridge ( $B_{12}, B_{13}, \dots$ ) within  $R_1$  that provides CST connectivity to that region.

8 If the connectivity between regions lies outside the domain and either has (or has IST connectivity to a  
9 region that has) more than one Bridge that provides connectivity to a Bridge outside the domain, then ISIS-  
10 SPB does not have the information necessary to select a particular Boundary Bridge. Address learning (for  
11 SPBV) or registration protocols can provide the necessary information. If more than one possibility remains,  
12 an SPT Bridge using SPBM mode cannot provide connectivity between the regions.

13 NOTE—SPBM mode will often be configured to permit connectivity only if the entire path lies within the domain.

## 14 27.8 Calculating SPT connectivity

15 Each SPT Bridge uses ISIS-SPB to calculate the shortest paths from each of the Bridges [item h) in 27.6] in  
16 its own SPT Region including itself, to each of the other Bridges in that region. The information used by  
17 ISIS-SPB to perform the necessary Dijkstra calculations is a subset of that used for the CIST calculation  
18 [item a), item b1), item c1) in 27.6]. The following information is computed for each SPT and retained for  
19 use by the state machines specified in Clause 13 and 27.9, 13.17, 13.36, and 13.29.34:

- 20 a) The root priority vector for the Bridge.

21 and for each of the Bridge's ports that is not a Boundary Port:

- 22 b) The Port Role.

- 23 c) The designated priority vector.

24 and for each of the Bridge's ports that is not a Boundary Port and has a Port Role of Designated Port:

- 25 d) The best root path priority vector out of those that would be calculated, using the same ISIS-SPB  
26 information, by the other SPT Bridges.

27 There can be several equal cost shortest paths between any given pair of Bridges, but unless ECMP is in use,  
28 only one path between the pair can be used in a given SPT Set. Ties are broken using an algorithm (27.17,  
29 28.5) that is independent of the order of SPT computation, that ensures that the SPTs in each SPT Set are  
30 symmetric, that allows path selection to be managed using the same variables that are used to manage active  
31 topologies in the absence of multiple paths, and that is likely to select different equal cost paths for different  
32 SPT Sets if configuration defaults are used.

33 When a VLAN is supported by an SPT Bridge using SPBM mode and loop mitigation (6.5.4.2, 27.14) is  
34 being used, each of the FDB entries that control forwarding for unicast frames can be created or modified as  
35 soon as the port providing the shortest path to the Bridge or end station using that address is known, without  
36 the need to use additional protocol or to complete the SPT computation. In that case, restoration of unicast  
37 connectivity after a physical topology failure is most rapidly achieved by beginning the SPT  
38 (re)computation with the SPT rooted at the calculating Bridge.

## 1 27.8.1 ISIS-SPB overload

2 IS-IS has an overload capability that applies to a node that does not allow transit traffic through this node for  
3 various operational reasons. This capability has also been added to ISIS-SPB [item c in 28.12.1] TLVs. Just  
4 as in normal IS-IS Overload modifies the shortest path results by not allowing Bridges with the overload bit  
5 set to be eligible to forward transit traffic. For the purpose of computing paths, any paths through Bridges  
6 with overload set are not considered shortest paths and the computation uses the remaining topology and the  
7 next shortest paths. Use of the overload condition is typically reserved for edge devices that would not  
8 benefit the network if they were to become transit switches.

9 In ISIS-SPB if overload were set in the only Bridge connecting an SPT Region this would result in a region  
10 split where the overload Bridge was connected to both halves of the region but traffic could not transit  
11 through the overload Bridge. Each section of the SPT Region that is split would behave normally but there  
12 would be incomplete connectivity between the split sections. ISIS-SPB would have a complete view of the  
13 region and this condition is relatively easy to detect.

## 14 27.9 Loop prevention

15 The state machines in Clause 13 use the calculated priority vectors and Port Roles for each tree (27.6, 27.8)  
16 to determine the tree's Port State (i.e., the setting of the per port learn (13.27.34) and forward (13.27.29)  
17 variables), and exchange SPB BPDUs or SPB Hello PDUs to convey Agreements (13.17) that allow these  
18 variables to become set for Root Ports, Designated Ports, and Master Ports without the risk of temporary  
19 loops.

20 The Port State Transition state machine (13.38) signals changes to the learn and forward variables for a port  
21 for the CIST through calling disableLearning(), disableForwarding(), enableLearning(), and  
22 enableForwarding() procedures. These implementation-dependent procedures prompt changes to the  
23 mechanisms that perform forwarding and/or learning for frames assigned to the CIST.

24 Similarly changes to forward for a port for an SPT prompt changes in the FDB entries that allow (or prevent)  
25 the ingress or egress of frames assigned to that SPT (27.13, 27.14, 27.16). In turn these prompt changes to  
26 the implementation-dependent mechanisms that use the entries to control forwarding.

27 These mechanisms can take time to respond to changes in learn or forward, and report their current state to  
28 the state machines (by setting the learning (13.27.35) and forwarding (13.27.30) variables) so that new  
29 connectivity on some ports can be made contingent on other ports not forwarding frames. The forwarding  
30 variable (for any given tree) is only cleared if frames assigned to that tree neither ingress nor egress the port.

## 31 27.10 SPVID and SPSourceID allocation

32 Each SPT Bridge uses ISIS-SPB to support the distributed allocation of SPVIDs (used by SPBV mode) and  
33 the 20-bit SPSourceIDs (used by SPBM mode), ensuring that all Bridges in the SPT Domain agree on the  
34 allocated values. The allocation protocol for these two types of identifier differs slightly, as a consequence of  
35 the differences in the number of values available and the number required for each Bridge.

36 Candidate values for these identifiers may be pre-configured, in some or all of the Bridges in the domain, but  
37 by default they are allocated dynamically. Each Bridge attempts to allocate the following values:

- 38 a) An SPSourceID for the Bridge.
- 39 b) An SPVID for each VLAN that is supported by an SPT Bridge using SPBV mode and for which:
  - 40 1) The Bridge is a potential source of frames, either from a protocol entity within the Bridge or by  
41 forwarding from a port on the Bridge that is a Boundary Port; or
  - 42 2) The Bridge has a pre-configured allocation, even if conflict resolution means that this allocated  
43 value is not used.

1 NOTE 1—Each SPT Bridge allocates an SPSourceID even if no VLANs are to be supported by SPBM mode, or the  
2 Bridge is configured not to transmit frames for those VLANs. The number of available SPSourceIDs is much greater  
3 than the number to be allocated; therefore, there is no need to complicate allocation scenarios by attempting to optimize  
4 some cases, however frequent.

5 NOTE 2—If the SPT Bridge does not have a pre-configured SPVID for a VLAN supported by SPBV mode, and has no  
6 need to transmit frames for that VLAN (possibly because there is no other Bridge in the domain that wishes to receive  
7 frames for the VLAN or because a VLAN Registration Entry does not allow the Bridge to transmit frames for that  
8 VLAN), then an SPVID is not allocated. These conditions can arise even if the Base VID to FID to MSTID  
9 configuration for the Bridge, and the resulting MCID, identifies the VLAN as supported by SPBV mode.

10 The allocation protocol resolves conflicting attempts by different Bridges. Pre-configured or dynamic  
11 allocations are communicated by the setting of the Configuration Flags in the ISIS-SPB TLV used for  
12 allocation. Conflicts for allocations of a given type are resolved by granting the allocation to the Bridge with  
13 the best priority (numerically least) Bridge Identifier (14.2.5). When the conflict occurs on an auto allocated  
14 value, the other Bridges attempt to satisfy their need for a value by changing their allocation to a new  
15 dynamically allocated value. In the case that two configured values conflict, these must be resolved by  
16 operator action. All Bridges are aware of these conflict resolution rules, so there is no need for additional  
17 protocol to confirm or announce the allocation.

18 Candidate values for dynamic allocation are chosen using a pseudo-random function of each Bridge's  
19 Bridge Identifier (thus reducing the chance of only one identifier being allocated each time all the Bridges  
20 transmit fresh allocation information). Values that the allocating Bridge knows to be already in use are  
21 excluded (thus ensuring that an allocation that has been in existence long enough to be included in the IS-IS  
22 database of all Bridges in the domain will not be disrupted). Assuming that the unallocated values are  
23 arranged as an ordered list, the Bridge performs a modulo operation on its Bridge Identifier by the number of  
24 free values, and selects the indicated value from the list. This operation is repeated to select the next  
25 candidate value.

26 NOTE 3—When a Bridge changes its allocations, i.e., allocates new values to itself as required for (a) or (b) above or  
27 releases existing values, ISIS-SPB will communicate the updated information to the other Bridges in the domain.  
28 However, the detailed transmission timing and the other contents of IS-IS PDUs is under the control of ISIS-SPB itself,  
29 and is not directly controlled by the allocation protocol. A single PDU will usually convey a number of allocation  
30 changes.

31 NOTE 4—SPT Bridges can use different pseudo-random candidate selection functions, without imperiling the eventual  
32 success of the protocol. Nonetheless, SPVID allocation conflicts are likely to be fewer, and more quickly resolved, if the  
33 Bridges in a domain use the same algorithm.

34 On first discovering an ISIS-SPB adjacency (27.2, Clause 3) an SPT Bridge does not perform any allocation  
35 before acquiring the IS-IS database. The SPT Bridge becomes aware of existing allocation through normal  
36 IS-IS operation. While acquiring the full IS-IS Database, the Bridge advertises SPSourceID = 0 in its LSPs,  
37 to indicate to other Bridges that it shall not be included in Shortest Path First (SPF) calculations. As soon as  
38 the Bridge has successfully allocated itself an SPSourceID, this allocated value shall be advertised in ISIS-  
39 SPB. If the Bridge is aware of dynamic allocations that it has been granted in the past, it may begin by  
40 retrying those allocations rather than performing a pseudo-random selection for each that is free.

41 Each SPT Bridge ages out the allocations, both configured and dynamic, made by other Bridges exactly as  
42 the allocation information ages out or is replaced in the IS-IS database.

43 Each SPT Bridge's SPSourceID can be any one of the possible  $2^{20}$  values, of which a small number (less  
44 than  $2^{10}$ ) are expected to be used, and no exceptional provision is made for the case of a Bridge not being  
45 able to allocate an SPSourceID. If an SPSourceID is not available, frames for VLANs supported by SPBM  
46 mode are discarded.

The pool of SPVIDs are those available for allocation and reserved in the MST Configuration Table. The MCID (13.8) communicated in SPT BPDUs ensures that each Bridge in an SPT Region has agreed to the same pool of SPVIDs. A quantity of 400 SPVIDs are pre-configured for auto allocation (13.8) for small SPT networks running SPBV. Additional SPVID allocations can be made out of the remaining free VID. An MST Configuration Table change that extends the available SPVID pool does not disturb existing allocations, but will affect the MCID—so the connectivity between adjacent Bridges will revert to the CST representing a region boundary, unless the procedures for hitless migration of MCIDs using Auxiliary MCID (27.4.1) are followed. If a Bridge is added to a region or a new SPBV VLAN configured and there are not enough SPVIDs to satisfy the demand, any SPBV VLAN that does not have a full allocation of SPVIDs falls back to CST operation using its Base VID. When enough SPVIDs become available, either by being freed from other SPBV VLANs or by increasing the size of the SPVID pool, and an SPBV VLAN obtains a full allocation of SPVIDs it advances to SPBV operation using the SPVID set. During periods when there are insufficient SPVIDs to satisfy all SPBV VLANs, Bridges that have successfully obtained allocations of SPVIDs to SPBV VLANs must maintain them to ensure stable behavior.

## 27.11 Allocation of VIDs to FIDs

The allocation of SPVIDs to FIDs (8.8.8) for SPBV is a local decision, subject to the following constraints:

- a) All SPVIDs (if any) supporting a given VLAN (identified by Base VID  $V_I$ , say) shall be allocated to the same FID ( $F_{SVI}$ , say).
- b) SPVIDs shall be allocated to FIDs ( $F_{SV1}, F_{SV2}, \dots$ ) that are different from those allocated to any VLAN's Base VID ( $F_{V1}, F_{VN} \dots$ ).
- c) VLANs supported by different SPT Sets always use different FIDs (both for SPBV and SPBM modes).
- d) If the VID to FID allocation table (8.8.8) has been configured to allocate two different Base VIDs to different FIDs ( $F_{V1}, F_{V2}$ ), then the SPVIDs used to support each of the VLANs identified by those Base VIDs shall be allocated to different FIDs ( $F_{SV1} \neq F_{SV2}$ ).
- e) If the VID to FID allocation table (8.8.8) configuration allocates two different Base VIDs to the same FID ( $F_{V3} = F_{V4}$ ), then the SPVIDs shall also be allocated to the same FID ( $F_{SV3} = F_{SV4}$ ). This is shared VLANs where two or more VLANs can share the same topology.
- f) SPVIDs allocated to FID in this manner do not show up in the MCID as changed.

NOTE 1—Frames for VLANs supported by SPBM mode are always assigned to an SPT Set within an SPT Region, never to the IST, and are always identified by each VLAN's Base VID.

NOTE 2—Constraint (b) allows the active topology for any SPBV supported VLAN to be changed from the IST to an SPT Set without requiring topology change signaling.

These constraints, and the fact that the MST Configuration Table's entries for VLANs supported by SPB are not configured directly but are a consequence of configuring the relationship between Base VIDs and FIDs (8.8.8) and between FIDs and MSTIDs (8.9.3), also ensure the following:

- g) SPT Bridges using SPBV and SPBM modes always use different FIDs, so SPBV learning cannot disrupt SPBM operation.
- h) VLANs with shared learning constraints (expressed by allocation of a common FID) are assigned to the same SPT Set.

If all the MAC addresses for a VLAN supported by SPBM mode are those of BCBs and BEBs, then the use of different FIDs for B-VLANs supported by the same SPT Set can seem unnecessary. However, the constraints could support additional capabilities and shall be followed.

## 1 27.12 SPBV SPVID translation

2 An SPT Bridge Port that is a Boundary Port (13.12) translates, on both ingress and egress, the VID assigned  
3 to a VLAN that is supported by SPBV. On reception, the Boundary Port uses the VID Translation Table (6.9)  
4 to translate the Base VID received in the tag to the SPVID for the SPT rooted at that Bridge. On  
5 transmission, the Boundary Port uses the Egress VID Translation Table (6.9) to map all of the SPVIDs for  
6 that VLAN to one Base VID. The Boundary Port's VID Translation Table is also configured to prevent any  
7 local VID from being translated to a relay VID within the SPVID range.

8 NOTE 1—One way to prevent local VIDs within the SPVID range from being translated to relay VIDs in the SPVID  
9 range is to change the default relay VID value for these entries to the reserved value 0xFFF, which would cause these  
10 frames to be discarded.

11 If it has not been possible to allocate SPVIDs to support a given VLAN, no translation is performed and the  
12 frame is carried on the IST within the region using the unmodified Base VID.

13 If a Boundary Port's untagged or priority tagged frames belong to a VLAN supported by SPBV, the PVID  
14 for that port is set to the SPVID for the SPT rooted at that Bridge, and the port should belong to the untagged  
15 set for each of the SPVIDs for that VLAN.

16 Frames received on ports internal to the region are not translated, whether they carry SPVIDs or Base VIDs.

17 NOTE 2—A frame within any Bridge within an SPT Region is considered as being forwarded within that region.  
18 Consequently a frame that is forwarded between two Designated Ports at the boundary of a region can have its VID  
19 translated on reception, from the VLAN's Base VID to the SPVID for the VLAN and SPT rooted at the Bridge, and on  
20 transmission, back to the Base VID. Translation is not dependent on forwarding, so the frame could have been equally  
21 forwarded through a port within the region.

## 22 27.13 VLAN topology management

23 An SPT Bridge using SPBV mode uses Dynamic VLAN Registration entries, for each VLAN it supports, to  
24 create a VLAN topology that is the pruned subset of the active topology that connects participants in that  
25 VLAN. The VLAN registration entries thus serve to prevent both loops and unnecessary flooding of frames  
26 through Bridge Ports and LANs that cannot provide connectivity to their destinations.

27 Each SPT Bridge uses ISIS-SPB with the information calculated for the CIST and each SPT (27.6, 27.7,  
28 27.8), and the following information from each Bridge in the SPT Domain with one or more Boundary  
29 Ports:

30 a) VLAN membership registration for each VLAN registered on a Boundary Port, subject to the  
31 registration controls defined for MVRP (11.2.3.2.3).

32 For each of its Bridge Ports that is not a Boundary Port, and for each VLAN supported by SPBV mode, the  
33 SPT Bridge computes the following potential values of control in VLAN registration entries:

- 34 b) Forwarded or Filtered, for the IST, for each port that is a Root Port or a Designated Port
- 35 c) Filtered, for the IST, for each port that is an Alternate Port or Backup Port
- 36 d) Forwarded or Filtered, for each SPT, for each port that is a Designated Port
- 37 e) Forwarded, for each SPT, for each port that is a Root Port
- 38 f) Filtered, for each SPT, for each port that is an Alternate Port or Backup Port

39 The potential control element for the CIST specifies that frames for the VLAN are to be Forwarded, if the  
40 port provides CIST connectivity to a Boundary Port that has registered the VLAN. Similarly the potential  
41 control element for an SPT Designated Port specifies Forwarded if that port provides the shortest path to a  
42 Bridge with a Boundary Port that has registered the VLAN, either directly (if that Bridge is in the same  
43 region) or via a Boundary Port that provides CST connectivity to the Bridge in another region in the domain.

1 VLAN Registration Entries support ingress filtering, so the potential control element always specifies  
2 Forwarded for each SPT's Root Port, thus supporting Open Host Groups (10.10.1). However, an SPVID is  
3 only allocated (27.10), to support a given VLAN over a given SPT, if frames for that VLAN can enter the  
4 SPT Region at the root of that SPT, so the potential control element might not be used.

5 Each SPT Bridge creates Dynamic VLAN Registration Entries using the potential control elements and the  
6 Port State variable forward (27.9) for each tree for each VLAN supported by SPBV as follows:

- 7 g) An entry for the Base VID specifies Registered for a port if:
  - 8 1) forward is True for the IST for the port and
  - 9 2) the potential control element for the port for the IST and the VLAN specifies Forwarded
  - 10 and specifies Not Registered for the port otherwise.
- 11 h) An entry for each SPVID specifies Registered for a port if:
  - 12 1) forward is True for the port for the SPT identified by the SPVID and
  - 13 2) the potential control element for the port for the SPT and the VLAN specifies Forwarded
  - 14 and specifies Not Registered for the port otherwise.

15 These Dynamic VLAN Registration control elements for each of the SPT Bridge's ports are subject to  
16 restrictions imposed by Static VLAN Registration Entries. Static VLAN Registration Entries shall not be  
17 administratively created for any SPVID, so the controls applied to shortest path forwarding are solely those  
18 determined at the boundaries of each SPT Region.

19 VLAN topology management for an SPT Bridge using SPBV, as specified in this subclause (27.13), makes  
20 use of Static and Dynamic VLAN Registration Entries that can be used with MVRP. However, their use in  
21 this clause is independent of whether MVRP is implemented or used, and does not require the Bridges in an  
22 SPT Domain to agree on its use. If MVRP is implemented and used on Boundary Ports, then MVRPDUs are  
23 transmitted and received on those ports (as permitted by the controls specified for MVRP) to exchange  
24 registration information with Bridges or end stations outside the SPT Domain.

25 Since SPBM mode only forwards frames whose destination and source addresses are known to ISIS-SPB,  
26 the filtering entries installed for these addresses can be used to control all forwarding for each SPBM  
27 supported VLAN. SPBM mode creates a Dynamic VLAN Registration Entry for the VLAN used by the SPT  
28 Bridge. Operators should not create Static VLAN Registration Entries for the VLAN used by SPBM mode.

## 29 **27.14 Individual addresses and SPBM**

30 Each SPT Bridge that supports SPBM mode may be configured to use loop prevention (6.5.4.1) and/or loop  
31 mitigation (6.5.4.2) for unicast frames assigned to VLANs supported by the SPT Bridge. Loop prevention is  
32 always used for multicast frames. Both loop prevention and loop mitigation use Dynamic Filtering Entries  
33 for individual MAC addresses for each VLAN supported by SPBM mode. These filtering entries serve both  
34 to implement ingress checking, effectively assigning each received frame to an SPT and ensuring that the  
35 frame is only forwarded if received on the Root Port of that tree, and to implement egress checking, ensuring  
36 that the frame is only forwarded through the port providing the shortest path to its destination.

37 SPBM mode uses VLAN membership configuration information distributed by ISIS-SPB to reduce the  
38 number of individual address filtering entries, i.e., {VID, Individual MAC Address} tuples that need to be  
39 made in each SPT Bridge. Entries for a given VID are made only for ports that are in the pruned subset of  
40 the active topology that connects participants in the VLAN with that Base VID.

41 NOTE—The reduction in individual address entries is most effective in very large SPBM-capable networks, using  
42 hundreds (or thousands) of Bridges, and hundreds of B-VLANs each covering a small subset of the Bridges, each subset  
43 supporting a number of backbone service instances. Using a large number of B-VLANs in such a network could  
44 significantly reduce the scope of the control flows used to create and maintain backbone service instances.

## 1 27.14.1 Loop mitigation

2 If loop mitigation is selected, each SPT Bridge can create or modify an individual address filtering entry (for  
3 a given VLAN) once the calculation of the SPT rooted at that Bridge (and in the SPT Set for that VLAN) has  
4 associated the address with one of the Bridge's ports, subject to satisfying constraints that prevent multicast  
5 loops. These constraints are those that govern the Port State transition of a Root Port to Forwarding (i.e., on  
6 setting the Port State variable forward true for SPT's Root Port, as specified in Clause 13). This subclause  
7 (27.14.1) specifies a sufficient, though not necessary way to meet those constraints. If any discrepancy exists  
8 between this summary and the Clause 13 specification, the latter takes precedence.

9 The Port Role Transition machine ensures that there are no disputes with the adjacent Bridge(s) with respect  
10 to the active topology, such as might arise from partial or one-way connectivity (13.21). Otherwise, the  
11 Dynamic Filtering Entry can be created or modified provided:

- 12 a) The entry was previously unused, or the operation of changing the entry ensures that no two ports  
13 can be receiving frames from or sending frames to the same {VID, Individual Address} tuple at the  
14 same time; and
- 15 b) The Static Filtering Entries that limit the propagation of the SPBM SPT-specific group addresses for  
16 that SPT have been deleted or specify Filter on all ports (27.15).

17 NOTE—Where a large number of SPT-specific group addresses are used, the effectiveness of loop mitigation as a  
18 strategy (for more rapidly restoring unicast connectivity after a component failure than might be achieved by using loop  
19 prevention) depends on the ability of the implementation to rapidly suspend multicast connectivity, as required by (b)  
20 above, possibly by distinguishing unicast and multicast forwarding.

## 21 27.14.2 Loop prevention

22 If loop prevention is selected, Dynamic Filtering Entries for individual MAC addresses for VLANs  
23 supported by SPBM mode reflect SPT Port States for both Root Ports and Designated Ports, for different  
24 SPTs in the SPT Set for each VLAN. The state machines specified in Clause 13 attempt to minimize the  
25 changes to filtering entries necessary following a network component failure by identifying conditions when  
26 the change in active topology constitutes a loop-free alternative. Otherwise, Dynamic Filtering Entries are  
27 removed as necessary as part of making the forwarding variable False, so that an Agreement Digest can be  
28 transmitted to adjacent Bridges and full connectivity restored.

29 NOTE—The Clause 13 state machines specify necessary conditions for creating new connectivity. These conditions can  
30 be satisfied in a number of ways, by processes that can execute in parallel in adjacent Bridges and in the same Bridge.  
31 The most effective way (time taken, resource expended) is implementation dependent, and is not specified as a set of  
32 fixed steps. For example, Static VLAN Registration Entries (or an implementation-dependent equivalent) could be used  
33 to disable forwarding to allow a fresh Agreement Digest to be sent at the earliest opportunity. Alternatively, where  
34 SPBM mode uses a large number of SPT-specific group MAC addresses to support many backbone service instances  
35 between rather fewer SPT Bridges, removing (or disabling) Dynamic Filtering Entries for individual addresses entries  
36 being used as an ingress check may be more expedient.

## 37 27.15 SPBM group addressing

38 When a B-VLAN is supported by an SPT Bridge using SPBM, the individual destination and source MAC  
39 addresses of each frame are those used by entities within SPT Bridges or within systems that include an SPT  
40 Bridge component, such as BEBs (Clause 3, Clause 25). SPBM mode assigns group addresses of local  
41 significance to the SPT Domain for use by those entities. For symmetric ECT Algorithms (28.8), group  
42 addresses are assigned to source rooted trees and include an SPSourceID (27.10). Taken together each  
43 frame's B-VID and SPSourceID identify the source rooted SPT used to forward the frame. For the ECMP  
44 ECT Algorithm (44.1.2), group addresses may be assigned to one of 16 source rooted trees per bridge or to  
45 one of 16 shared trees. Group addresses assigned to source rooted trees include an SPSourceID and I-SID,  
46 and the I-SID may be associated with a Tie-Break Mask. Together the B-VID, SPSourceID, and Tie-Break  
47 Mask identify the source rooted SPT used to forward the frame. Group addresses assigned to a shared tree  
48 include the Tie-Break Mask used in root node selection, and the I-SID. The B-VID and Tie-Break Mask

1 together identify a particular shared tree used to forward the frame. In all cases ISIS-SPB's knowledge of the  
2 addressed group and its assigned tree allows it to create a MAC Address Registration Entry (8.8.4) for the  
3 address, restricting propagation to the pruned subset of the tree that reaches the group's members.

4 In particular, a distinct group MAC address is assigned to each VIP (Clause 3) for use as the B-DA of the  
5 multicast frames that it transmits into an SPT Domain. Each VIP supports a single backbone service  
6 instance, so the B-DA identifies the I-SID for each customer frame that is multicast and its transmission is  
7 confined to LANs providing connectivity between BEBs supporting that service instance.

8 Figure 27-2 illustrates the general format of SPBM group MAC addresses. The octet and bit ordering and  
9 identification conventions used in this figure follow those of Figure 10 of IEEE Std 802-2014 [B7]. The  
10 conventions used to encode parameters with numeric values, such as the SPSourceID or I-SID, are those  
11 used elsewhere in this standard (14.1.1): the number is encoded as an unsigned binary numeral with bit  
12 positions in lower octet numbers having more significance. The least significant and the next to least  
13 significant bits of the first octet of the address, the Individual/Group and Universally/Locally administered  
14 bits, are both set denoting a locally administered group address. The two next most significant bits compose  
15 an SPBM address type, permitting alternative uses of the remaining bits of the address.

**Figure 27-2—SPBM group MAC address—general format**

16 This standard encodes the I-SID in the last three octets, and the value 0 or 1 in the address type field. Other  
17 values (2 and 3) are reserved for future standardization. The address format for group addresses assigned to  
18 a source rooted SPT is shown in Figure 27-3. In this format the SPSourceID is encoded in the first three  
19 octets.

**Figure 27-3—SPBM group MAC addresses—source rooted SPT**

20 Figure 27-4 shows the format for group addresses assigned to a shared tree. Four bits of octet 2 are used to  
21 encode the Tie-Break Mask identifying the shared tree. If the same group address were to be used in two  
22 shared trees, forwarding loops could be created. The Tie-Break Mask is included in the group address so that  
23 the addresses used in different shared trees are distinct and forwarding loops are not created. The remaining  
24 bits are set to zero, leaving a substantial portion of the SPBM type 1 address space available for future use.

The use of locally assigned group MAC addresses by SPBM mode does not affect the use of the same or different group MAC addresses for other VLANs. In addition to creating and managing the required FDB entries for each specific group address ( $GA_{SPBM}$ ) for any given Base VID ( $V_{SPBM}$ , say) that identifies an SPBM mode supported VLAN, an SPT Bridge using SPBM mode also manages the following entries:

- If the FDB contains a static entry specifying Forward (for any Bridge Port) for the wildcard VID and any specific group MAC address not required by this subclause (27.15) then an entry specifying Filter (for all Bridge Ports) is also created for that group address and each Base VID supported by SPBM mode.
- A Static Filtering Entry for All Group Addresses (for which no more specific Static Filtering Entry exists, (8.8.1) is created for each Base VID supported by SPBM mode, specifying that those addresses are to be filtered.

**Figure 27-4—SPBM group MAC addresses—shared tree**

## 27.16 Backbone service instance topology management

An SPT Bridge using SPBM mode uses Dynamic Filtering Entries to explicitly permit unicast communication between stations, thus restricting that communication to the shortest path between those stations. SPBM mode also uses Static Filtering Entries, for each VLAN it supports, to create a multicast topology that is the pruned subset of the active topology that connects BEBs supporting the same backbone service instance using that VLAN.

Each SPT Bridge uses ISIS-SPB with the information calculated for the CIST and each SPT (27.6, 27.7, 27.8), and the following information from each BEB in the SPT Domain:

- a) I-SID membership registration for each VLAN supported by SPBM mode

For each of its Bridge Ports, for each I-SID and each SPT supporting the VLAN supporting that I-SID, the SPT Bridge computes the potential filtering control element values, Forward or Filter, for each port that is a Designated Port or Root Port. The potential control element specifies Forwarded if that port provides the shortest path to a BEB that has registered the VLAN, either directly (if that Bridge is in the same region) or via a Boundary Port (if the Bridge is in another region in the domain). A value of Filter is associated with each port that is an Alternate Port or Backup Port for the SPT.

The SPT Bridge creates a Static Filtering Entry for the VLAN's B-VID and SPBM Group Address (27.15) for the I-SID and SPT, with a control element that specifies Forward if both the potential control element specifies Forward and the Port State variable forward (27.9) is True for the SPT for the port.

## 1 27.17 Equal cost shortest paths, ECTs, and load spreading

2 There can be several equal cost shortest paths between any given pair of Bridges, and the paths used by the  
3 SPTs in a given SPT Set are required to be symmetric (13.1), so the local tie-breaker [the lowest ISIS Local  
4 Circuit ID on the Bridge with the best (numerically least) SPB System Identifier (Clause 3)] is only used to  
5 select between links providing alternative connectivity between immediately adjacent Bridges. Equal cost  
6 tie breaking between paths that traverse different sets of Bridges is performed by calculating a unique  
7 identifier for each path that is independent of order used to compute trees. See 28.5 for a description of the  
8 Algorithm and the tie breakers.

9 The capability to support multiple VLANs using different ECTs allows a network administrator to choose  
10 different equal cost paths for different services by assigning services to selected VLANs. ECMP (Clause 44)  
11 provides the capability to spread load across equal cost shortest paths using a single SPBM VID.

12 A set of ECT Algorithms (28.8) is specified, each using a different tie breaker. The tie-breaking rules have  
13 been selected to provide a reasonable probability that different ECT Algorithms will choose different paths  
14 from a set of equal cost paths. ECT path selection can be controlled by selection of ECT Algorithm and by  
15 adjustment of Bridge Priorities.

16 SPB makes use of all nodes in the SPT region for forwarding.

## 17 27.18 Connectivity Fault Management for SPBM

18 Connectivity Fault Management (CFM) as specified in Clause 18 through Clause 22 provides capabilities  
19 useful in detecting, isolating, and reporting connectivity faults in VID-based service instances, backbone  
20 service instances, and TESIs. As with PBB-TE, SPBM disables flooding of frames with unknown  
21 destination address. This and other changes in behavior with SPBM require some modification to VLAN  
22 CFM functions. The modifications related to SPBM are summarized here.

23 In particular, this subclause summarizes SPBM considerations related to the following:

- 24 a) SPBM MA types (27.18.1)
- 25 b) SPBM MEP placement in a Bridge Port (27.18.2)
- 26 c) SPBM MIP placement in a Bridge Port (27.18.3)
- 27 d) SPBM modifications of the CFM protocols (27.18.4)

### 28 27.18.1 SPBM MA types

29 SPBM CFM uses three types of MA: SPBM VID MAs, SPBM path MAs, and SPBM group MAs.

30 An SPBM VID MA operates like a VLAN MA. For example, SPBM MEPs multicast CCM frames to all  
31 other MEPs and expect to receive CCM frames from all other MEPs in an SPBM VID MA. There are minor  
32 differences from VLAN MAs, primarily in the destination addresses used for CFM frames. SPBM VID  
33 MAs can be used to monitor and diagnose SPBM connectivity.

34 SPBM specifies two MA types for testing forwarding state installed by ISIS-SPB for specific addresses. In  
35 SPBM path MA CCMs are used to test the path for an individual destination MAC address between a pair of  
36 endpoints. This type of MA has only two MEPs, at two SPT Region boundary ports. An SPBM path MA is  
37 identified by a TE-SID comprising an ESP in each direction between the two endpoints. In an SPBM group  
38 MA CCMs are used to test a set of multicast trees used by a backbone service instance. This type of MA has  
39 multiple MEPs, each located at a CBP supporting the backbone service instance whose multicast trees are to  
40 be tested. An SPBM group MA is identified by the I-SID whose multicast trees it tests. The path taken by  
41 CCM frames depends on the current state of the network (i.e., paths are subject to rerouting triggered by

1 topology changes). A CCM defect detected by an SPBM path MA or SPBM group MA may indicate a  
2 problem with the forwarding state for the MAC addresses being tested. This standard does not specify the  
3 mechanisms that would be necessary to support Loopback and Linktrace on an SPBM path MA or SPBM  
4 group MA since full Loopback and Linktrace coverage can be provided by an SPBM VID MA. Therefore,  
5 there are no MHFs associated with an SPBM path MA or SPBM group MA.

## 6 27.18.2 SPBM MEP placement in a Bridge Port

7 SPBM MEPs are always Up MEPs and can only be placed on CBPs as these correspond to the demarcation  
8 points of the SPT Region. The SPBM MEPs are placed between the Frame filtering entity (8.6.3) and the  
9 Port filtering entities (8.6.1, 8.6.2, and 8.6.4) in the VID space identified by the EISS Multiplex Entity  
10 (6.17). An SPBM VID MEP is placed in the same location as a VLAN MEP as shown in Figure 27-5.

11 Since SPBM path MEPs and SPBM group MEPs must only see traffic using specific addresses, these MEPs  
12 need to be further differentiated by the TESI Multiplex Entity (6.19). This locates an SPBM path MEP or  
13 SPBM group MEP so that it receives CCMs only from the other MEPs in its MA. Figure 27-5 also shows an  
14 example of an SPBM path MEP and SPBM group MEP on a CBP.

Figure 27-5—SPBM MEP placement in a CBP

### 1 27.18.3 SPBM MIP placement in a Bridge Port

2 SPBM MIP creation is based on the algorithm described in 22.2.3. SPBM MIPs are created per identified  
3 VID on PNPs. Figure 22-9 depicts an example of a pair of SPBM MHFs on a PNP.

### 4 27.18.4 SPBM modifications of the CFM protocols

#### 5 27.18.4.1 Continuity Check protocol in an SPBM MA

6 The Continuity Check protocol is described in 20.1, and the corresponding state machines are presented in  
7 Clause 20. The modifications required to realize SPBM MAs include the following:

- 8 a) In the case of an SPBM VID MEP, the `destination_address` parameter is set to the group MAC  
9 address for the SPBM default I-SID (Table 9-3) for the Bridge on which the MEP is configured. In  
10 the case of an SPBM path MEP, the `destination_address` parameter is set to the MAC address  
11 indicated by the ESP-DA field of the ESP having in its ESP-SA field the MAC address of the MEP.  
12 In the case of an SPBM group MEP the `destination_address` parameter is set to the SPBM group  
13 MAC address assigned to the source MEP's CBP for the SPBM group MA's I-SID [item a) in  
14 20.11.1].
- 15 b) In the case of ECMP with flow filtering, the `flow_hash` and `time_to_live` parameters are set [item e)  
16 in 20.11.1].

17 All other Continuity Check processes are the same as those for a VID-based MA.

#### 18 27.18.4.2 Loopback protocol in an SPBM MA

19 The Loopback protocol is described in 20.2 and the corresponding state machines in Clause 20. The  
20 modifications required to realize the SPBM MA are summarized below:

- 21 a) To enable MIPs to selectively intercept LBMs that are targeting them, the PBB-TE MIP TLV  
22 (21.7.5) is inserted as the first TLV [item g) in 20.31.1] in an LBM. The format of the PBB-TE MIP  
23 TLV is described in 21.7.5 and is constructed as follows:
  - 24 1) The MIP MAC address field contains the MAC address of the MIP to which the LBM is  
25 targeted [item b) in 12.14.7.3.2].
  - 26 2) The Reverse VID field and Reverse MAC field are not used in SPBM.
- 27 b) An SPBM MHF forwards all received LBMs except those carrying a PBB-TE MIP TLV  
28 containing in their MIP MAC address field the MAC address of the MIP associated with that SPBM  
29 MHF [item f) in 20.28.1].
- 30 c) In the case of ECMP with flow filtering, the `flow_hash` and `time_to_live` parameters are set [item d)  
31 in 20.31.1].

32 NOTE—The MIP MAC address for an LBM does not have to be advertised by ISIS-SPB since it is only used locally to  
33 match the value provided in a PBB-TE MIP TLV.

34 All other Loopback processes are the same as those for a VID-based MA.

#### 35 27.18.4.3 Linktrace protocol in an SPBM MA

36 The Linktrace protocol is described in 20.3 and the corresponding state machines in Clause 20. The  
37 modifications required to realize the SPBM MA are summarized as follows:

- 38 a) The LTMs transmitted by a MEP associated with an SPBM MA use as the `destination_address`  
39 parameter the MAC address indicated in the LTM management request [item c) in 12.14.7.4.2].
- 40 b) No special `destination_address` validation tests are performed by the `ProcessLTM()` procedure in the  
41 case of SPBM MAs [item c) in 20.47.1].

- 1 c) To identify a possible egress port, an SPBM MIP queries the FDB of its associated bridge using the  
2 destination\_address and the vlan\_identifier of the LTM as the parameters for the lookup (20.47.1.2).  
3 In the case of ECMP with flow filtering, the flow\_hash value of the LTM is also used for the lookup,  
4 if required. For group addresses, LTMs can be further forwarded by SPBM MIPs even if the lookup  
5 identifies more than one Egress port.
- 6 d) In the case of ECMP with flow filtering, the flow\_hash and time\_to\_live parameters are set [item d]  
7 in 20.42.1].

8 All other Linktrace processes are the same as those for a VID-based MA.

## 9 **27.19 Using SPBV and SPBM modes**

10 This subclause provides one example topology of SPT Bridges using SPBV mode and one example  
11 topology of SPT Bridges using SPBM mode.

### 12 **27.19.1 Shortest Path Bridging—VID**

13 The primary advantage SPT Bridges operating in SPBV mode bring over spanning tree protocols is the more  
14 flexible shortest path forwarding. SPBV accomplishes this by using SPVIDs and VID translation (6.9) at  
15 SPT Region boundaries. All traffic within an SPT Region always takes a shortest path. Loops are prevented  
16 by never allowing traffic to be accepted on a non symmetric shortest path and enforced with loop prevention  
17 (13.17, 6.5.4.1).

18 An example campus network using SPBV is illustrated by Figure 27-6. The SPT Region contains eight SPT  
19 Bridges with two RST Bridges connected to the SPT Region. All VLANs within the SPT Region are  
20 supported by the SPT Bridges. The dashed lines represent the SPT for the SPVID of a Base VID (VID10)  
21 for which Access Bridge 1 is source (root of the SPT). The solid lines to the RST Bridges indicates spanning  
22 tree forwarding. VID translation from and to the respective SPVIDs occurs on the region boundary ports  
23 SPT Bridge D port 5 and SPT Bridge E port 3. SPT forwarding makes better use of a mesh network;  
24 however, it only will use a single path per Base VID. For example the Bridge D port 2 to Bridge B port 4  
25 link is not used by access Bridge 1 because the ECT Algorithm has chosen paths through Bridge C. If  
26 another VLAN is supported in this network the recommendation is to use a different ECT Algorithm that  
27 could choose D-B over C-B by using an appropriate tie breaker (28.8).

28 ISIS-SPB uses SPB Hellos to establish adjacencies within the SPT region and BPDUs to establish peering  
29 with RST Bridges. BPDUs from legacy Bridges L1 and L2 will indicate that they are able to use RSTP.  
30 Therefore, RSTP would be enabled and SPB Hello would be transmitted periodically but dropped. The ports  
31 connected to the legacy Bridges are enabled and block according to RSTP logic.

32 SPT Bridges using SPBV mode use the same principles as MSTP to form a logical Bridge with a CIST root  
33 port on Bridge A, which has the best (numerically least) Bridge Identifier in the SPT Region. The CIST in  
34 Figure 27-6 is a spanning tree rooted on Bridge A (not illustrated).

- 35 a) The eight Bridges in the SPT Region have the same MCID (13.8) or Auxiliary MCID (28.9).  
36 b) The CIST is computed in the SPT Region and maintains the spanning tree root costs (13.17).  
37 c) SPT BPDUs are exchanged by the SPT Bridges within the SPT Region (13.17).  
38 d) VLANs identified by other than the Base VIDs are supported by the CIST (13.17).

39 Legacy Bridges L1 and L2 can be aware of the SPB operation of Bridges but they only support RSTP and  
40 interface to the aggregation Bridges D and E using RST BPDUs. L1 and L2 learn from the received BPDUs  
41 that aggregation Bridge A is the Designated Bridge for VLAN 10 while a Bridge somewhere above the SPT  
42 region is the CIST Root for the network. Aggregation Bridge D receives traffic from L1 but uses an SPVID  
43 and the corresponding SPT from D to reach all nodes within the region and beyond. Normal learning of  
44 MAC addresses occurs.

**Figure 27-6—SPBV campus network example**

1 Dynamic VLAN Registration capabilities are supported natively for Base VLANs by utilizing the link state to  
2 auto enable forwarding on intermediate Bridges. Referring to Figure 27-6, if access Bridge 1 and  
3 aggregation Bridge A were the only Bridges with VID 10 registered on their boundary ports forwarding  
4 would automatically be setup on aggregation Bridge C to complete the data path between Bridge 1 and  
5 Bridge A. Only Bridges configured with the Base VID, Bridge 1 and Bridge A require SPVIDs. MVRP for  
6 other VLANs is supported on the CIST.

7 MAC Address Registration (8.8.4) is supported for the Base VLANs as outlined in 28.10. Group addresses for  
8 Base VLANs are distributed in ISIS-SPB. At the region boundaries MMRP is required to propagate  
9 registration to and from the SPT Region.

10 Since the SPT Region follows very similar design rules as the MST Region, RSTP and STP interwork with  
11 both. SPB interworks with MSTP and other SPT Regions with MSTP.

## 12 27.19.2 Shortest Path Bridging—MAC

13 An example SPT Bridge network using SPBM mode is illustrated by Figure 27-7. The SPBM mode example  
14 network is divided into two major areas: the customer equipment area, which is owned by the “customer”  
15 and is connected to the SPT BEBs using C-tagged or S-tagged interfaces; and the SPT Region, which is  
16 owned by the backbone provider and interconnects to the customer equipment and possibly to other SPT  
17 Bridges. There is no visibility of either backbone topology or B-MAC addresses outside the SPT Region,  
18 and consequently connections to other SPB or PBB areas will be identical to those to customer equipment.  
19 While this is primarily leveraging the capabilities of the PBBN the emphasis is that the separation of the  
20 address spaces proved by the PBB encapsulation provided useful capabilities of scaling even larger  
21 enterprise or data center networks (DCNs) where bridging and delivery of optimized unicast and multicast  
22 frames on an S-VLAN basis is desired.

**Figure 27-7—SPT Bridge Network using SPBM example**

1 The interface between an IB BEB and a customer Bridge is a CNP of an I-Component as specified in 6.10.  
2 The interfaces between BEBs and BCBs and between BCBs and other BCBs are PNPs. In Figure 27-7, these  
3 interfaces are over LANs labeled S and B. All exterior interfaces from a SPT Bridge network using SPBM  
4 mode are over S, or C LANs; whereas all interior interfaces within a SPT Bridge network support  
5 appropriate segments of SPB SPTs, each set of which is identified by one Base VID per forwarding  
6 topology. Each individual SPT within a set is identified by the B-MAC address of its source Bridge. The S  
7 and C VLANs (exterior interfaces) are at the boundary between the SPT Bridge network and the attached  
8 customer networks.

9 Within the network example, BEBs, BCBs, and the SPTs for each Base VID are secured so that only the  
10 network administrator operating the SPT Bridge network can manage the reception, transmission, and relay  
11 of frames between BEBs and BCBs. The arbitrary physical network topology of the SPT Bridge network  
12 and the connectivity that it provides to support segregated instances of the MAC Service is designed and  
13 managed by the network administrator to meet bandwidth and service availability requirements at the CBPs

1 and PIPs. Application of the service instance ingress and egress rules at these Ports in support of service  
2 instance selection and identification ensures that frames cannot be transmitted or received on any backbone  
3 service instance by any customer's equipment without prior agreement with the administrator of the SPT  
4 Bridge network.

5 The active topology of the SPT Bridge network is separated from the active topology of the customer  
6 equipment area. This is accomplished by isolating the BPDUs for each customer network from the SPT  
7 Bridge network at the BEBs that surround the perimeter of the SPT Region. The ISIS-SPB LSPs and SPT  
8 BPDUs, that support the active topology of the SPT Bridge network, are only exchanged on PNP and hence  
9 are not leaked into the customer bridged area.

10 B-MAC addresses are used to identify the destination BEB's PIP. These B-MAC addresses are advertised by  
11 each BEB to all other BEBs and BCBs in the SPT Bridge area in LSPs as part of the IS-IS routing  
12 exchanges. I-SID instances associated with each PIP are also advertised using the same mechanism. To  
13 perform the encapsulation and de-encapsulation of service frames, BEBs use the connection identifier stored  
14 in the FDB (8.8) to correlate C-MAC addresses to B-MAC addresses. At startup, after convergence of ISIS-  
15 SPB, the BEBs are aware of the location of B-MAC addresses in the topology, but have not learned the C-  
16 MAC addresses yet. When the C-MAC address is unknown, the BEB encapsulates the service frames using  
17 an SPBM Group address, which is analogous to the Backbone Service Instance Group address (26.4). This  
18 address is then multicast to the set of registered receivers that are those BEBs where that I-SID has been  
19 configured. The same holds true for the service frames having a group or broadcast destination address. An  
20 individual B-DA is used for forwarding unknown or group frames when the service is point-to-point and  
21 where the far end individual address is known. C-MAC addresses are learned by the provider BEB against  
22 the B-MAC address associated with the service interface on the BEB that sourced them (see Clause 25).

## 23 **27.20 Security considerations**

24 This clause contains no exceptional provisions for securing the operation of ISIS-SPB. ISIS has a number of  
25 optional capabilities that may be utilized. For example, ISIS-SPB does not prevent the use of the IS-IS  
26 Authentication TLV. If stronger security is required, IEEE 802.1AE™ MAC Security should be deployed on  
27 all SPT Bridge Ports, and the configuration of the controls provided by this standard to  
28 regulate the acceptance of spanning tree protocol information [e.g., restrictedRole and restrictedTen  
29 (13.27.64, 13.27.65)] should be set to reflect the degree of trust (i.e., authorization) accorded to the mutually  
30 authenticated securely communicating peer Bridges. SPT BPDUs include a flag that indicates that the  
31 attached LAN is not considered to be a part of the transmitting Bridge's SPT Region: this avoids one way  
32 participation in a region if one Bridge considers the authorization of another inadequate. Use of MAC  
33 Security in this way can ensure that only authenticated and authorized (i.e., trusted) Bridges participate in a  
34 region, as well as preventing unauthorized transmission of ISIS-SPB information or user data on LANs  
35 within the region.

## 1 28. ISIS-SPB Link State Protocol

2 Intermediate System to Intermediate System (IS-IS) is the link state routing protocol used for SPB  
3 (Clause 27). IS-IS is easily extended to carry the required Ethernet addresses, VLAN and Service  
4 membership information introduced by SPB. IS-IS is defined in ISO/IEC 10589:2002. When used for SPB,  
5 IS-IS has no IP dependencies. IS-IS also supports Multi-Topology (MT) and logical instances for easy  
6 virtualization of the link state protocol. This subclause specifies extensions to IS-IS for SPB. IS-IS extended  
7 for SPB will be referred to as *ISIS-SPB*. The SPB extensions are additive to IS-IS and do not preclude the  
8 IS-IS protocol being used for other purposes at the same time.

9 In VLANs that are configured to use SPB, ISIS-SPB controls forwarding (Clause 8) of individual and group  
10 addressed MAC frames. The Agreement Protocol (13.17), utilizes the ISIS-SPB link state database along  
11 with a synchronization mechanism carried in SPT BPDUs or SPB Hello PDUs. Locally on each Bridge, the  
12 Agreement Protocol logic is used to control the ISIS-SPB FDB updates and implement loop prevention  
13 logic. ISIS-SPB uses normal IS-IS procedures to update the link state database.

14 IS-IS uses SPB Hello PDUs and Link State PDUs (LSPs) to communicate between SPT Bridges. This clause  
15 (Clause 28) describes the relevant TLVs in the ISIS-SPB PDUs. Note that ISIS-SPB does not add any new  
16 PDU's to IS-IS it extends the currently defined PDUs.

17 Figure 28-2 through Figure 28-12 (in 28.12) illustrate the new TLVs and sub-TLVs for SPBV and SPBM.  
18 Note that SPBM, since it derives from PBB has the capability to indicate Service instance membership using  
19 the 24-bit I-SIDs. A default I-SID (I-SID 0x0000ff) maps to all SPT Bridges operating in SPBM mode  
20 allowing a default broadcast and group address capability for ISIS-SPB. The default I-SID is assigned to the  
21 default ECT Algorithm (LowPATHID, 28.7). I-SID group registrations via ISIS-SPB are similar to the  
22 MMRP capability but because they are delivered by IS-IS they involve no additional messaging. Group  
23 addresses are constructed by SPBM for each service instance/source and therefore do not require explicit  
24 advertisement.

25 The I-SID value of 0 is reserved by SPBM and is used as a deleted or free I-SID value in the TLVs. This  
26 reserved value may be used to avoid reorganizing LSPs when only one or a few I-SIDs are changed. This  
27 provides an optimization by allowing actual deletion (shuffling of the LSP contents) to be decoupled from  
28 the ISIS-SPB updates triggered by topology changes. LSPs may be reorganized during periodic updates  
29 thereby minimizing impacts.

30 SPBV and SPBM will operate either within an IS-IS level 1, or an ISIS level 2. As a result the TLVs  
31 specified here may propagate either in level 1 OR level 2 LSPs. IS-IS SPBM implementations shall support  
32 level 1 and may support level 2 operations. Multi-level ISIS-SPB is, however, for further study.

33 NOTE—IS-IS supports point-to-point links and shared LANs; however, only point-to-point is considered for ISIS-SPB  
34 in this specification. A future revision may add shared media. Clause 13 SPB description allow both point-to-point links  
35 and shared media.

### 36 28.1 ISIS-SPB control plane MAC

37 ISIS-SPB makes no changes to the IS-IS control plane addressing principles. However, ISIS-SPB defines  
38 two further addresses for the propagation of LSPs besides the three addresses already reserved by ISO (see  
39 Table 8-16). ISIS-SPB differentiates itself from IS-IS for Ipv4 etc. by the contents of the SPB Hello PDUs.  
40 The most important differentiation is the NLPID value for SPB (0xC1) [Annex X] which is carried in the  
41 SPB Hello protocols supported TLV and used to decide if a given adjacency should support SPB. ISIS-SPB  
42 carries this value in the Protocols Supported TLV (129) of IS-IS.

1 SPB operates either stand alone within an IS-IS instance, or shares an IS-IS instance and its adjacencies with  
2 other protocols as distinguished by the appropriate Network Layer Protocol Identifiers (NLPIDs). In order to  
3 accomplish this, ISIS-SPB may as one option use the same control plane MAC addressing as the other  
4 NLPIDs.

5 SPB does not advertise its NLPID on shared media interfaces.

## 6 **28.2 Formation and maintenance of ISIS-SPB adjacencies**

7 ISIS-SPB uses the IS-IS three-way handshake for IS-IS point-to-point adjacencies described in IETF  
8 RFC 5303 to form adjacencies when they can be formed. This subclause specifies the conditions under  
9 which they may be formed, and the conditions under which the link may be used for forwarding after an  
10 adjacency has formed.

11 a) The initial exchange of SPB Hello PDUs between a pair of IS-IS instances advertises the NLPID  
12 value(s) supported by each Bridge. If any NLPID values match, it is anticipated that an adjacency  
13 will be established to support the matched Network Layer Protocol(s).

14 This standard specifies subsequent behavior only for adjacencies that support SPB (NLPID value 0xC1).  
15 ISIS-SPB supports MTs, and if more than one topology is instantiated, the procedures below are applied  
16 independently to each topology instance.

17 b) The link supporting the adjacency is initialized to “SPB Operationally down.” This is signaled by  
18 setting the SPB Link Metric in the Link Metric Sub TLV (28.12.7) to the value  $(2^{24} - 1)$ . All SPB  
19 Link Metric values  $< (2^{24} - 1)$  signify “SPB Operationally up,” and the value advertised is that to be  
20 used in path computation.

21 c) The SPB Hello PDUs exchange MCID and Auxiliary MCID (28.4) values to determine whether  
22 VLANs are consistently allocated to an operational mode. If a Bridge detects that neither its MCID  
23 nor its Auxiliary MCID match the adjacency’s MCID or Auxiliary MCID, then the adjacency cannot  
24 be put into service, and no further tests are performed until an acceptable match has been achieved.

25 d) After an acceptable MCID match is achieved, configuration consistency for each Base VID in the  
26 topology is verified. The SPB Base VLAN-Identifiers sub-TLV (28.12.4) carried in SPB Hello  
27 PDUs carries, for each Base VID supported,

- 28 1) The Base VID value.
- 29 2) The ECT-ALGORITHM identifier (OUI or CID/Index) for that Base VID.
- 30 3) The SPB Hello Use-Flag (1-bit), set if this Bridge or any Bridge in the SPT Region is using  
31 this Base VID for traffic.
- 32 4) The M-Bit (1 bit), which indicates SPBM mode or SPBV mode.

33 Consistency is determined as follows:

- 34 — If either the local end or the far end SPB Hello Use-Flag of the adjacency are set, then only if  
35 the respective Base VID, ECT-ALGORITHM, and Mode bits match exactly is “matched” set  
36 for that Base VID.
- 37 — If both local end and far end SPB Hello Use-Flags are clear, then “matched” is set (to allow  
38 maintenance of the adjacency during ECT Algorithm and mode reassignment).

39 Only if “matched” is true for all Base VIDs in the topology is the link supporting the adjacency set to “SPB  
40 Operationally up,” and usable for forwarding.

41 e) Once the link supporting the adjacency has advanced to “SPB Operationally up” as above, a Bridge  
42 shall only modify the ECT-ALGORITHM or Mode bit associated with any Base VID when both the  
43 local end and far end SPB Hello Use-Flags are clear. A Bridge shall not modify the  
44 ECT-ALGORITHM or Mode bit associated with any Base VID when either local or far end SPB  
45 Hello Use-Flag is set. To do so is indicative of a serious error condition.

- 1 f) If a Bridge detects that an adjacent Bridge has altered its advertisement of the ECT-ALGORITHM  
2 or Mode bit associated with any Base VID while either the local or far end SPB Hello Use-Flags is  
3 set, it shall declare the link supporting the adjacency “SPB Operationally down.”  
4 NOTE—If the error condition arises because of aberrant behavior by a single Bridge, the condition described  
5 will be detected by all its adjacencies, and the behavior specified will cause the aberrant Bridge to be isolated  
6 from the SPT Region. This is the least damaging mitigation of such a condition.

### 7 **28.3 Loop prevention**

8 The Group Address FDB entries for SPBV and SPBM are under the control of the ISIS-SPB database  
9 exchange. Group address entries can be ensured to be loop-free when two neighboring Bridges agree never  
10 to install potentially loop-forming state derived from an unsynchronized topology in the FDB (13.17,  
11 6.5.4.1). This occurs by allowing ISIS-SPB to exchange link state messages and remove any older FDB  
12 entries that are no longer valid to any destination. Native IS-IS does not have a method for synchronizing the  
13 removal of state from the forwarding but it does have a method for synchronizing databases. ISIS-SPB  
14 augments this by using a digest of the database and adding the FDB condition. ISIS-SPB needs two  
15 modifications from regular IS-IS.

- 16 a) ISIS-SPB needs to remove any potential loop causing forwarding entries if its link state database is  
17 not synchronized with its neighbor Bridges.  
18 b) ISIS-SPB needs to synchronize with its neighbors Bridges before installing Group Address FDB  
19 entries to prevent any potential loops.

20 The Agreement Protocol (13.17) specifies how this applies to ISIS-SPB.

### 21 **28.4 The Agreement Digest**

22 The Agreement Digest specified in this clause includes a Computed Topology Digest used to determine  
23 whether a neighboring Bridge is operating with identical network topology information and thereby  
24 determine whether frames may be safely forwarded to the neighbor.

25 The Agreement Digest field (Figure 28-1) comprises six elements:

- 26 — The Agreement Digest Format Identifier  
27 — The Agreement Digest Format Capabilities  
28 — The Agreement Digest Convention Identifier  
29 — The Agreement Digest Convention Capabilities  
30 — The Agreement Digest Edge Count  
31 — The Computed Topology Digest

32 The Agreement Digest is carried as a structured 32-byte field in the ISIS-SPB Digest sub-TLV. Byte 1 is the  
33 most significant, Byte 32 is the least significant byte. These and all parameters carried in ISIS-SPB TLVs and  
34 sub-TLVs are encoded using the “big-endian” convention, in which lower numbered bits within each byte  
35 (those to the left) have higher significance.

#### 36 **28.4.1 Agreement Digest Format Identifier**

37 The Agreement Digest Format Identifier (4 bits) is carried in the most significant 4 bits of Byte 1 of the  
38 Agreement Digest field. Its purpose is to allow alternative digests to be defined at some time in the future.  
39 This release of the standard defines Digest Format 0. All future upgrades to the standard protocol will  
40 require recipients to be able to receive and process digests of this format.

|                                          | Octet | Length |
|------------------------------------------|-------|--------|
| Agreement Digest Format Identifier       | 1     | 4 bits |
| Agreement Digest Format Capabilities     | 1     | 4 bits |
| Agreement Digest Convention Identifier   | 2     | 4 bits |
| Agreement Digest Convention Capabilities | 2     | 4 bits |
| Agreement Digest Edge Count              | 3–4   | 2      |
| Reserved (set to 0)                      | 5–12  | 8      |
| Computed Topology Digest                 | 13–32 | 20     |

**Figure 28-1—Agreement Digest field format**

1 The Agreement Protocol (13.17) will not declare a topology match if the recipient does not support the  
2 Format value of this field, but otherwise it will operate as normal, so that the transmitter will receive an  
3 indication of the Digest Format Identifier and Capabilities of the receiver as a result of normal protocol  
4 operation.

#### 5 **28.4.2 Agreement Digest Format Capabilities**

6 The Agreement Digest Format Capabilities (4 bits) is carried in the least significant 4 bits of Byte 1 of the  
7 Agreement Digest field. Its purpose is to allow alternative digest Formats to be defined and advertised at  
8 some time in the future. In this version of the standard it is transmitted as value 0 and ignored on receipt.

#### 9 **28.4.3 Agreement Digest Convention Identifier**

10 The Agreement Digest Convention Identifier (4 bits) is carried in the most significant 4 bits of Byte 2 of the  
11 Agreement Digest field. Its purpose is to advertise the set of loop-free forwarding rules, for which the link  
12 state database information identified by the Digest acts as input, which are currently in use by the transmitter  
13 (13.17). The following rules are defined in this version of the standard:

- 14 — 1. indicates no digest match. Digests are exchanged but match is not required. Configured as off  
15 (Clause 17).
- 16 — 2. means the transmitter will continue loop-free forwarding of both multicast and unicast traffic  
17 either only after any change which occurs has been reflected in matched digests (strict agreement);  
18 or up to the limits of change specified by the rules in this version of the standard. This is the default.  
19 Configured as loopFreeBoth (Clause 17).
- 20 — 3. means the transmitter will continue loop-free forwarding of multicast traffic up to the limits of  
21 change specified by the rules in this version of the standard, and will continue forwarding of unicast  
22 traffic unconditionally. Configured as loopFreeMCastOnly (Clause 17).

23 NOTE—While it is recommended that all Bridges use the same convention, Bridges operate independently and the  
24 conventions can be different on individual Bridges. For loopFreeBoth and loopFreeMCastOnly as indicated, a Bridge  
25 may block all the respective traffic on change or allow “safe” traffic during change. Individual Bridges can have  
26 different definitions of “safety” applied to the forwarding allowed during digest mismatch.

#### 27 **28.4.4 Agreement Digest Convention Capabilities**

28 The Agreement Digest Convention Capabilities (4 bits) is carried in the least significant 4 bits of Byte 2 of  
29 the Agreement Digest field. Its purpose is to advertise the set of loop-free forwarding rule conventions that  
30 are understood by the transmitter. The value 0 declares that the transmitter understands conventions 1 to 3  
31 (above). Bridges conforming to this version of the standard transmit the value 0 and ignore this field on  
32 receipt.

## 1 28.4.5 Agreement Digest Edge Count

2 The Agreement Digest Edge Count (16 bits) is an unsigned integer carried in Byte 3 and Byte 4 of the  
3 Agreement Digest field. Its purpose is to provide one component of the Agreement Digest, which is simple  
4 to compute and powerful in detecting many simple topology mismatches.

5 This value is the sum modulo  $2^{16}$  of all Edges in the SPB topology. Each point-to-point physical link is  
6 counted as two Edges, corresponding to its advertisement by ISIS-SPB in an LSP flooded from either end of  
7 the link.

8 If more than one ISIS-SPB topology is configured, the Agreement Digest Edge Count accumulates all Edges  
9 in all configured topologies. If Edges are absent in a particular topology, they have the value 0 for this  
10 summation.

11 NOTE—MT SPB allows different Link Metrics to be used in different topologies. The Agreement Digest format  
12 specified here can only achieve a match between topologies when exactly the same set of Bridges are present in all  
13 topologies but the requirement that MCIDs match for all Bridges in an SPT Region means that this is not an additional  
14 constraint.

## 15 28.4.6 The Computed Topology Digest

16 The overall procedure for constructing the Computed Topology Digest is to:

- 17 — Form a signature of each Edge in the topology by computing the MD5 hash (IETF RFC 1321 [B20])  
18 of the significant parameters of the Edge, as defined below.
- 19 — Compute the Digest as the arithmetic sum of all Edges in the topology.

20 If more than one topology is declared in ISIS-SPB, the Computed Topology Digest covers all topologies  
21 declared, and this single value is advertised in the ISIS-SPB Digest sub-TLV. The SPB Digest sub-TLV is  
22 carried within the MT-Port-Cap TLV [IETF RFC 6165] with the MTID value of 0, which in turn is carried in  
23 an SPB Hello PDU.

24 NOTE 1—MD5 is widely reported to be cryptographically weak. This is not relevant in this application. What is  
25 required is a function exhibiting good avalanche properties such that signatures with potentially very similar input  
26 parameters have an infinitesimal probability of collision.

27 NOTE 2—This strategy allows the Digest to be incrementally computed when the topology changes, by subtracting the  
28 signatures of vanished Edges from the Digest and adding the signatures of new Edges. In general, the signature of an  
29 Edge therefore needs only to be computed once, when it is first advertised.

30 The input message to the MD5 hash for each Edge is constructed by concatenating the following fields in  
31 order, with the first field being the beginning of the message.

- 32 a) The Bridge Identifier (13.26.2) of the Bridge advertising the Edge with the greater Bridge Identifier  
33 value (8 bytes).
- 34 b) The Bridge Identifier of the Bridge advertising the Edge with the lesser Bridge Identifier value  
35 (8 bytes).
- 36 c) A variable number of 8-byte 3-tuples, one 3-tuple for each MTID (Clause 3) declared in ISIS-SPB.  
37 The 3-tuples are declared in descending order of MTID value, with the largest MTID declared first.

38 Each 3-tuple is constructed by concatenating the following fields in the order below:

- 39 d) A 2-byte field containing the 12-bit MTID value [IETF RFC 5120] in the least significant bits, with  
40 the most significant 4 bits of the field set to zero.
- 41 e) The SPB Link Metric [item c) in 12.25.6.1.2] for the Edge in this topology that has been advertised  
42 by the Bridge with the greater Bridge Identifier value (3 bytes).
- 43 f) The SPB Link Metric for the Edge in this topology that has been advertised by the Bridge with the  
44 lesser Bridge Identifier value (3 bytes).

1 If an Edge is not present in a topology, its SPB Link Metric is set to zero in that topology.

2 The value of the Computed Topology Digest is the arithmetic sum of all of the signatures returned by  
3 presenting every Edge message to MD5, treating the signature as an unsigned 16-byte integer and  
4 accumulating into a 20-byte integer. Every physical link is seen as two Edges, one advertised by each Bridge  
5 comprising the adjacency, and formally the Computed Topology Digest includes both.

6 NOTE 3—Although the Computed Topology Digest contains signatures for both Edges associated with each link, the  
7 construction defined above means that these are always identical. An implementation may choose to compute a single  
8 signature per link, and then double it before accumulating it into the Computed Topology Digest.

9 The value of the Computed Topology Digest is placed in Bytes 13 to 32 of the Agreement Digest field for  
10 transmission in the ISIS-SPB Digest sub-TLV.

11 Bytes 5 to 12 of the Agreement Digest field are unused in this version of this standard. They are set to zero  
12 on transmission and ignored on reception.

### 13 **28.5 Symmetric shortest path tie breaking**

14 When performing shortest paths computation there may be several equal cost shortest paths between the  
15 same Bridge pairs (27.17). In order to meet the congruency requirements, SPB requires that the computation  
16 produces a deterministic unique shortest path per SPT set independent of order or direction of computation.

17 The SPB symmetric (Clause 3) shortest path tie-breaking algorithm needs to be accurately specified or  
18 different versions of SPB would compute different SPTs. SPB requires symmetry and congruence in its  
19 unicast and multicast routing, so the operation of the algorithms defined for the base specification and  
20 constraints on their future extension are specified unambiguously.

21 NOTE—Exploration of path computation that produces various types of ECTs is beyond the scope of this standard.

22 Two mechanisms are used to provide for symmetric and congruent SPT calculation. The first mechanism  
23 addresses the possibility that different ends (nodes) of an adjacency advertise different values for the SPB  
24 Link Metric (28.12.7). To maintain determinism, the SPB shortest path calculation always uses the  
25 maximum of the two advertised SPB Link Metric values when accumulating path costs. The second  
26 mechanism addresses the situation in which two equal cost paths are found. To maintain determinism in this  
27 case, a tie-breaking algorithm is required that achieves the same result regardless of order of computation.

28 SPB is designed to support many tie-breaking algorithms for ECTs, and SPBM can assign traffic by I-SID to  
29 different B-VIDs assigned to different ECTs. SPB defines one required tie-breaking algorithm and an open  
30 framework for the creation of a very large number of additional algorithms. As part of the base standard, a  
31 number pre-defined tie-breaking algorithms are described using this framework with extensions for  
32 expansion in the future.

33 SPB accomplishes basic equal cost tie breaking by logically assigning a computation-order-independent  
34 identifier to each possible equal cost shortest path that it computes. This tie breaking is symmetric because it  
35 is independent of which direction the selection is done and it preserves reverse path congruency. This is  
36 referred to as the Path Identifier (PATHID). A PATHID is defined as the sorted list (ascending lexicographic  
37 order) of Bridge IDs that the path traverses including the endpoints.

38 When there are different equal cost shortest paths output by the SPF computation, each of them will have a  
39 unique PATHID. The PATHID for each distinct path will be the same whichever Bridge computes that  
40 PATHID. The PATHID will be the same for both the forward and reverse of a path (because they are sorted  
41 lists of Bridge-IDs). PATHIDs may be ranked and compared by successively comparing the sorted list of  
42 Bridge-IDs they contain. PATHID A is ranked “less than” PATHID B if it contains fewer Bridge-IDs:

43 e.g.: {9,15,22} < {7,8,9,10,22}

1 PATHID A is ranked “less than” PATHID B (of equal length) if its *i*’th Bridge-ID is less than B’s *i*’th  
2 Bridge-ID and all other Bridge-IDs up to the *i*’th are equal (lexicographic order).

3 e.g.: {9,15,22,99} < {9,15,22,100}

4 Both SPBV’s and SPBM’s default tie-breaking algorithm picks the equal cost path with the lowest PATHID  
5 as defined in the above ranking.

6 The above algorithm can be easily implemented efficiently by simply back tracking the two or more  
7 competing equal cost paths and picking the path that has the minimum PATHID between the fork and join  
8 points of the competing paths. A path selected in this manner will also be part of any longer shortest paths  
9 that transit the fork and join points, and so intermediate resolution of shortest path permutations can be  
10 performed and the state for discarded permutations need not be carried forward.

11 The Bridge Priority by default is the middle value equal to 8 of the 4-bit priority in the most significant part  
12 of the 2-byte field [ $8 \times 4096 = 32\,768$  middle of the priority range] on all Bridges, and so does not affect the  
13 tie-breaking results. Bridge Priority can be tuned by the operator and will therefore affect the pre-defined  
14 tie-breaking algorithm(s) in a deterministic manner.

## 15 **28.6 Symmetric ECT framework**

16 Each tie-breaking method is uniquely identified by an ECT Algorithm. The ECT Algorithm is a 32-bit  
17 number that contains an OUI or CID and an index. This document specifies an initial set of SPB ECT  
18 Algorithms together with a framework for a large number of other algorithms. The OUI or CID allows  
19 organizations to specify and manage their own algorithms and behaviors and to document them  
20 independently either through the IEEE, or through other SDOs, or to keep them proprietary/experimental  
21 should they desire. The different SPB ECT Algorithms defined in this document use the IEEE 802.1 OUI  
22 (00-80-C2). Index values 1 through 16 are associated with symmetric ECT Algorithms while one additional  
23 non-ECT spanning tree algorithm is defined with Index value 0.

24 The ECT Algorithm is unique for an SPT Set. One or more Base VIDs may be associated with an ECT  
25 Algorithm; and this association is advertised both in LSPs to all other Bridges in the SPT region and also is  
26 exchanged in the SPB Hellos. A Base VID should not be used within the SPT region until all Bridges agree  
27 on the relationship. Temporary disagreement between the Base VIDs assigned is expected and permitted  
28 between Bridges as Base VIDs with new ECT Algorithms are configured. Disagreements are allowed when  
29 the Base VIDs is not in use. Base VIDs may share the same ECT Algorithm regardless of mode.

30 In SPBM, an I-SID is associated with a Base VID and thus by inference with an ECT Algorithm as well.  
31 This permits an operator to assign traffic to a certain ECT-ALGORITHM and to move it as required to  
32 achieve a degree of traffic balancing. In SPBM mode this Base VID is the B-VID directly.

33 In SPBV mode the Base VID shall be used to lookup and find the proper SPVID for the source under  
34 consideration during the setting of VLAN Registration Entries. A VLAN supported by SPBV can be forced  
35 to use the spanning tree of the IST in cases where the Bridges do not agree on the configuration or are short  
36 on SPVID resources.

37 Bridges must consider all SPT sets and populate forwarding even if they do not define a VID. An ECT  
38 Algorithm can be defined to operate using only data already advertised by ISIS-SPB (for example the Low  
39 and High PathID algorithms), or, it may require additional tuning parameters that cannot be foreseen. To  
40 accommodate a future ECT Algorithm need for tuning parameters SPB supports the concept of Opaque ECT  
41 data.

1 To allow for nodal- and link-based ECT behavior in future requirement the Opaque ECT data may be  
2 advertised under both SPB nodal and/or link data. The Opaque ECT data begins with the 32-bit  
3 ECT-ALGORITHM identifier but the remainder of the data format is specific to future ECT Algorithms and  
4 is therefore opaque to this document.

5 An example use of this framework could be as follows. Consider the tie breaking that can be done by using  
6 a minimum sum over a secondary link metric and a hash-based but deterministic assignment of such  
7 secondary metrics to every link in the network. Further consider these secondary link metrics as tunable.  
8 Initially a new value for this ECT Algorithm is assigned and registering it with the appropriate numbering  
9 authority for the OUI or CID. The hash functions that create the secondary link metrics based for example  
10 on the two Bridge-IDs at each end of the link, could be defined. Then a format for a 32-bit opaque secondary  
11 metric could be defined which would be advertised as opaque data under the link data and prefixed with the  
12 ECT-ALGORITHM index for the new tie breaker. Migration to this new tie breaker would proceed in a  
13 manner consistent with any ECT Algorithm (28.9).

## 14 **28.7 Symmetric ECT**

15 In the case of multiple equal cost paths, multiple ECTs may be computed, in fact most efficient shortest path  
16 computations like Dijkstra actually produce all shortest paths from a root, i.e., an SPF tree, and different  
17 unique trees emerge depending on the tie breaking employed at the branch points. These different trees are  
18 distinguished in the forwarding plane by using SPVIDs (SPBV) or B-VIDs and B-MAC SAs (SPBM) for  
19 each “active topology”. In order to be repeatable a unique tie breaker (ECT Algorithm) is chosen for each  
20 SPT set as described in 28.5. Typically a small number of B-VIDs would satisfy most requirements for equal  
21 cost routes in the case of SPBM.

22 SPBV and SPBM support a set of symmetric (Clause 3) equal cost paths between any pair of Bridges for a  
23 given SPB instance/MTID. The symmetric shortest path algorithms are identified by the ECT Algorithm  
24 using the IEEE 802.1 OUI=00-80-C2 and with Index values 0..16. Index value 0 is somewhat special in that  
25 it relates the VID used for the CIST and is not a shortest path algorithm but is instead the spanning tree  
26 algorithm. The remaining algorithms are shortest path algorithms: The LowPATHID algorithm (index = 1) is  
27 the default SPT path computation tie breaker. SPB uses LowPATHID as the default SPT tie-breaking  
28 algorithm. SPB can use any alternate tie-breaking algorithm for another ECT when it is configured. The  
29 other defined algorithms use a computed shuffle of the LowPATHID algorithm. For example the  
30 HighPATHID ECT-ALGORITHM=<OUI=00-80-C2:index = 2> is just a rank inversion, which  
31 ones-complements the Bridge-IDs prior to doing the same comparisons as the LowPATHID algorithm. The  
32 remaining 14 pre-defined algorithms have indexes 3..16 and are defined in terms of a bit mask that they  
33 XOR the Bridge-IDs with prior to finding the minimum PATHID. Since they XOR over all 8 bytes, which  
34 include the Bridge-Priority and the SPB System Identifier, these algorithms can be tuned in deterministic  
35 ways by adjusting the Bridge-Priority. SPBM can advertise a Base VID for each of these unique symmetric  
36 shortest paths through the ECT SPB Instance sub-TLV (28.12.5).

37 SPB assigns a unique ECT Algorithm to a Base VID in the Base VID sub-TLV (28.12.4) and the SPB  
38 Instance sub-TLV (28.12.5). To allow migration between different ECT Algorithms, further ECT Algorithm  
39 and Base VID bindings may be advertised, unused, without interfering with the operation of currently used  
40 ECT Algorithms and Base VIDs. Once Bridges are configured to support the new ECT Algorithm and share  
41 a consistent Base VID for this algorithm, the algorithm may then be used by mapping I-SIDs to the Base  
42 VID for the desired ECT Algorithm.

43 SPBV also assigns a unique Base VID to each ECT Algorithm; however, the actual data path VID used  
44 depends on the source. Therefore, an SPVID shall be specified in the SPVID field in conjunction with the  
45 Base VID and ECT Algorithm in the SPB Instance sub-TLV. A similar procedure can be used with SPBV to  
46 introduce a Base VID that would not carry traffic until fully configured. Then services could be switched to  
47 the new VLAN. This is no different than introducing a new VLAN on RSTP for example.

## 28.8 Symmetric ECT Algorithm details

The exact method applied for computing the active topology of a VLAN assigned to ISIS-SPB control is determined by the ECT Algorithm configured for the given VLAN. A set of symmetric ECT Algorithms is defined to calculate SPT Sets for SPBV or SPBM VLANs. Two ECMP ECT Algorithms (44.1.2) are defined to calculate SPTs and shared trees for ECMP (Clause 44). Five explicit ECT Algorithms (45.1) are defined for VLANs associated with Explicit Trees (Clause 45).

Each of the standard symmetric ECT-ALGORITHM values is formed using the OUI=00-80-C2 and the Index=1..16. An Algorithm Mask is specified for each Index, and is exclusive-ORed with each octet of each of the Bridge Identifiers (2 octet Bridge Priority concatenated with the 6 octet SPB System Identifier) to generate Masked Bridge Identifiers for each of the candidate paths. Given any two paths, the one chosen for a given ECT Algorithm has the lowest PATHID formed from the ranked masked Bridge Identifiers, which will necessarily include a lowest masked Bridge Priority, excluding those common to both paths. This comparison gives the greatest weight to the (masked) Bridge Priority of each Bridge Identifier, allowing the path selection to be managed/tuned without creating additional identifiers or identifier components for each Bridge. The ECT-ALGORITHM values and corresponding Masks and their effects, in terms of prioritizing path selection by Bridge Priority, are given in Table 28-1.

**Table 28-1—Bridge Priority Masking**

| ECT-ALGORITHM | Algorithm MASK | Effect of using MASK on priority nibble                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00-80-C2-01   | 0x00           | The selected path includes Bridge with best (numerically lowest) Bridge Identifier after masking. In this case the masking 0x00 no effect and original administered Bridge priority values apply. When Bridge priority value is equal for two Bridge identifiers the lower system identifier determines the priority. (0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15).                                                                                                  |
| 00-80-C2-02   | 0xFF           | The selected path includes Bridge with best priority (numerically lowest) Bridge Identifier after masking. In this case the masking 0xFF reverses the original administered Bridge priority values. When Bridge priority value is equal for two Bridge identifiers the lower system identifier determines the priority. (15,14,13,12,11,10,9,8,7,6,5,4,3,2,1,0). Read vector as administered priority 0 equals 15, administered priority 15 equals 0 and so on. |
| 00-80-C2-03   | 0x88           | Bridges with Bridge Priority 8 will be treated as best priority for path selection, followed by Bridge Priorities of 9, 10, 11, and so on. (8,9,10,11,12,13,14,15,0,1,2,3,4,5,6,7). Read vector as administered priority 0 equals 8, administered priority 8 equals 0.                                                                                                                                                                                          |
| 00-80-C2-04   | 0x77           | Bridges with Bridge Priority 7 will be treated as best priority for path selection, followed by Bridge Priorities of 6, 5, 4, and so on. (7,6,5,4,3,2,1,0,15,14,13,12,11,10,9,8). Read vector as administered priority 0 equals 7, administered priority 7 equals 0.                                                                                                                                                                                            |
| 00-80-C2-05   | 0x44           | (4,5,6,7,0,1,2,3,12,13,14,15,8,9,10,11)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 00-80-C2-06   | 0x33           | (3,2,1,0,7,6,5,4,11,10,9,8,15,14,13,12)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 00-80-C2-07   | 0xCC           | (12,13,14,15,8,9,10,11,4,5,6,7,0,1,2,3)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 00-80-C2-08   | 0xBB           | (11,10,9,8,15,14,13,12,3,2,1,0,7,6,5,4)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 00-80-C2-09   | 0x22           | (2,3,0,1,6,7,4,5,10,11,8,9,14,15,12,13)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 00-80-C2-0A   | 0x11           | (1,0,3,2,5,4,7,6,9,8,11,10,13,12,15,14)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 00-80-C2-0B   | 0x66           | (6,7,4,5,2,3,0,1,14,15,12,13,10,11,8,9)                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 28-1—Bridge Priority Masking (continued)**

| ECT-ALGORITHM | Algorithm MASK | Effect of using MASK on priority nibble |
|---------------|----------------|-----------------------------------------|
| 00-80-C2-0C   | 0x55           | (5,4,7,6,1,0,3,2,13,12,15,14,9,8,11,10) |
| 00-80-C2-0D   | 0xAA           | (10,11,8,9,14,15,12,13,2,3,0,1,6,7,4,5) |
| 00-80-C2-0E   | 0x99           | (9,8,11,10,13,12,15,14,1,0,3,2,5,4,7,6) |
| 00-80-C2-0F   | 0xDD           | (13,12,15,14,9,8,11,10,5,4,7,6,1,0,3,2) |
| 00-80-C2-10   | 0xEE           | (14,15,12,13,10,11,8,9,6,7,4,5,2,3,0,1) |

1 NOTE 1—In these algorithms, the Algorithm Mask is applied to all octets of each Bridge Identifier. Thus if two  
2 alternative paths include only Bridges with one or a few Bridge Priorities, the Algorithm Mask will still reorder their  
3 priorities for inclusion on the path as it acts on the rest of the SPB System Identifier component of the Bridge Identifier  
4 field.

5 NOTE 2—If the two priority bytes in the 8-byte Bridge Identifier are all equal, then all Bridges have equal priority and  
6 ECT-ALGORITHM values 00-80-C2-01 and 00-80-C2-02 are exactly Low and High PATHID as described in 28.5.

## 7 28.9 ECT Migration

8 For orderly migration, each Base VID to ECT Algorithm assignment also has associated flags indicating  
9 active usage of the Base VID by services. The Use-Flag in the SPB Base VLAN-Identifiers sub-TLV  
10 (28.12.4) indicates a Bridge's awareness of use of the Base VID somewhere in the SPT Region, and the  
11 U-bit in the SPB Instance sub-TLV (28.12.5) indicates local use of this Base VID. The Use-Flag in the SPB  
12 Base VLAN-Identifiers sub-TLV is carried in the SPB Hello PDU, and is set once the Bridge advertising the  
13 algorithm has started either using or seeing the use of that ECT-ALGORITHM. ISIS-SPB enforces the  
14 following rules with respect to ECT Algorithms and their usage in order to protect the SPB network from  
15 outages created by incorrect configuration. If neighbors disagree on a Base VID to ECT-ALGORITHM  
16 assignment, then use of the adjacency for SPB traffic is permitted (i.e., the SPB Link Metric may be set less  
17 than  $2^{24} - 1$ ) only if both neighbors' Use-Flags associated with the Base VID are cleared (28.2).

18 If a new ECT Algorithm is implemented in all Bridges of an SPT Domain and intended to be used by a Base  
19 VID, then the assignment of the Base VID to the new ECT-ALGORITHM with Use-Flag cleared is first  
20 configured in the SPT Domain on a Bridge by Bridge basis. As soon as this configuration is complete,  
21 services (I-SIDs in SPBM or SPVIDs in SPBV) may be assigned to the given Base VID, which causes the  
22 local U-bit to be set, which will in turn cause the Use-Flag to be set for the given Base VID.

23 SPBV and SPBM have different migration capabilities after the introduction of a new ECT Algorithm. The  
24 following subclauses describe how SPBV and SPBM use a newly introduced ECT Algorithm.

### 25 28.9.1 Use of a new ECT Algorithm in SPBV

26 A new ECT Algorithm, which is implemented by each Bridge of an SPT Domain, gets to be used if it is  
27 configured to support a VLAN. In SPBV mode, the application of a new ECT Algorithm typically coincides  
28 with the introduction of a new VLAN supported by SPBV. That is, the Base VID of the new VLAN is  
29 assigned to the new ECT-ALGORITHM in the SPB Hello PDU Base VID and SPB Instance sub-TLVs  
30 (28.9). ISIS-SPB then allocates (27.10) the SPVIDs necessary for the support of the new VLAN. To support  
31 in-service upgrade from one set of VID / ECT Algorithm allocations to another, SPT Bridges allow graceful  
32 configuration of those services. Provided there is an operating SPBV or SPBM VLAN in a region, SPT  
33 Bridges can be configured within the Region for a new VLAN on a Bridge by Bridge basis. As long as the  
34 SPT Region is connected the Bridges supporting the new VLAN do not need to be directly connected.  
35 Intermediate Bridges are capable of populating forwarding without terminating services allowing them to  
36 participate in the VLAN.

1 The migration of a VLAN from an old ECT Algorithm to a new ECT Algorithm can be performed by the  
2 reassignment of the Base VID of the VLAN. That is, the Base VID is assigned to the new  
3 ECT-ALGORITHM instead of the old ECT-ALGORITHM on a Bridge by Bridge basis. In SPBV the  
4 forcing of one of the Bridges Base-VIDs to use the spanning tree algorithm as opposed to another algorithm  
5 forces all of the Bridges in the SPT region using that Base VID to spanning tree. Migration can then proceed  
6 to the new Base VID assignment until the last Bridge is configured to use the new ECT-ALGORITHM. The  
7 new assignment is then propagated in SPB Hello PDU Base VID and SPB Instance sub-TLVs (28.9) by  
8 ISIS-SPB within the SPT Domain. As soon as each SPT Bridge is configured with the Base VID assignment  
9 to the new ECT-ALGORITHM, the spanning tree assignment on the last Bridge is cleared.

10 NOTE 1—ISIS-SPB automatically performs the allocation and release of SPVIDs during the migration. The SPVIDs  
11 allocated for the Base VID old ECT-ALGORITHM assignment are released as soon as the assignment has been broken.  
12 These SPVIDs might be then allocated for the Base VID new ECT-ALGORITHM assignment. That is, there is no need  
13 for additional SPVID allocations if a Base VID supported by SPBV is migrated from an old ECT-ALGORITHM to a  
14 new one.

15 NOTE 2—SPBV does not support hitless migration. That is, the migration of a VLAN from an old ECT-ALGORITHM  
16 to a new ECT-ALGORITHM may cause traffic outage.

## 17 **28.9.2 Use of a new ECT Algorithm in SPBM**

18 SPBM offers the ability to map I-SIDs to Base VIDs as a load balancing option. In topologies with multiple  
19 equal cost paths the ability to spread traffic on a per I-SID basis comes from using the Base VIDs with  
20 different algorithms as specified in this clause.

21 When an I-SID is configured to be associated with a Base VID, that Base VID shall be consistently  
22 associated with the same ECT-ALGORITHM throughout the SPT Domain. Once at least one I-SID has been  
23 assigned to a Base VID the U-bit is set and advertised in subsequent LSPs, which also causes the Use-Flag  
24 to be set in SPB Hello PDUs.

25 SPBM supports in-service migration of an I-SID from an old ECT Algorithm to a new ECT Algorithm  
26 supported by each Bridge of an SPT Domain. In order to accomplish this, two complete Base VIDs must be  
27 configured in the SPT Domain. Then an I-SID under migration can be assigned to two Base VIDs at the  
28 same time: the old Base VID (old ECT-ALGORITHM), and the new Base VID (new ECT-ALGORITHM).  
29 The U-bit (in the SPB Instance sub-TLV, 28.12.5) is set by the advertising Bridge when there is at least one  
30 service using this VID. This propagates throughout the SPT domain, and any Bridge seeing at least one  
31 U-bit set in received LSPs (signifying that the indicated Base VID is being used by a service somewhere)  
32 sets the Use-Flag in its SPB Base VLAN-Identifiers sub-TLV (28.12.4).

33 I-SIDs will have originally been configured to be associated with the old Base VID (28.12.10). No filtering  
34 entry is set for the new Base VID in the FDBs as there is no Transmitter set on the new Base VID yet. I-SIDs  
35 can be configured to be associated with the new Base VID. Care must be taken to ensure the new Base VID  
36 is configured in all the required places. When a particular I-SID has been added to a new Base VID,  
37 ISIS-SPB detects that the I-SID is now associated with two Base VIDs and at each location that I-SID may  
38 receive traffic on either Base-VID. During this period individual addresses are available under both Base  
39 VIDs. The setting of the R and T bits still determines whether the group addresses are populated for each  
40 Bridge supporting that I-SID in either Base VID. In other words the same rules for a single Base VID are  
41 followed but two base VIDs are temporarily in use for received traffic. Traffic is “rolled” from the old Base  
42 VID to the new one by administrative reassignment of the I-SID at each service end-point from the old to the  
43 new B-VID. This can be an atomic action, and so at any instant only one Base VID will be used by any  
44 service originating frames. The association of the I-SID to the old Base VID is removed once all I-SIDs are  
45 configured to one Base VID. Furthermore, if this is the last I-SID removed from a Base VID the U-bit is  
46 cleared (in the SPB Instance sub-TLV) for the old Base VID to ECT-ALGORITHM assignment. Eventually  
47 the Use-Flag carried in the SPB Hello PDU will be cleared when all the Bridges have been configured.

## 1 28.10 MAC address registration

2 ISIS-SPB creates MAC Address Registration Entries (8.8.4) for group addresses in order to reach the  
3 members of a group. The group addresses are locally administered in case of SPBM (27.16), thus, they are  
4 only significant inside the SPT Region.

5 ISIS-SPB also installs MAC Address Registration Entries for universally administered group addresses as  
6 they might be used by SPBV. Furthermore, ISIS-SPB provides interworking with MMRP at the Boundary  
7 Ports of an SPT Region. That is, ISIS-SPB interprets MMRPDUs received at a Boundary Port and assembles  
8 the proper ISIS-SPB TLVs in order to advertise the corresponding MAC address registration inside the SPT  
9 Region. Furthermore, ISIS-SPB assembles and issues MMRPDUs on Boundary Ports if MAC address  
10 registration needs to be propagated outside of the SPT Region.

11 When an MMRPDU is received on a Boundary Port, ISIS-SPB disseminates the registration by sending  
12 LSPs with an SPBV MAC Address sub-TLV (28.12.9) filled according to the registration received from the  
13 MMRPDU. The MAC Address and Base VID values shall be copied from the MMRPDU, with the R bit set  
14 and T bit cleared. The SR bits (28.12.9) are set according to the Group service requirement information  
15 carried in the MMRPDU. When processing received SPBV MAC Address sub-TLVs that have the R bit set,  
16 SPT Bridges at the boundary of an SPT Region shall check whether they should filter or forward the frames  
17 received on their Boundary Port in the VLAN for which the registration applies. If the option is to forward  
18 frames, then they also send the SPBV MAC Address sub-TLV into the SPT Region for the MAC address  
19 under registration; but set the T bit, clear the R bit and for the VID value use the SPVID allocated to the  
20 given VLAN. ISIS-SPB then creates MAC Address Registration Entries inside the SPT Region based on the  
21 SPBV MAC Address sub-TLVs. Furthermore, if the Boundary Port is in the given VLAN's member set,  
22 then ISIS-SPB assembles the proper MMRPDU and issues it on the Boundary Port.

23 Besides interworking with MMRP at Boundary Ports, ISIS-SPB also takes into account the Registrar  
24 Administrative Control parameters (10.7.2).

25 NOTE—Creation of unnecessary MAC Address Registration Entries can be prevented by using the “Registration  
26 Forbidden” parameter for the proper Ports and VLANs.

## 27 28.11 Circuit IDs and Port Identifiers

28 IS-IS allows the formation of multiple adjacencies between two routers. ISIS-SPB supports only a single  
29 logical adjacency per MTID. Link Aggregation allows a single ISIS-SPB adjacency to cover multiple links,  
30 and this is the only method defined in this version of this standard by which multiple links between  
31 neighbors are supported. In cases where multiple potential adjacencies exist, each pair of peers using  
32 ISIS-SPB should choose the link with the lowest Local Circuit ID on the Bridge with the better (numerically  
33 lower) SPB System Identifier as the link over which to send and receive frames.

34 Procedures for using multiple adjacencies are not specified by this standard.

## 35 28.12 ISIS-SPB TLVs

36 All SPB TLVs and sub-TLVs are described. SPBV and SPBM share most of the same TLVs.  
37 Multi-Topology (MT) [Annex X] is introduced as well, but multiple SPT instances, each supporting a  
38 different VLAN, and each using either SPBV or SPBM can be described in a single topology instance. MT  
39 instances allow different topologies to be advertised, for example if there is a desire to use different metrics  
40 since there is only a single metric scheme within a topology.

1 SPB adds one new TLV and several new sub-TLVs that can be added to IS-IS PDUs, as described below.  
2 The new ISIS-SPB data have been organized to support multiple topologies within a single IS-IS instance.  
3 Each of the new sub-TLVs can be included in a TLV containing a topology instance identifier (MTID) value  
4 (as per [MT]) so that the computations can operate only on sub-TLVs specific to their topology instance. The  
5 intent of MT is to support the use of multiple metric sets when required. The construction of the MCID and  
6 the Agreement Digest (13.17, 28.4) requires that all SPT Bridges in an SPT region appear in all MT  
7 instances.

8 All parameters carried in the ISIS-SPB (sub-)TLVs defined below are encoded using the “big-endian”  
9 convention, in which higher significance bytes and bits within each byte appear to the left of and above  
10 bytes and bits of lower significance.

### 11 28.12.1 MT-Capability TLV

12 The MT-Capability TLV (Figure 28-2) is a top-level TLV for LSPs that provides Multi-Topology context. It  
13 identifies the MTID for sub-TLVs in LSPs.

|              | Octet | Length  |
|--------------|-------|---------|
| Type (144)   | 1     | 1       |
| Length (2)   | 2     | 1       |
| Overload Bit | 3     | 1 bit   |
| reserved     | 3     | 3 bits  |
| MTID         | 3–4   | 12 bits |

**Figure 28-2—MT-Capability TLV**

- 14 a) Type (8 bits) Value 144
- 15 b) Length (8 bits)
- 16 Total number of bytes contained in the value field.
- 17 c) Overload Bit (1 bit)
- 18 The overload bit is an ISIS-SPB MT instance-specific overload bit.
- 19 d) MTID (12 bits)
- 20 This is used to provide the ISIS-SPB Multi-Topology context for SPB sub-TLVs. This should be 0
- 21 when there is only one topology instance.

### 22 28.12.2 SPB MCID sub-TLV

23 This sub-TLV (Figure 28-3) shall be included in an MT-Port-Cap TLV [IETF RFC 6165] with MTID equal  
24 to 0 in SPB Hello PDUs to announce the Bridge’s MCID (13.8). This information should be the same on all  
25 Bridges in the topology being controlled by this ISIS-SPB instance. The MCID is controlled solely by  
26 configuration and is a digest of the protocol assignments for all possible VIDs. Two MCIDs are carried to  
27 allow transitions between configurations when the changes are non-critical. If neither MCID advertised by a  
28 neighbor matches either MCID on this Bridge the adjacency is a Region boundary.

|              | Octet  | Length |
|--------------|--------|--------|
| Type (4)     | 1      | 1      |
| Length (102) | 2      | 1      |
| MCID         | 3–53   | 51     |
| Aux MCID     | 54–104 | 51     |

**Figure 28-3—SPB MCID sub-TLV**

- 1 a) Type (8 bits) Value 4
- 2 b) Length (8 bits)
- 3 Total number of bytes contained in the value field.
- 4 c) MCID (51 bytes)
- 5 The complete MCID defined in (13.8) that identifies an SPT Region.
- 6 d) AUX-MCID (51 bytes)
- 7 In the case of migration and where the MCID will change but in a non-critical way, this MCID
- 8 contains the previous advertised MCID. The neighbor will not drop an adjacency if at least one of
- 9 these MCIDs matches either of its MCIDs.

### 10 28.12.3 SPB Digest sub-TLV

11 This sub-TLV (Figure 28-4) shall be included in an MT-Port-Cap TLV with MTID 0 in SPB Hello PDUs.  
12 The ISIS-SPB Agreement Digest (13.26.1, 28.4) is computed based on current topology and it changes when  
13 significant topology changes. The Agreement Digest is a key input into the Agreement Protocol (13.17),  
14 which provides multicast loop prevention. During the propagation of LSPs the Agreement Digest will vary  
15 between neighbors until the LSPs are common. The digest is a summarized means of determining agreement  
16 between nodes on the distance to all multicast roots, hence is essential for loop prevention. For each SPT  
17 where it has been determined the distance to the root has changed, unsafe multicast forwarding is blocked  
18 until the exchanged digests match.

|                  | Octet | Length |
|------------------|-------|--------|
| Type (5)         | 1     | 1      |
| Length (33)      | 2     | 1      |
| reserved         | 3     | 3 bits |
| V                | 3     | 1 bit  |
| A                | 3     | 2 bits |
| D                | 3     | 2 bits |
| Agreement Digest | 4–35  | 32     |

**Figure 28-4—SPB Digest sub-TLV**

- 19 a) Type (8 bits) Value 5
- 20 b) Length (8 bits)
- 21 Total number of bytes contained in the value field.
- 22 c) V (1 bit)
- 23 The Agreed Digest Valid Bit (13.27.7, 13.27.9). This bit is populated and read from the Agreement
- 24 Logic.
- 25 d) A (2 bits)
- 26 The agreement number 0–3, which aligns with BPDUs agreement number concept (13.27.11). When
- 27 the Agreement Digest for this node changes this number is updated and sent in the SPB Hello.
- 28 e) D (2 bits)
- 29 The discarded agreement number 0–3, which aligns with BPDUs agreement number concept
- 30 (13.27.12). When the Agreement Digest for this node changes this number is updated. Once an
- 31 Agreement has been sent it is considered outstanding until a matching or more recent Discarded
- 32 Agreement Number is received.
- 33 f) Agreement Digest (32 bytes)
- 34 An Agreement Digest as described in 28.4.

## 28.12.4 SPB Base VLAN-Identifiers sub-TLV

This sub-TLV (Figure 28-5) is included in an MT-Port-Cap TLV in an SPB Hello PDU to indicate the ECT Algorithms for the Base VIDs (and by implication the VID(s) used on the forwarding path for each SPT Set for a VLAN identified by a Base VID) that are in use. This information should be the same on all Bridges in the topology identified by the MT-Port-Cap TLV in which it is carried. Discrepancies between neighbors with respect to this sub-TLV are temporarily allowed during reconfiguration but at all times the active Base-VIDs (as determined by the state of the Use-Flag carried in this sub-TLV) shall agree and use the same ECT-ALGORITHM.

In the case of SPBM, the Base VID is the B-VID used to forward frames. In the case of SPBV, each source uses a different SPVID and a Base VID is used for frames transmitted on the IST. One or more Base VIDs are associated with an ECT Algorithm. This structure supports multiple SPT Sets within an IS-IS topology instance for both SPBV and SPBM. It also allows ECMP (Clause 44) for SPBM and the use of Explicit Trees (Clause 45) both for SPBV and SPBM within the same IS-IS topology instance supporting the SPT Sets.

|                    |               | Octet         | Length  |
|--------------------|---------------|---------------|---------|
| ECT-VID<br>Tuple 1 | Type (6)      | 1             | 1       |
|                    | Length (6n)   | 2             | 1       |
|                    | ECT Algorithm | 3–6           | 4       |
|                    | Base VID      | 7–8           | 12 bits |
|                    | U             | 8             | 1 bit   |
|                    | M             | 8             | 1 bit   |
|                    | reserved      | 8             | 2 bits  |
| ...                |               |               |         |
| ECT-VID<br>Tuple n | ECT Algorithm | (6n–3)–6n     | 4       |
|                    | Base VID      | (6n+1)–(6n+2) | 12 bits |
|                    | U             | 6n+2          | 1 bit   |
|                    | M             | 6n+2          | 1 bit   |
|                    | reserved      | 6n+2          | 2 bits  |

**Figure 28-5—SPB Base VLAN-Identifiers sub-TLV**

- a) Type (8 bits) Value 6
- b) Length (8 bits)  
The size of the value is ECT-VID Tuples\*6 bytes. Each 6-byte part of the ECT-VID tuple is formatted as described below.
- c) ECT-ALGORITHM (4 bytes)  
The ECT-ALGORITHM is advertised when the Bridge supports a given ECT-ALGORITHM (by OUI or CID/Index) on a given Base VID.
- d) Base VID (12 bits)  
The Base VID that is associate with the SPT Set.
- e) Use-Flag (1 bit)  
The Use-Flag is set if this Bridge, or any Bridge in the SPT Region is currently using this ECT-ALGORITHM and Base VID. The Use-Flag is calculated as the logical OR of the U-bit values of all Bridges in the region, as found in their SPB Instance sub-TLV (28.12.5) in the link state database. This definition includes the U-bit value of this Bridge.
- f) M-Bit (1 bit)  
The M-bit indicates if this is SPBM when set to 1 or SPBV mode when set to 0.
- g) 2 Reserved Bits set to 0.

## 28.12.5 SPB Instance sub-TLV

This sub-TLV (Figure 28-6) is carried within an MT-Capability TLV in the fragment ZERO LSP. It identifies the Bridge uniquely and identifies the ECT-ALGORITHM values supported by the Bridge and the Base VIDs and SPVIDs assigned to those algorithms. For SPBM, only the Base VID is valid and the SPVID is set to zero. In the case of SPBV, the Base VID is associated with the SPVID used for forwarding by the Bridge originating the TLV. There can be multiple ECT-ALGORITHM values specifying a number of ECTs. Alternatively, the ECT-ALGORITHM value can indicate that the VLAN is assigned to ECMP operation (Table 44-1) or to explicit path control (Table 45-1).

|                |                              | Octet           | Length  |
|----------------|------------------------------|-----------------|---------|
|                | Type (1)                     | 1               | 1       |
|                | Length                       | 2               | 1       |
|                | CIST Root Identifier         | 3–10            | 8       |
|                | CIST External Root Path Cost | 11–14           | 4       |
|                | Bridge Priority              | 15–16           | 2       |
|                | reserved                     | 17–18           | 11 bits |
|                | V                            | 18              | 1 bit   |
|                | SPSourceID                   | 18–20           | 20 bits |
|                | Number of Trees              | 21              | 1       |
| VID<br>Tuple 1 | U                            | 22              | 1 bit   |
|                | M                            | 22              | 1 bit   |
|                | A                            | 22              | 1 bit   |
|                | reserved                     | 22              | 5 bits  |
|                | ECT Algorithm                | 23–26           | 4       |
|                | Base VID                     | 27–28           | 12 bits |
|                | SPVID                        | 28–29           | 12 bits |
|                | ...                          |                 |         |
| VID<br>Tuple n | U                            | 8n+14           | 1 bit   |
|                | M                            | 8n+14           | 1 bit   |
|                | A                            | 8n+14           | 1 bit   |
|                | reserved                     | 8n+14           | 5 bits  |
|                | ECT Algorithm                | (8n+15)–(8n+18) | 4       |
|                | Base VID                     | (8n+19)–(8n+20) | 12 bits |
|                | SPVID                        | (8n+20)–(8n+21) | 12 bits |

**Figure 28-6—SPB Instance sub-TLV**

- a) Type (8 bits) Value 1
- b) Length (8 bits)  
Total number of bytes contained in the value field.
- c) CIST Root Identifier (64 bits)  
The CIST Root Identifier is for SPB interworking with RSTP and MSTP at SPT Region Boundaries. This is an imported value from a spanning tree.
- d) CIST External Root Path Cost (32 bits)  
The CIST External Root Path Cost is the cost from the spanning tree algorithm to the Root.
- e) Bridge Priority (16 bits)  
Bridge priority is the 16 bits that together with the low 6 bytes of the SPB System Identifier form the Bridge Identifier. The Bridge Identifier is the spanning tree compatible Bridge identifier. This is configured exactly as specified in IEEE Std 802.1D-2004 [B14]. This allows SPB to build a

compatible spanning tree using link state by combining the Bridge Priority and the SPB System Identifier to form the 8-byte Bridge Identifier. The 8-byte Bridge Identifier is also the input to the 16 pre-defined ECT tie-breaker algorithms.

f) V bit (1 bit)

The V bit (SPBM) indicates this SPSourceID is auto allocated (27.10). If the V bit is clear the SPSourceID has been configured and shall be unique. When a Bridge joining an SPT Region has formed at least one SPB adjacency, it can discover the previously allocated SPSourceIDs and it will allocate a SPSourceID according to the allocation logic (27.10).

g) SPSourceID (20 bits)

The SPSourceID (SPBM) is a 20-bit value used to construct group MAC address (27.15) for multicast frames originating from the origin (SPT Bridge) of the LSP that contains this sub-TLV. SPSourceID may be 0 if it has not been allocated (27.10) or if there is no SPBM service configured. When SPSourceID is 0 all information pertaining to this MTID SPB instance will be distributed but not acted upon until a valid SPSourceID is populated. If the SPSourceID conflicts with another SPSourceID from another Bridge the tie-breaker rules determine the winning Bridge (27.10).

h) Number of Trees (8 bits)

The Number of Trees is set to the number of VID tuples that follow (minimum one). The following seven fields make up a VID tuple. A sequence of VID tuples can occur in any order.

1) U-Bit (1 bit)

The U-bit is set if this Bridge is currently using this ECT-ALGORITHM for I-SIDs it sources or sinks or the SPVIDs it sources. This is importantly different from the Use-Flag found in the SPB Hello, which is set if a Bridge sees other nodal U-bits are set OR it sources or sinks itself.

2) M-Bit (1 bit)

The M-bit indicates if this is SPBM when set to 1 or SPBV mode when set to 0.

3) A bit (1 bit)

The A bit (SPB) when set declares this is an SPVID with auto allocation (27.10). If the SPVID value is zero, VID will be allocated once the Bridge has synchronized the IS-IS LSPs. Neighbor Bridges can distribute the LSPs but shall not populate FDBs (forwarding) for traffic from a Bridge that has an SPVID of 0. When the Bridge allocating is synchronized with the IS-IS adjacency, it will allocate one or more SPVIDs according to the allocation logic (27.10).

4) Reserved (5 bits)

Five bits reserved for future use shall be set to 0.

5) ECT-ALGORITHM (4 bytes)

ECT-ALGORITHM is advertised when the Bridge supports a given ECT-ALGORITHM (by OUI or CID/Index) on a given VID. This declaration shall match the declaration in the SPB Hello PDU originating from the same Bridge. When migrating from one algorithm to another discrepancies between algorithm and Base VID on different Bridges are allowed if the Use-Flag is clear.

6) Base VID (12 bits)

The Base VID that associated the SPT Set via the ECT-ALGORITHM.

7) SPVID (12 bits)

The SPVID is the Shortest Path VID when using SPBV mode. In SPBM mode it is not used and should be set to 0.

#### 28.12.6 SPB Instance Opaque ECT Algorithm sub-TLV

There are multiple ECT Algorithms defined for SPB, and in the future additional algorithms may be defined. These algorithms may use this optional sub-TLV (Figure 28-7) to carry new algorithm parameters, for example, tie-breaking data. There are two broad classes of ECT Algorithm: one which uses nodal data to

- 1 break ties and one which uses link data to break ties. This sub-TLV can associate opaque data with a node.
- 2 This sub-TLV is carried in an MT-Capability TLV in an LSP (along with a valid SPB Instance sub-TLV).
- 3 Multiple copies of this sub-TLV may be carried for different ECT-ALGORITHM values related to the node.

|                 | Octet        | Length   |
|-----------------|--------------|----------|
| Type (2)        | 1            | 1        |
| Length          | 2            | 1        |
| ECT-ALGORITHM   | 3–6          | 4        |
| ECT Information | 7–(Length+2) | variable |

**Figure 28-7—SPB Instance Opaque ECT-ALGORITHM sub-TLV**

- 4 a) Type (8 bits) Value 2
- 5 b) Length (8 bits)
- 6 Total number of bytes contained in the value field.
- 7 c) ECT-ALGORITHM (4 bytes)
- 8 ECT-ALGORITHM is advertised when the Bridge supports a given ECT-ALGORITHM (by OUI or
- 9 CID/Index) on a given VID.
- 10 d) ECT Information (variable)
- 11 ECT-ALGORITHM Information of variable length.

#### 12 28.12.6.1 ECMP ECT Algorithm sub-TLV

13 This TLV (Figure 28-8) is not required for SPBM symmetric ECT operation and is optional for SPBM  
 14 ECMP. This sub-TLV can be used to advertise a Bridge Priority value (most significant 2 bytes of the Bridge  
 15 Identifier) to be used in shared tree root Bridge selection (44.1.2) when using the normal Bridge Priority  
 16 (13.26.2) will not produce the desired result. Since Bridge Priority influences both source rooted tree  
 17 structure and shared tree root selection, this optional sub-TLV is provided for situations in which the desired  
 18 outcome for both of these selections cannot be achieved using a single Bridge Priority. This sub-TLV  
 19 associates an alternate Bridge Priority [item c) in 12.25.14.1.2] with a node for use with a particular  
 20 Tie-Break Mask. The alternate Bridge Priority is used instead of the normal Bridge Priority when the  
 21 associated Tie-Break Mask is used to select a shared tree root Bridge. This enables greater control over root  
 22 Bridge selection for shared trees, when needed. This sub-TLV is carried in an MT-Capability TLV in an LSP  
 23 (along with a valid SPB Instance sub-TLV).

|         |                             | Octet         | Length |
|---------|-----------------------------|---------------|--------|
| Tuple 1 | Type (2)                    | 1             | 1      |
|         | Length                      | 2             | 1      |
|         | ECT-ALGORITHM (00-80-C2-11) | 3–6           | 4      |
|         | Tie-Break Mask              | 7             | 4 bits |
|         | reserved                    | 7             | 4 bits |
| ...     | Bridge Priority             | 8–9           | 2      |
|         |                             |               |        |
|         |                             |               |        |
| Tuple n | Tie-Break Mask              | (3n+4)        | 4 bits |
|         | reserved                    | (3n+4)        | 4 bits |
|         | Bridge Priority             | (3n+5)–(3n+6) | 2      |

**Figure 28-8—ECMP ECT-ALGORITHM sub-TLV**

- 24 a) Type (8 bits) Value 2
- 25 b) Length (8 bits)
- 26 Total number of bytes contained in the value field.
- 27 c) ECT-ALGORITHM (4 bytes)

- 1 ECT-ALGORITHM is 00-80-C2-11 for ECMP.
- 2 d) Tie-Break Mask (4 bits)
- 3 A 4-bit mask that is repeated to form a 64-bit mask used in selecting the low Bridge Identifier from
- 4 a set of Bridge Identifiers. This selection process is used to select a shared tree root Bridge.
- 5 e) Bridge Priority (16 bits)
- 6 Bridge priority is the 16 bits that together with the low 6 bytes of the SPB System Identifier form the
- 7 Bridge Identifier. This Bridge Priority is used to form the Bridge Identifier used to select a shared
- 8 tree root bridge using the mask identified by the accompanying Tie-Break Mask field.

## 9 28.12.7 SPB Link Metric sub-TLV

10 This sub-TLV (Figure 28-9) is included in an Extended IS Reachability TLV (type 22) [IETF RFC 5305] or

11 MT Intermediate Systems TLV (type 222) [IETF RFC 5120]. If this sub-TLV is not present for an IS-IS

12 adjacency then that adjacency must not carry SPB traffic for the given topology instance. The maximum

13 metric value ( $2^{24} - 1$ ) signifies that the link shall not be used for SPB traffic (it is treated as “SPB

14 operationally down”).

15 NOTE—In ECMP the elimination of symmetry requirements could allow the use of a different metric for each link

16 direction; however, to maintain consistency ECMP shortest path algorithms continue to use the maximum metric value

17 in cases where the metrics advertised by adjacent nodes for a given link are different.

|                 | Octet | Length |
|-----------------|-------|--------|
| Type (29)       | 1     | 1      |
| Length (6)      | 2     | 1      |
| SPB Link Metric | 3–5   | 3      |
| Number PORTs    | 6     | 1      |
| Port Identifier | 7–8   | 2      |

**Figure 28-9—SPB Link Metric sub-TLV**

- 18 a) Type (8 bits) Value 29
- 19 b) Length (8 bits)
- 20 Total number of bytes contained in the value field.
- 21 c) SPB Link Metric (24 bits)
- 22 This indicates SPB Link Metric the administrative cost or weight of using this link as a 24-bit
- 23 unsigned number. Smaller numbers indicate lower weights and are more likely to carry SPB traffic.
- 24 Only one metric is allowed per SPB instance per link. If multiple metrics are required multiple SPB
- 25 instances are required, either within IS-IS or within several independent IS-IS instances. If there are
- 26 multiple links the metric for all links are the same.
- 27 d) Number PORTs (8 bits)
- 28 Number PORTs is the number of Port identifiers associated with this link.
- 29 e) Port Identifier (16 bits)
- 30 Port Identifier is the unique Port identifier comprising two parts, the Port Number and the Port
- 31 Priority field (13.27.47).

## 32 28.12.8 SPB Adjacency Opaque ECT Algorithm sub-TLV

33 There are multiple ECT Algorithms defined for SPB, and in the future additional algorithms may be defined.

34 The SPB Adjacency Opaque ECT Algorithm sub-TLV (Figure 28-10) may be included in an Extended IS

35 Reachability TLV (type 22) or MT Intermediate System TLV (type 222) to carry new algorithm parameters

36 associated with an adjacency. Multiple copies of this sub-TLV may be carried for different ECT Algorithms

37 related to the adjacency.

1

|                 | Octet        | Length   |
|-----------------|--------------|----------|
| Type (30)       | 1            | 1        |
| Length          | 2            | 1        |
| ECT-ALGORITHM   | 3–6          | 4        |
| ECT Information | 7–(Length+2) | variable |

**Figure 28-10—SPB Adjacency Opaque ECT-ALGORITHM sub-TLV**

- a) Type (8 bits) Value 30
- b) Length (8 bits)  
Total number of bytes contained in the value field.
- c) ECT-ALGORITHM (4 bytes)  
ECT-ALGORITHM is advertised when the Bridge supports a given ECT-ALGORITHM (by OUI or CID/Index) on a given VID.
- d) ECT Information (variable)  
ECT-ALGORITHM Information of variable length.

#### 28.12.9 SPBV MAC address sub-TLV

The SPBV MAC Address sub-TLV (Figure 28-11) is carried in an MT-Capability TLV in an LSP. It should be used for advertisement of group MAC addresses in SPBV mode. Individual MAC addresses will normally be distributed by reverse path learning, but carrying them in this sub-TLV is not precluded. It has the following format:

|                        |             | Octet         | Length  |
|------------------------|-------------|---------------|---------|
| MAC Address<br>Tuple 1 | Type (4)    | 1             | 1       |
|                        | Length      | 2             | 1       |
|                        | reserved    | 3             | 2 bits  |
|                        | S-R         | 3             | 2 bits  |
|                        | SPVID       | 3–4           | 12 bits |
|                        | T           | 5             | 1 bit   |
|                        | R           | 5             | 1 bit   |
|                        | reserved    | 5             | 6 bits  |
|                        | MAC Address | 6–11          | 6       |
| MAC Address<br>Tuple n | ...         |               |         |
|                        | T           | (7n–2)        | 1 bit   |
|                        | R           | (7n–2)        | 1 bit   |
|                        | reserved    | (7n–2)        | 6 bits  |
|                        | MAC Address | (7n–1)–(7n+4) | 6       |

**Figure 28-11—SPBV MAC Address sub-TLV**

- a) Type (8 bits) Value 4
- b) Length (8 bits)  
Total number of bytes contained in the value field.
- c) SR bits (2 bits)  
The SR bits are the service requirement parameter from MMRP. The service requirement parameters have the value 0 (Forward all Groups) (10.12.1.7) and 1 (Forward All Unregistered Groups) defined. However, this attribute may also be missing. So the SR bits are defined as 0 not declared, 1 Forward all Groups and 2 Forward All Unregistered Groups.

- 1 d) SPVID (12 bits)  
2 This is the SPVID and by association Base VID and the ECT-ALGORITHM and SPT Set that the  
3 MAC addresses defined below will use. If the SPVID is not allocated the SPVID Value is 0.  
4 NOTE—If the ECT algorithm in use is a spanning tree algorithm, this value should be populated with the Base  
5 VID.
- 6 e) T Bit (1 bit)  
7 This is the Transmit allowed Bit for the following group MAC address. This is an indication that  
8 SPBV group MAC address with SPVID of source should be populated (for the Bridge advertising  
9 this Group MAC), and installed in the FDB of transit Bridges, when the Bridge computing the trees  
10 is on the corresponding ECT-ALGORITHM shortest path between the Bridge advertising this group  
11 MAC address with the T bit set, and any receiver of this group MAC address. A Bridge that does not  
12 advertise this bit set for a group MAC address should have no forwarding state installed for traffic  
13 originating from that Bridge on other transit Bridges in the network.
- 14 f) R Bit (1 bit)  
15 This is the Receive allowed Bit for the following group MAC address. This is an indication that  
16 SPBV group MAC addresses as receiver should be populated (for Bridges advertising this group  
17 MAC address with the T bit set) and installed when the Bridge computing the trees lies on the  
18 corresponding shortest path for this ECT-ALGORITHM between this receiver and any transmitter  
19 on this group MAC address. An entry that does not have this bit set for an group MAC address is  
20 prevented from receiving on this group MAC address because transit Bridges will not install  
21 multicast forwarding state towards it in their FDBs or the traffic is explicitly filtered.
- 22 g) MAC Address (48 bits)  
23 The MAC Address is either a group address or an individual address. When the MAC address is a  
24 group address it declares this Bridge as part of the multicast interest for this destination MAC  
25 address. Multicast trees can be efficiently constructed for destination by populating Group Address  
26 FDB entries for the subset of the SPT that connects the Bridges supporting the multicast address.  
27 This replaces the function of MMRP for SPTs. The T and R bits above have meaning if this is a  
28 group address. Individual addresses are populated only as if the R bit was set. (Note that individual  
29 addresses could also be learned normally.)

#### 30 **28.12.10 SPBM Service Identifier and Unicast Address (ISID-ADDR) sub-TLV**

31 This sub-TLV (Figure 28-12) declares an individual B-MAC address and maps I-SIDs in the context of a  
32 B-VID to that B-MAC, allowing automatic creation of efficient group trees that are subsets of the SPT  
33 rooted at the node identified by that individual B-MAC address. In a symmetric ECT environment, the  
34 I-SIDs are mapped to a B-VID that is associated with a symmetric ECT Algorithm specifying the SPT Set.  
35 In ECMP the I-SIDs are mapped to a B-VID that is associated with the ECMP ECT Algorithm, which may  
36 specify a source rooted SPT or a shared tree for group addressed frames. Multicast trees can be selected per  
37 I-SID for maximum diversity. In the case of explicit trees, the I-SID is mapped to a B-VID allocated to one  
38 of the explicit ECT Algorithms (Table 45-1), and the B-MAC can be either an Individual MAC address or  
39 null. The null value indicates that the Backbone Service Instance Group address (26.4) is used by all sources  
40 of multicast traffic onto the given I-SID in (\*,G) mode on one simple tree as specified in 45.1.5. This  
41 sub-TLV is carried in an MT-Capability TLV in an LSP.

- 42 a) Type (8 bits) Value 3  
43 b) Length (8 bits)  
44 Total number of bytes contained in the value field.

|                  |                | Octet          | Length  |
|------------------|----------------|----------------|---------|
|                  | Type (3)       | 1              | 1       |
|                  | Length         | 2              | 1       |
|                  | B-MAC Address  | 3–8            | 6       |
|                  | reserved       | 9              | 4 bits  |
|                  | Base VID       | 9–10           | 12 bits |
| I-SID<br>Tuple 1 | T              | 11             | 1 bit   |
|                  | R              | 11             | 1 bit   |
|                  | Ts             | 11             | 1 bit   |
|                  | reserved       | 11             | 1 bit   |
|                  | Tie-Break Mask | 11             | 4 bits  |
|                  | I-SID          | 12–14          | 3       |
|                  | ...            |                |         |
| I-SID<br>Tuple n | T              | (4n+7)         | 1 bit   |
|                  | R              | (4n+7)         | 1 bit   |
|                  | Ts             | (4n+7)         | 1 bit   |
|                  | reserved       | (4n+7)         | 1 bit   |
|                  | Tie-Break Mask | (4n+7)         | 4 bits  |
|                  | I-SID          | (4n+8)–(4n+10) | 3       |

**Figure 28-12—SPBM Service Identifier and Unicast Address sub-TLV**

- 1 c) B-MAC Address (48 bits)
- 2 B-MAC Address is an individual MAC address on this Bridge. It may be either the single nodal
- 3 address, or may address a port or any other level of granularity relative to the Bridge. In the case
- 4 where the Bridge only has one B-MAC address this may be the same as the MAC address portion
- 5 SPB System Identifier of the Bridge. To add multiple B-MAC addresses, this sub-TLV shall be
- 6 repeated for each additional B-MAC address.
- 7 Each individual MAC address has one or more I-SIDs that are associated with this address. In PBB
- 8 terms this corresponds to a PIP B-MAC address. All B-MAC addresses that are used for individual
- 9 MAC addresses and for the Sources of Group MACs shall be associated with at least one I-SID. This
- 10 sub-TLV is initiated by IB-BEBs.
- 11 d) Base VID (12 bits)
- 12 The Base VID identifies the B-VID and by association the ECT-ALGORITHM and SPT Set that the
- 13 I-SIDs defined below will use.
- 14 e) T Bit (1 bit)
- 15 This is the Transmit allowed Bit for the following I-SID. This is an indication that a group MAC
- 16 Address Registration Entry (8.8.4) for this I-SID as source should be constructed and installed in the
- 17 FDB of a Bridge, if the Bridge is on the corresponding ECT-ALGORITHM path between the Bridge
- 18 advertising this I-SID with the T bit set and any receiver of this I-SID. A Bridge that does not
- 19 advertise this bit or the Ts bit set for an I-SID should have no forwarding state installed for traffic
- 20 originating from that Bridge on other Bridges in the network.
- 21 f) R Bit (1 bit)
- 22 This is the Receive allowed Bit for the following I-SID. This is an indication that a group MAC
- 23 Address Registration Entry (8.8.4) for this I-SID as receiver should be constructed and installed (for
- 24 Bridges advertising this I-SID with the T bit or Ts bit set) if a Bridge lies on the corresponding path
- 25 for this ECT-ALGORITHM between this receiver and any transmitter on this I-SID. An entry that
- 26 does not have this bit set for an I-SID is prevented from receiving on this group MAC addresses for
- 27 this I-SID because Bridges will not install multicast forwarding state towards it in their FDBs.

g) Ts Bit (1 bit)

The Ts bit indicates that this I-SID source uses a shared tree for multicast frames. The group MAC address for this I-SID source is constructed using the Tie-Break Mask and the I-SID (27.15, Figure 27-6). A group MAC Address Registration Entry (8.8.4) is installed in any bridge on the shared tree, selected by the Tie-Break Mask, between the advertising bridge and bridges that have the R bit set for the same I-SID. If both the T bit and Ts bit are set, the Ts bit takes precedence. This bit is ignored by ECT-ALGORITHM values in Table 28-1.

h) Tie-Break Mask (4 bits)

A 4-bit mask that is repeated to form a 64-bit mask used in selecting the low Bridge Identifier from a set of Bridge Identifiers. This selection process is used in multicast tree calculations to select a shared tree root Bridge and parent nodes in SPTs where equal cost paths are available. This field is ignored by ECT-ALGORITHMS in Table 28-1.

i) I-SID (24 bits)

I-SID is the 24-bit group service membership identifier. If two Bridges have an I-SID in common, intermediate Bridges on the unique shortest path between them will create forwarding state for the related B-MAC addresses. They will also construct multicast forwarding state using the I-SID and the Bridge's SPSrcID to construct a multicast DA. Each I-SID has a Transmit (T) and Receive (R) bit that indicates if the membership is as a Transmitter/Receiver or both (with both bits set). In the case where the Transmit (T) and Receive (R) bits are both zero, the I-SID is ignored (this forces a point-to-point capability that does not require Group address installation, but the advertised individual B-MAC address shall be processed and installed if required on the SPT). If more I-SIDs are associated with a particular B-MAC address than can fit in a single sub-TLV, this sub-TLV can be repeated with the same B-MAC address and MTID but with additional I-SID values. I-SID values can be in any order. Duplicate I-SIDs for a B-MAC address are allowed (within a sub-TLV, across two or more sub-TLVs, across two or more LSP fragments, or even across two or more LSPs). If the duplicates are in different B-VIDs, they are processed; otherwise, the T and R bits processed are the logical OR of the T and R bits of the two entries and it is processed as a single entry. (I-SID=0 is an exception that is always ignored, and allows a fast method to remove an I-SID without restructuring all the LSPs). Repacking an LSP (when I-SID=0 entries should be collapsed) can be done by moving entries from the high end into the empty I-SID=0 entries. To avoid outages temporary duplicates are allowed during this repacking and the entry further up in the LSP may later be removed without impact. The I-SID value 0x0000ff is reserved for SPB broadcast to all Bridges.

Item d), item h), and item i) are set to zero on transmit and ignored on receipt for SPBM symmetric ECT operation.

## 1 29. DDCFM operations and protocols

### 2 29.1 Principles of DDCFM operation

3 Data-driven and data-dependent connectivity fault management (DDCFM) comprises tools to facilitate the  
4 diagnosis and isolation of data-driven and data-dependent faults (DDFs) in Virtual Bridged Networks. This  
5 clause describes the functions of DDCFM and how they can be operated and managed. DDCFM is an  
6 extension to CFM specified by Clause 18 through Clause 22. As in the case of CFM, DDCFM capabilities  
7 can be used in networks operated by multiple independent organizations, each with restricted management  
8 access to others' equipment.

#### 9 29.1.1 Data-driven and data-dependent faults (DDFs)

10 There are two broad types of faults in Virtual Bridged Networks that affect only certain frames or sequences  
11 of frames. Simple data-dependent faults are those that result in the repetitive loss or misdirection of each of  
12 those frames, independently of any other frames, and are usually the result of simple misconfiguration or of  
13 a failure to appreciate the consequences of a configuration option (installing protocol-specific filters, for  
14 example). Data-driven faults are more complex: the presence (or absence) of some data frames causes or  
15 contributes to the loss of other frames. While the services supported by Virtual Bridged Networks are  
16 conceptually data independent, the use of data-driven techniques enables enhanced service delivery. To give  
17 three examples: multicast frame filtering and consequent bandwidth saving is facilitated by Internet Group  
18 Membership Protocol (IGMP) snooping; stateful firewalls are used to protect users connected to managed  
19 services; and efficient allocation of frames to the individual links of an aggregation (IEEE 802.1AX Link  
20 Aggregation) is often based on spotting conversations by looking at frame data.

#### 21 29.1.2 Basic principle to diagnose and isolate DDFs

22 The basic principle to diagnose DDFs is to isolate them to a small enough segment of the network, such as a  
23 Bridge Port, a member port of Link Aggregation Group (LAG) within a Bridge Port, or a LAN. Once DDFs  
24 are isolated, understanding the cause of the fault at this location becomes much easier.

25 The basic procedure to achieve isolation of a DDF is to divide the network into segments and determine  
26 whether certain data frames can traverse through each segment as expected. When a network segment is  
27 identified as faulty, the segment is further divided into smaller segments until a Bridge, a Bridge Port, or a  
28 member port of LAG within a Bridge Port is identified as not passing data frames as expected.

29 A DDF may not be apparent in the absence of live traffic (that is, when test data are used). DDCFM is  
30 designed to carry out the diagnosis while live traffic is being exchanged.

31 DDCFM facilitates diagnosis and consequent isolation of DDFs with the following two techniques: forward  
32 path test (FPT) and return path test (RPT).

##### 33 29.1.2.1 Forward path test (FPT)

34 The goal of FPT, as depicted in Figure 29-1, is to determine whether specified data frames (frames  
35 associated with a service instance, or data frames with certain destination addresses or VID, etc.) can reach a  
36 particular location (which could be a Bridge Port, or a member port of LAG within a Bridge Port) without  
37 error. FPT's Reflection Responder (RR) (29.2.2) reflects the identified data frames (e.g., a service instance  
38 or selected data frames) to a specific target location, which could be an end station, a Bridge, or a test device.  
39 The data frames to be reflected can also be continued to their original destination(s). This option, called the  
40 Continue option throughout this standard, is to support testing of a data stream in a manner transparent to the  
41 application sourcing or sinking that data stream.

**Figure 29-1—Forward path test (FPT)**

1 FPT can be configured on ports where no MPs exist. However, when they are implemented within MPs or  
2 configured on ports with MPs, better fault isolation can be achieved. For example, if the target location does  
3 not receive the expected reflected data frames in the specified time span, it can send a LBM (21.7) to verify  
4 the connectivity between the Target location and the MP on which the RR (29.2.2) is configured. For a  
5 network that supports MEPs but not MIPs, FPT can be used to diagnose segment connectivity by  
6 configuring an RR on an intermediate node to encapsulate the received CCM in RFM format (29.4.2) and  
7 forward them to a target location.

8 The receiver at the target location records the reflected frames for examination by the operator and may also  
9 transfer the reflected frames to an analysis function. Some examples of target location analyzers are as  
10 follows: comparing the reflected frames with the original ones to verify if there are any errors, running a  
11 proxy application at the target location to simulate the handshakes as if those frames actually reach their  
12 original destinations, etc.

13 As in CFM (Clause 18 through Clause 22), a network operator can only set or activate FPT's RR within its  
14 own maintenance domain. At the customer's request, a network provider may use DDCFM to verify  
15 whether DDFs occur within its domain. FPT's RR (29.2.2) can only be created or activated by a network  
16 provider's own Network Management System via secure interface. Therefore, customers or other operators  
17 cannot set an FPT RR (29.2.2) in a maintenance domain that does not belong to them.

18 In order for intermediate Bridges and/or a target location to distinguish the reflected data frames from other  
19 traffic, each reflected frame is encapsulated with an RFM header. The RFM header added to the reflected  
20 data frame carries the same Maintenance Domain level associated with the RR, so that the reflected data  
21 frames, each encapsulated with a proper RFM header, are contained within the same Maintenance Domain.  
22 The target location has to be in the same maintenance domain to receive the RFMs.

23 Depending on the conditions specified for selecting data frames to be reflected, some conditions can cause  
24 large amount of data frames to be reflected. If there are multiple locations within a network reflecting a large  
25 number of data frames simultaneously, excessive traffic could be added to some segments of the network,  
26 which may impact network performance. To avoid excessive traffic being added to the network by an RR,  
27 this standard recommends only one RR be activated at a time within one maintenance domain.

28 FPT consists of RR configuration, the action to reflect identified data frames, and the analysis of the  
29 reflected data frames. The last step, i.e., analysis of the reflected data frames, is beyond the scope of this  
30 standard.

### 29.1.2.2 Return path test (RPT)

The RPT is to determine whether a flow of data frames can be sent without error from a specific location within a network to a station or stations specified by the destination\_address associated with each of the frames under test. The RPT is achieved by an originating station encapsulating each frame of the flow under test with an SFM header, a DR (29.2.6) removing the SFM header, optionally placing its own MAC in the source\_address field of the decapsulated data frames, and sending the data frames to a station or stations as specified by the destination\_address field. By default, RPT's DR places its own MAC address in the source\_address field of the decapsulated data frames before sending them out. However, a network operator can force a DR not to change the source\_address field of the decapsulated data frame before sending it out to conduct special purpose testing.

The RPT allows a network operator to inject specific data frames into the network for testing purposes. To prevent one network operator from injecting traffic to other networks, it is necessary for the associated managed object to be created under secure mode and for SFM originator to be in the same Maintenance Domain as the MP on which DR is defined.

The Figure 29-2 illustrates a simple case of injected traffic from Node B to reach Node A. Multiple data frames can be injected and injected data frames could have different addresses or multicast addresses in their corresponding destination\_address field.

**Figure 29-2—Return path test (RPT)**

The RPT consists of the DR configuration, the sending of SFMs, the action to decapsulate and forward, and the analysis of the received data frames at their destination(s). The last step, i.e., the analysis of the received data frames at their destination(s), is beyond the scope of this standard.

### 29.1.2.3 Derived testing scenarios

FPT and RPT can be used together in various ways to achieve more sophisticated testing to diagnose and isolate DDFs. It is beyond the scope of this standard to elaborate different ways of combining FPT and RPT. This subclause only illustrates one example of using both FPT and RPT.

Figure 29-3 shows how to achieve segment fault isolation in the middle of a network using FPT and RPT together. By creating a DR and RR on two Bridge Ports in the middle of a network, a network operator can test whether the specified data frames can traverse through the segment. This type of testing is especially useful to diagnose DDFs out of firewall. This type of testing can also be used to diagnose a connectivity fault between two intermediate Bridge Ports (or two MIPs) by setting the RR filter (29.2.2.1) to the specified CCMs.

**Figure 29-3—Combination of FPT and RPT**

## 29.2 DDCFM Entity operation

This subclause specifies the following:

- a) FPT RR
- b) FPT RFM Receiver
- c) RPT DR
- d) RPT frames' SFM Originator

### 29.2.1 DDCFM implementation

The DDCFM protocol is performed by the RR, the DR, the RFM Receiver, and the SFM Originator. All of these entities are created and activated by operator commands. The operation of RR, DR, and SFM Originator are timer limited.

Both RFMs and SFMs are CFM PDUs and their format is described in 21.4 and 29.4. They are forwarded in the same way as regular CFM messages. An MEP at higher MD level shall drop the received RFMs and SFMs. An MEP at the same level shall process, but not forward, RFMs and SFMs received from its Active SAP, and shall drop RFMs/SFMs received from its Passive SAP. An MHF shall always forward RFMs/SFMs received from its SAPs and shall also process those at the same MD level received from its Active SAP.

The RR, RFM Receiver, DR, and SFM originator are CFM entities that are associated with a specific MD, enabling access only to the administrators of this MD. They can be placed at any point in the network that is bounded by any DoSAP of their corresponding MDs. Their relationship to MPs is guided by the MP component entities that the DDCFM entities also require. In particular, the RR does not require any of the MP's sub-functions (19.2 and 19.3) and correspondingly it is defined as an independent CFM shim. It can be placed at any Bridge Port bounded by the DoSAP of the RR's associated MD. It does not even require the EISS Multiplex Entity (6.17) or Backbone Service Instance Multiplex Entity (6.18). The same holds true for an SFM Originator. Note that both of them transmit CFM frames that are associated with a specific MA but the creation of these DDCFM entities themselves is not associated with an MA. This in practice means that one RR or SFM Originator can send RFMs or SFMs (respectively), which are associated with different MAs than the encapsulated frames. The other two DDCFM entities have a number of common subentities to the MPs. In particular, on top of their unique (MP) RFM Receiver and (MP) Decapsulator Responder state

machines, they require the functions provided by the Type Demultiplexer, Level Demultiplexer, and the OpCode Demultiplexer. In addition if the service is VLAN based, they also require the EISS Multiplex Entity. All of these make the implementation of the RFM receiver or the DR very simple in the case of an MP where they can reuse the MP component entities and provide the additional functions required by the MP RFM Receiver or MP Decapsulator Responder entities. Implementing these DDCFM entities on non-MPs would require all the previously mentioned MP subentities. Figure 29-5 shows an MP-independent RFM Receiver and Figure 29-6 shows an MP-independent DR. On the other hand, implementing these DDCFM entities on MPs would require only the addition of the MP Decapsulator Responder and MP RFM Receiver component entities in the MP architecture with the appropriate changes in the Opcode Demultiplexer as specified in 19.2 and 19.3.

## 29.2.2 FPT RR

The RR is a CFM protocol shim for filtering frames to be reflected, copying the filtered frames to the Passive SAP if the Continue option is set, and encapsulating each filtered frame with the RFM header (29.4.2). For an interface supporting DDCFM, an RR shim shall be allowed at EISS/ISS SAPs where MPs are allowed on the protocol stack shown in Figure 22-4, Figure 22-8, Figure 26-2, and Figure 26-8. By placing an RR shim on an aggregated port within a Bridge Port, the RR can reflect data frames from an member link of a LAG to test if specific data frames can go through the link.

The Figure 29-4 illustrates the component entities of an RR.

Figure 29-4—Detailed functions of RR

### 29.2.2.1 RR Filter

The RR Filter function within the RR filters frames from Active SAP that match the Reflection Filtering definition(s) [item b2) in 29.2.3]. When the RR is active and the sampling interval has expired, a frame that matches the Reflection Filter definition(s) is sent to RR Encapsulation to be reflected. A frame is passed to the Passive SAP when RR is not active, the frame does not match the Reflection Filter definition(s), or the Continue option is true.

1 To prevent data frames from being reflected multiple times within a network, RFM frames cannot be  
2 reflected. An RR Filter definition implicitly includes the condition of the OpCode in common CFM header  
3 not equal to RFM, in addition to all other conditions specified.

#### 4 **29.2.2.2 RR Encapsulation**

5 The RR Encapsulation function within the RR is for encapsulating the filtered frame with the appropriate  
6 RFM header. If a sampling interval is specified, once a frame meeting the Reflection Filtering definitions is  
7 identified within one sampling interval, no more frames shall be encapsulated until the next sampling  
8 interval starts.

#### 9 **29.2.2.3 RR Transmit**

10 RR Transmit identifies the egress port by querying FDB and forwards the RFM frames to the LOM entity of  
11 the identified egress port. The query uses the Reflection Target address [item b3) in 12.17.2.1.2] and the  
12 vlan\_identifier associated with the RFM [item c) in 29.3.3.3]. If there is no vlan\_identifier associated with  
13 the RFM, the PVID value of the port where RR is configured is used. If an egress port cannot be identified  
14 and the FloodingEnabled flag of the RR is true, then the RFM frame is sent to the LOM entity on every port  
15 associated with the VID set of the RFM frame. If the FloodingEnabled flag of the RR is false and an egress  
16 port cannot be identified, the RFM frame is dropped.

### 17 **29.2.3 RR-related parameters**

#### 18 **29.2.3.1 RR identification**

19 An RR is identified by the interface upon which the RR is created, a Maintenance Domain that identifies the  
20 administrative boundaries, and a value indicating the direction (Up or Down) in which the RR is facing. The  
21 interface upon which the RR is created can be a Bridge Port or a member port of a LAG of a Bridge Port.

#### 22 **29.2.3.2 MA for RR**

23 The primary VID associated with RR's MA is in the RFM emitted by the RR. When MA for an RR is set to  
24 0, then the VID of the filtered frame are used in the corresponding RFM.

#### 25 **29.2.3.3 RR Filter definition**

26 The RR Filter is for selecting data frames to be reflected. Multiple filters can be combined together by "&&  
27 (and)", "|| (or)", or "! (negation)" operations.

28 All Bridges supporting DDCFM shall support the following reflection filters (and may support additional  
29 Reflection Filters):

- 30 a) Reflect All—all frames are selected.
- 31 b) VLAN-based selection—all data frames associated with the specified VID are selected.
- 32 c) Destination address-based selection—all data frames with the specified destination address are  
33 selected.
- 34 d) Source address-based selection—all data frames with the specified source address are selected.
- 35 e) EtherType.

#### 1 **29.2.3.4 Sampling interval**

2 The sampling interval controls the maximum rate at which frames can be reflected. If no sampling interval is  
3 set, then all frames that arrive while the RR is active and match the filter criteria are reflected. If a sampling  
4 interval is specified then the first matching frame that arrives during the interval is reflected, other matching  
5 frames arriving in that interval are not reflected.

#### 6 **29.2.3.5 Continue option**

7 The Continue option [item b5) in 12.17.2.2.2] allows the selected data frames to be continued to their  
8 original destinations by making a copy of the selected frames to be reflected.

9 The Continue option is set to be true by default, which means that the selected data frames are branched to  
10 two directions—one direction to the RR Encapsulation function, and the other direction to the passive SAP.  
11 When the Continue option is set to be false, the selected frames shall only be forwarded to the RR  
12 Encapsulation function.

#### 13 **29.2.3.6 Duration for RR to remain active**

14 Reflecting data frames back into network can create extra traffic in the network. To prevent this action  
15 running forever, a duration [item b7) in 12.17.2.2.2] is used to limit the maximum amount of time for the RR  
16 to be running. Operator can also specify the maximum number of frames to be reflected. Once activated, RR  
17 shall remain active until either its specified duration expires or the maximum number of frames reflected is  
18 reached, whichever comes first. An active RR can also be deactivated by operator command before its  
19 duration expires.

#### 20 **29.2.3.7 Truncation flag**

21 If the received data frame causes the RFM encapsulated frame to exceed the Maximum Service Data Unit  
22 Size (6.5.8), either the data frame is truncated, or the data frame is split into two smaller frames and those  
23 two smaller frames are encapsulated by two separate RFM frames. If the Truncation flag is set to be true, the  
24 data frame shall be truncated to be encapsulated in one RFM.

#### 25 **29.2.4 Reflection Target and RFM Receiver**

26 The Reflection Target is where the RFM encapsulated reflected frames are forwarded to. The RFM Receiver  
27 is a function running on a Reflection Target to pass the received RFMs to their corresponding analyzers.

28 The Reflection Target has to be within the same Maintenance Domain as the RR in order to receive the RFM  
29 encapsulated data frames.

30 When an RFM Receiver is defined on a Bridge interface that does not support MP, the RFM Receiver is  
31 implemented as a separate CFM entity, as depicted in Figure 29-5 for receiving RFMs from Active SAP. It  
32 requires a number of the component entities that are required by an MP. If the RFMs are associated with a  
33 VID-based MA, the RFM receiver needs to be placed in a demultiplexer SAP provided by an EISS  
34 multiplex entity (6.17).

#### 35 **29.2.5 RPT-related parameters**

36 RPT configuration has two parts: one part is to configure SFM Originator and the other part is to configure  
37 DR.

**Figure 29-5—RFM Receiver on a non-MP**

## 29.2.6 Decapsulator Responder (DR)

The DR decapsulates SFMs and sends the decapsulated frames toward destinations specified by the destination\_address field of the decapsulated data frames. Under normal circumstance, the source\_address field of the decapsulated frame is replaced by the DR's own MAC address to avoid confusing other Bridges' learning in the network. However, a network operator can enforce the DR not to modify the source\_address field of the decapsulated frame for special purpose fault diagnosis. The DR configuration is specified in 12.17.4.1.

DR shim shall be allowed at EISS/ISS SAPs where MPs are allowed on the protocol stack shown in Figure 22-4, Figure 22-8, Figure 26-2, and Figure 26-8.

Multiple DRs can be created on one Bridge interface to receive SFMs at different MD levels or SFMs originated from different SFM Originators.

When an SFM is received by an active DR, it is examined for validity and discarded if invalid. If valid, the received SFM shall be decapsulated. The source\_address field of the decapsulated frame is replaced by DR's own MAC address unless SourceAddressStayFlag is set. The modified frame shall be used to identify the egress port by querying the FDB. The query uses the destination\_address and vlan\_identifier values of the decapsulated data frame. If the decapsulated frame is untagged, the PVID value of the port where DR is configured is used. The Boolean FloodingEnabled flag of the DR indicates if the frame is to be flooded or discarded if an egress port cannot be identified by FDB. Figure 29-6 illustrates the detailed functions of DR. DR shim can be placed at any places where MPs are allowed on the protocol stack as shown in Figure 22-8.

Figure 29-6—Return Path DR

## 29.2.7 SFM Originator

SFM Originator is for generating SFMs and sending the SFMs to the corresponding DR. Each SFM encapsulates one data frame. The SFM Originator configuration is specified in 12.17.5.1.

The Bridge interface on which SFM Originator is created does not have to support any MP. However, the SFM Originator has to be configured with the same Maintenance Domain level as the DR, so that the SFM can be forwarded to the DR. It is beyond the scope of this standard to address how SFMs are generated.

## 29.3 DDCFM protocols

This subclause specifies the DDCFM protocols in terms of a number of state machines, the variables and procedures associated with each machine.

### 29.3.1 RR variables

There is one instance of the following parameters per RR, except the nPendingRFMs variable, that is common to all RRs on the Bridge components (i.e., per Bridge component, but not per RR).

#### 29.3.1.1 RRcontinue

A Boolean variable for the RR's Continue option [item b5) in 12.17.2.2.2] attribute.

#### 29.3.1.2 nPendingRFMs

An integer value used to track the number of RFMs to be transmitted. nPendingRFMs is a variable that can be incremented by every RR's Encapsulation state machine and can be decremented by RR Transmit state machine.

nPendingRFMs is set to 0 when all of the RRs on the Bridge are deactivated.

### 1 **29.3.1.3 dataReceived**

2 dataReceived is a Boolean variable, which is set to true when there is a data frame received from (E)ISS, and  
3 set to false by the RR Filter state machine.

### 4 **29.3.1.4 dataFrame**

5 This variable is the data frame received from (E)ISS.

### 6 **29.3.1.5 nFilteredFrameList**

7 This variable keeps track of the number of filtered data frames to be reflected. This variable is incremented  
8 by RR Filter and decremented by RR's Encapsulation state machine.

### 9 **29.3.1.6 filteredFrameList**

10 This is a list of received data frames from RR Filter that have not been processed yet.

### 11 **29.3.1.7 nextFilteredFrame**

12 This variable copies the first one on the filteredFrameList to be reflected as RFM. Once a frame is copied to  
13 this variable, the frame is removed from the filteredFrameList.

### 14 **29.3.1.8 RRtime**

15 RRtime is the value of RR Duration (29.2.3.6).

### 16 **29.3.1.9 RRwhile**

17 RRwhile is a timer variable, which is initialized to RR Duration [item b7) in 12.17.2.2.2] when RR is  
18 activated and used by the RR Filter state machine to time out the active RR. RRwhile has granularity in  
19 seconds.

### 20 **29.3.1.10 RRsampInt**

21 RRsampInt is the sampling interval (29.2.3.4) during which the RR only reflects a maximum of one frame  
22 that meets the filter condition. When the sampling interval is not configured, RRsampInt is set to 0.

### 23 **29.3.1.11 RRsampWhile**

24 A timer variable used by RR Filter state machine to time out sampling interval.

### 25 **29.3.1.12 RRmaxFrames**

26 The maximum number of frames for RR to reflect after RR is activated [item b8) in 12.17.2.2.2]. Once  
27 activated, RR will stay active until either RRmaxFrames is reached or RRwhile (29.3.1.9) expires,  
28 whichever comes first. If RRmaxFrames is set to 0, the RR stays active until RRwhile (29.3.1.9) expires.

### 29 **29.3.1.13 RRframeCount**

30 A counter used by the RR's Encapsulation state machine to keep track of the number of data frames to be  
31 reflected. Once RRframeCount is equal to or greater than RRmaxFrames, RR is deactivated.

### 32 **29.3.1.14 filterMatched**

33 A Boolean variable that is set to true if the data frame received matches with the RR's filter conditions and  
34 false if the data frame received does not match the RR's filter conditions.

### 1 **29.3.1.15 RRactive**

2 RRactive is true when the corresponding RR is active and false otherwise.

### 3 **29.3.1.16 nextRFMtransID**

4 The value to place in the RFM Transaction Identifier field of the next RFM to be transmitted.  
5 nextRFMtransID is incremented by 1 by the RR's processRRencap() procedure with each transmission.

6 This variable is readable as a managed object [item b14) in 12.17.2.3.3].

### 7 **29.3.1.17 maxDataTLVvalueSize**

8 This is the maximum number of bytes allowed to be copied into Reflected Data TLV's value field in order to  
9 keep the RFM's SDU size not exceeding its Maximum Service Data Unit Size (MSDUS) (6.5.8).

10 The length of an RFM PDU is 12 octets (4 bytes for CFM header + 1 byte for End TLV(0) + 4 bytes  
11 Transaction Identifier + 3 bytes Reflected Data TLV Length/Type field) + the actual number of bytes of the  
12 reflected data frame. If there is no other optional TLV for the RFM data frame<sup>41</sup>, then:

13 a)  $\text{maxDataTLVvalueSize} = \text{MSDUS} - (5 \text{ (CFM common header length)} + 4 \text{ (Transaction Identifier)} +$   
14  $3 \text{ (Reflected Data Frame TLV Length/Type field)}).$

### 15 **29.3.1.18 reflectedDataLength**

16 This variable is to hold the value for the Length field of Reflected Data TLV (29.4.2.4).

## 17 **29.3.2 RR Filter procedures**

18 The following procedures are defined for the RR Filter state machine:

- 19 a) filterFrame()
- 20 b) forwardFrame()
- 21 c) loadFilteredFrameList()

### 22 **29.3.2.1 forwardFrame()**

23 This procedure passes the frame received to (E)ISS Passive SAP.

### 24 **29.3.2.2 filterFrame()**

25 filterFrame() is called when RRactive is true and there is a data frame received from EISS. This procedure  
26 performs the following steps:

- 27 a) If the received data frame from (E)ISS SAP meets the Reflection Filter definition(s), then returns  
28 true.
- 29 b) Otherwise, returns false.

### 30 **29.3.2.3 loadFilteredFrameList()**

31 This procedure adds the received frame to the filteredFrameList.

<sup>41</sup> Even though not required, implementers may choose to include other optional TLVs in RFM. If extra TLVs are included in a RFM, the maxDataTLVvalueSize has to be decremented by the number of bytes taken by the extra TLV.

### 1 29.3.3 RR Encapsulation procedures

2 The following procedures are defined for the RR Encapsulation state machine:

- 3 a) processRRencap()
- 4 b) splitFilteredFrame()
- 5 c) constructRFM()

#### 6 29.3.3.1 processRRencap()

7 processRRencap() is called when RR is activated and filteredFrameList is not empty. There are two local  
8 variables in this procedure: DataFrame\_1 and DataFrame\_2, which are used when the filtered frame has to  
9 be truncated or split into two frames to be reflected.

10 processRRencap() processes the incoming data frame from the RR Filter as follows:

- 11 a) Set the reflectedDataLength variable to the length of the nextFilteredFrame.
- 12 b) If the value of reflectedDataLength is larger than the Bridge's maxDataTLVvalueSize (29.3.1.17),  
13 then call splitFilteredFrame (nextFilteredFrame, DataFrame\_1, DataFrame\_2) and then perform the  
14 following two steps:
  - 15 1) If Truncation flag is set, call constructRFM(TLV\_type, maxDataTLVvalueSize,  
16 DataFrame\_1), where the TLV\_type is set to the "Truncated Data TLV" type value defined by  
17 Table 21-5.
  - 18 2) If the Truncation flag is not set, perform the following two steps:
    - 19 i) Call constructRFM(TLV\_type, maxDataTLVvalueSize, DataFrame\_1), where the TLV\_  
20 type is set to the "Data Part 1 TLV" type value defined by Table 21-5.
    - 21 ii) Call constructRFM(TLV\_type, reflectedDataLength – maxDataTLVvalueSize, Data-  
22 Frame\_2), where the TLV\_type is set to the "Data Part 2 TLV" type value defined by  
23 Table 21-5.
- 24 c) Otherwise, call constructRFM(TLV\_type, reflectedDataLength, nextFilteredFrame), where  
25 TLV\_type is set to the "Data TLV" type value defined by Table 21-5.

#### 26 29.3.3.2 splitFilteredFrame()

27 This procedure is called when the nextFilteredFrame causes the length of RFM's SDU size to be larger than  
28 the Maximum Service Data Unit Size (6.5.8). There are three parameters for this procedure:

- 29 a) nextFilteredFrame, which is an input to the procedure.
- 30 b) DataFrame\_1, which contains the first maxDataTLVvalueSize number of bytes from the  
31 nextFilteredFrame.
- 32 c) DataFrame\_2, which contains the remaining bytes from the nextFilteredFrame.

33 splitFilteredFrame() performs the following steps:

- 34 — Copy the maxDataTLVvalueSize number of bytes from the nextFilteredFrame to DataFrame\_1.
- 35 — Copy the remaining bytes from the nextFilteredFrame to DataFrame\_2.

#### 36 29.3.3.3 constructRFM()

37 This procedure is to construct a RFM frame and increment the nPendingRFMs by 1. There are three  
38 parameters passed into this procedure:

- 39 a) TLV\_Type, which could be 3 (i.e., Data TLV) (21.5.6), 9 (Truncated Data TLV) (21.5.1.1), 10 (Data  
40 Part 1 TLV), or 11 (Data Part 2 TLV).
- 41 b) TLV\_Length, which is the length of the reflected data frame.
- 42 c) Data frame to be included in the TLV value field.

1 This procedure constructs the RFM (E)M\_UNITDATA.request by the following steps:

- 2 d) Set the source\_address parameter to the MP's or Bridge interface's own MAC address.
- 3 e) If the Reflection Target Address [item b4) in 12.17.2.2.2] is not specified, then source\_address of the  
4 selected data frame is copied to the RFM's destination\_address parameter; otherwise, Reflection  
5 Target Address is copied to the RFM's destination\_address parameter.
- 6 f) Set the priority and drop\_eligible parameters to the priority and drop\_eligible attributes of the  
7 Reflection Responder managed object (12.17.2.2.2).
- 8 g) In a VLAN-aware Bridge, the primary VID associated with the RR's MA [item b1) in 12.17.2.1.2] is  
9 used as the vlan\_identifier. If the RR's MA is set to 0, the vlan\_identifier is determined by the  
10 following:
  - 11 1) If the RR is defined on an S-VLAN component, use the S-VID if the S-VID is present in the  
12 selected data frame; otherwise, use the PVID of the port where RR is configured.
  - 13 2) If the RR is defined on a C-VLAN component, use the C-VID if the C-VID is present in the  
14 selected data frame; otherwise, use the PVID of the port where the RR is configured.
- 15 h) Copy RFM OpCode to the RFM's OpCode Field.
- 16 i) Copy the RR's Maintenance Domain Level [item a) in 12.17.2.1.2] to the RFM's MDLevel field.
- 17 j) Copy the first parameter (TLV\_Type) to the Reflected Data TLV Type field.
- 18 k) Copy the second parameter (TLV\_Length) to the Reflected Data TLV Length field.
- 19 l) Copy the third parameter (Data frame) to the Reflected Data TLV value field.
- 20 m) Copy the nextRFMtransID to the RFM Transaction Identifier field. Increment nextRFMtransID by  
21 1, wrapping around from  $2^{32} - 1$  to 0.
- 22 n) Increment nPendingRFMs by 1.
- 23 o) Set the frame\_check\_sequence parameter to the unspecified value; sets the connection\_identifier to  
24 null.

#### 25 **29.3.4 RR Transmit procedure**

26 The following procedure is defined for the RR Transmit state machine:

- 27 a) xmitRFM()

##### 28 **29.3.4.1 xmitRFM()**

29 xmitRFM() is called by the RR Transmit state machine. It queries the FDB in order to identify an egress  
30 port. The set of potential transmission ports, normally created by the Active Topology enforcement (8.6.1),  
31 is the set of all Bridge interfaces that are both in the active set of the vlan\_identifier associated with the  
32 RFM, and that are in the Forwarding state for that vlan\_identifier.

- 33 a) Query FDB using the RFM's destination\_address field and vlan\_identifier parameter values.
- 34 b) If an egress port is identified and the identified Egress port meets the following conditions:
  - 35 1) The Egress port does not have a Down MEP with higher MD level than the RFM's MD,
  - 36 2) The Egress port does not have an Up MEP with same or higher MD level as the received  
37 RFM's MD,
  - 38 1) then send an RFM EM\_UNITDATA.request to the egress port's LOM SAP. Otherwise, drop  
39 the received RFM frame.
- 40 c) If an egress port cannot be identified:
  - 41 2) When the FloodingEnabled flag of the RR [item b7) in 12.17.2.1.2] is not set, drop the frame.

42 When the FloodingEnabled flag of the RR is set, send M\_UNITDATA.request to the LOM's SAP of every  
43 forwarding port that meets the conditions 1) and 2) of item b) above.

### 1 29.3.5 RR-related state machines

### 2 29.3.5.1 RR Filter state machine

3 Figure 29-7 depicts the state machine for RR Filter.

### Figure 29-7—RR Filter state machine

1 Figure 29-8 describes the state machine for RR Encapsulation.

**Figure 29-8—RR Encapsulation state machine**

## 2 29.3.5.2 RR Transmit state machine

3 RR Transmit state machine (Figure 29-9) can be shared by multiple RRs activated on the Bridge.

**Figure 29-9—RR Transmit state machine**

## 4 29.3.6 RFM Receiver variables

5 The following variables are local to the RFM Receiver state machine. There is one instance of these  
6 variables per RFM Receiver.

### 7 29.3.6.1 RFMreceived

8 RFMreceived is a Boolean variable, which is set to true by the MP OpCode Demultiplexer when an RFM is  
9 received, and cleared by the RFM Receiver state machine.

## 29.3.6.2 RFMPDU

RFMPDU is a record of the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the last RFM received by the MP OpCode Demultiplexer (19.2.7).

## 29.3.7 RFM Receiver procedure

The procedure listed in 29.3.7.1 and 29.3.7.2 is defined for the RFM receiver.

### 29.3.7.1 ReceiveRFM()

ReceiveRFM() procedure performs the following steps:

- a) If the destination\_address field of the received RFM does not match the RFM Receiver's MAC address, drops the frame.
- b) Otherwise, pass the received RFMPDU to RFM Analyzer.<sup>42</sup>

Even though RFM Analyzer is out of the scope of this standard, RFM Analyzer has to be able to recognize the value in Reflected Data TLV (29.3.3.2), which could be:

- A whole data frame being reflected; or
- A truncated data frame being reflected; or
- The first portion of the data frame being reflected; or
- The second portion of the data frame being reflected.

If an RFM Receiver is configured on an MP and the RFM Receiver does not receive any RFMs within the expected time frame, it can send a LBM (21.7) to the MP on which the RR is defined to verify the connectivity to the MP. If there is no LBR received, ReceiveRFM() can report an alarm to the network administrator.

### 29.3.7.2 RFM Receiver state machine

Figure 29-10 describes the state machine for RFM Receivers.

Figure 29-10—RFM Receiver state machine

<sup>42</sup> RFM Analyzer is out of the scope of this standard.

### 1 **29.3.8 DR variables**

2 There is one instance of the parameters listed in 29.3.8.1 through 29.3.8.7 per DR.

#### 3 **29.3.8.1 DRwhile**

4 A timer variable used by the Decapsulator Responder state machine to time out the active DR. DRwhile has  
5 a granularity finer than or equal to 1 s.

#### 6 **29.3.8.2 DRtime**

7 The time that the DR can remain active after its activation.

#### 8 **29.3.8.3 SFMPDU**

9 SFMPDU is a record of the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the  
10 SFM received by the MP OpCode Demultiplexer (19.2.7) when an SFM is received.

#### 11 **29.3.8.4 DRactive**

12 DRactive variable represents the activation status of the corresponding DR. DRactive is set to true when the  
13 corresponding DR is activated and set to false when the corresponding DR is deactivated or its duration  
14 expires. When DRactive is false, all SFMs received by the Bridge interface are dropped.

#### 15 **29.3.8.5 SFMreceived**

16 SFMreceived is set to true by the OpCodeDemultiplexer (19.2.7) when an SFM is received.

#### 17 **29.3.8.6 previousSFMtransId**

18 previousSFMtransId variable keeps the value of SFM Transaction Identifier of the previously received SFM  
19 frame. The previousSFMtransId variable is initialized to zero when the DR is activated.

#### 20 **29.3.8.7 SFMsequenceErrors**

21 SFMsequenceErrors variable keeps the total number of out-of-sequence SFMs received.  
22 SFMsequenceErrors is initialized to zero when the DR is activated.

### 23 **29.3.9 DR procedures**

24 The DR has the following procedures:

- 25 a) ProcessSFM()
- 26 b) DropSFM()

#### 27 **29.3.9.1 processSFM()**

28 Called by the Decapsulator Responder state machine when an SFM is received and the DR is active.  
29 processSFM() processes the incoming SFM in SFMPDU as follows:

- 30 a) The SFM is examined for validity using the methods used for CFM as described in (20.46) and  
31 discarded if invalid.
- 32 b) If the destination\_address of the SFM does not match the DR's own MAC address or the  
33 source\_address of the SFM does not match with DR's SFM Originator [item b2) in 12.17.4.3.2], the  
34 frame is discarded.

- 1 c) If the SFM frame passes these tests, the frame carried in its Original Data TLV (29.4.3.4) is  
2 decapsulated to create an (E)M\_UNITDATA.request as follows:
- 3 1) The destination\_address parameter is set to the destination\_address of the frame in the Original  
4 Data TLV.
- 5 2) If the SourceAddressStayFlag [item b1) in 12.17.4.3.2] is false, the source\_address parameter  
6 is set to the DR's MAC address; otherwise, the source\_address parameter is set to the  
7 source\_address of the frame in the Original Data TLV.
- 8 3) The vlan\_identifier, priority, drop\_eligible, and mac\_service\_data\_unit parameters are set as  
9 follows:
- 10 i) If the DR is configured on a port of an S-VLAN component, and the TPID of the frame in  
11 the Original Data TLV indicates the S-TAG, the vlan\_identifier, priority, and drop\_eligible  
12 parameters are taken from the corresponding values in the Tag Control Information (TCI)  
13 and the mac\_service\_data\_unit is taken from the remainder of the frame following the TCI  
14 and excluding the last four octets (FCS).
- 15 ii) If the DR is configured on a port of a C-VLAN component, and the TPID in the Original  
16 Data TLV indicates a C-TAG, the vlan\_identifier, priority, and drop\_eligible parameters  
17 are taken from the corresponding values in the TCI, and the mac\_service\_data\_unit is  
18 taken from the remainder of the frame in the Original Data TLV following the TCI and  
19 excluding the last four octets (FCS).
- 20 iii) Otherwise, the vlan\_identifier is set to the PVID for the port on which the DR is config-  
21 ured, the priority is set to the priority of the SFM, the drop\_eligible parameter is set to the  
22 value of drop\_eligible for the SFM, and the mac\_service\_data\_unit is taken from the  
23 frame in the Original Data TLV immediately following the source\_address and excluding  
24 the last four octets (FCS).
- 25 4) Sets the frame\_check\_sequence parameter to the unspecified value (IEEE Std 802.1AC).
- 26 5) Sets the connection\_identifier parameter to null.
- 27 d) ProcessSFM() queries the FDB using the destination\_address and vlan\_identifier parameters of the  
28 (E)M\_UNITDATA.request. The set of potential transmission ports, normally created by the Active  
29 Topology enforcement (8.6.1), is the set of all Bridge Ports that are both in the member set of the  
30 vlan\_identifier and that are in the Forwarding state for that vlan\_identifier.
- 31 1) If an Egress Port is identified, the decapsulated frame is carried to the related LOM SAP for  
32 transmission.
- 33 2) If an Egress Port is not identified and the FloodingEnabled flag of the DR is set, the  
34 decapsulated frame is flooded to the LOM SAP of all forwarding ports in the VID set;  
35 otherwise, the frame is discarded.
- 36 e) If the received SFM is not the first frame received by the DR and the value of SFM Transaction  
37 Identifier field in the received SFM is not 1 greater than the value saved in the previousSFMtransId,  
38 increment SFMsequenceErrors by 1.
- 39 f) Set the value of previousSFMtransId to the value of the SFM Transaction Identifier field of the  
40 received SFM.

#### 41 29.3.9.2 DropSFM()

42 Called by Decapsulator Responder state machine whenever the DR is not active in order to silently discard  
43 the received SFM frames.

### 29.3.10 Decapsulator Responder state machine

Once the DR is configured and activated by network administrator, it remains active until the configured timer expires or being deactivated by the network administrator (see Figure 29-11).

Figure 29-11—Decapsulator Responder state machine

## 29.4 Encoding of DDCFM PDUs

This subclause specifies the method of encoding DDCFM PDUs. The specifications include the following:

- The format of RFM
- The format of SFM

### 29.4.1 RFM and SFM Header

The RFM Header and SFM Header are same as the Common CFM Header defined by Table 21-2, with extra OpCodes defined for RFM and SFM (Table 21-3).

### 29.4.2 RFM format

The RFM format is shown in Table 29-1.

#### 29.4.2.1 Flags

(1 octet) in RFM. The Flags field of the Common CFM Header for RFM is reserved for future use.

#### 29.4.2.2 First TLV Offset

(1 octet) The First TLV Offset field of the Common CFM Header in a RFM is transmitted as 4.

**Validation Test:** The First TLV Offset field of the Common CFM Header in a RFM contains a value greater than or equal to 4.

**Table 29-1—RFM format**

| Field                                                                   | Octet                                                     |
|-------------------------------------------------------------------------|-----------------------------------------------------------|
| Common CFM Header                                                       | 1–4                                                       |
| RFM Transaction Identifier                                              | 5–8                                                       |
| Reserved for definition in future versions of the protocol <sup>a</sup> |                                                           |
| Reflected Data TLV                                                      | First TLV Offset + 5                                      |
| Additional TLV                                                          | First TLV Offset + 5<br>+ Length of<br>Reflected Data TLV |
| End TLV (0)                                                             |                                                           |

<sup>a</sup> This field has 0 length in this version 0 of DDCFM. It is shown in order to stress that additional information can be present in future versions of DDCFM, and that a version 0 receiver ignores its contents, if present.

### 1 29.4.2.3 RFM Transaction Identifier

2 (4 octets) An RR copies the content of nextRFMtransID variable (29.3.1.16) to this field.

### 3 29.4.2.4 Reflected Data TLV

4 Reflected Data TLV in RFM is a Data TLV (21.5.6) to contain the reflected data frame. The Length field is  
5 the total octets of the reflected data frame.

6 The Type field of the Reflected Data TLV could be one of the following four values (Table 21-5):

- 7 a) Data TLV Type value, which is 3
- 8 b) Truncated Data TLV Type value, which is 9
- 9 c) Data-Part-1 TLV Type value, which is 10
- 10 d) Data-Part-2 TLV Type value, which is 11

### 11 29.4.2.5 Additional RFM TLVs

12 The following TLVs may be included in a RFM by each MP originating RFM (RR):

- 13 a) Send ID TLV (21.5.3)
- 14 b) Organization-Specific TLVs (21.5.2)

15 The Additional RFM TLVs may be placed in any order.

### 16 29.4.3 SFM format

17 The SFM format is shown in Table 29-2.

#### 18 29.4.3.1 Flags

19 (1 octet) in SFM. The Flags field of the Common CFM Header for SFM is reserved for future use.

#### 20 29.4.3.2 First TLV Offset

21 (1 octet) The First TLV Offset field of the Common CFM Header in an SFM is transmitted as 4.

22 **Validation Test:** The First TLV Offset field of the Common CFM Header in an SFM contains a value  
23 greater than or equal to 4.

**Table 29-2—SFM format**

| Field                                                                   | Octet                                                    |
|-------------------------------------------------------------------------|----------------------------------------------------------|
| Common CFM Header                                                       | 1–4                                                      |
| SFM Transaction Identifier                                              | 5–8                                                      |
| Reserved for definition in future versions of the protocol <sup>a</sup> |                                                          |
| Original Data TLV                                                       | First TLV Offset + 5                                     |
| Additional TLVs                                                         | First TLV Offset + 5 +<br>Length of Original<br>Data TLV |
| End TLV (0)                                                             |                                                          |

<sup>a</sup> This field has 0 length in this version 0 of DDCFM.

### 1 29.4.3.3 SFM Transaction Identifier

2 (4 octets) SFM originator may use this field to distinguish the order of SFMs sent. DR may use this identifier  
3 to check the order of the received SFMs.

### 4 29.4.3.4 SFM Original Data TLV

5 SFM Original Data TLV is a Data TLV (21.5.6) to contain the original data frame. The Length field is the  
6 total octets of the original data frame, including its destination\_address, source\_address, TPID, TCI,  
7 Length/Type, client data, pad, and FCS fields.

### 8 29.4.3.5 Additional SFM TLVs

9 The following TLVs may be included in an SFM by each SFM Originator:

- 10 a) Send ID TLV (21.5.3)
- 11 b) Organization-Specific TLVs (21.5.2)

12 The Additional SFM TLVs may be placed in any order.

## 1 30. Principles of congestion notification

2 Congestion notification comprises capabilities for detecting and mitigating queue congestion for selected  
3 classes of traffic in Virtual Bridged Networks. These capabilities can be used in networks with a bandwidth-  
4 delay product on the order of 5 Mbits or less in order to decrease the likelihood of frame loss for Congestion  
5 Controlled Flows (CCFs). As the geographical size, per-hop delay, and/or maximum hop count of a network  
6 grow, causing the bandwidth-delay product of the network to increase beyond this value, oscillations in  
7 buffer occupancy begin, and their amplitude increases gracefully with bandwidth-delay product. If the  
8 parameters controlling the algorithm are not adjusted accordingly and the sizes of the Bridges' buffers are  
9 not increased, frames are then likely to be lost due to congestion.

10 Congestion notification depends on the formation of a cooperating set of systems including VLAN Bridges  
11 and end stations to achieve the reduction in frame loss. By partitioning the Bridges' and end stations'  
12 resources, frames sourced or sunk by noncooperating end stations or Bridges can be carried with minimal  
13 contention with CCFs for those resources. Accordingly, congestion notification entities (Clause 31) are  
14 specified as shims that make use of and provide the ISS or EISS (IEEE Std 802.1AC, 6.8) at SAPs within the  
15 network. The operation of the congestion notification protocol is described in Clause 32, and the formats of  
16 the CNM and Congestion Notification TLV are described in Clause 33.

17 This clause provides the context necessary to understand the congestion notification protocol: how  
18 congestion controlled regions of networks are identified; how CCFs are identified and separated from other  
19 frames; and how congestion notification entities in Bridges and end stations operate.

20 This clause introduces the concepts essential to congestion notification as follows:

- 21 a) The problem and requirements on the solution are presented (30.1).
- 22 b) The basic principles of the Quantized Congestion Notification protocol (QCN) are presented,  
23 including descriptions of a CP that sends a CNM to a RP (30.2).
- 24 c) A CCF consists of frames, all with the same priority value, and all assigned to a single Flow queue  
25 and RP in the originating end station (30.3).
- 26 d) A Congestion Notification Priority Value (CNPV) is one of the eight priority values that has been  
27 configured exclusively for the use of CCFs in the congestion-aware systems of a Virtual Bridged  
28 Network (30.4).
- 29 e) A CN-TAG can be transmitted with every data frame in a CCF, and is returned in every CNM (30.5).
- 30 f) A CND is constructed as a subset of Bridges and end stations in a Virtual Bridged Network, all of  
31 which are configured to handle a particular CNPV, the resources of which subset are defended by the  
32 Bridges whenever the offered load exceeds the network capacity (30.6).
- 33 g) The relationship of Multicast data to congestion notification is explained (30.7).
- 34 h) The peering relationship of RPs and CPs in PBNs and PBBNs is explained (30.8).

### 35 30.1 Congestion notification design requirements

36 The congestion notification protocol, congestion notification algorithm (QCN), and supporting protocols  
37 specified in this standard meet requirements for the following:

- 38 — CCF and network performance.
- 39 — Limiting the implementation complexity, of both RPs and CPs.
- 40 — Not over-constraining the design of Bridged Networks using CCF.
- 41 — Facilitating interoperability, coexistence, and deployment into existing networks, and limiting the  
42 administrative effort associated with using CCF in a network.

43 NOTE 1—QCN is designed to operate over a wide range of conditions. This subclause (30.2) necessarily uses  
44 qualitative terms such as “low probability,” “small,” “stable,” and “modest” (for brevity). The bibliography (Annex X)  
45 provides references (Alizadeh et al. [B1]) to studies of QCN performance for various network and traffic configurations,  
46 using both simulation and a fluid model (see 30.3 for the necessary equations, and for network sizing recommendations).

1 The following performance requirements are met for s CCFs (30.3):

- 2 a) There is a very low probability of frame discard due to buffer overflow at a CP.
- 3 b) The average buffer occupancy at each CP that is a Current Congestion Point (CCP) for one or more  
4 CCFs is a small fraction of the bandwidth delay product, and largely independent of the number of  
5 CCFs, thus ensuring that loss avoidance does not result in large and fluctuating transit delays.
- 6 c) The buffer occupancy at a CCP has a low probability of underflow, i.e., of becoming empty and thus  
7 failing to use available bandwidth when an RP is rate limiting a CCF as a result of CNMs received  
8 from that CCP.
- 9 d) When multiple CCFs with a single CCP share that CCP, they obtain very nearly the same share of  
10 the bandwidth. When multiple CCFs have one or more CCPs in common they each obtain a share of  
11 bandwidth resources proportional to their share of contested resources.
- 12 e) The low probability of buffer overflow and underflow at a CCP is maintained for both small and  
13 large numbers of CCFs, and when CCFs or the load offered by a given CCF changes.
- 14 f) The bandwidth provided to each CP by its attached LAN will be used, at all times, i.e., if the CP's  
15 buffer is not empty it will transmit, given the available bandwidth. The fact that the bandwidth  
16 available to one CCF passing through a given CP can be constrained by another CCP will not reduce  
17 the bandwidth through that CP for other CCFs not sharing the CCP.

18 NOTE 2—The probability of frame loss in the absence of CCF naturally depends on the response of higher layer  
19 protocols to increasing transit delay, and the importance of avoiding loss on their response. Highly loss sensitive  
20 protocols typically lack loss avoidance mechanisms, and no such mechanisms are assumed in the analysis of QCN.

21 NOTE 3—Requirements a) through d) can be summarized by characterizing the performance of QCN as stable,  
22 responsive, and (proportionally) fair with respect to buffer occupancy processes. Requirements e) and f) demand that  
23 available resources are used, and that stability not depend on having a large number of slowly changing CCFs.

24 The following requirements limit the complexity and hence the cost of Bridge Port (CP) support for CCF:

- 25 g) The CCF state retained by each Bridge Port is fixed, and determined solely by the number of  
26 congestion management transmission queues (i.e., by the number of CPs, one per CNPV, up to a  
27 maximum of 7) and the per CP requirements of the congestion notification algorithm (QCN).
- 28 h) A CP does not retain any per CCF or per RP state, nor is it required to allocate any data frame  
29 passing through the CP to a CCF or an RP. All the information necessary for a CP to address a CNM  
30 to an end station, and for that end station to identify the CCF and RP from the CNM, is contained in  
31 each frame of a CCF.
- 32 i) The buffering required, at each CP, to avoid frame loss should be a small fraction of the network's  
33 bandwidth delay product.

34 The following requirements limit the complexity and hence the cost of end station (RP) support for CCF:

- 35 j) The CCF state retained by each end station for each congestion managed transmission queue, i.e.,  
36 for each RP, is fixed.
- 37 k) The end station state requirements of QCN are determined solely by the number of RPs, and are  
38 independent of the number of CCFs and the number of CPs in the network.
- 39 l) The number of CCFs, the identification of each CCF, the allocation of transmitted frames to CCFs,  
40 and the allocation of CCFs to RPs is determined by each end station independently.
- 41 m) The end station is not required to transmit any additional frames, as a consequence either of  
42 transmitting or of receiving a frame for a CCF.
- 43 n) The CN-TAG for each CCF is independent of changes in RP state information.
- 44 o) The CCF protocol and QCN do not use any higher-layer protocol information carried in frames.
- 45 p) QCN calculations are simple and can be performed rapidly: i.e., the number of operations required  
46 to process each event is fixed, and all multiplications and divisions can be reduced to the use of  
47 factors of 2 or the use of a fixed and small lookup table. An RP does not attempt to calculate control  
48 loop gains and delays and other, potentially rapidly changing CCF-dependent variables.

1 NOTE 4—A CP or an RP can retain additional state for the purposes of management, but this state is not required by the  
2 CCF protocol or QCN.

3 NOTE 5—An end station can use higher layer protocol information to decide whether a frame is to be allocated to a  
4 CCF, and to select a CCF.

5 The following requirements ensure that CCF does not over-constrain the design of the network, or limit the  
6 use of protocols that determine the active topology of the network:

- 7 q) RPs and CPs are unaware of the path taken by frames through the network, require no signaling  
8 from the network of changes in path, and take no exceptional action when paths change.
- 9 r) An RP does not assume that all frames that it transmits, or any identifiable subset of those frames  
10 such as those identified by the end station as belonging to a single CCF or transmitted to the same  
11 destination, are constrained to follow the same path through the network. An RP can transmit frames  
12 to many different destinations, and transmission to a given destination can be multi-path.

13 The following requirements support interoperability, facilitate deployment, and limit the administrative  
14 effort required to use CCF:

- 15 s) The boundaries of each CND are determined automatically.
- 16 t) The destination of a CCF can lie outside the transmitting end station's CND, and the destination end  
17 station can be unaware of the use of CCF within the CND. Incremental deployment of CCF is  
18 therefore possible.
- 19 u) The feedback provided in each CNM provides the receiving RP with the information needed to act  
20 on that CNM, and does not require the RP to know or interpret information about the sending CP.
- 21 v) PBBNs can be interposed into a CND, in order to reduce the number of MAC addresses learned by  
22 Bridges in environments with large numbers of (perhaps virtual) end stations.

23 These requirements have a number of additional consequences for the design of QCN, including the  
24 following:

- 25 w) Additional mechanisms to determine round trip time are not required, as the algorithm is robust over  
26 its targeted range of round trip time.
- 27 x) QCN cannot regulate frame transmission by acknowledgments, as does Transmission Control  
28 Protocol/Internet Protocol (TCP/IP), see IETF RFC 791 and IETF RFC 793 [B19].

## 29 30.2 Quantized Congestion Notification protocol (QCN)

30 This subclause provides an overview of the baseline simulation of the QCN algorithm (Alizadeh et al. [B1])  
31 used to develop this standard. This introduction provides no normative text. It will focus on the key features  
32 of the QCN algorithm, omitting the normative details given in the rest of this standard.

33 The QCN algorithm is composed of the following two parts:

- 34 a) **CP algorithm:** the mechanism by which a congested Bridge or end station buffer samples outgoing  
35 frames and generates a feedback message (CNM, 33.3, in this standard) addressed to the source of  
36 the sampled frame. The feedback message contains information about the extent of congestion at the  
37 CP.
- 38 b) **RP algorithm:** the mechanism by which a Rate Limiter (RL) associated with a source decreases its  
39 sending rate based on feedback received from the CP, and increases its rate *unilaterally* (without  
40 further feedback) to recover lost bandwidth and probe for extra available bandwidth.

### 30.2.1 The CP algorithm

A Bridge containing a CP is modeled as an ideal output-queued Bridge. The CP buffer is shown in Figure 30-1. The goal of the CP is to maintain the buffer occupancy at a desired operating point,  $Q_{eq}$ .<sup>43</sup> The CP computes a congestion measure  $F_b$  (defined below) and, with a probability depending on the severity of congestion, selects a frame from the incoming stream and sends the value of  $F_b$  in a feedback message to the source of the selected frame.

**Figure 30-1—Congestion detection in QCN CP**

Let  $Q$  denote the instantaneous queue size and  $Q_{old}$  denote the queue size when the last feedback message was generated. Let  $Q_{off} = Q - Q_{eq}$  and  $Q_{\delta} = Q - Q_{old}$ .

Then  $F_b$  is given by Equation (30-1).

$$F_b = -(Q_{off} + wQ_{\delta}) \quad (30-1)$$

where  $w$  is a non-negative constant, taken to be 2 for the baseline simulation. The value of  $F_b$  is quantized to 6 bits before transmission, based on  $Q_{eq}$  and  $w$ .

The interpretation is that  $F_b$  captures a combination of queue size excess ( $Q_{off}$ ) and rate excess ( $Q_{\delta}$ ). Indeed,  $Q_{\delta} = Q - Q_{old}$  is the *derivative* of the queue size and equals input rate less output rate. Thus, when  $F_b$  is negative, the buffer is oversubscribed. When  $F_b < 0$ , Figure 30-2 shows the probability with which a congestion message is reflected back to the source as a function of  $|F_b|$ . The feedback message contains the value of  $F_b$ , quantized to 6 bits. When  $F_b \geq 0$ , there is no congestion and no feedback messages are sent.

**Figure 30-2—Sampling (reflection) probability in QCN CP as a function of  $|F_b|$**

<sup>43</sup> In simulation, setting  $Q_{eq}$  to 20% of the physical buffer size (150 000 octets) produced good results.

### 30.2.2 Basic RP algorithm

The RP is not given positive rate-increase signals by the network. Also, there are no acks at Layer 2 to trigger rate increases. Therefore, the RP requires a local mechanism to determine when, and by how much, the send rate is increased. Before proceeding to explain the RP algorithm, readers need the following terminology:

- **Current Rate (CR):** The transmission rate of the Rate Limiter (RL) at any time.
- **Target Rate (TR):** The sending rate of the RL *just before* the arrival of the last feedback message, and the new goal for the Current Rate.
- **Byte Counter:** A counter at the RP for counting the number of bytes transmitted by the RL. It triggers rate increases by the RL. See 30.2.2.2.
- **Timer:** A clock at the RP that is also used for triggering rate increases at the RL. The main purpose of the timer is to allow the RL to rapidly increase the rate when its sending rate is very low and bandwidth becomes available. See 30.2.3.

This clause now explains the RP algorithm assuming that only the byte counter is available. Later, how the timer is integrated into the RP algorithm is briefly explained. Figure 30-3 shows the basic RP behavior.

Figure 30-3—QCN RP operation

#### 30.2.2.1 Rate decreases

Rate decreases occur only when a feedback message is received, in which case *CR* and *TR* are updated as follows in Equation (30-2) and Equation (30-3):

$$TR \leftarrow CR \quad (30-2)$$

$$CR \leftarrow CR(1 - G_d|F_{bmax}|) \quad (30-3)$$

where the constant  $G_d$  is chosen so that  $G_d|F_{bmax}| = 1/2$ , i.e., the sending rate can decrease by at most 50%.

#### 30.2.2.2 Rate increases

Rate increases occur in two phases: Fast Recovery and Active Increase.

1 *Fast Recovery (FR)*. The byte counter is reset every time a rate decrease is applied and the RP enters the FR  
2 state. FR consists of 5 cycles, each cycle equal to 150 kB of data transmission by the RL. The RP counts the  
3 cycles of the byte counter. At the end of each cycle, *TR* remains unchanged while *CR* is updated as follows  
4 in Equation (30-4):

$$5 \quad CR \leftarrow \frac{1}{2}(CR + TR) \quad (30-4)$$

6 The cycle duration of 150 kB is chosen to correspond to the transmission of 100 frames, each 1500 bytes  
7 long. The idea is that when the RL has transmitted 100 frames and, given that the minimum sampling  
8 probability at the CP is 1%, if it has not received a feedback message then it may infer that the CP is  
9 uncongested. Therefore, it increases its rate as above, recovering some of the bandwidth it lost at the  
10 previous rate decrease episode. Thus, the goal of the RP in FR is to *rapidly recover* the rate it lost at the last  
11 rate decrease episode.<sup>44</sup>

12 *Active Increase (AI)*. After 5 cycles of FR have completed, the RP enters the Active Increase (AI) phase  
13 where it probes for extra bandwidth on the path. During AI, the byte counter counts out cycles of 50 frames  
14 (this can be set to 100 frames for a less frequent probing). At the end of each cycle, the RL updates *TR* and  
15 *CR* as follows in Equation (30-5) and Equation (30-6):

$$16 \quad TR \leftarrow TR + R_{AI} \quad (30-5)$$

$$17 \quad CR \leftarrow \frac{1}{2}(CR + TR) \quad (30-6)$$

18 where  $R_{AI}$  is a constant chosen to be 5 Mb/s in the baseline simulation.

### 19 30.2.3 RP algorithm with timer

20 Since rate increases using the Byte Counter occur at a frequency proportional to the current sending rate of  
21 the RL, when *CR* is very small, the duration of Byte Counter cycles when measured in seconds can become  
22 unacceptably large. Since the speed of bandwidth recovery (or responsiveness) is a key performance metric,  
23 a Timer was included in QCN.

24 The Timer functions similarly as the Byte Counter: it is reset when a feedback message arrives, enters FR  
25 and counts out 5 cycles of *T* ms duration (*T* is 10 ms long in the baseline), and then enter AI where each  
26 cycle is *T*/2 ms long.

27 The Byte Counter and Timer jointly determine rate increases at the RL as shown in Figure 30-4. After a  
28 feedback message is received, they each operate independently and execute their respective cycles of FR and  
29 AI. Together, they determine the state of the RL and its rate changes as follows:

30 a) The RL is in FR if *both* the Byte Counter and the Timer are in FR. In this case, when either the Byte  
31 Counter or the Timer completes a cycle, *CR* is updated according to Equation (30-4).

32 b) The RL is in AI if *only one of* the Byte Counter and the Timer is in AI. In this case, when either  
33 completes a cycle, *TR* and *CR* are updated according Equation (30-5) and Equation (30-6).

34 c) The RL is in HAI (for Hyper-Active Increase) if *both* the Byte Counter and the timer are in AI. In  
35 this case, the *i*th time that a cycle for either the Byte Counter or the Timer is completed, *TR* and *CR*  
36 are updated as shown in Equation (30-7) and Equation (30-8):

$$37 \quad TR \leftarrow TR + iR_{HAI} \quad (30-7)$$

$$38 \quad CR \leftarrow \frac{1}{2}(CR + TR) \quad (30-8)$$

39 where  $R_{HAI}$  is constant set to 50 Mb/s in the baseline simulation (Figure 30-3). So the increments to  
40 *TR* in HAI occur in multiples of 50 Mb/s.

41 Thus, the Byte Counter and Timer should be viewed as providing the RL opportunities to increase the rate.  
42 Their state determines the state of, and hence the amount of rate increase at, the RL.

<sup>44</sup> The BIC-TCP algorithm [B68] has a similar Fast Recovery mechanism.

**Figure 30-4—Byte Counter and Timer interaction with Rate Limiter**

1 It is very important to note that the RL goes to HAI only after at least 500 frames have been sent and  
 2 50 ms have passed since the last congestion feedback message was received. This doubly ensures that  
 3 aggressive rate increases occur only after the RL provides the network adequate opportunity (in frames sent  
 4 for possible sampling) for sending rate decrease signals should there be congestion. This is vital to ensure  
 5 the stability of the algorithm, and while optimizations can be performed to improve its responsiveness, in the  
 6 interests of stability and simplicity, the baseline simulation (Alizadeh et al. [B1]) took no further  
 7 optimization steps.

### 8 **30.3 Congestion Controlled Flow (CCF)**

9 A CCF consists of all of the frames passing through a single Flow queue (31.2.2.1) in an originating end  
 10 station. Examples of CCFs include, but are not limited to,

- 11 a) The frames carrying data for a single User Datagram Protocol (UDP, IETF RFC 768 STD0006)
- 12 connection.
- 13 b) All of the frames generated by a particular process running in an end station.
- 14 c) All of the frames being transmitted by an end station that produce the same value when a hash
- 15 computation is performed on the source and destination IP addresses, UDP vs. Transmission Control
- 16 Protocol (TCP) selection, and source and destination UDP/TCP port numbers of the IP packets
- 17 carried by those frames.
- 18 d) All of the frames passing through an RP that have the same destination\_address parameter.
- 19 e) All of the frames being transmitted by an end station.
- 20 f) All of the frames passing through a Bridge Port sharing identical source\_address,
- 21 destination\_address, and priority parameters.
- 22 g) All of the frames leaving a router that contain IP packets, and have identical values for their source
- 23 and destination IP addresses, UDP vs. TCP selection, and source and destination UDP/TCP port
- 24 numbers.
- 25 h) All of the frames with a certain value for the priority parameter.

26 All of the frames in a given CCF are sent with the same priority value, which is a CNPV (30.4).

27 Not all frames transmitted by an end station with an RP need be CCFs. Frames not belonging to CCFs  
 28 bypass the Flow queues and RPs.

### 1 30.4 Congestion Notification Priority Value (CNPV)

2 A CNPV consists of one value of the priority parameter such that all of the Bridges' and end stations' ports  
3 in a Congestion Notification Domain (CND) are configured to assign frames at that value to the same CP  
4 and/or an RP. Different CNPVs correspond to classes of applications, or even single applications, such as  
5 interprocess communications or disk storage data, that have different requirements for such network  
6 resources as latency or bandwidth. Since there are eight values for the priority parameter, a single port in a  
7 Virtual Bridged Network can support as many as seven CNPV values; at least one value is required for best-  
8 effort traffic.

### 9 30.5 Congestion Notification tag (CN-TAG)

10 An end station may add a CN-TAG to every frame it transmits from a CCF. The CN-TAG contains a Flow  
11 Identifier field. The destination\_address, Flow ID, and a portion of the frame that triggered the transmission  
12 of the CNM are the means provided by this standard by which a station can determine to which RP a CNM  
13 applies. How the station makes that determination is beyond the scope of this standard. The reasons for  
14 adding a CN-TAG include the following:

- 15 a) An end station can identify a particular flow within a CCF that triggered the CNM.
- 16 b) It can be simpler for the end station to use a Flow ID, rather than to parse the returned  
17 mac\_service\_data\_unit of the original triggering frame, in order to identify either the RP or the  
18 particular flow.
- 19 c) Depending on the application, e.g., if fragmented IP datagrams are transmitted, it can be impossible  
20 to determine either the RP or the particular flow based solely on a returned mac\_service\_data\_unit.

21 An end station that has only a single RP per CNPV, or that is able to identify the RP on the basis of the  
22 returned portion of the triggering frame, can omit transmitting the CN-TAG. The CP always returns a  
23 CN-TAG in a CNM with the triggering frame's Flow ID, or with a 0 Flow ID, if the triggering frame has no  
24 CN-TAG. The fixed format for the CNM minimizes the effort required of the CP to generate the CNM.

### 25 30.6 Congestion Notification Domain (CND)

26 In order for congestion notification to successfully control congestion in a Virtual Bridged Network, the  
27 managed objects controlling the congestion notification state machines in the Bridges and end stations in  
28 that network have to be configured with values that are appropriate to the characteristics of the CCFs  
29 generated by the applications that expect congestion controlled services. For example,

- 30 a) If frames that were not originated from an RP can enter a CP experiencing congestion, then the  
31 CNMs generated by that CP upon receipt of those frames cannot correct the problem, and  
32 congestion notification cannot operate correctly.
- 33 b) Congestion notification cannot operate correctly if a CP's configuration is inappropriate for the  
34 CCFs passing through it, or if priority values are regenerated in a manner that moves frames in and  
35 out of CNPVs.
- 36 c) Frames transmitted from an end station with a CN-TAG cannot be understood by an end station that  
37 is not congestion aware.

38 Congestion-aware Bridges therefore construct a CND, within which a particular CNPV is supported. A  
39 CND is a connected subset of the Bridges and end stations in a Virtual Bridged Network that are  
40 appropriately configured to serve a particular CNPV. This standard does not assume that every Bridge in a  
41 Virtual Bridged Network will be capable of congestion control, does not assume that every capable Bridge  
42 will be so configured, and does not assume that the subset of Bridges in a Virtual Bridged Network forming  
43 a CND that serves one CNPV will be the same subset that form a CND serving another CNPV.

1 CNDs can be created by configuring the Bridges and end stations in a network, or they can be created  
2 automatically, using an additional Type Length Value element, the Congestion Notification TLV (D.2.7),  
3 that this standard adds to the IEEE 802.1AB Link Layer Discovery Protocol (LLDP). Either way, every  
4 Bridge Port knows, for each CNPV, whether its neighbor(s) are or are not all configured with a matching  
5 CNPV.

6 NOTE—If CND boundaries are configured individually, rather than through LLDP, and there is an error in the  
7 configuration, there is a risk that frames not originating from RPs will pass through a CP, or that RP-originated frames  
8 will pass through a congested Port that has no CP. Either case can result in congestion that cannot be alleviated, with  
9 consequent excessive discarding of RP-originated data frames. In addition, such misconfiguration can result in a  
10 congestion-aware end station being unable to communicate with a congestion unaware end station, because the latter is  
11 receiving CN-TAGs that it does not understand.

12 Making each CND/CNPV independent, rather than making a single determination of neighbor capabilities  
13 based on whether all CNPVs are configured the same for all Ports attached to the LAN, allows a CND to be  
14 added to or removed from a network already using another CND, without disrupting the operation of the  
15 first CND.

## 16 30.7 Multicast data

17 Although control of multicast streams is not an object of this standard, and no simulations or experiments  
18 involving multicast data were utilized in the writing of this standard, the transmission of multicast data  
19 through a CCF is not prohibited. Some applications primarily send unicast data, but send occasional  
20 multicast frames for purposes such as discovery. Transmission of multicast data has been allowed in order to  
21 allow well-designed applications using a very small percentage of multicast traffic to operate on a CNPV.

22 Multicast streams are often sent to multiple destinations along multiple paths through the network, and a  
23 unicast stream normally travels along a single path. Therefore, a multicast stream is more likely to encounter  
24 any congested ports that exist in a network than is a unicast stream. The consequences of sending multicast  
25 streams on a CCF include the following:

- 26 a) The RP could limit the CCF to the rate of the slowest (most congested) path taken by the multicast.
- 27 b) The chances of unintended fate sharing are higher in a CCF that included multicast streams. That is,  
28 a multicast stream is more likely to unnecessarily slow down a unicast stream sharing the same CCF  
29 than one unicast stream is likely to slow down another.

## 30 30.8 Congestion notification and additional tags

31 The transmission of a CNM from a CP to an RP makes the CP and RP peer entities in the sense discussed in  
32 IEEE Std 802.1AC. An example of this peering relationship for a VLAN Bridged Network is illustrated in  
33 Figure 30-5, with the CP-RP relationship shown by a heavy dashed line.

Figure 30-5—CP–RP peering in VLAN Bridged Network

PBBs (Clause 25) could be used in a data center environment, in order to reduce the number of MAC addresses that have to be learned in the core of the network. The I-component (5.7) of a PBB adds and removes I-TAGs (9.7) on data frames. However, as illustrated in Figure 30-6,<sup>45</sup> adding an I-TAG to a data frame by an I-component impairs the ability of a CP in the core of that network to return a CNM that will be meaningful to the originating end station. The following two difficulties follow from the fact that a CP in a BCB is not a peer of the RP in an end station:

- a) The BCB CP cannot parse the I-TAG and C-TAG, which is necessary in order to find the RP's MAC address and the data frame's CN-TAG, in order to build an I-TAG-encapsulated, CNM addressed to the RP.
- b) There is no MAC address available to the BCB CP that would be a valid source\_address in the CNM when received by the RP.

In order to provide the benefits of PBBNs or other hierarchical bridging technologies to the data center environment, an interworking function (32.16) is defined to allow core CPs to peer with end stations.

Figure 30-6—CP–RP peering in PBBN

<sup>45</sup> In the configuration chosen for illustration for the data center environment in Figure 30-6, each S-VLAN component of an I-components is, in effect, a Provider Bridge (5.10). That is, each CNP in an I-component is virtualized and multiplied, and connected to a corresponding virtual PEP of a C-VLAN component offering a single CEP facing the end station. This offers a C-TAG interface to the end station, without incurring the burden of an additional layer of S-TAGs.

## 31. Congestion notification entity operation

This clause specifies the following:

- a) The architecture of the CP in the Forwarding Process in a congestion-aware Bridge component or end station (31.1).
- b) The architecture of a CP and an RP in a congestion-aware end station (31.2).

NOTE—Clause 30 introduces the principles of congestion notification operation and the network architectural concepts that support it. Clause 32 specifies the protocols operated by entities defined in this clause. Clause 33 specifies the encoding of the PDUs used by congestion notification.

The models of operation in this clause provide a basis for specifying the externally observable behavior of congestion notification, and are not intended to place additional constraints on implementations; these can adopt any internal model of operation compatible with the externally observable behavior specified. Conformance of equipment to this standard is purely in respect of observable protocol.

### 31.1 Congestion-aware Bridge Forwarding Process

Figure 8-12 illustrates the details of the Bridge Forwarding Process. Figure 22-1 shows a different view of those details, rearranged so that those entities of the Forwarding Process that are concerned only with a single Bridge Port can be put in the proper relationship to entities such as CFM shims. Figure 31-1 shows only the queuing functions of Figure 22-1, as modified for a congestion-aware Bridge. Two new entities are added for the congestion-aware Bridge: the CP (31.1.1) and the CP ingress multiplexer (31.1.2).

Figure 31-1—CPs and congestion-aware queues in a Bridge

### 1 31.1.1 Congestion Point (CP)

2 As described in 32.8 and 32.9, based on the state of its internal variables, and a frame given the CP by the  
3 Queuing frames entity (8.6.6) in an EM\_UNITDATA.request (parameters) (32.9.3), a CP either inserts the  
4 frame into its attached queue or discards the frame, and can generate a CNM, based on the frame. Discarded  
5 frames are counted in the variable cpDiscardedFrames (32.8.12). Frames successfully queued are counted in  
6 the variable cpTransmittedFrames (32.8.13). Any CNM generated is passed to the CP ingress multiplexer  
7 (31.1.2, Figure 31-1) or Flow multiplexer (31.2.4, Figure 31-2) for transmission back to the RP that sourced  
8 the frame.

9 Congestion notification does not operate correctly if frames not belonging to a CCF are allowed to pass  
10 through a CP. The CND operations (32.1) help to ensure that the only frames passing through a CP belong to  
11 CCFs.

12 The CP shall remove the CN-TAG from every frame passing through it with a priority value (a CNPV) for  
13 which the port on which the CP resides is acting in cptEdge or cptInterior CND defense mode.

14 The functions of Figure 22-1 could be implemented in different ways than that illustrated, without altering  
15 the externally observed behavior of the conformant equipment. For example, the CP could pass a copy of the  
16 output frame triggering a CNM to a function in the higher layer interfaces of a Bridge, which in turn, could  
17 generate the CNM. However, in order to provide a management interface that is useful over a wide range of  
18 implementations, the following provisions are made:

- 19 a) CNMs generated on a Bridge Port are not counted in the Frames Received [item a) in 12.6.1.1.3] or  
20 Octets Received [item b) in 12.6.1.1.3] counters.
- 21 b) CNMs generated on one Bridge Port are counted, as are ordinary data frames, on the Bridge Ports (if  
22 any) on which they are output.

23 If a Bridge supports the dot1agCfmVlanTable or the ieee8021CfmVlanTable, its CPs transmit each CNM to  
24 the Primary VID associated with the vlan\_identifier of the frame triggering the CNM's transmission.

### 25 31.1.2 CP ingress multiplexer

26 Inserts the CNMs generated by the CPs (31.1.1) among the frames received from the LAN.

## 27 31.2 Congestion-aware end station functions

28 Figure 31-2 illustrates the architecture of the queue functions of a congestion-aware end station. These  
29 functions offer a service to higher layers through a single instance of the ISS or EISS, and utilize an instance  
30 of the ISS or EISS to connect to the lower layers. The Output flow segregation function is presumed to  
31 exercise control over the higher layers' ability to present frames for transmission through the ISS or the  
32 EISS, and the Reception selection function to control the flow of frames to the higher layers, by means of  
33 additional parameters local to this instance of the ISS or the EISS and/or locally significant LMI parameters  
34 (IEEE Std 802.1AC), neither of which are specified by this standard.

35 In Figure 31-2, the outbound queue block, in the lower left of Figure 31-2, is exactly the same as the output  
36 queues in a Bridge Port that is not congestion aware, as illustrated in Figure 22-1.

37 The remaining entities illustrated in Figure 31-2 are those that are peculiar to a congestion-aware end  
38 station, and are further described in the following subclauses.

Figure 31-2—Congestion-aware queue functions in an end station

### 1 31.2.1 Output flow segregation

2 For each frame received from the upper layers for transmission, the Output flow segregation entity:

- 3 a) Assigns the frame a priority parameter based on the priority presented from the upper layer and/or  
4 upon other criteria, unspecified by this standard.
- 5 b) Determines, using priority value and the Flow Select Database (31.2.3), to which Flow queue, if any,  
6 the frame is to be assigned.
- 7 c) If the frame is not assigned to any Flow queue (the frame's priority is not a CNPV), passes the frame  
8 directly to the Flow multiplexer entity (31.2.4).
- 9 d) If the frame is assigned to a particular Flow queue (the frame's priority is a CNPV), enqueues the  
10 frame in the selected Flow queue.
- 11 e) For frames that are assigned to a Flow queue, depending on the state of the Flow queue to which the  
12 frame is assigned, and through means unspecified by this standard, can influence the higher layers'  
13 presentation of further frames to the Output flow segregation entity.

14 The Output flow segregation entity never discards a frame. Every frame presented to it is either passed to the  
15 Flow multiplexer entity (31.2.4) or stored in a Flow queue, as described previously. This standard assumes  
16 that the Output flow segregation entity can apply means, unspecified by this standard, to prevent the upper  
17 layers from offering a frame that should be stored in a Flow queue, but for which the Flow queue has  
18 insufficient resources.

19 The default configuration for an end station shall have a single Flow queue per CNPV. An end station may  
20 support additional Flow queues, or support more than one CNPV with a single Flow queue.

21 NOTE—Requirements for a default configurations do not imply that explicit action via SNMP is required to change  
22 from the default. For example, managed objects in an end station can be adjusted by an application program.

23 If the Output flow segregation function in an end station can change its method for assigning frames to Flow  
24 queues, it shall not do so in a manner that impairs the ability of any compliant CP implementation to throttle  
25 the data from the sourcing end station, and shall not materially increase the likelihood of misordered frame  
26 transmissions in a manner that adversely impacts the higher layers' functions.

### 27 31.2.2 Per-CNPV station function

28 There is one Per-CNPV station function on each Port of a congestion-aware end station for each priority  
29 value that is a CNPV. All of the frames passing through a Per-CNPV station function have the same CNPV  
30 priority parameter value.

31 As illustrated in Figure 31-3, each Per-CNPV station function is composed of the following entities:

- 32 a) One or more Flow queues (31.2.2.1).
- 33 b) One or more RPs (31.2.2.2), each associated with exactly one Flow queue, each comprising:
  - 34 1) A RP state machine (31.2.2.3) for each RP.
  - 35 2) A Rate Limiter (31.2.2.4) for each RP.
- 36 c) One Flow Selection function (31.2.2.5).

#### 37 31.2.2.1 Flow queue

38 A Flow queue is a first-in-first-out queue of frames, all for the same CNPV. An Output flow segregation  
39 entity selects the Flow queue into which a given frame is inserted, and an RP determines when a frame is  
40 removed from a Flow queue.

41 NOTE—The Flow queue is a notional convention used to unambiguously describe the behavior of the RP. An end  
42 station can implement the Flow queue without explicitly storing frames in a queue, based on its knowledge of the state of  
43 the higher-layer applications supplying the frames.

**Figure 31-3—Per-CNPV station function**

#### 1 31.2.2.2 Reaction Point (RP)

2 A single RP is associated with each Flow queue. An RP is composed of a RP state machine (31.2.2.3) and a  
3 Rate Limiter (31.2.2.4).

#### 4 31.2.2.3 RP state machine

5 A single RP state machine is associated with each Flow queue. As described in detail in Clause 32, the RP  
6 state machine consists of a timer (32.12), variables (32.10, 32.11, and 32.13), procedures (32.14), and a state  
7 machine (32.15) that determine the value of the `rpLimiterRate` variable (32.13.8), which, via the Rate  
8 Limiter (31.2.2.4), controls the transmission of frames from the Flow queue. The state machine and  
9 variables, in turn, are controlled by the frames input, managed objects (12.20.4), the Output flow segregation  
10 entity (31.2.1), and the CNMs received from the CNM demultiplexer (31.2.5).

#### 11 31.2.2.4 Rate Limiter

12 A single Rate Limiter is associated with each Flow queue. The Rate Limiter enforces the output rate,  
13 `rpLimiterRate` (32.13.8), determined by the RP state machine (31.2.2.3). The octets in the frames passed  
14 from the Rate Limiter to the Flow Selection function (31.2.2.5) are counted in `rpByteCount` (32.13.2). The  
15 details of the operation of the Rate Limiter are not specified by this standard, but the measurable output rate  
16 is specified.

17 For a given measurement period  $T$ ,  $R_T$  is defined as the integral of `rpLimiterRate` over  $T$ , and  $L_T$  as the  
18 number of octets actually output to the LAN, including preambles, inter-frame gaps, etc., stemming from  
19 frames that pass through that RP's Rate Limiter. An end station shall ensure that:

$$20 \quad L_T \leq (1.05 \times R_T) + (16 \text{ maximum-sized frames}) \quad (31-1)$$

21 for the two values of  $T$  = one second and  $T$  = 1 million bits divided by the physical line rate (in bits per  
22 second), where any number of simultaneous measurements can start at any time.

1 NOTE 1—The rate computations and variables [Equation (31-1), 32.13.6, 32.11.6, etc.] include all of the octets  
2 associated with a frame on the LAN, including preambles, inter-frame gaps, etc., and thus reflect actual physical data  
3 rates. However, the resource actually protected by congestion notification is octets in buffers, not octet times on wires.  
4 Per-frame overhead on the LAN is added to serve as a reasonable approximation, made at the RP, to the actual size of the  
5 frame in the Bridges' or end stations' buffers. The extra 5% margin in Equation (31-1) is provided because this  
6 approximation is inexact.

7 NOTE 2—Although the simulations have been studied with a burst of one maximum-sized frame, this standard allows  
8 the end stations to send data in bursts of 16 maximum-sized frames, primarily to ease implementations. Larger bursts of  
9 data have a negative impact on the overall performance of the QCN algorithm, and can lead to lower link utilization.

### 10 31.2.2.5 Flow Selection

11 The Flow Selection function decides from which Flow queue in its Per-CNPV station function, if any, a  
12 frame will be offered to the Flow multiplexer. Whenever the output queue that receives frames from the  
13 Flow Selection function (via the Flow multiplexer) is full, the Flow Selection function shall not present any  
14 frame to the Flow multiplexer; this ensures that no frames in CNPVs will be discarded in the Port due to a  
15 lack of room in the output queue.

16 By means unspecified in this standard, the Flow Selection function selects frames to pass to the Flow  
17 multiplexer from the uncontrolled Flow queues (31.2.2.1) and Rate Limiters (31.2.2.4). Whenever a frame is  
18 passed from a Rate Limiter through the Flow Selection function to the Flow multiplexer, the Flow Selection  
19 function calls TransmitDataFrame (32.14.3) to update the RP variables (32.13). If the port's neighbor is  
20 ready to receive frames with CN-TAGs for the frame's CND (defense mode is `cptInteriorReady`), the Flow  
21 Selection function may insert a CN-TAG (30.5) at the beginning of the frame's `mac_service_data_unit`, and  
22 if not (any CND defense mode other than `cptInteriorReady`), it shall not insert a CN-TAG. (See 33.2 for a  
23 further explanation of CN-TAG insertion.)

### 24 31.2.3 Flow Select Database

25 The Flow Select Database is used by the Output flow segregation (31.2.1) entity to determine to which Flow  
26 queue (31.2.2.1) a given frame is assigned.

27 The means by which the Flow Select Database selects a Flow queue is unspecified by this standard.

### 28 31.2.4 Flow multiplexer

29 The Flow multiplexer merges the frames from the Per-CNPV station functions' Flow Selection functions  
30 (31.2.2.5), the frames bypassing the Per-CNPV station functions, and the CNM frames from the CPs  
31 (31.1.1), and delivers the frames to the Queuing frames (8.6.6) entity in the end station's output path.

### 32 31.2.5 CNM demultiplexer

33 The CNM demultiplexer identifies CNMs received from the LAN, uses the Flow ID (33.2.1) and/or  
34 Encapsulated priority (33.4.7) to determine to which RP (31.2.2.2) each CNM is intended, and directs them  
35 to the correct RPs. This standard does not specify whether or how the end station can use the Flow ID to  
36 further identify one or more individual flows within a Flow queue and its associated RP. If a CNM is  
37 received that has no CN-TAG, or a CN-TAG whose Flow ID is unknown to the RP, the CNM is discarded.  
38 All non-CNM frames are passed to the Input flow segregation entity (31.2.6).

### 1 31.2.6 Input flow segregation

2 For each frame received from the lower layers for reception, the Input flow segregation entity:

- 3 a) If the frame's priority is not a CNPV, decides, in an unspecified manner, whether to pass the frame to  
4 an unspecified queue, pass it to the higher layers, or discard it.
- 5 b) If the frame's priority is a CNPV, passes the frame to a CP (31.1.1), selected by unspecified means,  
6 for processing.

7 NOTE 1—For example, an end station might support a single CP, or support one CP per CNPV, per VID, per  
8 application, or per data flow. Neither these nor any choices for CP selection are required by this standard.

9 The Input flow segregation entity never discards a CNPV frame. Every CNPV frame presented to it is  
10 passed to a CP, as described previously.

11 NOTE 2—This does not mean that a station cannot drop CNPV frames. See 31.2.7.

### 12 31.2.7 End station input queue

13 The number and operation of end station input queues and the method used to drain these queues (i.e., to  
14 select and transfer frames to the receiving higher layer applications) are not specified by this standard.  
15 However, the procedures performed by a CP (32.9) require that its associated end station input queue exist,  
16 and possess certain operational parameters (32.8).

17 In the unfortunate event that a misconfiguration or an unfortunate sequence of frame transmissions results in  
18 more CNM frames arriving at a station than it can process, an end station input queue can fill up, and discard  
19 a frame presented to it by its CP or by the Input flow segregation (31.2.6) entity.

### 20 31.2.8 Reception selection

21 The Reception selection entity selects frames for delivery to the upper layers. It takes the place of the  
22 Transmission selection entity (8.6.8) of a congestion-aware Bridge. The selection algorithm depends on  
23 interactions between the applications receiving the data, the operating system supporting those applications,  
24 and the received frames that are not specified by this standard. The Reception selection entity is shown in  
25 Figure 31-2 for completeness, to indicate that frames enqueued by the Queuing frames entity (8.6.6) are, in  
26 fact, removed from the queues.

27 If the first octets of the `mac_service_data_unit` of a frame selected by the Reception selection entity are a  
28 CN-TAG, Reception selection removes the CN-TAG from the `mac_service_data_unit` before passing the  
29 frame to the higher layers. (See 33.2 for a further explanation of CN-TAG removal.)

## 1 32. Congestion notification protocol

2 Congestion-aware systems can participate in the congestion notification protocols specified in this clause:

- 3 a) CND operations (32.1).
- 4 b) The variables controlling congestion notification at the end station or Bridge component (32.2) and  
5 Port and CNPV levels (32.3).
- 6 c) The variables (32.4), procedures (32.5), and state machine (32.6) that control the defense of a CND.
- 7 d) The congestion notification protocol (32.7).
- 8 e) The variables (32.8) and procedures (32.9) that define a CP.
- 9 f) The variables associated with all (32.10), or a subset of (32.11), the RPs on a given Port and CNPV.
- 10 g) The timer (32.12), variables (32.13), procedures (32.14), and state machine (32.15) that define the  
11 operation of a single a RP.
- 12 h) The processing of CNMs by a congestion notification and encapsulation interworking function  
13 (32.16).

14 NOTE—Clause 30 introduces the principles of congestion notification operation and the network architectural concepts  
15 that support it. Clause 31 breaks down the congestion notification entities into their components. Clause 33 specifies the  
16 encoding of the PDUs used by congestion notification.

### 17 32.1 CND operations

18 As described in 30.6, a CND is a connected subset of a Virtual Bridged Network configured to support a  
19 particular CNPV. This standard provides a means whereby a VLAN Bridge or end station can recognize the  
20 like-configured ports of a CND (32.1.1), and defend its CND against incoming frames from outside the  
21 CND.

#### 22 32.1.1 CND defense

23 Unless every Bridge along a path between two congestion-aware end stations using a particular CNPV is  
24 configured for congestion notification (belongs to a CND), and unless the Bridges ensure that frames not in  
25 CNPVs use different queues than the queues used by those two end stations, those end stations will not  
26 accrue the advantages that congestion notification offers. Therefore, steps must be taken at the boundaries of  
27 a CND to protect both the CND and the network outside the CND.

28 Every frame received on a Port passes through the ISS Support by specific MAC procedures  
29 (IEEE Std 802.1AC), which can change the priority parameter of the received frame, using the Port's  
30 Priority regeneration table, Table 6-4. This table can be controlled by a managed object (12.6). In addition,  
31 in order to prevent frames not in CNPVs from entering CP-controlled queues, each Port's Priority  
32 regeneration table can be modified.

33 If a Port's neighbor is known to also be configured for a particular CNPV, the entry in the Port's Priority  
34 regeneration table for that CNPV is ignored, and the priority is never changed on input. The Bridge  
35 component or end station connected to that Port can be trusted to use that CNPV. If the Port's neighbor is  
36 known to not be configured for a particular CNPV, the entry in the Port's Priority regeneration table for that  
37 CNPV shall be overridden to translate the CNPV to an alternate non-CNPV value. The neighboring system  
38 is not trusted, so the priority values of any frames carrying the CNPV's value are changed. Altering the  
39 priority values of received frames defends the CND from frames not originating from an RP. Similarly, if a  
40 CNPV is configured on any Port, then on that Port, the Port's Priority regeneration table shall be overridden  
41 to prevent any other priority value from being remapped into that CNPV.

1 If a port has multiple neighbors, or if the neighbor on a Port is not congestion aware, then the CN-TAGs  
2 shall be removed from any frames transmitted on a CNPV. This ensures that the benefits of congestion  
3 notification can be provided as far as possible along a path from a congestion-aware source to a  
4 noncongestion-aware destination. Furthermore, CN-TAGs shall be removed from any frames transmitted  
5 from a CNPV toward a system that is congestion aware, but is still remapping the CNPV to a non-CNPV  
6 priority.

7 Thus, for each priority value, the CND defense mode can take one of the following four values, whether  
8 derived from LLDP or set by managed variables:

- 9 — **cptDisabled:** The congestion notification capability is administratively disabled for this priority  
10 value and port. This priority is not a CNPV. The priority regeneration table (6.9.4) controls the  
11 remapping of input frames on this port to or from this priority. CN-TAGs are neither added by an  
12 end station nor stripped by a Bridge.
- 13 — **cptEdge:** On this port and for this CNPV, the priority parameters of input frames are remapped to an  
14 alternate (non-CNPV) value, and no priority value is remapped to this CNPV, regardless of the  
15 priority regeneration table. CN-TAGs are not added by an end station and are removed from frames  
16 before being output by a Bridge.
- 17 NOTE—The cptEdge CND defense mode is optional for an end station. See 32.4.9.
- 18 — **cptInterior:** On this port and for this CNPV, the priority parameters of input frames are not  
19 remapped to another value, and no priority value is remapped to this CNPV, regardless of the  
20 priority regeneration table. CN-TAGs are not added by an end station, and are removed from frames  
21 before being output by a Bridge.
- 22 — **cptInteriorReady:** On this port and for this CNPV, the priority parameters of input frames are not  
23 remapped to another value, and no priority value is remapped to this CNPV, regardless of the  
24 priority regeneration table. CN-TAGs can be added by an end station and are not removed from  
25 frames by a Bridge.

26 The determination of the operational state of a CNPV on a given port is determined by variables and by  
27 LLDP (32.1.1, 32.2.1, 32.3.7, 32.3.4, 32.4.1, 32.4.3).

28 Taken together, these capabilities ensure that as long as the default values of the managed variables  
29 controlling CND defense are not overridden with incorrect values:

- 30 a) A data frame received by an end station on a CNPV has been governed by congestion notification  
31 along its entire path from the transmitting end station.
- 32 b) Uncontrolled data streams sourced by an end station that is congestion unaware cannot pass through  
33 a CP, with a resultant excessive loss of congestion-aware frames.
- 34 c) A data frame carrying a CN-TAG cannot be delivered to a system that is congestion unaware, and  
35 thus be unreadable by that system.

36 It is therefore recommended that the network administrator allow CND recognition to operate automatically  
37 (32.1.2).

38 CND defense operates on each LAN separately; it does not ensure the existence of an end-to-end  
39 congestion-aware path from end station to end station through a VLAN Bridged Network. Misconfiguration,  
40 the presence along the path of a congestion unaware Bridge, or the activation of a new Bridge or LAN  
41 (temporarily) can cause frames to exit a CND, and hence the following to occur:

- 42 d) Data frames can be transmitted by a congestion-aware end station on a CNPV, then be uncontrolled  
43 for congestion along some part of their path, and be delivered to an end station on a non-CNPV  
44 priority value with no CN-TAG.

- 1 e) If a congestion-aware end station transmits data frames with CN-TAGs, and is connected to a  
2 congestion unaware end station along a path consisting entirely of congestion unaware or  
3 misconfigured Bridges, the receiving end station will be unable to understand the CN-TAG, and thus  
4 unable to process the data frames.
- 5 f) If a system generates CNMs on a CNPV (not recommended, see 32.2.2), they can be delivered on a  
6 non-CNPV priority value with no CN-TAG.

### 7 **32.1.2 Automatic CND recognition**

8 Congestion notification can use the Link Layer Discovery Protocol (LLDP), defined in IEEE Std 802.1AB,  
9 to advertise the CNPVs supported on a Bridge's or end station's port, to determine whether the other  
10 Bridges' or end stations' ports connected to the same LAN are configured for those same CNPVs, and to  
11 control the operation of the CND defenses (32.1.1).

12 Multiple instances of LLDP can be run on a single port. Each instance's LLDPDUs use a different  
13 destination\_address and therefore can reach different distances through a Virtual Bridged Network,  
14 depending on the types of the devices in that network and their connectivity. Since any Bridge that is not  
15 congestion aware can spoil the ability of the Virtual Bridged Network to minimize frame loss, the selection  
16 of which LLDP instance is used for CND defense defaults to the Nearest Bridge Address (01-80-C2-00-00-  
17 0E). This instance minimizes the reach of LLDP, and hence the risk that a noncongestion-aware Bridge is  
18 present.

19 As described in D.2.7, a single Congestion Notification TLV can be inserted into the LLDPDUs transmitted  
20 from any Bridge or end station port that is configured to support a CNPV. The Congestion Notification TLV  
21 carries two fields that together provide for automatic control the of the CND defenses:

- 22 a) Eight per-priority CNPV indicators (D.2.7.3), one per priority level, indicating whether each priority  
23 is or is not a CNPV on this port; and
- 24 b) Eight per-priority Ready indicators (D.2.7.4), one per priority level, indicating whether the priority  
25 remap defenses are disabled on this port.

26 For every CNPV configured on a port, if LLDP finds exactly one remote neighbor, and if that neighbor's  
27 database in the port's LLDP table carries a Congestion Notification TLV (D.2.7) with that CNPV's bit set in  
28 the per-priority CNPV indicators, then that CNPV is known to be configured on the remote system's port.  
29 This condition is summarized by the `cnpdRcvdCnpv` variable (32.4.11). Similarly, the `cnpdRcvdReady`  
30 variable (32.4.11) indicates whether the remote neighbor has or has not turned off its priority remapping  
31 defense. The read-only managed object `cnpdAutoDefenseMode` (32.4.3) indicates the results of the LLDP.

### 32 **32.1.3 Variables controlling CND defense**

33 In order to control CND defense, CN component managed objects (12.21.1), CN component priority  
34 managed objects (12.21.2), CN Port priority managed objects (12.21.3), and Congestion Point managed  
35 objects (12.21.4) override and are overridden by each other as follows:

- 36 a) Altering the CN component managed object (12.21.1) or CN component priority managed object  
37 (12.21.2) does not alter the values of any of the other managed objects (12.21.3, 12.21.4, 12.21.6).
- 38 b) If `cngMasterEnable` (32.2.1) is FALSE, all congestion notification activity is suppressed; the Priority  
39 Regeneration Table (6.9.4) operates normally, and CNMs, CN-TAGs, and LLDP Congestion  
40 Notification TLVs are never generated and are always ignored on receipt. If TRUE, the other  
41 managed objects control the operation of congestion notification.
- 42 c) The Port/priority and component objects override each other as shown in Table 32-1 and Table 32-2.  
43 In each case, if the Port/priority object contains the specified value, the component or component/  
44 priority object controls the specified function.

**Table 32-1—LLDP instance selection managed object overrides**

| (Per-port per-priority)<br>cnpdLdpInstanceChoice<br>32.4.4 | (Component per-priority)<br>cncpLdpInstanceChoice<br>32.3.6 | Congestion<br>Notification TLV<br>is sent/received | LLDP instance is<br>selected by                               |
|------------------------------------------------------------|-------------------------------------------------------------|----------------------------------------------------|---------------------------------------------------------------|
| cnlNone                                                    | any                                                         | No                                                 | None selected                                                 |
| cnlAdmin                                                   | any                                                         | Yes                                                | (Per-port per-priority)<br>cnpdLdpInstanceSelector<br>32.4.5  |
| cnlComponent                                               | cnlNone                                                     | No                                                 | None selected                                                 |
| cnlComponent                                               | cnlAdmin                                                    | Yes                                                | (Component per-priority)<br>cncpLdpInstanceSelector<br>32.3.7 |

**Table 32-2—CND defense mode selection managed object overrides**

## 1 32.2 CN component variables

2 Every congestion-aware end station or Bridge component has a set of CN component variables to control the  
3 overall operation of congestion notification. All of these variables are included in the CN component  
4 managed object (12.21.1). Variables marked, “CP only” are not required for an end station that does not  
5 support CPs. The CN component variables include the following:

- 6 a) cngMasterEnable (32.2.1)
- 7 b) cngCnmTransmitPriority (32.2.2)
- 8 c) cngDiscardedFrames (32.2.3)
- 9 d) cngErroredPortList (32.2.4)

### 1 32.2.1 cngMasterEnable

2 A Boolean value specifying whether congestion notification is enabled in this Bridge component or end  
3 station.

### 4 32.2.2 cngCnmTransmitPriority

5 (CP only) The priority value to be used when transmitting CNMs from this Bridge component or end station  
6 (default 6) [item h) in 32.9.4].

7 NOTE—If cngCnmTransmitPriority is itself a CNPV, then it is possible that another CP could generate a CNM in  
8 response to a CNM sent by this Port. Although this is not desirable, the fact that CNMs are sent in response to only a  
9 sampling of frames means that the network will not fail due to an excessive number of CNMs.

### 10 32.2.3 cngDiscardedFrames

11 (CP only) The total number of frames discarded from full CP queues. This is the total of the values of all  
12 cpDiscardedFrames (32.8.12) variables for this end station or Bridge component.

### 13 32.2.4 cngErroredPortList

14 (CP only) A list of Ports whose alternate priority values (cnpdAlternatePriority, 32.4.6) specify a CNPV,  
15 where 0 indicates that the Bridge's alternate priority value (cncpAlternatePriority, 32.3.2) specifies a CNPV.

16 NOTE—The alternate priority (cncpAlternatePriority, 32.3.2, or cnpdAlternatePriority, 32.4.6) for a given CNPV cannot  
17 itself be a CNPV. But, because alternate priority values can be set using different managed objects for different CNPVs,  
18 invalid configurations can be specified. cngErroredPortList provides the network administrator with a list of Ports that  
19 could have invalid configurations.

## 20 32.3 Congestion notification per-CNPV variables

21 An instance of the congestion notification per-CNPV variables exists for each CNPV in a congestion-aware  
22 end station or Bridge component to control CN for all Ports in the end station or Bridge component.  
23 Variables marked “CP only” are not required for an end station that does not support CPs. The congestion  
24 notification per-CNPV variables include the following:

- 25 a) cncpDefModeChoice (32.3.1)
- 26 b) cncpAlternatePriority (32.3.2)
- 27 c) cncpAutoAltPri (32.3.3)
- 28 d) cncpAdminDefenseMode (32.3.4)
- 29 e) cncpCreation (32.3.5)
- 30 f) cncpLldpInstanceChoice (32.3.6)
- 31 g) cncpLldpInstanceSelector (32.3.7)

### 32 32.3.1 cncpDefModeChoice

33 An enumerated value specifying how the CND defense mode and alternate priority for all Ports for this  
34 CNPV are to be selected, unless overridden (32.1.3) by the variables in the CND defense per-Port per-CNPV  
35 variables (32.4), either one of the following:

- 36 1) **cpcAdmin:** The Port's default CND defense mode for this priority is controlled by  
37 cncpAdminDefenseMode (32.3.4) and the alternate priority by cncpAlternatePriority (32.3.2);  
38 or
- 39 2) **cpcAuto:** The Port's default CND defense mode for this priority is controlled by LLDP and the  
40 Congestion Notification TLV (cnpdAutoDefenseMode, 32.4.3) and the alternate priority by  
41 cncpAutoAltPri (32.3.3).

### 1 32.3.2 cncpAlternatePriority

2 (CP only) An alternate priority value to which this priority value is to be remapped when the Port's CND  
3 defense mode is cptEdge for this priority (default value 0). This can be overridden by cnpdAlternatePriority  
4 (32.1.3, 32.4.6).

### 5 32.3.3 cncpAutoAltPri

6 An integer indicating the next lower priority value than this CNPV that is not a CNPV in an end station or  
7 Bridge component, or the next higher non-CNPV, if all lower values are CNPVs (32.1.1).

### 8 32.3.4 cncpAdminDefenseMode

9 An enumerated value controlling the CND defense mode (30.6) for all Ports for this CNPV in this Bridge  
10 component or end station: cptDisabled (1), cptInterior (2, the default value), cptInteriorReady (3), or  
11 cptEdge (4) (32.1.1). This can be overridden by cnpdAdminDefenseMode (32.1.3, 32.4.2).

### 12 32.3.5 cncpCreation

13 An enumerated value controlling the applicability of this CN component priority managed object to the  
14 Ports in that Bridge component or end station, either one of the following:

- 15 1) **cncpAutoEnable:** The cnpdDefModeChoice variable (32.4.1) in any CN Port priority  
16 managed object created as a result of the creation of this CN component priority managed  
17 object or the creation of a Port is given the value cpcComp (3); or
- 18 2) **cncpAutoDisable:** The cnpdDefModeChoice variable (32.4.1) in any CN Port priority  
19 managed object created as a result of the creation of this CN component priority managed  
20 object or the creation of a Port is given the value cpcAdmin (1).

### 21 32.3.6 cncpLldpInstanceChoice

22 Determines the method by which the component LLDP instance selector, specifying on which LLDP  
23 instance the Congestion Notification TLV is to carry information for this priority, is determined (32.1.1),  
24 either one of the following:

- 25 1) **cnlNone:** if LLDP is not to carry Congestion Notification TLVs on any Port or priority; or
- 26 2) **cnlAdmin:** If cncpLldpInstanceSelector (32.3.7) governs LLDP instance selection for all Ports  
27 and priorities (this is the default value).

28 This choice can be overridden (32.1.3) on a per-Port per-priority basis by cnpdLldpInstanceChoice (32.4.4).

### 29 32.3.7 cncpLldpInstanceSelector

30 A reference to the LLDP destination address table entry whose LLDPDUs are to carry Congestion  
31 Notification TLVs for this Bridge component or end station (32.1.1). The use of this variable is controlled by  
32 cncpLldpInstanceChoice (32.3.6).

## 1 32.4 CND defense per-Port per-CNPV variables

2 For each Port in a congestion-aware end station or Bridge component, and for each priority value for which  
3 a set of congestion notification per-CNPV variables exists, there is an instance of the CND defense per-Port  
4 per-CNPV variables. These variables control congestion notification on the port for a CNPV, including CND  
5 defense. Variables marked, “CP only” are not required for an end station that does not support CPs. The  
6 CND defense per-Port per-CNPV variables include the following:

- 7 a) `cnpdDefModeChoice` (32.4.1)
- 8 b) `cnpdAdminDefenseMode` (32.4.2)
- 9 c) `cnpdAdminDefenseMode` (32.4.2)
- 10 d) `cnpdAutoDefenseMode` (32.4.3)
- 11 e) `cnpdLldpInstanceChoice` (32.4.4)
- 12 f) `cnpdLldpInstanceSelector` (32.4.5)
- 13 g) `cnpdAlternatePriority` (32.4.6)
- 14 h) `cnpdXmitCnpvCapable` (32.4.7)
- 15 i) `cnpdXmitReady` (32.4.8)
- 16 j) `cncpDoesEdge` (32.4.9)
- 17 k) `cnpdAcceptsCnTag` (32.4.10)
- 18 l) `cnpdRcvdCnpv` (32.4.11)
- 19 m) `cnpdRcvdReady` (32.4.12)
- 20 n) `cnpdIsAdminDefMode` (32.4.13)
- 21 o) `cnpdDefenseMode` (32.4.14)

### 22 32.4.1 `cnpdDefModeChoice`

23 An enumerated value specifying how the CND defense mode and the alternate priority of the Port for this  
24 priority is to be determined, (30.6, 32.1.1, 32.1.1):

- 25 1) **cpcAdmin:** The Port’s CND defense mode for this priority is controlled by  
26 `cnpdAdminDefenseMode` (32.4.2), and the alternate priority by `cnpdAlternatePriority` (32.4.6);
- 27 2) **cpcAuto:** The Port’s CND defense mode for this priority is controlled by LLDP and the  
28 Congestion Notification TLV (`cnpdAutoDefenseMode`, 32.4.3) and the alternate priority by  
29 `cncpAutoAltPri` (32.3.3); or
- 30 3) **cpcComp:** The Port’s CND defense mode for this priority is controlled by  
31 `cncpDefModeChoice` (32.3.1) and the alternate priority by `cncpAutoAltPri` (32.3.3) (this is the  
32 default value).

### 33 32.4.2 `cnpdAdminDefenseMode`

34 An enumerated value specifying the CND defense mode of the Port for this priority, if and only if  
35 `cnpdDefModeChoice` (32.4.1) has the value `cpcAdmin` (1) (30.6, 32.1.1, 32.1.1):

- 36 1) **cptDisabled:** The CP is disabled on this port for this CNPV. Priority regeneration on input is  
37 controlled by the priority regeneration table. This is the same behavior as when  
38 `cngMasterEnable` (32.2.1) has the value `FALSE`. (This is the default value.);
- 39 2) **cptInterior:** The priority parameter of frames input are not remapped to or from this priority,  
40 and CN-TAGs are not output;
- 41 3) **cptInteriorReady:** The priority parameter of frames input are not remapped to or from this  
42 priority, and CN-TAGs can be output; or
- 43 4) **cptEdge:** The priority parameter of frames input at this priority are remapped to an alternate  
44 value, frames at other priorities are not remapped to this priority, and CN-TAGs are not output.

### 1 32.4.3 cnpdAutoDefenseMode

2 An enumerated value indicating the operating mode: cptInterior (2), cptInteriorReady (3), or cptEdge (4), in  
3 which the Port would operate for this CNPV if cnpdDefModeChoice (32.4.1) had the value cpcAuto (2).

4 NOTE—cncpAdminDefenseMode (32.3.4) is controlled by the network administrator. The object  
5 cnpdAutoDefenseMode (32.4.3) indicates what the CND defense mode would be, if it were controlled by the LLDP  
6 Congestion Notification TLV.

### 7 32.4.4 cnpdLldpInstanceChoice

8 Port and priority LLDP instance selector, specifying on which LLDP instance the Congestion Notification  
9 TLV is to carry information for this priority on this Port (32.1.1):

- 10 1) **cnlNone:** No LLDP Congestion Notification TLV is to carry Per-priority CNPV indicators or  
11 Per-priority Ready indicators on this Port for this priority;
- 12 2) **cnlAdmin:** cnpdLldpInstanceSelector (32.4.5) governs which LLDP instance is to carry Per-  
13 priority CNPV indicators and Per-priority Ready indicators for this priority in its Congestion  
14 Notification TLV on this Port; or
- 15 3) **cnlComponent:** cnpdLldpInstanceSelector (32.3.7) governs LLDP instance selection for this  
16 Port and priority (this is the default value).

### 17 32.4.5 cnpdLldpInstanceSelector

18 A reference to the LLDP destination address table entry for an LLDP instance selector, specifying on which  
19 LLDP instance the Congestion Notification TLV is to carry information for this priority on this Port, if and  
20 only if cnpdLldpInstanceChoice (32.4.4) is set to cnlAdmin (2). Default value is 1. (32.1.1);

### 21 32.4.6 cnpdAlternatePriority

22 (CP only) An alternate priority value to which this priority value is to be remapped when the Port's CND  
23 defense mode is cptEdge for this priority, if and only if cnpdDefModeChoice (32.4.1) is set to cpcAdmin (1)  
24 (default value 0).

### 25 32.4.7 cnpdXmitCnpvCapable

26 Per-port per-priority Boolean variable indicating whether a given priority on this Port is (TRUE) or is not  
27 (FALSE) currently operating as a CNPV. cnpdXmitCnpvCapable is transmitted in the per-priority CNPV  
28 indicators in the Congestion Notification TLV (D.2.7.3). The variable is TRUE if and only if all of the  
29 following conditions are met:

- 30 a) cngMasterEnable (32.2.1) is TRUE; and
- 31 b) The CND defense mode, as selected by cncpDefModeChoice, cncpAdminDefenseMode,  
32 cnpdDefModeChoice, and cnpdAdminDefenseMode, according to Table 32-2, is not cptDisabled.

### 33 32.4.8 cnpdXmitReady

34 Per-port per-priority Boolean variable indicating whether the priority remap defenses for this port and  
35 CNPV have been disabled. cnpdXmitReady is transmitted in the per-priority Ready indicators in the  
36 Congestion Notification TLV (D.2.7.4). This variable is set and reset by the CND defense state machine  
37 (32.6).

### 1 **32.4.9 cncpDoesEdge**

2 Boolean variable indicating whether the cptEdge CND defense mode (32.1.1) is (TRUE) or is not (FALSE)  
3 implemented on this port for this priority. This variable is TRUE in a Bridge. In an end station, it may be  
4 either TRUE or FALSE. This variable is not a managed object.

5 NOTE—This variable, when FALSE, causes the state machine in Figure 32-1 to pass through the CNDD\_EDGE state  
6 directly to the CNDD\_INTERIOR state. Since the state machine takes, in theory, no time to execute, it is impossible to  
7 tell from any measurement taken outside the system whether the actions specified in the CNDD\_EDGE state are actually  
8 executed.

### 9 **32.4.10 cnpdAcceptsCnTag**

10 Boolean variable indicating whether the CN-TAG is (TRUE) or is not (FALSE) acceptable on data frames  
11 received on this port for this CNPV. This variable is TRUE in a Bridge. In an end station, it may be either  
12 TRUE or FALSE. This variable is not a managed object.

13 NOTE—This variable can be used by an end station that finds it convenient for the adjacent Bridge to remove CN-TAGs  
14 from frames on a CNPV. By preventing this Port and CNPV's cnpdXmitReady variable from being set TRUE, (see  
15 Figure 32-1) cnpdAcceptsCnTag prevents the adjacent device's CND defense state machine (32.6) from advancing from  
16 the CNDD\_INTERIOR state to the CNDD\_INTERIOR\_READY state, and thus prevents it from transmitting a  
17 CN-TAG on this CNPV.

### 18 **32.4.11 cnpdRcvdCnpv**

19 Per-port per-priority Boolean variable indicating the presence of an LLDP neighbor's Congestion  
20 Notification TLV (D.2.7). cnpdRcvdCnpv is TRUE only if all of the following are true:

- 21 a) An LLDP instance is selected by cncpLldpInstanceSelector (32.3.7) and cnpdLldpInstanceSelector  
22 (32.4.5);
- 23 b) The selected LLDP instance indicates that the Port has a single neighbor;
- 24 c) The selected LLDP instance's neighbor information includes a Congestion Notification TLV; and
- 25 d) That Congestion Notification TLV's Per-priority CNPV indicators field has a value of 1 in the  
26 position corresponding to this CNPV.

### 27 **32.4.12 cnpdRcvdReady**

28 Per-port per-priority Boolean variable indicating that the neighboring system has turned off its CND  
29 defenses. cnpdRcvdReady is TRUE only if all of the following are true:

- 30 a) cnpdRcvdCnpv is TRUE; and
- 31 b) The bit in the same Congestion Notification TLV's (D.2.7) Per-priority Ready indicators field  
32 (D.2.7.4) has a value of 1 in the position corresponding to this CNPV.

### 33 **32.4.13 cnpdIsAdminDefMode**

34 Boolean variable derived from the managed objects, indicating to the CND defense state machine (32.6)  
35 whether the CND defense mode is being forced to a particular state by the managed objects, as shown in  
36 Table 32-3.

37 NOTE—The purpose of this variable is to simplify the Boolean expressions in Figure 32-1.

### 38 **32.4.14 cnpdDefenseMode**

39 Enumerated value, indicating the management choice for the CND defense mode, if any, as shown in  
40 Table 32-3. The value of this variable is not defined if the managed variables indicate no choice for the CND  
41 defense mode.

42 NOTE—The purpose of this variable is to simplify the exit condition expressions in Figure 32-1.

**Table 32-3—Determining cnpdIsAdminDefMode and cnpdDefenseMode**

| (Per-port per-priority)<br>cnpdDefModeChoice<br>(32.4.1) | (Component per-priority)<br>cncpDefModeChoice<br>(Clause 32) | cnpdIsAdminDefMode<br>(32.4.13) is | cnpdDefenseMode<br>(32.4.14) is obtained<br>from           |
|----------------------------------------------------------|--------------------------------------------------------------|------------------------------------|------------------------------------------------------------|
| cpcAdmin                                                 | Any                                                          | TRUE                               | (Per-port per-priority)<br>cnpdAdminDefenseMode<br>32.4.2  |
| cpcAuto                                                  | Any                                                          | FALSE                              | Not defined                                                |
| cpcComp                                                  | cpcAdmin                                                     | TRUE                               | (Component per-priority)<br>cncpAdminDefenseMode<br>32.3.4 |
| cpcComp                                                  | cpcAuto                                                      | FALSE                              | Not defined                                                |

## 32.5 CND defense procedures

There are three procedures associated with the CND defense state machine. They are as follows:

- a) DisableCnpvRemapping() (32.5.1)
- b) TurnOnCnDefenses() (32.5.2)
- c) TurnOffCnDefenses() (32.5.3)

### 32.5.1 DisableCnpvRemapping()

Removes any overrides by congestion notification of the Priority Regeneration Table (6.9.4).

### 32.5.2 TurnOnCnDefenses()

Overrides the Priority Regeneration Table (6.9.4) to use the alternate priority specified by cncpAlternatePriority (32.3.2), cncpAutoAltPri (32.3.3), and cnpdAlternatePriority (32.4.6) for frames with this CNPV, instead of the value in the Priority Regeneration Table.

### 32.5.3 TurnOffCnDefenses()

Overrides the Priority Regeneration Table (6.9.4) to not alter the priority of incoming frames with this CNPV, instead of using the value in the Priority Regeneration Table.

## 32.6 CND defense state machine

The CND defense state machine is illustrated in Figure 32-1. A congestion-aware Bridge component or end station shall implement one CND defense state machine per port per priority level.

NOTE—In Figure 32-1, global transitions are associated with each value of cnpdDefenseMode when the CND defense mode is chosen by the managed variables; the nonglobal transitions from state to state can take place only when the CND defense mode is chosen by LLDP.

Figure 32-1—CND defense state machine

## 32.7 Congestion notification protocol

Clause 32 is a detailed specification of the state machines required to implement the QCN algorithm introduced in 30.2. Table 32-4 shows the correlation between the description of QCN in 30.2, the state machine variables in this clause, and the CNM PDU fields in 33.4.

There are two stateful participants in the congestion notification protocol:

- a) The CP (31.1.1) shall behave in a manner that is indistinguishable, from an observer external to a system, from a strict implementation of the variables in 32.8 and the procedures in 32.9.
- b) The RP (31.2.2.2) shall behave in a manner that is indistinguishable, from an observer external to a system, from a strict implementation of the timer in 32.12, variables in 32.13, the procedures in 32.14, and the state machine in 32.15.

**Table 32-4—Correspondence of QCN and CCF message fields**

| Quantized Congestion Notification protocol, 30.2                  | Congestion notification protocol, 32.7                | Congestion Notification Message, 33.3 |
|-------------------------------------------------------------------|-------------------------------------------------------|---------------------------------------|
| <b>Quantized Feedback calculation (32.8.9, item e) in 32.9.4)</b> |                                                       |                                       |
| $F_b$ (30.2.1)                                                    | —                                                     | cpFb (33.4.3)                         |

## 1 32.8 CP variables

2 The following variables control the operation of a CP:

- 3 a) cpMacAddress (32.8.1)
- 4 b) cpId (32.8.2)
- 5 c) cpQSp (32.8.3)
- 6 d) cpQLen (32.8.4)
- 7 e) cpQLenOld (32.8.5)
- 8 f) cpW (32.8.6)
- 9 g) cpQOffset (32.8.7)
- 10 h) cpQDelta (32.8.8)
- 11 i) cpFb (32.8.9)
- 12 j) cpEnqueued (32.8.10)
- 13 k) cpSampleBase (32.8.11)
- 14 l) cpDiscardedFrames (32.8.12)
- 15 m) cpTransmittedFrames (32.8.13)
- 16 n) cpTransmittedCnms (32.8.14)
- 17 o) cpMinHeaderOctets (32.8.15)

### 1 32.8.1 cpMacAddress

2 The MAC address, belonging to the system transmitting the CNM PDU, used as the source\_address of  
3 CNMs sent from this CP [item b) in 32.9.4].

### 4 32.8.2 cpId

5 Unsigned integer. A number that uniquely identifies a CP in a Virtual Bridged Network [item p) in 32.9.4].

6 NOTE—This standard does not specify whether the Congestion Point Identifier (CPID) reported in a CNM by a CP that  
7 serves multiple CNPVs does or does not have the same value for its different CNPVs.

### 8 32.8.3 cpQSp

9 Unsigned integer. The set-point for the queue. This is the target number of octets in the CP's queue [item e)  
10 in 32.9.4]. Default value 26000.

### 11 32.8.4 cpQLen

12 Unsigned integer. The current number of octets in the CP's queue [item c) in 32.9.4].

### 13 32.8.5 cpQLenOld

14 Unsigned integer. The previous value of cpQLen. cpQLenOld is updated from cpQLen each time  
15 GenerateCnmPdu() is called [item c) in 32.9.4].

### 16 32.8.6 cpW

17 Real number. cpW is the weight to be given to the change in queue length in the calculation of cpFb  
18 (32.8.9). Default value 2. Although cpW is specified as a real number, it is constrained to be a power of 2,  
19 e.g., 1/2, 1, 2, 4. In practice, therefore, it can be represented as a shift distance (plus an addition) in item e) in  
20 32.9.4.

### 21 32.8.7 cpQOffset

22 The signed integer value of the transmitting CP's cpQSp (32.8.3) – cpQLen (32.8.4) used to calculate cpFb  
23 (32.8.9), and thus the Quantized Feedback field (33.4.3).

### 24 32.8.8 cpQDelta

25 The signed integer value of the transmitting CP's cpQLen (32.8.4) – cpQLenOld (32.8.5) used to calculate  
26 cpFb (32.8.9), and thus the Quantized Feedback field (33.4.3).

### 27 32.8.9 cpFb

28 Signed integer. Calculated just before the CP attempts to enqueue a frame:

29 
$$\text{cpFb} = \text{cpQOffset} - \text{cpW} \times \text{cpQDelta},$$

30 where

31 
$$\text{cpQDelta} = \text{cpQLen} - \text{cpQLenOld} \quad \text{cpQOffset} = \text{cpQSp} - \text{cpQLen}$$

32 cpFb has two terms. The first term is the difference between the current and the desired queue lengths  
33 (cpQOffset, 32.8.7). The second is a weight factor cpW times the difference cpQDelta (32.8.8) between the  
34 current and the previous queue lengths. Thus, a multiple of the first derivative of the queue size is subtracted  
35 from the current nonoptimality of the queue, so that if the queue length is moving toward the set point  
36 cpQSp, cpFb will be closer to 0 than if the queue length is moving away from cpQSp.

### 1 **32.8.10 cpEnqueued**

2 Signed integer. The number of octets remaining to be enqueued by the CP before a CNM PDU is to be  
3 generated (32.9.3).

### 4 **32.8.11 cpSampleBase**

5 Unsigned integer. The minimum number of octets to enqueue in the CP's queue between CNM PDU  
6 transmissions (32.9.3). Default value 150 000.

### 7 **32.8.12 cpDiscardedFrames**

8 The number of frames offered to this CP that were discarded because of a full output queue (31.1.1).

### 9 **32.8.13 cpTransmittedFrames**

10 The number of data frames enqueued for transmission on this CP's output queue (31.1.1).

### 11 **32.8.14 cpTransmittedCnms**

12 The number of CNMs transmitted by this CP [item s] in 32.9.4].

### 13 **32.8.15 cpMinHeaderOctets**

14 The minimum number of octets that the CP is to return in the Encapsulated MSDU field (33.4.10) of each  
15 CNM it generates [item k] in 32.9.4]. Default value 0.

## 16 **32.9 CP procedures**

17 The procedures used in a CP include the following:

- 18 a) Random() (32.9.1)
- 19 b) NewCpSampleBase() (32.9.2)
- 20 c) EM\_UNITDATA.request (parameters) (32.9.3)
- 21 d) GenerateCnmPdu() (32.9.4)

22 A CP needs no state machine; the procedure EM\_UNITDATA.request (parameters), called each time a  
23 frame is presented for queuing, triggers all of the CP's functions.

### 24 **32.9.1 Random**

25 The Random function takes two parameters, min and max, and returns a pseudo-random number in the range  
26  $\text{min} \leq \text{number} < \text{max}$ . This function shall be initialized so that it generates a different value each time the  
27 system is reset.

### 28 **32.9.2 NewCpSampleBase()**

29 Called by EM\_UNITDATA.request (parameters) (32.9.3) when generating a new value for cpSampleBase  
30 (32.8.11) from the CNM PDU Quantized Feedback field (33.4.3) last generated by GenerateCnmPdu().  
31 NewCpSampleBase() returns a real number according to Table 32-5.

32 NOTE—The values in Table 32-5 are chosen so that the value returned by NewCpSampleBase() can be an integer to be  
33 used in a division, rather than a real number to be used in a multiplication.

**Table 32-5—NewCpSampleBase() return value as a function of cpFb**

| Quantized Feedback / 8 | Value returned by NewCpSampleBase() |
|------------------------|-------------------------------------|
| 0                      | 1                                   |
| 1                      | 1/2                                 |
| 2                      | 1/3                                 |
| 3                      | 1/4                                 |
| 4                      | 1/5                                 |
| 5                      | 1/6                                 |
| 6                      | 1/7                                 |
| 7                      | 1/8                                 |

### 32.9.3 EM\_UNITDATA.request (parameters)

A CP offers an instance of the EISS (6.8) to the Queuing frames function (8.6.6). When called upon to enqueue a frame, the CP:

- a) Determines the number of octets of buffer space required to enqueue the frame, and subtracts that number from cpEnqueued (32.8.10).
- b) If cpEnqueued  $\leq 0$ , then:
  - 1) Calculates a new value for cpFb according to 32.8.9.
  - 2) Calls GenerateCnmPdu() to conditionally transmit a CNM PDU.
  - 3) Replaces cpEnqueued with cpSampleBase  $\times$  NewCpSampleBase()  $\times$  Random(0.85, 1.15), and if the result is less than zero, resets cpEnqueued to 0.

The accuracy of the sample jitter introduced by the function Random(0.85, 1.15) is not critical to the success of congestion notification. The amount of jitter introduced by this function should be no more than  $0.75 \leq \text{jitter} < 1.25$  and no less than  $0.875 \leq \text{jitter} < 1.125$ .

### 32.9.4 GenerateCnmPdu()

Called by the CP to conditionally generate a CN-TAGged CNM PDU for output. GenerateCnmPdu()

- a) Uses the source\_address of the frame triggering the CNM PDU as the destination\_address of the generated CNM PDU.
- b) Uses cpMacAddress (32.8.1) as the source\_address of the CNM PDU.
- c) Replaces the value of cpQLenOld (32.8.5) with cpQLen (32.8.4).
- d) If cpFb is greater than or equal to 0, or if the destination\_address parameter of the CNM PDU is a Group, and not an Individual, address, does nothing; no further processing takes place, and no CNM PDU is transmitted.
- e) Fills the Quantized Feedback field (33.4.3) of the CNM PDU as follows:
  - if  $(\text{cpFb} < -\text{cpQSp} \times (2 \times \text{cpW} + 1))$   
Quantized Feedback = 63
  - else  
Quantized Feedback =  $-\text{cpFb} \times 63 / (\text{cpQSp} \times (2 \times \text{cpW} + 1))$
- f) If the Quantized Feedback field equal to 0 does nothing; no further processing takes place, and no CNM PDU is transmitted.

- g) If the first octets of the `mac_service_data_unit` of the frame triggering the CNM PDU are a CN-TAG, copies the Flow Identifier field (33.2.1) from that CN-TAG to the CN-TAG of the CNM, else fills the Flow Identifier field of the CNM's CN-TAG with 0.

- h) Sets the priority parameter of the CNM PDU from `engCnmTransmitPriority` (32.2.2).

NOTE 1—The default value for the priority of a CNM PDU is 6. CNM PDUs are not expected to be sent in high volumes, but undelivered CNM PDUs reduce the ability of congestion notification to prevent lost data frames. Priority 7 is typically reserved for control traffic that, if not delivered, can result in the loss of connectivity in the Bridged Network.

- i) Sets the `vlan_identifier` of the CNM PDU from the `vlan_identifier` of the frame triggering the CNM PDU, if the `dot1agCfmVlanTable` is not implemented, else the Primary VID of that `vlan_identifier`.

- j) Fills the Encapsulated destination MAC address field (33.4.8) of the CNM PDU with the `destination_address` parameter of the frame triggering the CNM PDU.

- k) Fills the Encapsulated MSDU field (33.4.10) of the CNM PDU with the first octets of the remainder of the `mac_service_data_unit` following the CN-TAG, if present, of the frame triggering the CNM PDU. The minimum number of octets is the value of `cpMinHeaderOctets` (32.8.15), or the whole of the `mac_service_data_unit` following the CN-TAG, if it is shorter, and the maximum is 64.

- l) Fills the Encapsulated MSDU length field (33.4.9) of the CNM PDU with the number of octets inserted into the Encapsulated MSDU field (33.4.10).

- m) Inserts the encapsulation appropriate to the CP's port, as specified in 33.3, at the beginning of the `mac_service_data_unit`.

NOTE 2—This encapsulation is changed by the Bridge, if required, before the CNM PDU is output on a port that uses a different encapsulation from the CP's port.

- n) Fills the Version field (33.4.1) of the CNM PDU with 0.

- o) Fills the ReservedV field (33.4.2) of the CNM PDU with 0.

- p) Fills the Congestion Point Identifier field (33.4.4) of the CNM PDU from the variable `cpId` (32.8.2).

- q) Computes and fills the `cnmQOffset` and `cnmQDelta` fields (33.4.5, 33.4.6) from the variables `cpQOffset` and `cpQDelta`.

- r) Fills the Encapsulated priority field (33.4.7) from the priority parameter of the frame triggering the CNM PDU.

- s) Increments `cpTransmittedCnms` (32.8.14).

- t) Passes the CN-TAG and CNM PDU as an `EM_UNITDATA.indication` to the higher layers (Figure 31-1), if the CP is in a Bridge, or to the Flow multiplexer (31.2.4), if the CP is in an end station (Figure 31-2).

## 32.10 RP per-Port per-CNPV variables

There is one set of these variables per Port per CNPV in a congestion-aware end station. A set of RP per-Port per-CNPV variables is created or deleted whenever a CN Port priority managed object is created or deleted. All of the RPs (if more than one) associated with a given Port and CNPV share a single set of the RP per-Port per-CNPV variables.

### 32.10.1 rpppMaxRps

An unsigned integer controlling the maximum number of RPs allowed for this CNPV on this Port (default 1). An end station shall not create more than `rpppMaxRps` on a given Port, but it can create fewer.

### 32.10.2 rpppCreatedRps

The number of times an RP's `rpEnabled` variable has been set TRUE at this priority level on this Port [item e) in 32.4.14].

### 1 32.10.3 rpppRpCentiseconds

2 An integer containing the number of RP-centiseconds accumulated by RPs at this priority level on this Port.  
3 This variable is incremented once per centisecond (10 ms) for each RP on this Port whose rpEnabled  
4 variable (32.13.1) is TRUE.

5 NOTE—Reading rpppRpCentiseconds and SysUpTime<sup>46</sup> at two different times allows a management entity to compute  
6 the average number of RPs present for a priority and Port by dividing the change in rpppRpCentiseconds by the change  
7 in SysUpTime (which is measured in centiseconds).

### 8 32.11 RP group variables

9 There is one set of RP group variables for each group of RPs belonging to a particular CNPV on a Port in a  
10 congestion-aware end station. It is an implementation choice whether each RP rate control state machine  
11 (32.15) has its own set of RP group variables or shares them with another RP rate control state machine on  
12 the same Port and the same CNPV. This standard does not specify how RPs are grouped together for  
13 management purposes, except that all of the RPs controlled by a single set of RP group variables shall serve  
14 a single CNPV. At the extremes, a single set of RP group variables could control all of the RPs serving the  
15 same CNPV, or each RP could be controlled by its own set of RP group variables. The RP group variables  
16 include the following:

- 17 a) rpgEnable (32.11.1)
- 18 b) rpgTimeReset (32.11.2)
- 19 c) rpgByteReset (32.11.3)
- 20 d) rpgThreshold (32.11.4)
- 21 e) rpgMaxRate (32.11.5)
- 22 f) rpgAiRate (32.11.6)
- 23 g) rpgHaiRate (32.11.7)
- 24 h) rpgGd (32.11.8)
- 25 i) rpgMinDecFac (32.11.9)
- 26 j) rpgMinRate (32.11.10)

#### 27 32.11.1 rpgEnable

28 A Boolean value controlling the rpEnabled variables for all of the RP rate control state machines controlled  
29 by this Reaction Point group managed object. If rpgEnable is TRUE, the controlled rpEnabled variables are  
30 not held in the FALSE state, thus enabling the RPs to pay attention to received CNMs. If rpgEnable is  
31 FALSE, the controlled rpEnabled variables are held in the FALSE state, thus disabling the RPs.

#### 32 32.11.2 rpgTimeReset

33 Unsigned integer. RpWhile (32.12.1) is reset to either rpgTimeReset or rpgTimeReset / 2 (with random  
34 jitter—see Figure 32-2 in 32.15, RPR\_ACTIVE\_TIME) each time it reaches 0, according to the state of the  
35 RP rate control state machine. Default value 15 ms.

#### 36 32.11.3 rpgByteReset

37 Unsigned integer. rpByteCount (32.13.2) is reset to either rpgByteReset or rpgByteReset / 2 (with random  
38 jitter—see Figure 32-2 in 32.15, RPR\_ACTIVE\_BYTE) each time it reaches 0, according to the state of the  
39 RP rate control state machine. Default value 150 000 octets.

<sup>46</sup> From IETF RFC 3418.

#### 1 **32.11.4 rpgThreshold**

2 Unsigned integer. Specifies the number of times rpByteStage or rpTimeStage can count before the RP rate  
3 control state machine advances states. Default value is 5.

#### 4 **32.11.5 rpgMaxRate**

5 Unsigned integer. The maximum rate, in bits per second, at which an RP can transmit. Default value is the  
6 speed of the Port. A system shall support a nonzero minimum value for rpgMaxRate no larger than 5 Mb/s.  
7 This rate includes all bits consequent to transmitting the frame on the LAN, including preamble, inter-frame  
8 gap, etc. rpgMaxRate is configurable in multiples of 1 Mb/s.

#### 9 **32.11.6 rpgAiRate**

10 Unsigned integer. The rate, in bits per second, used to increase rpTargetRate in the  
11 RPR\_ACTIVE\_INCREASE state in Figure 32-2 in 32.15. Default value 5 Mb/s. This rate includes all bits  
12 consequent to transmitting the frame on the LAN, including preamble, inter-frame gap, etc. rpgAiRate is  
13 configurable in multiples of 1 Mb/s.

#### 14 **32.11.7 rpgHaiRate**

15 Unsigned integer. The rate, in bits per second, used to increase rpTargetRate in the  
16 RPR\_HYPER\_INCREASE state in Figure 32-2 in 32.15. Default value 50 Mb/s. This rate includes all bits  
17 consequent to transmitting the frame on the LAN, including preamble, inter-frame gap, etc. rpgHaiRate is  
18 configurable in multiples of 1 Mb/s.

#### 19 **32.11.8 rpgGd**

20 Real number. Multiplied times the Quantized Feedback field (33.4.3) received in a CNM PDU to decrease  
21 rpTargetRate. Default value 1/128. rpgGd is configurable as a power of 2, e.g., 1/256, 1/128, 1/64.

#### 22 **32.11.9 rpgMinDecFac**

23 Real number. The minimum factor by which the current RP transmit rate rpCurrentRate can be changed by  
24 reception of a CNM. Default value is 0.5.

#### 25 **32.11.10 rpgMinRate**

26 Unsigned integer. The minimum value, in bits per second, for rpCurrentRate (32.13.6) Default value is  
27 10 Mb/s. A system shall support a minimum value for rpgMinRate no larger than 10 Mb/s. This rate includes  
28 all bits consequent to transmitting the frame on the LAN, including preamble, inter-frame gap, etc.  
29 rpgMinDecFac is configurable in multiples of 1 Mb/s.

### 30 **32.12 RP timer**

31 An RP implements one timer as follows:

- 32 a) RpWhile (32.12.1).

#### 33 **32.12.1 RpWhile**

34 Timer counter for controlling the RP rate control state machine (32.15). RpWhile operates normally when  
35 rpFreeze (32.13.7) is FALSE, and shall not be decremented when rpFreeze is TRUE.

## 1 32.13 RP variables

2 Each RP rate control state machine (32.15) has its own set of RP variables. The RP variables include the  
3 following:

- 4 a) rpEnabled (32.13.1)
- 5 b) rpByteCount (32.13.2)
- 6 c) rpByteStage (32.13.3)
- 7 d) rpTimeStage (32.13.4)
- 8 e) rpTargetRate (32.13.5)
- 9 f) rpCurrentRate (32.13.6)
- 10 g) rpFreeze (32.13.7)
- 11 h) rpLimiterRate (32.13.8)
- 12 i) rpFb (32.13.9)

### 13 32.13.1 rpEnabled

14 Boolean. Controls RP rate control state machine. If TRUE, state machine is running. If FALSE, state  
15 machine is held in the RPR\_RESET state. Initialized to FALSE when an RP rate control state machine is  
16 created. Held in the FALSE state if rpgEnable (32.11.1) has the value FALSE.

### 17 32.13.2 rpByteCount

18 Unsigned integer. Counts octets passed from the Rate Limiter (31.2.2.4) to the Flow Selection function  
19 (31.2.2.5). The counting down of rpByteCount to or past 0 triggers a reevaluation of rpCurrentRate  
20 (32.13.6).

### 21 32.13.3 rpByteStage

22 Unsigned integer. Counts the number of times rpByteCount has counted down to or past 0 since the last  
23 CNM was received.

### 24 32.13.4 rpTimeStage

25 Unsigned integer. Counts the number of times RpWhile has counted down to 0 since the last CNM was  
26 received.

### 27 32.13.5 rpTargetRate

28 Unsigned integer. The target rate, in bits per second, toward which rpCurrentRate is heading. This rate  
29 includes all bits consequent to transmitting the frame on the LAN, including preamble, inter-frame gap, etc.

### 30 32.13.6 rpCurrentRate

31 Unsigned integer. The rate, in bits per second, at which the Rate Limiter (31.2.2.4) transmits data from its  
32 Flow queue when rpFreeze (32.13.7) is FALSE. (The actual output of the Rate Limiter is controlled by  
33 rpLimiterRate, 32.13.8.) This rate includes all bits consequent to transmitting the frame on the LAN,  
34 including preamble, inter-frame gap, etc.

### 35 32.13.7 rpFreeze

36 Boolean. When FALSE, the RP and Rate Limiter operate normally. When TRUE, rpLimiterRate is held to  
37 the value 0, to suppress the transmission of frames. rpFreeze is FALSE when there is room for frames from  
38 this RP in the output queue, and TRUE when not.

### 1 32.13.8 rpLimiterRate

2 Unsigned integer. The rate, in bits per second, at which the Rate Limiter (31.2.2.4) transmits data from its  
3 Flow queue. rpLimiterRate is equal to rpCurrentRate (32.13.6) as long as rpFreeze (32.13.7) is FALSE, and  
4 0, when rpFreeze is TRUE. This rate includes all bits consequent to transmitting the frame on the LAN,  
5 including preamble, inter-frame gap, etc.

### 6 32.13.9 rpFb

7 Unsigned integer. The value last received in the Quantized Feedback field (33.4.3) of a CNM PDU or 0.

## 8 32.14 RP procedures

9 The following procedures are used by the RP rate control state machine and the Output flow segregation  
10 function (31.2.1):

- 11 a) ResetCnm (32.14.1)
- 12 b) TestRpTerminate (32.14.2)
- 13 c) TransmitDataFrame (32.14.3)
- 14 d) ReceiveCnm (32.14.4)
- 15 e) ProcessCnm (32.14.5)
- 16 f) AdjustRates (32.14.6)

### 17 32.14.1 ResetCnm

18 Called whenever the RP rate control state machine enters the RPR\_RESET state (Figure 32-2 in 32.15) to  
19 set the following variables:

- 20 — rpCurrentRate = rpgMaxRate
- 21 — rpTargetRate = rpgMaxRate
- 22 — rpByteCount = rpgByteReset
- 23 — rpFb = 0

### 24 32.14.2 TestRpTerminate

25 Called by the Flow Selection function (31.2.2.5) each time a frame is passed from the Per-CNPV station  
26 function's Rate Limiter (31.2.2.4) to the Flow multiplexer (31.2.4). If:

- 27 a) rpCurrentRate equals rpgMaxRate
- 28 b) The Flow queue is empty
- 29 c) rpEnabled is TRUE

30 Then TestRpTerminate sets rpEnabled (32.13.1) to FALSE, which disables the RP until another CNM is  
31 received.

32 NOTE—Condition b) can be met when all frames limited by a given Rate Limiter have been processed. See 31.2.2.1.

### 33 32.14.3 TransmitDataFrame

34 TransmitDataFrame() is called each time a frame is passed from a Rate Limiter (31.2.2.4) to the Port's Flow  
35 multiplexer (31.2.4). TransmitDataFrame() subtracts the length of the transmitted frame from rpByteCount  
36 (32.13.2) and may insert a CN-TAG containing the Flow ID of the Flow queue at the beginning of the  
37 frame's mac\_service\_data\_unit.

38 If an end station is VLAN-aware or priority-aware, and if a CN-TAG is added to a frame, the CN-TAG shall  
39 follow the VLAN or priority tag in the frame.

#### 1 32.14.4 ReceiveCnm

2 Called whenever a CNM is received. ReceiveCnm() performs the following actions:

- 3 a) The CNM is validated according to 33.4.11 and is discarded if invalid.
- 4 b) If the CNM frame carries a CN-TAG (33.2), the Flow ID from that CN-TAG (33.2.1) is used to  
5 identify the particular RP rate control state machine to which this CNM applies.
- 6 c) If the receiving end station is unable to identify the particular RP rate control state machine to which  
7 this CNM applies, it discards the CNM, and no further processing takes place.
- 8 d) Sets the rpFb variable from the CNM's Quantized Feedback field (33.4.3).
- 9 e) If the selected RP rate control state machine's rpEnabled variable is FALSE and is not held FALSE  
10 because rpgEnable (32.11.1) has the value FALSE, and the CNM's cnmQOffset field (33.4.5) is  
11 positive, then rpEnabled is reset to TRUE, and the variable rpppCreatedRps (32.10.2) is  
12 incremented.

13 These actions activate the selected RP rate control state machine, if it was not active (rpEnabled == FALSE),  
14 and also cause the RP rate control state machine to process the received CNM.

#### 15 32.14.5 ProcessCnm

16 Called whenever the RP rate control state machine enters the RPR\_CNM\_RECEIVED state (Figure 32-2 in  
17 32.15) to perform the following actions:

```
18     if (rpByteStage != 0) {  
19         rpTargetRate = rpCurrentRate;  
20         rpByteCount = rpgByteReset;  
21     }  
22     rpByteStage = 0;  
23     rpTimeStage = 0;  
24     dec_factor = (1 - (rpgGd * rpFb));  
25     if (dec_factor < rpgMinDecFac)  
26         dec_factor = rpgMinDecFac;  
27     rpCurrentRate = rpCurrentRate * dec_factor;  
28     if (rpCurrentRate < rpgMinRate)  
29         rpCurrentRate = rpgMinRate;  
30     RpWhile = rpgTimeReset;
```

#### 31 32.14.6 AdjustRates

32 AdjustRates is called whenever the RPR\_ADJUST\_RATES, RPR\_ACTIVE\_INCREASE, or  
33 RPR\_HYPER\_INCREASE states are entered. It takes one parameter, *increase*, that specifies how much to  
34 increase rpTargetRate, and performs the following actions:

```
35     if ((rpByteStage == 1) || (rpTimeStage == 1)) && (rpTargetRate > 10 * rpCurrentRate)  
36         rpTargetRate = rpTargetRate / 8;  
37     else  
38         rpTargetRate = rpTargetRate + increase;  
39     rpCurrentRate = (rpTargetRate + rpCurrentRate)/2;  
40     if (rpCurrentRate > rpgMaxRate)  
41         rpCurrentRate = rpgMaxRate;
```

1

Figure 32-2—RP rate control state machine

## 32.15 RP rate control state machine

The RP rate control state machine is illustrated in Figure 32-2. In this figure, the RPR\_RESET state has no exit. The state machine is held in the RPR\_RESET state as long as either the general system initialization variable “BEGIN” is TRUE or the rpEnabled variable, local to the particular instance of the RP rate control state machine, is FALSE. When “BEGIN” becomes FALSE and rpEnabled TRUE, the state machine remains in the RPR\_RESET state until a CNM is received by ReceiveCnm (32.14.4) with a Quantized Feedback field (33.4.3) that is less than 0. ReceiveCnm places that field into rpFb (32.13.9), which condition forces the state machine into the RPR\_CNM\_RECEIVED state. When that state resets rpFb to 0, progress through the state machine continues either until another CNM is received and rpFb is set to a nonzero value, or until the state machine is deactivated by TestRpTerminate (32.14.2) setting rpEnabled to FALSE.

## 32.16 Congestion notification and encapsulation interworking function

As mentioned in 30.8, a hierarchical Bridged Network, e.g., a PBBN, can require a congestion notification and encapsulation interworking function for a CP in the core of the network to generate a CNM that can reach the RP, which is presumably outside the core. This general case is illustrated in Figure 32-3. In the network illustrated, encapsulation and decapsulation functions peer with each other to encapsulate the data frames inside some kind of wrapper, e.g., an S-TAG and/or an I-TAG.

Figure 32-3—CP-RP peering in any hierarchical Bridged Network

Not all encapsulation schemes are equivalent. It is useful to divide hierarchical Bridged Networks into two categories for the purpose of defining congestion notification and encapsulation interworking functions, based on the mac\_service\_data\_unit of a data frame carrying (optionally) a CN-TAG as seen by a CP residing in a core Bridge, with one of these cases further subdivided as follows:

- a) In a network where the original end station’s mac\_service\_data\_unit, including the optional CN-TAG, comprises the first octets of the mac\_service\_data\_unit at the core Bridge’s CP, there is no need for a congestion notification and encapsulation interworking function. For example, a PBN in which the C-TAGs are not carried across the core needs no interworking function.
- b) In a network where an encapsulation comprises the first octets of the mac\_service\_data\_unit at the core Bridge’s CP, a congestion notification and encapsulation interworking function is required. It is useful to make a further distinction, in this case:
  - 1) The MAC addresses of Ports in the Bridges where the encapsulation and decapsulation functions are performed are the destination and source addresses of frames crossing the core Bridges. For example, in a PBBN, the I-TAG, and perhaps an S-TAG and/or a C-TAG as well, can be present as the first octets of the mac\_service\_data\_unit, and the source\_address and destination\_address parameters visible to the core Bridge’s CP are the addresses of PIPs in BEBs.

2) In other networks, although an encapsulation is in the first octets of the `mac_service_data_unit` at the core Bridge's CP, the source and destination MAC addresses are not altered by the encapsulation and decapsulation operations. For example, in a PBN in which both a C-TAG and an S-TAG are carried across the core, the C-TAG occupies the first octets of the `mac_service_data_unit` as seen by a core Bridge's CP.

In either type of network covered by case b), the core Bridge's CP is configured by the network administrator to return, in the Encapsulated MSDU field of the CNM PDU (33.4.10), the leading octets of the `mac_service_data_unit` of the data frame triggering transmission of the CNM. Since the CN-TAG of the data frame, if present, is buried behind encapsulations unknown to the CP, when the CN-TAG and CNM are built according to 32.9.4, the Flow ID returned in the CN-TAG of the CNM is filled with 0. The network administrator configures the CP to return at least enough octets of the data frame's `mac_service_data_unit` to include the CN-TAG of the original data frame transmitted by the RP.

The difference between case 1) and case 2), preceding, lies in the means used by the Port containing the congestion notification and encapsulation interworking function to recognize the CNM in order to translate it. In case 1), the CNM is addressed to that Port, and has a CN-TAG and the CNM encapsulation, instead of a data frame tag and encapsulation. In case 2), the only reliable indicator of a CNM that needs to be transformed, as opposed for example, to a CNM returned by the destination end station's CP, can be the presence of an encapsulation known to the interworking function in the Encapsulated MSDU field (33.4.10) of the CNM PDU.

When the CNM generated by the core Bridge's CP reaches a congestion notification and encapsulation interworking function, that interworking function uses the information in the CNM PDU, including the encapsulated data frame information, to construct a CN-TAG and CNM PDU to send to the RP. The steps taken are as follows:

- c) In case 1), where the CNM is returned to the MAC address of the interworking function's Port, the `destination_address` parameter is obtained from the appropriate source address found in the Encapsulated MSDU field, and the `source_address` parameter is a MAC address belonging to the Bridge containing the interworking function, and valid in the context of the newly generated CNM, for example, a management port address.
- d) In case 2), where the CNM is recognized by the presence of the encapsulation in the Encapsulated MSDU field, the `source_address`, and `destination_address` parameters are unchanged.
- e) The `vlan_identifier` is obtained from the Encapsulated MSDU field.
- f) The `drop_eligible` parameter is False.
- g) The priority parameter used is the value configured for a CP on a Port in the Bridge in which the interworking function resides, and through which the CNM passes.
- h) The Encapsulated priority field (33.4.7) is obtained from the Encapsulated MSDU field, or if not present there, the Encapsulated priority is left unchanged.

NOTE—In spite of the provisions for CND defense in this clause, it is possible for a network administrator to configure a network so that the priority of a CCF data frame is not preserved. For example, in a PBN, two CNPVs could be mapped to the same S-TAG priority, and the C-TAG not configured to be carried across the network. In that case, an end station with an RP on each of those CNPVs, and that does not distinguish between those RPs using CN-TAGs, would be unable to assign returned CNMs to the right RP. At least some of its CCFs would not be constrained, and uncontrolled congestion would likely result. It is therefore recommended that the CN-TAG be included across a PBN, or that each CNPV be mapped to a separate priority in the backbone.

- i) If a CN-TAG is found in the Encapsulated MSDU, its Flow ID is copied to the CN-TAG of the newly generated CNM, else 0 is used for that CN-TAG's Flow ID.
- j) The encapsulation in the Encapsulated MSDU field of the CNM PDU, up to and including the CN-TAG (which is not necessarily present), is elided, the remainder (if any) of the Encapsulated MSDU field moved up to the first octets of the field, and the Encapsulated MSDU length field reduced accordingly.

### 33. Encoding of congestion notification PDUs

This clause specifies the method of encoding congestion notification PDUs. The specifications include the following:

- a) The general structure and encoding of congestion notification PDUs (33.1)
- b) The format used for the CN-TAG (33.2)
- c) The encapsulation used for a CNM (33.3)
- d) The format used for the CNM (33.4)

The format of the IEEE 802.1AB Type Length Value (TLV) used to signal that a VLAN Bridge or end station is congestion aware, and the state of its CN defense mode, is specified in D.2.7.

NOTE—Clause 30 introduces the principles of congestion notification operation and the network architectural concepts that support it. Clause 31 breaks down the congestion notification entities into their components. Clause 32 specifies the protocols operated by these components.

#### 33.1 Structure, representation, and encoding

All congestion notification PDUs contain an integral number of octets.

The octets in a congestion notification PDU are numbered starting from 1 and increasing in the order they are put into the MSDU that accompanies a request to or indication from the instance of the MAC Internal Sublayer Service (ISS or EISS) used by a congestion notification entity.

The bits in an octet are numbered from 1 to 8 in order of increasing bit significance, where 1 is the LSB in the octet.

Where octets and bits within a congestion notification PDU are represented using a diagram, octets shown higher on the page than subsequent octets and octets shown to the left of subsequent octets at the same height on the page are lower numbered; bits shown to the left of other bits within the same octet are higher numbered.

Where two or more consecutive octets are represented as hexadecimal values, lower numbered octet(s) are shown to the left and each octet following the first is preceded by a hyphen, e.g., 01-80-C2-00-00-00.

When consecutive octets are used to encode a binary number, the lower octet number has the more significant value. When consecutive bits within an octet are used to encode a binary number, the higher bit number has the most significant value. When bits within consecutive octets are used to encode a binary number, the lower octet number composes the more significant bits of the number. A flag is encoded as a single bit, and is set (TRUE) if the bit takes the value 1, and clear (FALSE) otherwise. The remaining bits within the octet can be used to encode other protocol fields.

#### 33.2 CN-TAG format

The means for identifying CN-TAG PDUs consist of two octets containing the EtherType value shown (in hexadecimal notation) in Table 33-1.

In a VLAN Bridge, the shim that supports the EISS (IEEE Std 802.1AC, 6.8, Figure 22-4) is below the Queuing shim (8.6.6, 8.6.7, 8.6.8, 31.1.1). The CN-TAG is examined by the CP, which is part of the Queuing shim. Therefore, the CN-TAG will be further from the source\_address and destination\_address fields, and closer to the end of the frame, than a VLAN tag added by 6.8, if any. In order for a Bridge to be able to recognize the CN-TAG in a data frame, an end station shall insert the CN-TAG and VLAN tag in the relative order required by a Bridge: addresses, VLAN tag, CN-TAG, data.<sup>47</sup>

**Table 33-1—CN-TAG Encapsulation**

|                       | Octet | Length |
|-----------------------|-------|--------|
| Tag EtherType (22-E9) | 1     | 2      |
| Flow Identifier       | 3     | 2      |

### 33.2.1 Flow Identifier

The meaning and encoding of the Flow Identifier field are not specified by this standard. A CP shall not interpret the value in a Flow Identifier field. The Flow ID returned in the CN-TAG of a CNM is used by an end station's CNM demultiplexer (31.2.5) to identify the RP, the Flow queue, or a group of one or more individual flows, from which was transmitted the data frame that triggered the CNM.

### 33.3 Congestion Notification Message (CNM)

The means for identifying CNM PDUs consist of two octets containing the EtherType value shown (in hexadecimal notation) in Table 33-2.

**Table 33-2—CNM Encapsulation**

|                       | Octet | Length   |
|-----------------------|-------|----------|
| PDU EtherType (22-E7) | 1     | 2        |
| CNM PDU               | 3     | 24 to 88 |

### 33.4 Congestion Notification Message PDU format

The format of a Congestion Notification Message (CNM) PDU is illustrated in Table 33-3. If the frame that triggered the transmission of the CNM carried a CN-TAG, then that CN-TAG is retained in the frame carrying the CNM PDU; otherwise, a CN-TAG with a FlowID of 0 is used in the frame carrying the CNM PDU.

#### 33.4.1 Version

This field, 4 bits in length, shall be transmitted with the value 0, and shall be ignored on receipt. The Version field occupies the most significant bits of the first octet of the CNM PDU.

#### 33.4.2 ReservedV

This field, 6 bits in length, shall be transmitted with the value 0, and shall be ignored on receipt. The ReservedV field occupies the least significant 4 bits of the first octet, and the most significant 2 bits of the second octet, of the CNM PDU.

<sup>47</sup> There are other tags, e.g., the IEEE 802.1AE MAC Security tag, not included in this abbreviated list.

**Table 33-3—Congestion Notification Message PDU**

|                                      | Octet | Length |
|--------------------------------------|-------|--------|
| Version                              | 1     | 4 bits |
| ReservedV                            | 1, 2  | 6 bits |
| Quantized Feedback                   | 2     | 6 bits |
| Congestion Point Identifier          | 3     | 8      |
| cnmQOffset                           | 11    | 2      |
| cnmQDelta                            | 13    | 2      |
| Encapsulated priority                | 15    | 2      |
| Encapsulated destination MAC address | 17    | 6      |
| Encapsulated MSDU length             | 23    | 2      |
| Encapsulated MSDU                    | 25    | 0–64   |

### 33.4.3 Quantized Feedback

This field, 6 bits in length, contains the Quantized Feedback value calculated by the CP's EM\_UNITDATA.request (parameters) procedure (32.9.3). The Quantized Feedback field occupies the least significant bits of the first two octets of the CNM PDU.

### 33.4.4 Congestion Point Identifier

This field, 8 octets in length, uniquely identifies the CP that triggered the transmission of this Congestion Notification Message PDU format within the CND. Because the transmitting system can format the Congestion Point Identifier (CPID) in any manner, a receiving RP shall not assign any meaning to subfields within a CPID.

NOTE—Making the CPID 8 octets long removes the connection between CP identity and the source MAC address of the CNM PDU. One way to achieve the requirements for uniqueness of the CPID would be to use a Port's MAC address as the high-order 6 octets of the CPID, and use the low-order two octets of the CPID to hold the priority of the CP's queue and/or an indication of the physical port.

### 33.4.5 cnmQOffset

The two's-complement signed integer value of  $(-1 \times \text{cpQOffset})$  (32.8.7) of the transmitting CP in units of 64 octets. This standard does not specify whether cpQOffset is rounded or truncated to obtain cnmQOffset. If the value of cpQOffset is less than  $-32\,768$ , a value of  $-32\,768$  is used in cnmQOffset, and if greater than  $32\,767$ , then  $32\,767$  is used.

### 33.4.6 cnmQDelta

The two's-complement signed integer value of the transmitting CP's cpQDelta (32.8.8) in units of 64 octets. This standard does not specify whether cpQDelta is rounded or truncated to obtain cnmQDelta. If the value of cpQDelta is less than  $-32\,768$ , a value of  $-32\,768$  is used in cnmQDelta, and if greater than  $32\,767$ , then  $32\,767$  is used.

NOTE—Although cnmQDelta is not used by the RP, it is included in the CNM PDU to aid the network administrator when adjusting configuration parameters.

#### 1 **33.4.7 Encapsulated priority**

2 This field, 2 octets in length, contains the priority parameter of the frame that triggered the transmission of  
3 this CNM in the most significant 3 bits of the field. The remaining bits of the field are transmitted as 0, and  
4 ignored on receipt.

#### 5 **33.4.8 Encapsulated destination MAC address**

6 This field, 6 octets in length, contains the destination\_mac\_address parameter of the frame that triggered the  
7 transmission of this CNM.

#### 8 **33.4.9 Encapsulated MSDU length**

9 This field, 2 octets in length, contains the number of octets returned in the Encapsulated MSDU field  
10 (33.4.10).

#### 11 **33.4.10 Encapsulated MSDU**

12 This field, a maximum of 64 octets in length, contains the initial octets of the mac\_service\_data\_unit of the  
13 frame that triggered the transmission of this CNM.

#### 14 **33.4.11 CNM Validation**

15 A CNM PDU received by a CNM demultiplexer (31.2.5) shall be considered invalid and be discarded if the  
16 following condition is TRUE:

- 17 a) There are fewer than 24 octets in the mac\_service\_data\_unit.

18 A CNM PDU received by a CNM demultiplexer (31.2.5) may be considered invalid and be discarded if the  
19 following condition is TRUE:

- 20 b) The CNM PDU has no CN-TAG.

21 NOTE 1—The variable cnpdAcceptsCnTag (32.4.10), when set FALSE in an end station, indicates to the neighboring  
22 Bridge that the CN-TAG is to be removed from all frames, including CNMs, transmitted to the end station. It is not  
23 recommended that an end station set cnpdAcceptsCnTag to FALSE if this would result in the end station discarding  
24 CNMs for lack of a CN-TAG.

25 The following condition shall not cause a received CNM PDU to be considered invalid:

- 26 c) There are nonzero bits in the Version (33.4.1) or ReservedV (33.4.2).

27 NOTE 2—These rules permit information to be added to the CNM PDU following the Encapsulated MSDU field  
28 (33.4.10) in later revisions of this standard.

## 1 34. Forwarding and Queuing Enhancements for time-sensitive streams 2 (FQTSS)

### 3 34.1 Overview

4 This clause describes a set of tools that can be used to support the forwarding and queuing requirements of  
5 time-sensitive streams. In this context, a “time-sensitive stream” is taken to be a stream (flow) of traffic,  
6 transmitted from a single source station (Talker), destined for one or more destination stations (Listeners),  
7 where the traffic is sensitive to timely delivery, and in particular, requires transmission latency to be  
8 bounded. Such streams include video or audio data streams, where there is a desire to limit the amount of  
9 buffering required in the receiving station (Listener). The description in this clause (Clause 34) applies when  
10 the transmission gates for scheduled traffic (8.6.8.4) are continuously open, as closing those gates affects the  
11 availability of bandwidth.

12 NOTE 1—An example of the need to support time-sensitive stream requirements would be a live performance where a  
13 video image of the performance is simultaneously projected on a screen in the auditorium, and it is desirable for the  
14 sound and image to be “in sync” with the performance.

15 The term “stream reservation class” (SR class) refers to a traffic class whose bandwidth can be reserved for  
16 time-sensitive streams using the Stream Reservation Protocol (SRP). FQTSS specifies the relationship  
17 between an SR class and the underlying tools of this standard, such as traffic class, priority, and transmission  
18 selection.

19 NOTE 2—The FQTSS functions described in this clause are intended for use with SRP, with the exception of  
20 `adminIdleSlope` [item c) in 34.3]. The `adminIdleSlope` parameter is intended for TSN configuration models that do not  
21 use SRP. In the fully centralized model of TSN configuration (46.1.3.3), the CNC entity can use `adminIdleSlope` to  
22 reserve bandwidth for a traffic class.

23 In order to address the needs of such traffic in Bridges, the following are provided:

- 24 a) A means of detecting the boundary between a set of Bridges that support SRP (an SRP domain) and  
25 surrounding Bridges that do not support SRP. This mechanism is described in 34.2.
- 26 b) A set of bandwidth availability parameters for each port that are used to record the maximum  
27 bandwidth available to a given outbound queue, and the actual bandwidth reserved, for that queue.  
28 These parameters are described in 34.3.
- 29 c) A discussion of the relationship between the size of the layer 2 “payload” (the MSDU) carried in a  
30 frame and how that relates to the actual bandwidth that will be consumed when that MSDU is  
31 transmitted on a particular Port (34.4).
- 32 d) Specifications for the default configuration of SR classes, including the mapping of the priorities  
33 associated with received frames onto the traffic classes available on the transmission Ports of a  
34 Bridge (34.5).
- 35 e) Specifications for use of transmission selection algorithms for SR classes (34.6).

### 36 34.2 Detection of SRP domains

37 The concepts of time-sensitive streams, the Stream Reservation Protocol (SRP), and the traffic forwarding  
38 and shaping functions that support stream transmission (e.g., 8.6.8.1), rely on the ability of each Bridge to  
39 detect whether each of its Ports is at the edge of a region of connected Bridges that support SRP on a  
40 particular priority, so that the Priority Code Point values associated with traffic entering an *SRP domain*  
41 (3.269) can be properly regenerated at the boundary of the domain, as described in 6.9.4.

1 Bridges detect the edge of an SRP domain by observing SRP behavior. If a Bridge receives SRP  
2 registrations using a particular priority, then it is reasonable to believe that they are being received from an  
3 SRP-capable device; the SRP engine can therefore signal which Ports of a Bridge are at the boundary of an  
4 SRP domain. The per-Port, per-SR class, *SRPdomainBoundaryPort* parameter determines whether a Port is  
5 considered to be at the edge of an SRP domain or within the core of the domain, as defined in 35.1.4. This  
6 parameter is controlled by the operation of SRP.

7 NOTE—SRP domain detection is based on the assumption that a device connected to a Port either is SRP capable for a  
8 given SR class, or is not SRP capable for that SR class. SRP provides a boundary detection mechanism through the  
9 exchange of MSRPDU; the boundary of a domain therefore expands to include Ports as SRP attributes are declared.  
10 The position of the domain boundary has no effect on the transmission of SRP frames; rather, it reflects where SRP  
11 activity is occurring. Ports are removed from the SRP domain when they are removed from the active topology.

### 12 34.3 The bandwidth availability parameters

13 The following bandwidth availability parameters exist for each Port, and for each traffic class, N, that is  
14 configured as an SR class (34.5):

- 15 a) *portTransmitRate* as defined in 8.6.8.2;
- 16 b) *deltaBandwidth(N)*: The bandwidth, represented as a percentage of *portTransmitRate*, that can be  
17 reserved by SRP for use by the queue associated with traffic class N. The interpretation of  
18 *deltaBandwidth(N)* is determined by the value of the associated *lockClassBandwidth(N)* as specified  
19 in 34.3.1 and 34.3.3.
- 20 c) *adminIdleSlope(N)*: The bandwidth, in bits per second, that has been requested by management to  
21 be reserved for use by the queue associated with traffic class N. If SRP is in operation for traffic  
22 class N, this parameter has no effect. If SRP is not in operation for traffic class N, then the value of  
23 *operIdleSlope(N)* is always equal to the value of *adminIdleSlope(N)*.
- 24 d) *operIdleSlope(N)*: The actual bandwidth, in bits per second, that is currently reserved for use by the  
25 queue associated with traffic class N (see 34.6.1 and 34.6.2).
- 26 e) *classMeasurementInterval(N)*: The interval of time, in seconds, over which SRP's TSpec (34.4,  
27 35.2.2.8.4) is measured for traffic class N at the Talker.
- 28 f) *lockClassBandwidth(N)*: The Boolean parameter that determines the interpretation of  
29 *deltaBandwidth(N)*. For the value false (default), *deltaBandwidth(N)* is specified in 34.3.1. For the  
30 value true, *deltaBandwidth(N)* is specified in 34.3.3.

31 In all cases, bandwidth is defined in terms of the actual bandwidth consumed when frames are transmitted  
32 through the Port, not the size of the MSDU “payload” carried within those frames. Subclause 34.4 discusses  
33 the relationship between MSDU size and actual bandwidth consumed. The bandwidth availability  
34 parameters and their use as described in this clause (Clause 34) do not take into account any interruption to  
35 bandwidth availability resulting from the operation of stream gates (8.6.5.2).

#### 36 34.3.1 deltaBandwidth when lockClassBandwidth is false

37 When *lockClassBandwidth(N)* is false, *deltaBandwidth(N)* is the additional bandwidth, represented as a  
38 percentage of *portTransmitRate*, that can be reserved by SRP for use by the queue associated with traffic  
39 class N, in addition to the *deltaBandwidth(N)* values associated with higher priority queues with  
40 *lockClassBandwidth(N)* false. For a given traffic class N, the total bandwidth that can be reserved is the sum  
41 of the *deltaBandwidth* values for traffic class N and all higher traffic classes with *lockClassBandwidth(N)*  
42 false, minus any bandwidth reserved by higher traffic classes (i.e., configured as SR classes).

43 The default value of *lockClassBandwidth(N)* is false. This default can be changed using the managed  
44 objects of the Bandwidth Availability Parameter Table (12.20.1).

1 The default value of  $\text{deltaBandwidth}(N)$  for the highest numbered traffic class supported is 75%, and for any  
2 lower numbered traffic classes, the default value is 0%. The  $\text{deltaBandwidth}(N)$  for a given  $N$ , plus the  
3  $\text{deltaBandwidth}(N)$  values for any higher priority queues (larger values of  $N$ ) defines the total percentage of  
4 the Port's bandwidth that can be reserved for that queue and all higher priority queues. For the highest  
5 priority queue, this means that the maximum value of  $\text{operIdleSlope}(N)$  is  $\text{deltaBandwidth}(N)\%$  of  
6  $\text{portTransmitRate}$ . However, if  $\text{operIdleSlope}(N)$  is actually less than this maximum value, any lower  
7 priority queue with  $\text{lockClassBandwidth}(N)$  false can make use of the reservable bandwidth that is unused  
8 by the higher priority queue. So, for queue  $N-1$ , the maximum value of  $(\text{operIdleSlope}(N) +$   
9  $\text{operIdleSlope}(N-1))$  is  $(\text{deltaBandwidth}(N) + \text{deltaBandwidth}(N-1))\%$  of  $\text{portTransmitRate}$ .

10 NOTE 1—For example, suppose two queues, 3 and 2, are configured as SR classes A and B, respectively. Suppose  
11  $\text{deltaBandwidth}(3)$  for SR class A is currently 20%, and  $\text{deltaBandwidth}(2)$  for SR class B is currently 30%, and  
12  $\text{lockClassBandwidth}$  is false for both. If  $\text{operIdleSlope}(3)$  is currently 10% of  $\text{portTransmitRate}$ , then half of queue 3's  
13 maximum allocation is unused, and the maximum value of  $\text{operIdleSlope}(2)$  is therefore currently 40% of  
14  $\text{portTransmitRate}$ . However, if  $\text{operIdleSlope}(3)$  increases to the full 20% that it is entitled to use, the maximum value of  
15  $\text{operIdleSlope}(2)$  reduces to 30% of  $\text{portTransmitRate}$ .

16 NOTE 2—The sum of the  $\text{deltaBandwidth}(N)$  values for all values of  $N$  should be chosen such that there is sufficient  
17 bandwidth available for any nonreserved (best-effort, strict-priority) traffic; the default values are chosen such that the  
18 sum of the  $\text{deltaBandwidth}(N)$  values is 75%, so no more than 75% of the Port's available bandwidth is permitted to be  
19 reserved. This ensures that when using default settings, there is at least 25% of the Port's bandwidth available for  
20 nonreserved traffic. However, as these default settings may be inappropriate for some situations (e.g., links that offer  
21 very high bandwidth, or networks with very low levels of nonreserved traffic), they can be modified by management.

### 22 34.3.2 $\text{deltaBandwidth}$ when $\text{lockClassBandwidth}$ is true

23 When  $\text{lockClassBandwidth}(N)$  is true,  $\text{deltaBandwidth}(N)$  is the maximum bandwidth, represented as a  
24 percentage of  $\text{portTransmitRate}$ , that can be reserved by SRP for use by the queue associated with traffic  
25 class  $N$ . The bandwidth limit of  $\text{deltaBandwidth}(N)$  is not related to higher or lower priority traffic classes  
26 (i.e., it is not truly a delta).

27 NOTE—For example, suppose two queues, 3 and 2, are configured as SR classes A and B, respectively. Suppose  
28  $\text{deltaBandwidth}(3)$  for SR class A is currently 20%,  $\text{deltaBandwidth}(2)$  for SR class B is currently 30%, and  
29  $\text{lockClassBandwidth}$  is true for both. If  $\text{operIdleSlope}(3)$  is currently 10% of  $\text{portTransmitRate}$ , then half of queue 3's  
30 maximum allocation is unused. Nevertheless, the maximum value of  $\text{operIdleSlope}(2)$  remains 30% of  
31  $\text{portTransmitRate}$ . The value of  $\text{operIdleSlope}(2)$  cannot increase to 40%, because 20% is locked to use by  
32  $\text{operIdleSlope}(3)$ .

### 33 34.3.3 Bandwidth availability parameter management

34 The values of  $\text{deltaBandwidth}(N)$  and  $\text{adminIdleSlope}(N)$  can be changed by management, using the  
35 management operations defined in 12.20. If the stream reservation mechanisms defined in SRP are  
36 supported, then the values of  $\text{operIdleSlope}(N)$  are determined solely by the operation of SRP. If the stream  
37 reservation mechanisms defined in SRP are not supported, then the values of  $\text{operIdleSlope}(N)$  are equal to  
38 the values requested by management in the corresponding  $\text{adminIdleSlope}(N)$  parameters.

39 It is possible for the value of  $\text{portTransmitRate}$  for a Port to change as a result of the normal operation of the  
40 underlying MAC Service (e.g., as a result of the operation of IEEE 802.1AX Link Aggregation, or as a result  
41 of dynamic changes in bandwidth of the physical layer technology itself, as can occur in wireless LAN  
42 technologies); it is also possible for management action to change the values of  $\text{deltaBandwidth}(N)$  for a  
43 Port. In either case, the consequence could be one of the following:

- 44 a) The sum of the  $\text{operIdleSlope}(N)$  values for the Port could now exceed the total reservable  
45 bandwidth allowed for the Port, or the  $\text{operIdleSlope}(N)$  value for a given queue could now exceed

- 1 the reservable bandwidth allowed for the queue, as defined in 34.3.1 and 34.3.2. Consequently, there  
2 could be streams currently active on the Port that can no longer be supported.
- 3 b) The bandwidth now available to a given queue could mean that there are streams that are currently  
4 inactive that could be supported on the Port.
- 5 c) Active streams that continue to be supported after the change could see their latency guarantee  
6 change.

7 In either case, corrective action, either by management or by the stream reservation mechanisms defined in  
8 SRP, is required in order to restore the parameters to a consistent set of values. In order to indicate that there  
9 have been changes in the bandwidth availability database, a signal, *bandwidthAvailabilityChanged*, is  
10 generated for each Port whenever the bandwidth availability parameters *portTransmitRate* or  
11 *deltaBandwidth(N)* are changed; this signal is used by SRP to trigger recalculation of the set of streams that  
12 can be reserved on the Port.

13 NOTE—During recalculation of stream reservations, the Bridge might be temporarily unable to honor bandwidth  
14 reservation commitments or forward best-effort traffic.

## 15 34.4 Deriving actual bandwidth requirements from the size of the MSDU

16 The forwarding and queuing mechanisms defined in this clause use bandwidth parameters that are defined in  
17 terms of the actual bandwidth used when frames are transmitted on the medium that supports the MAC  
18 Service available through the Port. In contrast, the SRP makes use of a traffic specification (TSpec) for each  
19 stream that defines the maximum number of bits per frame (*MaxFrameSize*), of the *mac\_service\_data\_unit*  
20 parameter that is relayed by the relay function of the Bridge, and a maximum frame rate  
21 (*MaxIntervalFrames*), in frames per class measurement interval, for that stream; i.e., the TSpec takes no  
22 account of the per-frame overhead associated with transmitting the MSDU over a given medium. However,  
23 when SRP determines the value to be used for the *operIdleSlope(N)* parameter associated with a given  
24 queue, it is necessary for this value to include the per-frame overhead that will be incurred when frames are  
25 transmitted on that Port.

26 NOTE 1—The frame rate in a TSpec is measured over the *classMeasurementInterval* (34.3) that depends upon the SR  
27 class associated with the stream. Default values for *classMeasurementInterval* are specified in 34.5.

28 For the purposes of calculating the bandwidth consumption of a stream, it is assumed that the stream data is essentially  
29 of constant size and transmission rate, so these maxima can be used to directly define an assumed maximum payload  
30 size and the maximum frame rate in frames per second; i.e.,

$$31 \quad \text{assumedPayloadSize} = \text{MaxFrameSize} \quad (34-1)$$

$$32 \quad \text{maxFrameRate} = \text{MaxIntervalFrames} \times (1/\text{classMeasurementInterval}) \quad (34-2)$$

33 where *classMeasurementInterval* is measured in seconds.

34 NOTE 2—As stated, the calculation of bandwidth from TSpec parameters assumes that the stream data is essentially of  
35 constant frame size, and hence, the approximations shown in this section are valid. If the data varies significantly in  
36 frame size, then the calculation of per-frame overhead using these assumptions could be significantly in error.

37 From this, and also from local knowledge of the protocol stack that supports the Bridge Port, it is possible to  
38 determine the overhead that is added to the per-frame MSDU payload when a frame is transmitted. There are  
39 at least the following sources of per-frame overhead:

- 40 a) Any VLAN tags and security tags (see IEEE Std 802.1AE) that are added to the layer 2 payload as it  
41 passes through the various service interfaces in the Port's protocol stack.
- 42 b) The MAC framing (header and trailer octets, plus any padding octets that are required to meet  
43 minimum frame size limitations) that is added by the underlying MAC Service.
- 44 c) Any physical layer overhead, such as preamble characters and inter-frame gaps.

The precise per-frame overhead will therefore depend upon the protocol stack and the underlying MAC technology.

The actual bandwidth needed to support a given stream is therefore defined as follows [using *assumedPayloadSize* from Equation (34-1)]:

$$actualBandwidth = (perFrameOverhead + assumedPayloadSize) \times maxFrameRate \quad (34-3)$$

### 34.5 Default SR class configuration

This subclause (34.5) makes traffic class, priority, transmission selection algorithm, and *classMeasurementInterval* recommendations for use with FQTSS.

The recommended mappings of priorities to traffic classes meet the following constraints:

- a) Priority values that correspond to SR classes are mapped onto traffic classes that support the credit-based shaper algorithm as the transmission selection algorithm.
- b) Traffic classes that support the credit-based shaper algorithm have a higher priority than traffic classes that support the strict priority (or any other) transmission selection algorithm.
- c) At least one traffic class supports the credit-based shaper algorithm, and at least one traffic class supports the strict priority transmission selection algorithm.

NOTE 1—The constraint that there is at least one traffic class that supports the strict priority transmission selection ensures that there is at least one traffic class that can support traffic that is not subject to bandwidth reservation, such as “best effort” traffic.

The recommended priority to traffic class mappings for a network that supports SR class A (using priority 3) and SR class B (using priority 2) are shown in Table 34-1. The recommended priority to traffic class mappings for a system that supports only SR class B (using priority 2) are shown in Table 34-2. These mappings can be changed using the managed objects of the Traffic Class Table for each Port (12.6.3).

The corresponding configuration for the Transmission Selection Algorithm Table (see 8.6.8) is that the traffic classes that are shaded in the tables are configured to use the credit-based shaper algorithm, and the remaining traffic classes are configured to use the strict priority algorithm. Traffic classes that are shaded correspond to default SR classes. These defaults can be changed using the managed objects of the Transmission Selection Algorithm Table (12.20.2).

NOTE 2—The mapping shown in Table 34-1 for the case of only two available traffic classes maps two SR classes to a single traffic class. While this is a permissible configuration, in general it is desirable, and in some applications, can be a requirement, to assign SR classes to distinct traffic classes, as is done in this table for the cases where three or more traffic classes are available. The mappings shown deal only with one or two supported SR classes; a similar mapping strategy can be adopted if more than two SR classes are supported.

Table 34-1 and Table 34-2 specify a default configuration of SR class A as priority 3, and SR class B as priority 2. These defaults can be changed using the managed objects of the SR Class to Priority Mapping Table (12.20.4).

The default *classMeasurementInterval* (34.3) of SR class A is 125 μs. The default *classMeasurementInterval* of SR class B is 250 μs. These defaults can be changed using the managed objects of the Bandwidth Availability Parameter Table (12.20.1).

### 34.6 Transmission selection

Transmission selection (8.6.8) is used to shape the transmission of a Stream’s frames in accordance with the bandwidth that has been reserved on a given outbound queue for a traffic class.

**Table 34-1—Default priority to traffic class mappings for SR classes A and B**

|          |             | Number of available traffic classes |   |   |   |   |   |   |
|----------|-------------|-------------------------------------|---|---|---|---|---|---|
|          |             | 2                                   | 3 | 4 | 5 | 6 | 7 | 8 |
| Priority | 0 (Default) | 0                                   | 0 | 0 | 0 | 0 | 0 | 1 |
|          | 1           | 0                                   | 0 | 0 | 0 | 0 | 0 | 0 |
|          | 2           | 1                                   | 1 | 2 | 3 | 4 | 5 | 6 |
|          | 3           | 1                                   | 2 | 3 | 4 | 5 | 6 | 7 |
|          | 4           | 0                                   | 0 | 1 | 1 | 1 | 1 | 2 |
|          | 5           | 0                                   | 0 | 1 | 1 | 1 | 2 | 3 |
|          | 6           | 0                                   | 0 | 1 | 2 | 2 | 3 | 4 |
|          | 7           | 0                                   | 0 | 1 | 2 | 3 | 4 | 5 |

**Table 34-2—Default priority to traffic class mappings for SR class B only**

|          |             | Number of available traffic classes |   |   |   |   |   |   |
|----------|-------------|-------------------------------------|---|---|---|---|---|---|
|          |             | 2                                   | 3 | 4 | 5 | 6 | 7 | 8 |
| Priority | 0 (Default) | 0                                   | 0 | 0 | 0 | 0 | 1 | 1 |
|          | 1           | 0                                   | 0 | 0 | 0 | 0 | 0 | 0 |
|          | 2           | 1                                   | 2 | 3 | 4 | 5 | 6 | 7 |
|          | 3           | 0                                   | 0 | 0 | 1 | 1 | 2 | 2 |
|          | 4           | 0                                   | 1 | 1 | 2 | 2 | 3 | 3 |
|          | 5           | 0                                   | 1 | 1 | 2 | 2 | 3 | 4 |
|          | 6           | 0                                   | 1 | 2 | 3 | 3 | 4 | 5 |
|          | 7           | 0                                   | 1 | 2 | 3 | 4 | 5 | 6 |

1 The following transmission selection algorithm shall be supported for FQTSS, configured as the default for  
2 SR class A and/or B:

3 a) Credit-based shaper algorithm, specified in 8.6.8.2

4 The following transmission selection algorithm may be supported for FQTSS, configured using the  
5 managed objects of the Transmission Selection Algorithm Table (12.20.2):

6 a) Strict priority algorithm, specified in 8.6.8.1

7 The following transmission technique may be supported for FQTSS, configured using the managed objects  
8 for scheduled traffic (12.29):

9 a) Scheduled traffic, specified in 8.6.8.4

#### 10 **34.6.1 Credit-based shaper**

11 The *operIdleSlope(N)* parameter (34.3) is used by the credit-based shaper algorithm (8.6.8.2) as its  
12 *idleSlope* for the corresponding queue, to shape outbound traffic.

13 The *operIdleSlope(N)* parameter is also used to reserve space in the queue of the traffic class that is assigned  
14 to the SR class.

15 In order for an end station to successfully participate in the transmission and reception of time-sensitive  
16 streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing  
17 mechanisms employed in Bridges. The requirements for end stations that participate as “Talkers”—i.e.,  
18 sources of time-sensitive streams—are different from the requirements that apply to “Listeners”—i.e., the  
19 destination station(s) for the streams.

##### 20 **34.6.1.1 Talker behavior**

21 In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a  
22 requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated  
23 with SR classes exclusively for transmitting stream data. It is also necessary for the Talker, and the Bridges  
24 in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the  
25 Talker’s streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter  
26 requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other  
27 management means.

28 End stations that are Talkers shall exhibit transmission behavior for frames that are part of time-sensitive  
29 streams that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way  
30 they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream  
31 data frames from a Port. In effect, the queuing model for a Talker Port, and for a given priority, can be  
32 considered to look like Figure 34-1.

33 The Talker places frames into the queue associated with an individual stream based on the Tspec for that  
34 stream; i.e., during each *classMeasurementInterval*, it can place up to *MaxIntervalFrames* data frames, each  
35 no longer than *MaxFrameSize* into that stream’s queue.

36 The queue associated with each individual stream uses the credit-based shaper algorithm, with the *idleSlope*  
37 set to the bandwidth requirement of the stream on that transmission Port, as the means of determining the  
38 rate at which data frames for that stream are placed in the outbound queue for the priority that the stream is  
39 using. The outbound queue for that priority, in turn, makes use of the credit-based shaper algorithm, with the  
40 *idleSlope* set to the sum of the *idleSlope* values for all streams using that priority on that transmission Port,  
41 as the means of determining the rate at which data frames for that stream are selected for transmission.

**Figure 34-1—Queuing model for a Talker station**

1 Transmission selection in a Talker operates in the same way as in a Bridge; from this point of view, a Talker  
2 can be thought of as if it is a single-port Bridge.

3 For streams that make use of SR class A or SR class B, it is a requirement that the rate at which frames for  
4 any given stream are selected for placement in its per-stream queue does not exceed the bandwidth reserved  
5 for the stream, measured over the *classMeasurementInterval* (34.3) for the SR class. For some combinations  
6 of stream bandwidth requirement and transmission Port data rate, this can place a limit on the frame size that  
7 can be used when transmitting stream data.

8 NOTE—The sole implication of the *classMeasurementInterval* is its effect on frame size, because the shaper behavior  
9 itself is independent of the *classMeasurementInterval*. The intent in limiting the *classMeasurementInterval* is to limit  
10 frame size, as this is a major contribution to the latency experienced by a frame in transit through a time-sensitive  
11 network (see discussion in Annex L).

#### 12 34.6.1.2 Listener behavior

13 The primary requirement for a Listener end station using the credit-based shaper is that it is capable of  
14 buffering the amount of data that could be transmitted for a stream during a time period equivalent to the  
15 accumulated maximum jitter that could be experienced by stream data frames in transmission between  
16 Talker and Listener. From the point of view of the specification of the forwarding and queuing requirements  
17 for time-sensitive streams, it is assumed that the Listener will assess the buffering required for a stream as  
18 part of the stream bandwidth reservation mechanisms employed by the implementation.

#### 19 34.6.2 Strict priority

20 The *operIdleSlope(N)* parameter (34.3) represents the total outbound bandwidth for the queue of traffic  
21 class N, and *operIdleSlope(N)* shall be used to reserve space in the queue of the associated traffic class N.

22 NOTE 1—The *operIdleSlope(N)* parameter is not used by the algorithm for transmission selection (8.6.8.1).

23 When SRP is used for reservation of a stream, the egress Port that uses strict priority will place frames into  
24 its outbound queue based on the Tspec for that Stream. The TSpecs of all Streams that egress the Port are  
25 used to compute the *operIdleSlope(N)*.

1 When SRP is not used, the worst-case bandwidth for traffic class N is computed by a management client  
2 (e.g., CNC of 46.1.3.3, using TSpecs from the CUC) for the queue of the associated traffic class N. The  
3 management client uses *adminIdleSlope(N)* to configure this bandwidth in the station (12.20.1). Since  
4 *operIdleSlope(N)* is equal to *adminIdleSlope(N)*, *operIdleSlope(N)* is used to reserve space in the queue of  
5 the associated traffic class N. Since the priority associated with traffic class N is not using SRP, that priority  
6 does not need to be configured as an SR class (i.e., assigned an SRclassID using 12.20.4).

7 NOTE 2—As an example of a traffic class configured using *adminIdleSlope(N)*, consider a traffic class that is protected  
8 using scheduled traffic (8.6.8.4). This protected traffic class can use the strict priority algorithm. Traffic in the protected  
9 window requires queue reservation in order to ensure that adequate storage exists in its queue. The CNC entity of  
10 46.1.3.3 can use *adminIdleSlope(N)* to ensure that the queue for the protected traffic class is of sufficient size.

11 NOTE 3—Although *adminIdleSlope(N)* is specified as bits per second, with regard to reserving queue space for a shorter  
12 interval of time, it is best to assume that *adminIdleSlope(N)* is uniform over the entire second. For example, for a traffic  
13 class that is protected using scheduled traffic (8.6.8.4), if AdminCycleTime is 1 ms, *adminIdleSlope(N)* is divided by  
14 1000 to determine the worst-case traffic for that AdminCycleTime.

### 15 34.6.3 Scheduled traffic

16 When SRP uses Centralized Network Configuration (CNC), scheduled traffic (8.6.8.4) can be used in a  
17 Talker as well as the Bridges to each Listener. For information, refer to the specifications for externalControl  
18 TRUE in 35.2.2.10.

19 When SRP is fully distributed (externalControl FALSE in 35.2.2.10), use of scheduled traffic in Bridges is  
20 not specified for SRP's Streams. If scheduled traffic is used in a Talker, that Talker appends the  
21 TSpecTimeAware TLV to its Talker Advertise. If the nearest Bridge supports the optional capability of  
22 translating scheduled traffic in the Talker to the transmission selection used in Bridges (i.e., 34.6.1 or  
23 34.6.2), the nearest Bridge propagates Talker Advertise. As specified in 35.2.2.10.6, if the nearest Bridge  
24 does not support the TSpecTimeAware TLV, the nearest Bridge fails the Stream (propagates Talker Failed).

25 NOTE—For an example using scheduled traffic in a Talker, refer to U.1.1.

## 1 35. Stream Reservation Protocol (SRP)

2 SRP utilizes three signaling protocols [MMRP (10.9), MVRP (Clause 11), and MSRP (35.1)] to establish  
3 stream reservations across a bridged network.

4 Within SRP the Multiple MAC Registration Protocol (MMRP) may be used to control the propagation of  
5 Talker registrations throughout the bridged network (35.2.4.3.2).

6 The Multiple VLAN Registration Protocol (MVRP) is used by end stations and Bridges to declare  
7 membership in a VLAN where a Stream is being sourced. This allows the Data Frame Priority  
8 [35.2.2.8.5(a)] to be propagated along the path from Talker to Listener(s) in tagged frames. MSRP will not  
9 allow Streams to be established across Bridge Ports that are members of the untagged set (8.8.10) for the  
10 related VID.

11 The Multiple Stream Registration Protocol (MSRP) is a signaling protocol that provides end stations with  
12 the ability to reserve network resources that will guarantee the transmission and reception of data streams  
13 across a network with the requested QoS. These end stations are referred to as Talkers (devices that produce  
14 data streams) and Listeners (devices that consume data streams).

15 Talkers declare attributes that define the stream characteristics so Bridges have the necessary information  
16 available when they need to allocate resources for a Stream. Listeners declare attributes that request  
17 reception of those same streams. Bridges along the path from Talker to Listener process, possibly adjust, and  
18 then forward these MSRP attribute declarations. Bridges associate Talker and Listener attributes via the  
19 StreamID present in each of those attributes, which result in changes to the extended filtering services and  
20 allocation of internal resources when streams are “brought up.”

21 In order to establish the SRP domain boundaries, Bridges exchange SR class characteristics with each other  
22 and with end stations via MSRP. Neighboring devices that have identical SR class characteristics are  
23 considered to be in the same SRP domain and streams may be established between those devices.

24 MSRP provides a limited error reporting capability that is utilized when a Listener’s request to receive a  
25 stream cannot be honored because of some resource constraint within the network.

26 MSRP also supports the concept of data stream importance. For example, an emergency announcement  
27 would be flagged with a more important “rank” than a stream providing background music. This ranking  
28 ability allows the Bridges to replace less important streams with more important streams without requiring  
29 intervention from the end stations.

30 There is a considerable body of experience in supplying data streams with guarantees for QoS parameters  
31 such as latency, latency variation, or bandwidth. In particular, routers and hosts use the Internet Protocol (IP)  
32 and the Resource Reservation Protocol (RSVP, IETF RFC 2205, and IETF RFC 2750) to achieve such  
33 guarantees. Supplying guarantees to a data stream requires the following two components:

- 34 a) A definition of the resources to be allocated and configured, by end stations and network nodes, for  
35 the support of a data stream; and
- 36 b) A protocol for end stations to signal to the network nodes their data streams’ requirements, for  
37 network nodes to distribute those requirements among each other, and for the network nodes to  
38 signal the success or failure of the attempt to reserve resources to support the guarantees.

39 RSVP supplies the signaling protocol for routers to support data streams in routed networks. This and the  
40 following clauses define a protocol to support data streams in bridged networks.

41 The preceding description of SRP as a signaling protocol corresponds to the Fully distributed model  
42 (46.1.3.1) for TSN configuration. SRP also supports the Centralized network/distributed user model  
43 (46.1.3.2) for TSN configuration, which can be used to enable enhanced features (see 35.2.2.10). In order to

1 use the Centralized network/distributed user model, the MRP External Control (12.32.4) feature is enabled  
2 in the Nearest Bridge (8.6.3) to each Talker and Listener. Instead of propagating (signaling) through Bridges,  
3 SRP messages are exchanged with a Centralized Network Configuration (CNC) entity. The CNC uses  
4 remote management protocols (e.g., SNMP, NETCONF) in order to configure Bridges to meet the Stream  
5 requirements of each Talker and Listener.

## 6 **35.1 Multiple Stream Registration Protocol (MSRP)**

7 MSRP supports the reservation of resources for streams, each destined for one or more Listeners, and each  
8 from a single source, across a bridged network. Transmitted data that conforms to a successful stream  
9 reservation will not be discarded by any Bridge due to congestion on a LAN. In order to propagate requests  
10 for reservations, MSRP defines an *MRP application* that provides the Stream resource registration service  
11 defined in 35.2.3. MSRP makes use of the MRP Attribute Declaration (MAD) function, which provides the  
12 common state machine descriptions defined for use in MRP-based applications. The MRP architecture, and  
13 MAD are defined in Clause 10. MSRP defines a new MRP Attribute Propagation (MAP) function, to  
14 provide an attribute propagation mechanism.

15 MSRP propagates registrations for stream reservations in a manner similar to the operation of MMRP (10.9)  
16 and MVRP (11.2), which are used for registering Group membership and individual MAC address  
17 information, and VLAN membership, respectively. Unlike MMRP and MVRP, however, the registered  
18 attributes can be combined, discarded, or otherwise altered, as they are propagated by the participating  
19 Bridges.

20 In order to make and keep QoS guarantees all devices in a bridged network must participate in the signaling  
21 and queuing operations required of Bridges. For example, this would include IEEE 802.11 wireless media  
22 access points and stations. Thus, MSRP provides a means for Bridges or end stations running MSRP to  
23 cooperate both with higher network layers, such as routers or hosts running RSVP, and with lower network  
24 layers, such as wireless media.

25 MSRP is also responsible for establishing the SRP domain boundary for a particular SR class. All systems  
26 that support a particular SR class are in the same SRP domain if they use the same priority. An SRP domain  
27 boundary exists for an SR class when neighboring devices use different priorities for the SR class.

28 Figure 35-1 illustrates the architecture of MSRP in the case of a two-Port Bridge and an end station.

29 The version of MSRP is distinguished by the ProtocolVersion of MRP. ProtocolVersion 0x00 (MSRPv0) is  
30 the original version. ProtocolVersion 0x01 (MSRPv1) or higher specifies new AttributeTypes (35.2.2.4) that  
31 provide enhanced capabilities. This standard specifies MSRPv1 (35.2.2.1). In order to meet interoperability  
32 goals, implementations of this version shall support the original AttributeTypes specified in MSRPv0 as well  
33 as the enhanced AttributeTypes. The interoperability goals require a network of mixed MSRPv0 and  
34 MSRPv1 end stations and Bridges to provide a quality of service that is as good as or better than a complete  
35 MSRPv0 network.

36 For both MSRPv0 and MSRPv1, each MSRP Participant declares the Domain attribute prior to other MSRP  
37 attributes in order to determine SR class boundaries. The MSRPv1 end station or Bridge also uses this  
38 Domain exchange to determine the ProtocolVersion of its neighboring MSRP Participant. If the neighbor is  
39 MSRPv0, then only the original AttributeTypes are exchanged with that neighbor, although the  
40 ProtocolVersion will be set to the value defined in 35.2.2.1 [see item b) in 10.8.3.5]. If the neighbor is  
41 MSRPv1, then both original and enhanced AttributeTypes can be exchanged with that neighbor. For a  
42 Bridge, this means that it is possible to register an enhanced AttributeType from one Port and propagate and  
43 declare that same attribute to another Port as an original AttributeType. To enable this mixture of  
44 AttributeTypes, the MSRP Attribute Propagation (35.2.4) specifies the translation from each enhanced  
45 AttributeType to its corresponding original AttributeType.

**Figure 35-1—Operation of MSRP**

1 For propagation of an MSRP attribute from one Port using MSRPv1 to another Port using MSRPv1, the  
2 AttributeType is not changed. This allows original AttributeTypes to propagate through a Bridged Network  
3 as is, without translation to enhanced AttributeTypes.

4 NOTE—MRP (Clause 10) has limitations on the total amount of attribute data that can be exchanged between  
5 participants. Therefore, the larger each MSRP attribute's value, the fewer total Streams can be reserved in the network.  
6 Due to the enhanced features, the enhanced AttributeType is larger than the original AttributeType. If the Talker and  
7 Listeners of a Stream do not need the enhanced features, use of the original AttributeTypes can allow for a larger number  
8 of total Streams. If all Talkers and Listeners in the network use original AttributeTypes, the maximum number of  
9 Streams in an all-MSRPv1 network is the same as an all-MSRPv0 network.

### 10 35.1.1 MSRP and Shared Media

11 Classic shared media, such as IEEE 802.3 half-duplex Carrier Sense Multiple Access with Collision Detect  
12 (CSMA/CD), cannot provide latency or bandwidth guarantees, because their operation depends on random  
13 timers. Such media are therefore not supported by MSRP.

14 There are other shared media where one node on the medium exercises control over access to the medium by  
15 the other nodes. For example, an IEEE 802.11 infrastructure wireless medium has a single Access Point  
16 (AP) that controls access by the AP and the stations attached to the wireless medium so that some guarantee  
17 of latency and bandwidth can be made, subject to frame loss caused by data corruption errors. Similarly, an  
18 IEEE 802.3 Ethernet Passive Optical Network has a single Optical Line Terminal (OLT) that controls access  
19 to the optical medium by itself and some number of Optical Network Units (ONUs).

20 Different kinds of shared media use different techniques to allocate opportunities to transmit, and these  
21 techniques can have various dependencies on frame sizes, station-to-station vs. station-to-head data paths, or  
22 other factors. Rather than introducing the complexities of every such medium into MSRP, this standard takes  
23 advantage of the presence of a controlling entity to map medium-specific characteristics to the capabilities  
24 of MSRP.

1 MSRP defines and requires the existence of a Designated MSRP Node (DMN) on any shared medium. This  
2 DMN provides the MSRP services for the shared medium and determines each station's ability to receive the  
3 MSRPDU's transmitted by other stations on the medium. A Non-DMN Port shall be configured to only  
4 process the MSRPDU's transmitted by DMN Ports, and ignore the MSRPDU's transmitted by other Non-  
5 DMN Ports. Furthermore, the DMN has the absolute control of the resource allocation on the shared  
6 medium. Given these two facts, a DMN can effectively control which reservations are and are not successful  
7 on the medium it controls.

8 Annex C provides examples on various shared media.

## 9 35.1.2 Behavior of end stations

### 10 35.1.2.1 Talkers

11 To announce the Streams that can be supplied and their characteristics, Talkers use the MAD\_Join.request  
12 primitive (10.2) to make the Talker Declarations (35.2.1.3). To indicate the Streams that are no longer  
13 supplied, Talkers use the MAD\_Leave.request primitive (10.2) to withdraw their Talker Declarations.

14 The Talker shall issue an MVRP VLAN membership declaration prior to issuing the Talker Declaration. The  
15 MVRP VLAN membership shall contain the vlan\_identifier of the DataFrameParameters [item b) in  
16 35.2.2.8.3], so that the neighboring Bridge adds the associated Bridge Port to the member set for the VLAN.

17 NOTE—VLAN membership is needed for the Talker when the neighboring Bridge has the Enable Ingress  
18 Filtering parameter set (8.6.2).

19 Talker Declarations are propagated by MSRP such that the Listeners and Bridges are aware of the presence  
20 of Talkers and the Streams that are offered. Talker Declarations are also used to gather QoS information  
21 along their paths. Based on the gathered QoS information, Talker Declarations are classified as follows:

- 22 a) **Talker Advertise:** An advertisement for a Stream that has not encountered any bandwidth or other  
23 network constraints along the network path from the Talker. Listeners that request attachment to this  
24 Stream are likely to create a reservation with the described QoS. A Talker Advertise will continue to  
25 be declared as long as the resources continue to be available.
- 26 b) **Talker Failed:** An advertisement for a Stream that is not available to the Listener because of  
27 bandwidth constraints or other limitations somewhere along the path from the Talker.

28 A Talker Advertise shall not be declared if there are not sufficient bandwidth and resources available. If a  
29 Talker Advertise is being declared and the required bandwidth or resources become unavailable the Talker  
30 Advertise shall be withdrawn and a Talker Failed may be declared. A Talker is allowed to transition directly  
31 from a Talker Advertise to a Talker Failed without waiting for the Talker Advertise to be deregistered from  
32 the network (see 35.2.6).

33 Talkers respond to the registration and deregistration events of Listener Declarations (35.2.1.3), signaled by  
34 MAD as follows:

35 On receipt of a MAD\_Join.indication for a Listener Declaration, the Talker first merges (35.2.4.4.3) the  
36 Listener Declarations that it has registered for the same Stream. Then the Talker examines the StreamID  
37 (35.2.2.8.2) and Declaration Type (35.2.1.3) of the merged Listener Declaration. If the merged Listener  
38 Declaration is associated with a Stream that the Talker can supply, and the DeclarationType is either Ready  
39 or Ready Failed (i.e., one or more Listeners can receive the Stream), the Talker can start the transmission for  
40 this Stream immediately. If the merged Listener Declaration is an Asking Failed, the Talker shall stop the  
41 transmission for the Stream, if it is transmitting.

1 On receipt of a MAD\_Leave.indication for a Listener Declaration, if the StreamID of the Declaration  
2 matches a Stream that the Talker is transmitting, then the Talker shall stop the transmission for this Stream, if  
3 it is transmitting.

#### 4 **35.1.2.2 Listeners**

5 To indicate what Streams they want to receive, Listeners use the MAD\_Join.request primitive (10.2) to make  
6 the Listener Declarations (35.2.1.3). To indicate the Streams that are no longer wanted, Listeners use the  
7 MAD\_Leave.request primitive (10.2) to withdraw their Listener Declarations.

8 The Listener Declaration also conveys the results of the bandwidth and resource allocation along its path  
9 back to the Talker. Based on those results, Listener declarations are classified as follows:

- 10 a) **Listener Ready:** One or more Listeners are requesting attachment to the Stream. There is sufficient  
11 bandwidth and resources available along the path(s) back to the Talker for all Listeners to receive the  
12 Stream.
- 13 b) **Listener Ready Failed:** Two or more Listeners are requesting attachment to the Stream. At least  
14 one of those Listeners has sufficient bandwidth and resources along the path to receive the Stream,  
15 but one or more other Listeners are unable to receive the stream because of network bandwidth or  
16 resource allocation problems.
- 17 c) **Listener Asking Failed:** One or more Listeners are requesting attachment to the Stream. None of  
18 those Listeners are able to receive the Stream because of network bandwidth or resource allocation  
19 problems.

20 NOTE 1—The reader will notice that the Talker response to Ready and Ready Failed declarations is the same: the Talker  
21 can begin transmitting the Stream. Talkers might choose to pass the Ready Failed response to a higher layer protocol that  
22 could notify the user that the Stream is flowing, but not all Listeners are receiving it. It would be the responsibility of that  
23 higher layer to respond to this information as appropriate.

24 If the Listener receives a Talker Advertise declaration, and the Listener is ready to receive the Stream, the  
25 Listener shall issue an MSRP Listener Ready declaration for the Stream.

26 The Listener shall issue an MVRP VLAN membership declaration prior to issuing the MSRP Listener  
27 Ready declaration. The MVRP VLAN membership shall contain the vlan\_identifier of the Talker Advertise  
28 DataFrameParameters [item b) in 35.2.2.8.3], so that the neighboring Bridge adds the associated Bridge Port  
29 to the member set for the VLAN.

30 If the *talkerVlanPruning* parameter (35.2.4.3.4) is not enabled in the Bridges in the path from Talker to the  
31 Listener, the Listener receives Talker Advertise prior to declaring MVRP VLAN membership. The Listener  
32 can then use the registered Talker Advertise to obtain the vlan\_identifier for declaration of MVRP VLAN  
33 membership. This is the default behavior for the *talkerVlanPruning* parameter.

34 If one or more Bridges in the path from Talker to the Listener have enabled the *talkerVlanPruning*  
35 parameter, the Listener declares VLAN membership prior to receiving the Talker Advertise declaration. The  
36 *talkerVlanPruning* parameter instructs the Bridge to filter Talker declarations for the VLAN (in addition to  
37 the VLAN-tagged data frames of the stream). If the *talkerVlanPruning* parameter is enabled and the VLAN  
38 is not Registration Fixed (8.8.10), the Listener obtains knowledge of the Talker's vlan\_identifier from a  
39 higher layer protocol above IEEE Std 802.1Q and uses that knowledge to declare the membership for the  
40 vlan\_identifier with MVRP.

41 If *talkerPruning* or *talkerPruningPerPort* is enabled, the Listener must issue an MMRP registration for the  
42 Stream's destination MAC address as described in 35.2.4.2 before the Talker Advertise will be received.

1 If the Listener receives a Talker Failed declaration, and the Listener is ready to receive the Stream, the  
2 Listener shall issue either an MSRP Listener Asking Failed declaration or an MSRP Listener Ready  
3 declaration for the Stream.

4 There is no requirement for the order in which the Talker and Listener declarations are communicated. The  
5 Listener Declaration can be made before the Listener receives an associated Talker Declaration, in which  
6 case the Listener shall issue a Listener Asking Failed declaration.

7 NOTE 2—One reason for the Listener to issue Listener Ready in response to Talker Failed is that the Listener wants to  
8 inform the network that it is ready to proceed in case the Talker's state changes from failed to ready in the future.

### 9 **35.1.3 Behavior of Bridges**

10 MSRP-aware Bridges register and deregister Talker and Listener declarations on the Bridge Ports according  
11 to the procedures defined in MRP (Clause 10), and automatically generate deregistration of stale  
12 registrations. Any changes in the state of registration are processed by the MSRP Attribute Propagation  
13 (35.2.4) function, and disseminated in the network by making or withdrawing Talker and Listener  
14 declarations as defined in the Talker attribute propagation (35.2.4.3) and Listener attribute propagation  
15 (35.2.4.4).

16 In general, Talker declarations are propagated to all other Bridge Ports. There are *talkerPruning* [item b) in  
17 35.2.1.4], *talkerPruningPerPort* [item k) in 35.2.1.4], and *talkerVlanPruning* [item l) in 35.2.1.4]  
18 parameters that limit the scope of Talker declaration propagation. Listener declarations are only propagated  
19 to the Bridge Port with the associated Talker declaration (i.e., matching StreamID). If there is no associated  
20 Talker declaration registered on any Bridge Port then Listener declaration will not be propagated.

#### 21 **35.1.3.1 Blocked Declarations**

22 For the purposes of MSRP Attribute Propagation (35.2.4), a Declaration is said to be “blocked” on a Bridge  
23 Port if the state of the spanning tree instance identified by the *vlan\_identifier* in the *DataFrameParameters*  
24 (35.2.2.8.3) of the Declaration, on that Bridge Port, has any value other than Forwarding. In an end station's  
25 MSRP Participant, no Declaration is ever blocked.

#### 26 **35.1.4 SRP domains and status parameters**

27 An SRP domain is a set of stations (end stations and/or Bridges), their Ports, and the attached individual  
28 LANs, that satisfy all of the following conditions for a given SR class:

- 29 a) Those stations that transmit streams all support the credit-based shaper algorithm, defined in 8.6.8,  
30 as the transmission selection method for the SR class.
- 31 b) The stations all support SRP as the means of creating bandwidth reservations for the SR class.
- 32 c) Those stations that transmit streams all associate the same priority value with the SR class.
- 33 d) Each Port in the set is either an SRP domain core port or an SRP domain boundary port.
- 34 e) Each SRP domain core Port in the set is connected, via an individual LAN that is part of the active  
35 topology, to an SRP domain core Port of another station in the set.

36 In Bridges that support the SRP, and for each SR class supported by the Bridge, an  
37 **SRPdomainBoundaryPort** parameter is associated with each Port of the Bridge.

38 Each **SRPdomainBoundaryPort** parameter has a Boolean value. The value of the **SRPdomainBoundaryPort**  
39 parameter for a given SR class is TRUE if the operation of SRP has determined that the Port is an SRP  
40 domain boundary port (3.269) for that SR class; otherwise, the Port either is an SRP domain core port  
41 (3.270) for that SR class or is not part of that SRP domain, and the **SRPdomainBoundaryPort** parameter  
42 value is FALSE.

## 1 35.2 Definition of the MSRP application

2 MSRP maintains two categories of variables. The first category is used internally by the application state  
3 machines. These are defined in detail in the subclauses that follow.

4 MSRP also defines another category of variables identified as MRP elements that are communicated in  
5 MSRPDUs between stations on a network. These protocol elements include the MRP frame addressing and  
6 other fields defined in the MRPDUs. The MSRP FirstValue fields, which are used to exchange the MSRP  
7 attributes, are also defined here.

### 8 35.2.1 Definition of internal state variables

9 The following variables and parameters are utilized by various state machines within MSRP:

- 10 a) Port Media Type (35.2.1.1);
- 11 b) Direction (35.2.1.2);
- 12 c) Declaration Type (35.2.1.3);
- 13 d) SRP parameters (35.2.1.4);

#### 14 35.2.1.1 Port Media Type

15 MSRPDU processing on a port is handled differently depending on the type of medium the port is attached  
16 to. For example, the DMN on a shared medium port that receives MSRPDUs from one station shall update  
17 and retransmit those attributes so that all stations on that medium are updated appropriately. The possible  
18 values are as follows:

- 19 a) **Access Control Port:** Transmitter controls access to the medium on which it is sending, so either it  
20 is the DMN for a shared medium, or it is a port on a full-duplex point-to-point medium.
- 21 b) **Non-DMN shared medium Port:** Transmitter is attached to a shared medium, but does not control  
22 access to the medium.

#### 23 35.2.1.2 Direction

24 The Direction field is derived from the MSRP AttributeType definitions (35.2.2.4). The Direction indicates  
25 whether this is a Talker: MSRP AttributeType definitions of type Talker Advertise Vector Attribute Type  
26 [item a) in 35.2.2.4], Talker Failed Vector Attribute Type [item b) in 35.2.2.4], or Talker Enhanced Vector  
27 Attribute Type [item e) in 35.2.2.4]. Set Direction to zero for Talker attributes. or a Listener MSRP  
28 Declaration, and takes one of the following two values:

- 29 a) **Talker:** MSRP AttributeType definitions of type Talker Advertise Vector Attribute Type [item a) in  
30 35.2.2.4], Talker Failed Vector Attribute Type [item b) in 35.2.2.4], or Talker Enhanced Vector  
31 Attribute Type [item e) in 35.2.2.4]. Set Direction to zero for Talker attributes.
- 32 b) **Listener:** MSRP AttributeType definitions of type Listener Vector Attribute Type [item c) in  
33 35.2.2.4] or Listener Enhanced Vector Attribute Type [item f) in 35.2.2.4]. Set Direction to one for  
34 Listener attributes.

#### 35 35.2.1.3 Declaration Type

36 The Declaration Type field is derived from the MSRP AttributeType definitions (35.2.2.4) and the MSRP  
37 FourPackedEvents (35.2.2.7.2). The Declaration Type indicates the specific type of the Talker or Listener  
38 MSRP Declaration.

1 For a Talker, the value of the Declaration Type component is either:

- 2 a) **Advertise:** MSRP AttributeType definitions of Talker Advertise Vector Attribute Type [item a) in  
3 35.2.2.4] or Talker Enhanced Vector Attribute Type [item e) in 35.2.2.4] with  
4 Status.StatusInfo.TalkerStatus equal to Ready (35.2.2.10.9). Set Declaration Type to zero for Talker  
5 Advertise.
- 6 b) **Failed:** MSRP AttributeType definitions of Talker Failed Vector Attribute Type [item b) in 35.2.2.4]  
7 or Talker Enhanced Vector Attribute Type [item e) in 35.2.2.4] with Status.StatusInfo.TalkerStatus  
8 equal to Failed (35.2.2.10.9). Set Declaration Type to one for Talker Failed.

9 For a Listener, the value of the Declaration Type component is one of the following:

- 10 c) **Asking Failed:** MSRP AttributeType definitions of Listener Vector Attribute Type [item c) in  
11 35.2.2.4] with MSRP FourPackedType equal to Asking Failed [item b) in 35.2.2.7.2] or Listener  
12 Enhanced Vector Attribute Type [item f) in 35.2.2.4] with Status.StatusInfo.ListenerStatus equal to  
13 Failed (35.2.2.10.9). Set Declaration Type to two for Listener Asking Failed.
- 14 d) **Ready:** MSRP AttributeType definitions of Listener Vector Attribute Type with MSRP  
15 FourPackedType equal to Ready [item c) in (35.2.2.7.2) or Listener Enhanced Vector Attribute Type  
16 [item f) in 35.2.2.4] with Status.StatusInfo.ListenerStatus equal to Ready (35.2.2.10.9). Set  
17 Declaration Type to three for Listener Ready.
- 18 e) **Ready Failed:** MSRP AttributeType definitions of Listener Vector Attribute Type with MSRP  
19 FourPackedType equal to Ready Failed [item d) in 35.2.2.7.2] or Listener Enhanced Vector  
20 Attribute Type [item f) in 35.2.2.4] with Status.StatusInfo.ListenerStatus equal to PartialFailed  
21 (35.2.2.10.9). Set Declaration Type to four for Listener Ready Failed.

#### 22 35.2.1.4 SRP parameters

23 The following parameters are used by SRP:

- 24 a) **portTcMaxLatency:** The maximum per-port per-traffic class latency, expressed in nanoseconds, a  
25 frame may experience through the underlying MAC Service. There may be different latency  
26 numbers for different traffic classes on the same port.
- 27 b) **talkerPruning:** Enabling this parameter on the Bridge will limit the Talker declarations to Ports that  
28 have the Streams destination\_address [item a) in 35.2.2.8.3] in the MAC Address Registration  
29 Entries (8.8.4), such as by using MMRP.
- 30 c) **streamAge:** A per-port per-stream 32-bit unsigned value used to represent the time, in seconds, since  
31 the control element for the associated port most recently became forwarding in the Dynamic  
32 Reservations Entries (8.8.7) corresponding to the stream's destination\_address. This value is used  
33 when determining which streams have been configured the longest. Streams with a numerically  
34 larger streamAge are considered to be configured earlier than other streams and therefore carry a  
35 higher implicit importance.
- 36 NOTE 1—A 32-bit unsigned value allows for expressing a streamAge of up to 136 years.
- 37 d) **msrpEnabledStatus:** MSRP shall have the ability to be enabled (true) or disabled (false) on a  
38 device. When MSRP is enabled on a device it shall cause a reset of all MSRP state machines on all  
39 ports. This affects the Applicant and Registrar state machines. The state of this parameter shall be  
40 persistent over power-up restart/reboot.
- 41 e) **msrpPortEnabledStatus:** MSRP shall have the ability to be enabled (true) or disabled (false) on the  
42 ports of a device. When MSRP is enabled or disabled on a port of a device it shall cause MAP to be  
43 rerun on all MSRP enabled ports so existing attributes can be propagated to the port just enabled.  
44 This affects the Applicant and Registrar state machines. The state of this parameter shall be  
45 persistent over power-up restart/reboot.

- 1 f) **msrpMaxFanInPorts:** The total number of ports on a Bridge that are allowed to establish  
2 reservations for inbound Streams. This number may be less than the total number of ports with  
3 msrpPortEnabledStatus set TRUE, which will result in lower maximum latency because of limits on  
4 the amount of possible interfering traffic. A value of zero (0) indicates no fan-in limit is being  
5 specified and calculations involving fan-in will only be limited by the number of MSRP enabled  
6 ports. Example calculations of delay associated with fan-in can be found in the paper “Calculating  
7 the Delay Added by Qav Stream Queue” [B3].
- 8 g) **msrpLatencyMaxFrameSize:** Calculation of the maximum latency through a Bridge is in-part  
9 related to the maximum size of an interfering frame. The maximum size is defined to be 2000 octets  
10 by default. This parameter allows a smaller or larger value to be used in the latency calculations for  
11 the particular Bridge implementation. msrpLatencyMaxFrameSize does not imply any type of  
12 policing of frame size, it is only used in the latency calculations.
- 13 h) **SRPdomainBoundaryPort (35.1.4):** A per-port, per-SR class, Boolean parameter that contains the  
14 value TRUE if the port is an SRP Domain Boundary Port; otherwise, it contains the value FALSE.  
15 The parameter for a given SR class and Port shall be set to TRUE if any of the following conditions  
16 are met:
  - 17 1) The port is declaring an MSRP Domain attribute for that SR class, and the port has no MSRP  
18 Domain attribute registrations for that SR class, or
  - 19 2) The port is declaring an MSRP Domain attribute for that SR class, and the port has at least one  
20 MSRP Domain attribute registration for that SR class with a different priority, or
  - 21 3) One or more ports which support that SR class are declaring MSRP Domain attributes for that  
22 SR class, and this port does not support that SR class.
- 23 In all other cases the parameter shall be set to FALSE.
- 24 i) **SR\_PVID:** The Stream Reservation Port VLAN Identifier is a per-port parameter that contains the  
25 default VID for Stream-related traffic. It shall contain a valid VID value (Table 9-2) and may be  
26 configured by management. If the value has not been explicitly configured, the SR\_PVID shall  
27 assume the default SR\_PVID defined in Table 9-2. This value is passed to the Talker via the  
28 SRclassVID (35.2.2.9.4) contained in the MSRP Domain attribute.
- 29 j) **neighborProtocolVersion:** Each Port provides a neighborProtocolVersion parameter that specifies  
30 the MSRP ProtocolVersion of the neighboring MSRP Participant on that Port. The initial value is  
31 0x00. When an MSRP Domain attribute is registered (received) on the Port, the value of the  
32 attribute’s MRP ProtocolVersion (35.2.2.1) is copied to this parameter.
- 33 k) **talkerPruningPerPort:** When the talkerPruning parameter is disabled (false), each Port provides a  
34 talkerPruningPerPort parameter to control MAC address pruning for that Port. For more  
35 information, refer to 35.2.4.3.3.
- 36 l) **talkerVlanPruning:** Enabling this parameter on the Bridge will limit the Talker declarations to Ports  
37 that have the Stream’s vlan\_identifier [item b) in 35.2.2.8.3] registered as a member in the VLAN  
38 Registration Entries (8.8). For more information, refer to 35.2.4.3.4.
- 39 m) **maxSRclasses:** This parameter provides the maximum number of SR classes supported by the  
40 Bridge.

## 41 35.2.2 Definition of MRP elements

### 42 35.2.2.1 MSRP application address

43 The group MAC address used as the destination address for MRPDUs destined for MSRP Participants shall  
44 be the group MAC address for “Individual LAN Scope group address, Nearest Bridge group address” as  
45 specified in Table 8-1, Table 8-2, and Table 8-3 (C-VLAN, S-VLAN, and TPMR component Reserved  
46 addresses, respectively).

47 NOTE—Using this address will guarantee that MSRPDUs are never forwarded by an 802.1 Bridge, although MSRP-  
48 aware Bridges do propagate the MSRP attributes.

### 1 35.2.2.2 MSRP application EtherType

2 The EtherType used for MRPDUs destined for MSRP Participants shall be the MSRP EtherType identified  
3 in Table 10-2.

### 4 35.2.2.3 MSRP ProtocolVersion

5 The ProtocolVersion for the version of MSRP defined in this standard takes the hexadecimal value 0x01.

6 NOTE—Although an MSRP Participant for this standard transmits MRPDUs using ProtocolVersion 0x01, the MSRP  
7 Participant ~~also must process~~ received MRPDUs using ~~other~~ ProtocolVersions ~~0x01 or 0x00~~, as specified in 10.8.3.5.

### 8 35.2.2.4 MSRP AttributeType definitions

9 MSRP defines six AttributeTypes (10.8.2.2) that are carried in MRP exchanges. The numeric values for the  
10 AttributeType are shown in Table 35-1 and their use is defined by the following list:

- 11 a) **Talker Advertise Vector Attribute Type:** Attributes identified by the Talker Advertise Vector  
12 Attribute Type are instances of VectorAttributes (10.8.1), used to identify a sequence of values of  
13 Talker advertisements for related Streams that have not been constrained by insufficient bandwidth  
14 or resources. This Attribute Type applies to all versions of MSRP.
- 15 b) **Talker Failed Vector Attribute Type:** Attributes identified by the Talker Failed Vector Attribute  
16 Type are instances of VectorAttributes, used to identify a sequence of values of Talker  
17 advertisements for related Streams that have been constrained by insufficient bandwidth or  
18 resources. This Attribute Type applies to all versions of MSRP.
- 19 c) **Listener Vector Attribute Type:** Attributes identified by the Listener Vector Attribute Type are  
20 instances of VectorAttributes, used to identify a sequence of values of Listener requests for related  
21 Streams regardless of bandwidth constraints. Listener Vector Attribute Types are subdivided into  
22 individual Declaration Types via the MSRP FourPackedEvents (35.2.2.7.2). This Attribute Type  
23 applies to all versions of MSRP.
- 24 d) **Domain Vector Attribute Type:** Attributes identified by the Domain Vector Attribute Type are  
25 instances of VectorAttributes, used to identify a sequence of values that describe the characteristics  
26 of an SR class. This Attribute Type applies to all versions of MSRP.
- 27 e) **Talker Enhanced Vector Attribute Type:** Attributes identified by the Talker Enhanced Vector  
28 Attribute Type are instances of VectorAttributes (10.8.1), used to identify a sequence of values of  
29 Talker advertisements for related Streams. Talker Enhanced Vector Attribute Types are subdivided  
30 into individual Declaration Types (35.2.1.3) via the Status.StatusInfo.TalkerStatus (35.2.2.10.9).  
31 This Attribute Type applies to ProtocolVersion 0x01 or higher.
- 32 f) **Listener Enhanced Vector Attribute Type:** Attributes identified by the Listener Enhanced Vector  
33 Attribute Type are instances of VectorAttributes, used to identify a sequence of values of Listener  
34 requests for related Streams. Listener Enhanced Vector Attribute Types are subdivided into  
35 individual Declaration Types (35.2.1.3) via the Status.StatusInfo.ListenerStatus (35.2.2.10.9). This  
36 Attribute Type applies to ProtocolVersion 0x01 or higher.

### 37 35.2.2.5 MSRP AttributeLength definitions

38 The AttributeLength field (10.12.1.8) in instances of the Talker Advertise Vector Attribute Type shall be  
39 encoded in MRPDUs (10.8) as an unsigned binary number, equal to the value shown in Table 35-2.

40 The AttributeLength field in instances of the Talker Failed Vector Attribute Type shall be encoded in  
41 MRPDUs as an unsigned binary number, equal to the value shown in Table 35-2.

42 The AttributeLength field in instances of the Listener Vector Attribute Type shall be encoded in MRPDUs as  
43 an unsigned binary number, equal to the value shown in Table 35-2.

**Table 35-1—AttributeType Values**

| AttributeType            | Value | Used when<br>neighborProtocolVersion is<br>0x00 | Used when<br>neighborProtocolVersion is<br>0x01 or higher |
|--------------------------|-------|-------------------------------------------------|-----------------------------------------------------------|
| Talker Advertise Vector  | 1     | yes                                             | yes                                                       |
| Talker Failed Vector     | 2     | yes                                             | yes                                                       |
| Listener Vector          | 3     | yes                                             | yes                                                       |
| Domain Vector            | 4     | yes                                             | yes                                                       |
| Talker Enhanced Vector   | 5     | no                                              | yes                                                       |
| Listener Enhanced Vector | 6     | no                                              | yes                                                       |

**Table 35-2—AttributeLength Values**

| AttributeType            | Value     |
|--------------------------|-----------|
| Talker Advertise Vector  | 25 (0x19) |
| Talker Failed Vector     | 34 (0x22) |
| Listener Vector          | 8         |
| Domain Vector            | 4         |
| Talker Enhanced Vector   | variable  |
| Listener Enhanced Vector | variable  |

<sup>1</sup> The AttributeLength field in instances of the Domain Vector Attribute Type shall be encoded in MRPDUs as  
<sup>2</sup> an unsigned binary number, equal to the value shown in Table 35-2.

<sup>3</sup> The AttributeLength field in instances of the Talker Enhanced Vector Attribute Type and Listener Enhanced  
<sup>4</sup> Vector Attribute Type shall be encoded in MRPDUs as an unsigned binary number. The value of  
<sup>5</sup> AttributeLength varies according to the TLVs contained in the attribute's value, but shall not change during  
<sup>6</sup> the duration of the attribute's declaration.

#### <sup>7</sup> **35.2.2.6 MSRP AttributeListLength definitions**

<sup>8</sup> The AttributeListLength field (10.12.1.9) shall be encoded in MRPDUs (10.8) as an unsigned binary  
<sup>9</sup> number, equal to the number of octets contained within the AttributeList. This field can be used when  
<sup>10</sup> calculating the number of octets to skip to proceed to the next Message (or Message EndMark) in the  
<sup>11</sup> MRPDU.

#### <sup>12</sup> **35.2.2.7 MSRP Vector definitions**

##### <sup>13</sup> **35.2.2.7.1 MSRP ThreePackedEvents**

<sup>14</sup> The ThreePackedEvent vectors are encoded as defined in 10.8.2.10.1.

### 35.2.2.7.2 MSRP FourPackedEvents

MSRP FourPackedEvents are only used by the Listener Vector Attribute Type [item c) in 35.2.2.4]. Within the FourPackedEvent, there are four possible values for the FourPackedType (10.8.2.10.2) as explained in the following list. The numeric values for the MSRP FourPackedEvents are shown in Table 35-3.

- a) **Ignore:** The StreamID referenced by FirstValue+n is not defined in this MSRPDU. When using this FourPackedType, the AttributeEvent (10.8.2.10.1) value, encoded in the ThreePackedEvent, shall be set to zero on transmit and ignored on receive.
- b) **Asking Failed:** The StreamID referenced by FirstValue+n has a declaration type of Listener Asking Failed.
- c) **Ready:** The StreamID referenced by FirstValue+n has a declaration type of Listener Ready.
- d) **Ready Failed:** The StreamID referenced by FirstValue+n has a declaration of type Listener Ready Failed.

**Table 35-3—FourPackedEvent Values**

| FourPackedType | Value |
|----------------|-------|
| Ignore         | 0     |
| Asking Failed  | 1     |
| Ready          | 2     |
| Ready Failed   | 3     |

NOTE 1—In terms of efficient use of octets within an MSRP packet, placing nineteen (19) Ignores between two Listener declarations uses less octets than using two VectorAttributes to declare the Listener attributes separately. A single Listener VectorAttribute takes 12 octets, two attributes would take 24 octets. Declaring 21 attributes (two valid attributes with 19 Ignores in between) takes 12 octets, plus 6 additional ThreePackedEvents, plus 5 additional FourPackedEvents for a total of 23 octets.

NOTE 2—MSRP FourPackedEvents are not used for the Listener Enhanced Vector Attribute Type [item f) in 35.2.2.4], which uses the Status.StatusInfo.ListenerStatus (35.2.2.10.9) to distinguish Declaration Types (35.2.1.3).

### 35.2.2.8 MSRP FirstValue definitions (Stream reservations, original)

There are four Attribute Declarations defined for the original ProtocolVersion 0x00 of MSRP (35.2.2.4), three of which are related to stream reservations: Talker Advertise, Talker Failed, and Listener. The fourth attribute type, Domain, is used to discover the SRP domain, as well as the ProtocolVersion of each Port's neighbor, and is described in 35.2.2.9.

NOTE—This version of MSRP requires implementation of the original attributes of 35.2.2.8 and the enhanced attributes of 35.2.2.10. The specifications for enhanced attributes are based on the specifications for original attributes.

The Talker Advertise attribute contains all the characteristics that a Bridge needs in order to understand the resource requirements and importance of the referenced stream.

The Talker Failed attribute contains all the fields carried in the Talker Advertise Attribute, plus additional information regarding resource or bandwidth availability failures.

Listener attributes carry three subtypes: Ready, Ready Failed, and Asking Failed. These Listener subtypes are encoded in the FourPackedEvent (35.2.2.7.2).

1 FirstValue shall be incremented one or more times when NumberOfValues is greater than one. Incrementing  
2 FirstValue within MSRP is defined as follows:

- 3 a) Add 1 to Unique ID [item b) in 35.2.2.8.2], and
- 4 b) Add 1 to Stream destination\_address [item a) in 35.2.2.8.3].

5 The example shown in Table 35-4 illustrates the use of FirstValue and NumberOfValues within MSRP. This  
6 example shows four Streams (a, b, c, and d) to be declared. In order to use the efficient packing techniques  
7 of MRP it would be preferable to assign these Streams sequential StreamIDs and destination\_addresses as  
8 shown. Notice that StreamID yy-yy-yy-yy-yy-yy:00-04 is missing from this table (between Stream “c” and  
9 “d”). MSRP allows declaration of all four StreamIDs in a single VectorAttribute by setting  
10 NumberOfValues=5, with the StreamID = yy-yy-yy-yy-yy-yy:00-01 and a destination\_address of xx-xx-xx-  
11 xx-xx-25. Setting the fourth FourPackedEvent to Ignore [item a) in 35.2.2.7.2] notifies MSRP that the  
12 StreamID between “c” and “d” is not in use.

**Table 35-4—MSRP FirstValue NumberOfValues example**

| Stream | StreamID                | destination_address |
|--------|-------------------------|---------------------|
| a      | yy-yy-yy-yy-yy-yy:00-01 | xx-xx-xx-xx-xx-25   |
| b      | yy-yy-yy-yy-yy-yy:00-02 | xx-xx-xx-xx-xx-26   |
| c      | yy-yy-yy-yy-yy-yy:00-03 | xx-xx-xx-xx-xx-27   |
| d      | yy-yy-yy-yy-yy-yy:00-05 | xx-xx-xx-xx-xx-29   |

13 The FirstValue field within MSRP comprises several components: StreamID (35.2.2.8.2),  
14 DataFrameParameters (35.2.2.8.3), TSpec (35.2.2.8.4), PriorityAndRank (35.2.2.8.5), Accumulated Latency  
15 (35.2.2.8.6), and FailureInformation (35.2.2.8.7). MSRP does not support changes in any of the FirstValue  
16 fields for an existing StreamID. If a Talker wishes to tear an old Stream down and bring a new Stream  
17 up, with a different FirstValue, utilizing the same StreamID, there must be at least two LeaveAllTime  
18 (Table 10-7) time periods between when the Talker removes the existing Stream registration and declares the  
19 new Stream. This guarantees that MRP has enough time to remove the current attribute from all devices in  
20 the network. If the new declaration were to occur too quickly the associated Streaming data could be  
21 corrupted because the FDB may allow the new Stream data to start flowing while the old Stream bandwidth  
22 constraints are still configured. When the Bridge detects this occurring it will fail the Talker Advertise with  
23 the appropriate FailureInformation (35.2.2.8.7). Talkers may tear a Stream down and bring the same Stream  
24 back up immediately, as long as the FirstValue has not changed.

### 25 35.2.2.8.1 Structure definition

26 The FirstValue for Talker Advertise, Talker Failed, and Listener attributes in MSRPDU exchanged  
27 according to the protocol specified in this subclause shall have the following structure:

- 28 a) The first eight octets contain the *StreamID* (35.2.2.8.2).
- 29 This is the end of the Listener attribute. If this is a Talker Advertise or Talker Failed attribute  
30 continue as follows:
- 31 b) Following the StreamID are eight octets containing the *DataFrameParameters* (35.2.2.8.3).
- 32 c) Following the DataFrameParameters are four octets containing the *TSpec* (35.2.2.8.4).
- 33 d) Following the TSpec is one octet containing the *PriorityAndRank* (35.2.2.8.5).
- 34 e) Following the PriorityAndRank are four octets containing the *AccumulatedLatency* (35.2.2.8.6).
- 35 This is the end of the Talker Advertise attribute. If this is a Talker Failed attribute continue as  
36 follows:

**Figure 35-2—Format of the components of the reservation FirstValue fields**

- 1 f) Following the AccumulatedLatency are nine octets containing the *FailureInformation* (35.2.2.8.7).
- 2 The following partial BNF production gives the formal description of the MSRPDU FirstValue structure for
- 3 the Talker Advertise attribute:
- 4 FirstValue ::=StreamID, DataFrameParameters, TSpec, PriorityAndRank, AccumulatedLatency
- 5 The following partial BNF production gives the formal description of the MSRPDU FirstValue structure for
- 6 the Talker Failed attribute:
- 7 FirstValue ::=StreamID, DataFrameParameters, TSpec, PriorityAndRank, AccumulatedLatency,
- 8 FailureInformation
- 9 The following partial BNF production gives the formal description of the MSRPDU FirstValue structure for
- 10 the Listener attribute:
- 11 FirstValue ::=StreamID
- 12 Figure 35-2 illustrates the structure of the MSRPDU FirstValue components. Each MSRP Attribute shall
- 13 only use those structures as defined by the partial BNF productions described previously. The octet numbers
- 14 shown represent the octet location within the FirstValue field.

### 1 35.2.2.8.2 StreamID

2 The 64-bit StreamID is used to match Talker registrations with their corresponding Listener registrations  
3 (35.2.4). The StreamID comprises the following two subcomponents:

- 4 a) A 48-bit MAC Address associated with the Talker sourcing the stream to the bridged network. The  
5 entire range of MAC addresses are acceptable.
- 6 b) A 16-bit unsigned integer value, Unique ID, used to distinguish among multiple streams sourced by  
7 the same Talker.

8 StreamIDs are unique across the entire bridged network and are generated by the system offering the stream,  
9 or possibly a device controlling that system. A system reserving resources for more than one stream in the  
10 same bridged network shall use a StreamID that is unique among all StreamIDs in that bridged network. The  
11 combination of these two subcomponents ensure that such an assignment is possible.

12 NOTE 1—The spanning tree protocol ensures that there can be at most one path from a Talker to its Listener(s). Multiple  
13 Declarations for the same StreamID can therefore occur briefly, during changes in the active topology of the bridged  
14 network.

15 NOTE 2—The MAC address component of the StreamID can, but does not necessarily, have the same value as the  
16 source\_address parameter of any frame in the actual data stream. For example, the StreamID can be assigned by a TSN  
17 CUC (see 46.1.3.3), using a pool of MAC addresses that the TSN CUC maintains.

18 NOTE 3—If the MAC addresses used to construct StreamIDs are not unique within the network, duplicate StreamIDs  
19 can be generated, with unpredictable results for SRP.

### 20 35.2.2.8.3 DataFrameParameters

21 The DataFrameParameters component of the MSRP Attribute specifies the EISS parameters that are  
22 common to all frames belonging to the data stream for which this MAD is reserving resources. This  
23 information is used by Bridges to create Dynamic Reservation Entries (8.8.7). The parameters are as  
24 follows:

- 25 a) The destination\_address
- 26 b) The vlan\_identifier

27 The destination\_address specifies the destination MAC address of the streaming data frames. Only one  
28 Stream is allowed per destination\_address. MSRP does not describe the actual streaming data, only the  
29 bandwidth associated with that stream.

30 The use of destination\_address for both a Stream and “best effort” traffic (34.5) is outside the scope of SRP.  
31 SRP only supports destination\_addresses that are multicast or locally administered addresses.

32 NOTE—MSRP enforces reserved bandwidth guarantees by filtering Stream destination addresses (35.2.4.4.2) for  
33 Streams that do not have a reservation. This blocks all traffic to that destination address. If that destination address was  
34 also being used for “best effort” traffic that device would no longer be reachable.

35 Systems that are not VLAN aware shall use the value SRclassVID (35.2.2.9.4) for the vlan\_identifier in the  
36 DataFrameParameters. VLAN-aware systems may use any valid VID (1 through 4094).

### 37 35.2.2.8.4 TSpec

38 The 32-bit TSpec component is the TSpec associated with a Stream. It consists of the following two  
39 elements (which are encoded as described in 10.8.1.1):

- 40 a) **MaxFrameSize:** The 16-bit unsigned MaxFrameSize component is used to allocate resources and  
41 adjust queue selection parameters in order to supply the QoS requested by an MSRP Talker  
42 Declaration. It represents the maximum frame size that the Talker will produce, excluding any  
43 overhead for media-specific framing (e.g., preamble, IEEE 802.3 header, Priority/VID tag, CRC,  
44 interframe gap). As the Talker or Bridge determines the amount of bandwidth to reserve on the

egress port it will calculate the media-specific framing overhead on that port and add it to the number specified in the MaxFrameSize field.

b) **MaxIntervalFrames:** The 16-bit unsigned MaxIntervalFrames component is used to allocate resources and adjust queue selection parameters in order to supply the QoS requested by an MSRP Talker Declaration. It represents the maximum number of frames that the Talker can initiate in one classMeasurementInterval (34.3).

NOTE—Consider the example of a Class A 48kHz stereo audio stream encapsulated in an Ethernet frame (see IEEE Std 1722™ [B18]). The audio data within the frame would contain two sets of six 32-bit samples, plus a 32-octet header, for a total of 80 octets per frame sent once every class measurement interval (34.4). Therefore, MaxFrameSize=80, and MaxIntervalFrames=1. An IEEE 802.3 port on a Bridge would also add 42 octets of media-specific framing overhead (8-octet preamble, 14-octet IEEE 802.3 header, 4-octet IEEE 802.1Q priority/VID Tag, 4-octet CRC, 12-octet IFG). When the Bridge calculates the amount of bandwidth to reserve it would combine 42 octets of media-specific framing overhead with the MaxFrameSize of 80 octets, to arrive at a total frame size of 122 octets per class measurement interval. This represents a total bandwidth of approximately 7.7 Mb/s (122 octets × 8 b/octet × 8000 frames/s).

Table 35-5 contains some examples of various forms of audio and video Streams with their associated TSpec components.

**Table 35-5—TSpec components examples**

| Source                                                                   | Raw bit rate | Media-specific framing overhead | TSpec MaxFrameSize | TSpec MaxIntervalFrames            |
|--------------------------------------------------------------------------|--------------|---------------------------------|--------------------|------------------------------------|
| 48kHz stereo audio stream (32-bit samples) Class A (IEEE Std 1722 [B18]) | ~3 Mb/s      | ~4.7 Mb/s                       | 80                 | 1<br>(8 000 frames/s)              |
| 96kHz stereo audio stream (32-bit samples) Class A (IEEE Std 1722 [B18]) | ~6 Mb/s      | ~4.7 Mb/s                       | 128                | 1<br>(8 000 frames/s)              |
| MPEG2-TS video Class B (IEEE Std 1722 [B18])                             | ~24 Mb/s     | ~2.5 Mb/s                       | 786                | 1<br>(4 000 frames/s) <sup>a</sup> |
| SD SDI (Level C) uncompressed Class A (SMPTE 259M-2008 [B63])            | 270 Mb/s     | ~15 Mb/s                        | 1442               | 3<br>(24 000 frames/s)             |
| SD SDI (Level D) uncompressed Class A (SMPTE 259M-2008 [B63])            | 360 Mb/s     | ~20 Mb/s                        | 1442               | 4<br>(32 000 frames/s)             |
| HD SDI 1080i uncompressed Class A (SMPTE 292M-2008 [B64])                | 1.485 Gb/s   | ~80 Mb/s                        | 1486               | 16<br>(128 000 frames/s)           |
| HD SDI 1080p uncompressed Class A (SMPTE 424M-2008 [B65])                | 2.97 Gb/s    | ~160 Mb/s                       | 1486               | 32<br>(256 000 frames/s)           |

<sup>a</sup> The MPEG-2 TS entry in this table (third row) is shown as Class B traffic, which runs at a default frame rate of 250 µs/frame or 4000 frames/s. Class A traffic runs at a default rate of 8000 frames/s.

### 35.2.2.8.5 PriorityAndRank

a) **Data Frame Priority:** The 3-bit Data Frame Priority component specifies the priority value used to generate the Priority Code Point the referenced data streams will be tagged with. It indicates the priority EISS or ISS parameter that will be used in all frames belonging to the data stream for which this MAD is reserving resources. This parameter determines which queue the frame is placed into on

an output Bridge Port. In accordance with 10.8.1.1 these three bits are in the most significant positions (8, 7, and 6). The priority specified here is associated with the SR Classes as described in 34.5.

- b) **Rank:** The single-bit Rank component is used by systems to decide which streams can and cannot be served, when the MSRP registrations exceed the capacity of a Port to carry the corresponding data streams. If a Bridge becomes oversubscribed (e.g., network reconfiguration, IEEE 802.11 bandwidth reduction), the Rank will also be used to help determine which Stream or Streams can be dropped. A lower numeric value is more important than a higher numeric value. In accordance with 10.8.1.1 this bit is in position 5.

For streams that carry emergency data such as North America 911 emergency services telephone calls, or fire safety announcements, the Rank shall be 0. Nonemergency traffic shall set this bit to a 1.

NOTE—It is expected that higher layer applications and protocols can use the Rank to indicate the relative importance of streams based on user preferences expressed by means beyond the scope of this standard. The values and defaults provided by this Standard are sufficient to order streams on a first-come-first-served basis, with special priority provided for emergency services.

- c) **Reserved:** This 4-bit field shall be zero filled on transmit and ignored on receive. In accordance with 10.8.1.1 these four bits are in the least significant positions (4, 3, 2, and 1).

### 35.2.2.8.6 Accumulated Latency

The 32-bit unsigned Accumulated Latency component is used to determine the worst-case latency that a Stream can encounter in its path from the Talker to a given Listener. The latency reported here is not intended to increase during the life of the reservation. If some event occurs that would increase the latency beyond the original guarantee, MSRP will change the Talker Advertise to a Talker Failed and report Failure Code=7 (Table 35-6).

NOTE 1—An example of how latency could increase is if the speed of the underlying media were to decrease, such as one might see on a wireless link.

The initial value sent by the Talker is set to *portTcMaxLatency* plus any amounts specified in the REGISTER\_STREAM.request, and its value is increased by each Bridge as the Talker Declaration propagates through the network.

The *portTcMaxLatency* per hop is equal to the sum of the following:

- a) (equal or higher priority traffic) the time required to empty the queue in which frames of that priority are placed, if that queue and all higher priority queues are full.
- b) (lower priority traffic) the time required to transfer one lower priority frame of maximum size that could have just started transmitting as the current priority frame was queued up.
- c) (internal processing) the worst-case time required by the Bridge to transfer a received frame from the input port to the output queue.
- d) (wire propagation time) the time required for the first bit of the frame to propagate from the output port to the receiving device.
- e) (media access delay) the time required to wait for the media to become available for transmission.

For item a) the total number of ports with *msrpPortEnabledStatus* set TRUE, and the *msrpMaxFanInPorts* will effect these calculations.<sup>48</sup>

For item a) and item b) the maximum size of the interfering traffic is limited to *msrpLatencyMaxFrameSize* octets.

<sup>48</sup> Example calculations for latency are contained in the paper “Calculating the Delay Added by Qav Stream Queue” [B3].

1 For item d), the propagation time, if the managed object for Propagation Delay (12.32.2) is supported,  
2 txPropagationDelay shall be used. Otherwise, in the absence of better information, a value of 500 ns shall be  
3 used.

4 NOTE 2—This implies that no type of frame flow control can be used on the associated data stream frames.

5 The Listener can use this information to decide if the Latency is too large for acceptable presentation of the  
6 stream. The Accumulated Latency component is in units of nanoseconds.

#### 7 **35.2.2.8.7 FailureInformation**

8 At the point when a Talker Advertise Declaration is transformed into a Talker Failed Declaration, the system  
9 making the transformation adds information that indicates, to the Listeners registering the Talker Failed  
10 Declaration, the cause of the failure and the identity of the system at which the failure occurred. The  
11 subcomponents of the FailureInformation include:

- 12 a) The system identifier, which is the Bridge Identifier (13.26.2) of the Bridge or the 48-bit MAC  
13 Address of the end station's port extended to 64-bits by prepending 16 bits of zero, that changed the  
14 Declaration Type from Advertise to Failed.

15 NOTE 1—Bridge Identifiers are normally constructed from MAC Addresses that are unique in the bridged LAN but are  
16 not required to be constructed in that manner; therefore, there is a possibility of an end station MAC Address colliding  
17 with the Bridge ID.

- 18 b) The Failure Code, which is represented by a single octet containing the value shown in Table 46-16.

19 NOTE 2—Although the table of failure codes (Table 46-16) is located in a subclause associated with MSRPv1, the  
20 codes are compatible with MSRPv0.

#### 21 **35.2.2.9 MSRP FirstValue definitions (Domain discovery)**

22 The Domain attribute contains all the information that a Bridge Port needs in order to determine the location  
23 of the SRP domain boundary [item h) in 35.2.1.4]. The Domain attribute is also used to detect the  
24 ProtocolVersion of the neighboring MSRP Participant on each Bridge Port [item j) in 35.2.1.4].

25 The MSRP Participant shall declare (transmit) its Domain attribute after MAC\_Operational (IEEE Std  
26 802.1AC) transitions to TRUE and prior to declaring a Talker Advertise, Talker Failed, or Listener attribute.

27 FirstValue shall be incremented one or more times when NumberOfValues is greater than one. Incrementing  
28 FirstValue for the MSRP Domain attribute is defined as follows:

- 29 a) Add 1 to SRclassID (35.2.2.9.2), and  
30 b) Add 1 to SRclassPriority (35.2.2.9.3).

31 The choice of encoding and incrementing with this rule means that if one class (e.g., class B) is supported,  
32 with the default values, then the FirstValue will be {5,2,VID} (class B, priority 2, and a VID) and the  
33 NumberOfValues field will be set to 1. If class A and class B are supported, with the default values, the  
34 FirstValue will again be {5,2,VID}, but the NumberOfValues fields will be set to 2. Applying the above  
35 incrementing rule to {5,2,VID} generates the value {6,3,VID}, i.e., class A, priority 3, and a VID, which is  
36 needed for the default case.

37 NOTE—If the SR Class to Priority Mapping Table (12.20.4) is configured through management such that SR class ID  
38 values do not increment contiguously with priority values, the declared domains need to be encoded in multiple Domain  
39 Vector Attributes. For example, if the SR class ID and priority rows are {2,4}, {3,0}, {4,1}, {5,2}, and {6,3}, two  
40 Domain attributes are needed: one Domain with FirstValue {2,4,VID} and NumberOfValues one, and a second Domain  
41 with FirstValue {3,0,VID} and NumberOfValues four.

1 **35.2.2.9.1 Structure definition**

2 The FirstValue for the Domain attribute in MSRPDU exchanged according to the protocol specified in this  
3 subclause shall have the following structure:

- 4 a) The first octet contains the *SRclassID* (35.2.2.9.2).  
5 b) Following the *SRclassID* is an octet containing the *SRclassPriority* (35.2.2.9.3).  
6 c) Following the *SRclassPriority* are two octets containing the *SRclassVID* (35.2.2.9.4).

7 The following BNF production gives the formal description of the MSRPDU FirstValue structure for the  
8 Domain attribute:

9 FirstValue ::= SRclassID, SRclassPriority, SRclassVID

10 Figure 35-3 illustrates the structure of the MSRPDU FirstValue components for the Domain attribute.

**Figure 35-3—Format of the components of the Domain FirstValue**

11 **35.2.2.9.2 SRclassID**

12 SRclassID is a numeric representation of the SR classes that are supported by a particular Bridge Port. The  
13 mapping of SR class letter to SR class ID is shown in Table 35-6.

**Table 35-6—SR class ID**

| SR class | SR class ID |
|----------|-------------|
| A        | 6           |
| B        | 5           |
| C        | 4           |
| D        | 3           |
| E        | 2           |
| F        | 1           |
| G        | 0           |

14 NOTE—When SRP is supported, only one SR class is required. Only SR classes A and B can be enabled by default.  
15 Additional SR classes must be configured through use of management (12.20.4, 34.5).

### 1 35.2.2.9.3 SRclassPriority

2 This field holds the Data Frame Priority [item a) in 35.2.2.8.5] value that will be used for streams that  
3 belong to the associated SR class. Whenever an end station's MAC\_Operational (IEEE Std 802.1AC)  
4 transitions to TRUE, its SRclassPriority shall be set to the default SR class priority (Table 6-5) until an  
5 SRclassPriority declaration is received from a neighboring device, at which time it shall be set to the  
6 declared value. An end station cannot change its default mapping of SR class to priority (see 12.20.4).

7 NOTE—This allows two end stations that are connected back-to-back to share streams, while also providing an end  
8 station the flexibility to change to the SRclassPriority of a attached network (i.e., neighboring Bridge).

### 9 35.2.2.9.4 SRclassVID

10 This field contains the SR\_PVID [item i) in 35.2.1.4] that the associated streams will be tagged with by the  
11 Talker. Whenever an end station's MAC\_Operational (IEEE Std 802.1AC) transitions to TRUE, its  
12 SRclassVID shall be set to the default SR\_PVID (Table 9-2) until an SRclassVID declaration is received  
13 from a neighboring device, at which time it shall be set to the declared value.

14 NOTE—This allows two end stations that are connected back-to-back to share streams, while also providing an end  
15 station the flexibility to change to the SRclassVID of a attached network.

### 16 35.2.2.10 MSRP FirstValue definitions (Stream reservations, enhanced)

17 This subclause specifies two Attribute Types for enhanced stream reservations: Talker Enhanced and  
18 Listener Enhanced.

19 The specifications of the enhanced Attribute Types (35.2.2.10) are based on the specifications of the original  
20 Attribute Types (35.2.2.8), with differences stated explicitly.

21 As compared to the original Attribute Types, the enhanced Attribute Types use a Type-Length-Value (TLV)  
22 encoding for MSRP FirstValue. MSRP FirstValue contains a list of TLVs. Each TLV consists of a Type field  
23 that specifies what the Value field contains, a Length field that specifies the number of octets in the Value  
24 field, and the Value field. The Value contains one or more elements encoded in binary. The TLV encoding  
25 enables flexibility in the structure of MSRP FirstValue, such as support for optional features.

26 This subclause specifies the structure of MSRP FirstValue as well as the Type and Length for each TLV. This  
27 subclause also specifies the binary encoding of the elements within the Value of each TLV. The semantic  
28 specification of each element in the TLV's Value is provided as a reference to the corresponding group of  
29 elements in TSN User/network configuration information (46.2).

30 The transmission of octets in MSRP FirstValue is specified in 10.8.1.1. The encoding of the Value of each  
31 TLV is specified in a figure, and the representation in the figure is specified in 10.8.1.1. Elements marked as  
32 “reserved” shall be transmitted as zero and ignored on reception. When an element is not a multiple of 8 bits  
33 in length, the element is organized from most significant bit of the octet to least significant bit. Boolean  
34 elements are a single bit. When an element's Length in the figure is a decimal number only, Length specifies  
35 the number of octets for the element. When an element's Length in the figure is a decimal number followed  
36 by “bits,” Length specifies the number of bits for the element.

37 FirstValue shall be incremented one or more times when NumberOfValues is greater than one, as follows:

- 38 a) Add 1 to Unique ID of the StreamID TLV (46.2.3.1), and
- 39 b) Add 1 to each element of the DataFrameSpecification TLV (46.2.3.4) that identifies the Stream:
  - 40 1) If the IEEE802-MacAddresses TLV is used, add 1 to DestinationMacAddress.
  - 41 2) If the IPv4-tuple TLV is used, add 1 to DestinationIpAddress.
  - 42 3) If the IPv6-tuple TLV is used, add 1 to DestinationIpAddress.

1 This rule for incrementing FirstValue is the same as the original Attribute Types (35.2.2.8), with the addition  
2 of optional support for IP destination address as the unique identification of the Stream.

3 NOTE 1—For an example of incrementing FirstValue for DestinationMacAddress, refer to 35.2.2.8.

4 NOTE 2—As compared to the fixed attribute values of the original AttributeTypes, the use of TLVs in the enhanced  
5 AttributeTypes allows each attribute value to vary based on the use of sub-TLVs. This imposes an additional constraint  
6 when NumberOfValues is greater than one such that all FirstValues must use the same sub-TLVs.

7 NOTE 3—As specified in 35.2.3.1, when a Talker or Listener has a *neighborProtocolVersion* of 0x00 (i.e., Nearest  
8 Bridge is MSRPv0), declarations must use only the original Attribute Types (35.2.2.8). If the application of the Talker/  
9 Listener is using the enhanced features of this subclause (35.2.2.10), an internal translation is needed in order to  
10 determine if the original Attribute Type can be declared. This internal translation is similar to the translation specified for  
11 MAP in a Bridge (Table 35-11 and Table 35-16), but it is outside the scope of this standard. If the enhanced features do  
12 not translate successfully to an original Attribute Type, the Talker or Listener can choose to either a) declare the failure  
13 to the network using an original Attribute Type (e.g., Talker Failed Vector of Table 35-1) or b) return an error up to the  
14 application of the Talker/Listener.

15 Some of the enhanced features of this subclause require the assistance of a Centralized Network  
16 Configuration (CNC) entity. As described in the introduction to Clause 35, in order to use a CNC with SRP,  
17 the MRP External Control (12.32.4) feature is enabled in the Nearest Bridge (8.6.3) to each Talker and  
18 Listener. Therefore, when a Talker or Listener uses an enhanced feature, the success or failure of the Stream  
19 reservation depends on the externalControl (12.32.4.1) parameter on the Port connected to the Talker/  
20 Listener, as follows:

21 **a) externalControl TRUE**

22 SRP messages are exchanged with the CNC, and the CNC uses those SRP messages to learn the  
23 requirements for each Stream. The CNC uses remote management protocols (e.g., SNMP,  
24 NETCONF) in order to learn the capabilities of the Bridges between each Talker and its Listeners.  
25 The CNC is not required to support all Bridge features, but for the Bridge features that it supports, it  
26 compares the Bridge's capabilities to the configuration needed in order to meet each Stream's  
27 requirements. If the CNC successfully configures the Bridges for the Stream, the CNC shall use  
28 MRP External Control to declare a Talker Advertise attribute to each Listener and a Listener Ready  
29 attribute to the Talker. If the CNC fails to configure the Bridges for the Stream, the CNC shall use  
30 MRP External Control to declare a Talker Failed attribute to each Listener and a Listener Ready  
31 Failed or Listener Asking Failed attribute to the Talker.

32 **b) externalControl FALSE**

33 When MRP External Control is not used, SRP messages propagate through Bridges, and the Bridges  
34 configure themselves for the Stream reservation. Some enhanced features can be supported with this  
35 model, and other enhanced features cannot be supported. In the specifications of this subclause, the  
36 phrase “When the externalControl attribute is FALSE” is used to specify failure conditions when  
37 MRP External Control is not used for the Talker/Listener. If this phrase is not used, the feature is  
38 fully supported in the absence of MRP External Control (i.e., CNC).

### 1 35.2.2.10.1 Structure definition

- 2 The FirstValue of each attribute shall consist of a list of one or more TLVs. Each TLV shall contain a single  
3 octet TLV type, followed by a single octet TLV length, followed by multiple octets for the TLV value.  
4 The TLV type shall use a value specified in Table 35-7.

**Table 35-7—TLV types**

| TLV                       | TLV type | TLV length |
|---------------------------|----------|------------|
| Talker                    | 1        | variable   |
| StreamID                  | 2        | 8          |
| StreamRank                | 3        | 1          |
| EndStationInterfaces      | 4        | variable   |
| InterfaceID               | 5        | variable   |
| DataFrameSpecification    | 6        | 18         |
| IEEE802-MacAddresses      | 7        | 12         |
| IEEE802-VlanTag           | 8        | 2          |
| IPv4-tuple                | 9        | 15         |
| IPv6-tuple                | 10       | 39         |
| TrafficSpecification      | 11       | 9          |
| TSpecTimeAware            | 12       | 12         |
| UserToNetworkRequirements | 13       | 5          |
| InterfaceCapabilities     | 14       | variable   |
| Listener                  | 15       | variable   |
| Status                    | 16       | variable   |
| StatusInfo                | 17       | 3          |
| AccumulatedLatency        | 18       | 4          |
| InterfaceConfiguration    | 19       | variable   |
| TimeAwareOffset           | 20       | 4          |
| FailedInterfaces          | 21       | variable   |

- 5 The TLV length shall contain the number of octets in the TLV value that follows. The TLV value is specified  
6 in subsequent subclauses for each TLV.

1 The following Backus-Naur Form (BNF) production gives the formal description of the MSRPDU  
2 FirstValue structure for the Talker Enhanced attribute:

```
3     TalkerEnhanced_FirstValue ::= Talker, Status
4     Talker ::= Type, Length,
5         StreamID,
6         StreamRank,
7         [ EndStationInterfaces, ]
8         [ DataFrameSpecification, ]
9         TrafficSpecification,
10        [ TSpecTimeAware, ]
11        [ UserToNetworkRequirements, ]
12        [ InterfaceCapabilities, ]
13    Status ::= Type, Length,
14        StatusInfo,
15        AccumulatedLatency
16        [ InterfaceConfiguration ]
17        [ FailedInterfaces ]
18    StreamID ::= Type, Length, value specified in 35.2.2.10.2
19    StreamRank ::= Type, Length, value specified in 35.2.2.10.3
20    EndStationInterfaces ::= Type, Length, value specified in 35.2.2.10.4, 35.2.2.10.4
21    DataFrameSpecification ::= Type, Length, value specified in 35.2.2.10.5, 35.2.2.10.5
22    TrafficSpecification ::= Type, Length, value specified in 35.2.2.10.6
23    TSpecTimeAware ::= Type, Length, value specified in 35.2.2.10.6
24    UserToNetworkRequirements ::= Type, Length, value specified in 35.2.2.10.7
25    InterfaceCapabilities ::= Type, Length, value specified in 35.2.2.10.8, 35.2.2.10.8
26    StatusInfo ::= Type, Length, value specified in 35.2.2.10.9
27    AccumulatedLatency ::= Type, Length, value specified in 35.2.2.10.10
28    InterfaceConfiguration ::= Type, Length, value specified in 35.2.2.10.11
29    FailedInterfaces ::= Type, Length, value specified in 35.2.2.10.12
30    Type BYTE ::= corresponding TLV Type from Table 35-7
31    Length BYTE ::= corresponding TLV Length (number of octets in TLV Value)
```

32 The following Backus-Naur Form (BNF) production gives the formal description of the MSRPDU  
33 FirstValue structure for the Listener Enhanced attribute:

```
34     ListenerEnhanced_FirstValue ::= Listener, Status
35     Listener ::= Type, Length,
36         StreamID,
37         [ EndStationInterfaces, ]
38         [ UserToNetworkRequirements, ]
39         [ InterfaceCapabilities ]
40    StatusGroup ::= Type, Length,
41        StatusInfo,
42        [ InterfaceConfiguration ]
43        [ FailedInterfaces ]
44    StreamID ::= Type, Length, value specified in 35.2.2.10.2
45    EndStationInterfaces ::= Type, Length, value specified in 35.2.2.10.4, 35.2.2.10.4
46    UserToNetworkRequirements ::= Type, Length, value specified in 35.2.2.10.7
47    InterfaceCapabilities ::= Type, Length, value specified in 35.2.2.10.8, 35.2.2.10.8
48    StatusInfo ::= Type, Length, value specified in 35.2.2.10.9
49    InterfaceConfiguration ::= Type, Length, value specified in 35.2.2.10.11
50    FailedInterfaces ::= Type, Length, value specified in 35.2.2.10.12
51    Type BYTE ::= corresponding TLV Type from Table 35-7
52    Length BYTE ::= corresponding TLV Length (number of octets in TLV value)
```

### 35.2.2.10.2 StreamID

The StreamID group is specified in 46.2.3.1.

Figure 35-4 specifies the encoding of the value for the StreamID TLV.

|            | Octet | Length |
|------------|-------|--------|
| MacAddress | 1     | 6      |
| UniqueID   | 7     | 2      |

**Figure 35-4—Value of StreamID TLV**

The MacAddress is encoded in a manner consistent with the MAC address of a frame header.

The semantics of the MacAddress and UniqueID elements of the enhanced StreamID TLV are the same as the semantics of the Mac Address and Unique ID of the original StreamID structure (35.2.2.8.2).

Requirements for incrementing UniqueID are specified in 35.2.2.10.

### 35.2.2.10.3 StreamRank

The StreamRank group is specified in 46.2.3.2.

Figure 35-5 specifies the encoding of the value for the StreamRank TLV.

|          | Octet | Length |
|----------|-------|--------|
| reserved | 1     | 7 bits |
| Rank     | 1     | 1 bit  |

**Figure 35-5—Value of StreamRank TLV**

The semantics of the Rank element of the enhanced StreamRank TLV are the same as the semantics of the Rank of the original PriorityAndRank structure (35.2.2.8.5).

### 35.2.2.10.4 EndStationInterfaces

The EndStationInterfaces group is specified in 46.2.3.3.

The Value of the EndStationInterfaces TLV shall consist of one or more InterfaceID TLVs. An InterfaceID TLV is provided for each interface used by the Stream's Talker/Listener.

Figure 35-6 specifies the encoding of the value for the InterfaceID TLV.

Group length: 6 + NameLength

|               | Octet | Length     |
|---------------|-------|------------|
| MacAddress    | 1     | 6          |
| InterfaceName | 7     | NameLength |

**Figure 35-6—Value of InterfaceID TLV**

The MacAddress is encoded in a manner consistent with the MAC address of a frame header.

If the InterfaceName element is not used, its NameLength is zero, and InterfaceName does not exist in the InterfaceID's Value.

EndStationInterfaces does not exist in the original Attribute Types (MSRPv0). EndStationInterfaces enhances MSRP for optional support of CNC.

1 EndStationInterfaces specifies the identification of physical interfaces (distinct points of attachment) in the  
2 end station acting as a Talker/Listener. EndStationInterfaces is used by the CNC to locate the Talker/Listener  
3 in the topology. EndStationInterfaces can also be used by end stations with two or more interfaces.

4 When the externalControl attribute is TRUE (12.32.4.1), EndStationInterfaces should be included in the  
5 attribute declared by the Talker or Listener. If the CNC does not have the information needed to identify the  
6 Talker/Listener Ports in the topology, the CNC is likely to fail the Stream reservation (35.2.2.10).

7 When the externalControl attribute is FALSE (12.32.4.1), if EndStationInterfaces contains more than one  
8 interface, the Nearest Bridge shall fail the Stream reservation. The fully distributed model does not specify  
9 support for multiple interfaces. To fail the Stream reservation, the Nearest Bridge shall change Talker  
10 Advertise to Talker Failed and report Failure Code=25 (Table 46-16) and also change Listener Ready or  
11 Listener Ready Failed to Listener Asking Failed and report Failure Code=25.

12 Since the EndStationInterfaces is only used by MRP External Control (12.32.4) for communication with a  
13 CNC, the EndStationInterfaces TLV shall be removed from the MSRP FirstValue prior to propagation with  
14 MAP (35.2.4).

### 15 35.2.2.10.5 DataFrameSpecification

16 The DataFrameSpecification group is specified in 46.2.3.4.

17 The TLV for DataFrameSpecification shall consist of Type and Length, followed by a Value that consists of  
18 a list of one or more TLVs for each field in the user's frame. The list of TLVs within the  
19 DataFrameSpecification value shall be ordered from start of frame to end of header.

20 Figure 35-7 specifies the encoding of the value for the IEEE802-MacAddresses TLV. The MAC addresses  
21 are encoded in a manner consistent with the MAC address of a frame header.

|                       | Octet | Length |
|-----------------------|-------|--------|
| DestinationMacAddress | 1     | 6      |
| SourceMacAddress      | 7     | 6      |

**Figure 35-7—Value of IEEE802-MacAddresses TLV**

22 Figure 35-8 specifies the encoding of the value for the IEEE802-VlanTag TLV.

|                     | Octet | Length  |
|---------------------|-------|---------|
| Priority Code Point | 1     | 3 bits  |
| Reserved            | 1     | 1 bit   |
| VLAN ID             | 1     | 12 bits |

**Figure 35-8—Value of IEEE802-VlanTag TLV**

Figure 35-9 specifies the encoding of the value for the IPv4-tuple TLV. The IP addresses are encoded in a manner consistent with the IP address of a packet header.

|                      | Octet | Length |
|----------------------|-------|--------|
| SourceIpAddress      | 1     | 4      |
| DestinationIpAddress | 5     | 4      |
| Dscp                 | 9     | 1      |
| Protocol             | 10    | 2      |
| SourcePort           | 12    | 2      |
| DestinationPort      | 14    | 2      |

**Figure 35-9—Value of IPv4-tuple TLV**

Figure 35-10 specifies the encoding of the value for the IPv6-tuple TLV. The IP addresses are encoded in a manner consistent with the IP address of a packet header.

|                      | Octet | Length |
|----------------------|-------|--------|
| SourceIpAddress      | 1     | 16     |
| DestinationIpAddress | 17    | 16     |
| Dscp                 | 33    | 1      |
| Protocol             | 34    | 2      |
| SourcePort           | 36    | 2      |
| DestinationPort      | 38    | 2      |

**Figure 35-10—Value of IPv6-tuple TLV**

The semantics of the DestinationMacAddress of the enhanced DataFrameSpecification TLV (IEEE802-MacAddresses sub-TLV) are the same as the semantics of the destination\_address of the original DataFrameParameters structure (35.2.2.8.3). The semantics of the VlanId of the enhanced DataFrameSpecification TLV (IEEE802-VlanTag sub-TLV) are the same as the semantics of the vlan\_identifier of the original DataFrameParameters structure (35.2.2.8.3). The semantics of the PriorityCodePoint element of the enhanced DataFrameSpecification TLV are the same as the semantics of the Data Frame Priority of the original PriorityAndRank structure (35.2.2.8.5).

Requirements for incrementing destination addresses of DataFrameSpecification are specified in 35.2.2.10.

In order to apply TSN behavior to Streams (e.g., reserved bandwidth guarantees), MSRP must be able to distinguish one Stream from another Stream and to distinguish Streams from non-TSN traffic (e.g., best-effort). This requires unique identification of each Stream within the user (i.e., Talker and Listener) as well as the network (i.e., Bridges).

As compared to the original Attribute Types (MSRPv0), the enhancements of the DataFrameSpecification TLV support Stream transformation (46.1.4).

Stream transformation is an optional feature in MSRP Participants. Since Stream Transformation can be supported in either end station or Bridge, one of the following methodologies may be chosen:

**a) No Stream Transformation**

When Stream transformation (46.1.4) is not supported, the user's identification of the Stream must be the same as the network's identification (i.e., destination MAC address and VLAN ID). This is the methodology used for MSRPv0. This methodology requires the following in each end station (Talker/Listener):

- 1) The destination MAC address of the user's data frame shall be either multicast (group) or a locally administered unicast (individual). A multicast MAC address is allocated by the user (e.g., a higher layer protocol like IEEE Std 1722 [B18]). Only one Stream is allowed per destination MAC address. The destination MAC address shall be provided as the DestinationMacAddress element of the IEEE802-MacAddresses sub-TLV of the DataFrameSpecification TLV.

NOTE—When Stream transformation is not supported, MSRP prohibits a DestinationMacAddress element that is universal unicast (i.e., individual MAC address of the Listener). Since the Listener's universal unicast MAC address is used for non-TSN traffic, it does not uniquely identify the Stream. The VLAN ID alone does not distinguish the Stream's traffic because Bridges can be configured to egress non-TSN traffic using the same VLAN ID that the Stream is using.

- 2) The Talker uses its individual MAC address as the source MAC address of the data frame. The source MAC address shall be provided as the SourceMacAddress element of the IEEE802-MacAddresses sub-TLV of the DataFrameSpecification TLV.
- 3) The data frame shall use a VLAN tag containing a Priority Code Point (PCP) and a VLAN ID, both provided in the IEEE802-VlanTag sub-TLV of the DataFrameSpecification TLV. The Talker uses the value SRclassPriority of the Domain attribute (35.2.2.9.3) for the PriorityCodePoint. If the Talker has knowledge of a specific VLAN ID to use, any valid VlanId can be specified (1 to 4094). If the Talker does not have knowledge of a specific VLAN ID to use, the VlanId uses the value from the SRclassVID of the Domain attribute (35.2.2.9.4).

#### b) Stream Transformation in end station

When Stream transformation (46.1.4) is performed in the end station (Talker/Listener), the end station relies on the network to provide the network's identification of the Stream (i.e., destination MAC address and VLAN ID). The network identification is provided by the CNC through the use of MRP External Control (12.32.4) in the Nearest Bridge (8.6.3). This methodology requires the following in each end station (Talker/Listener):

- 1) The Talker's DataFrameSpecification TLV shall not be included in the Talker attribute. This indicates to the CNC that Stream transformation is performed in the end station. Since the user's data frame identification is not used in the network, the DataFrameSpecification is not relevant to Bridges.
- 2) The end station's InterfaceCapabilities TLV (46.2.3.7) shall set VlanTagCapable=true and CB-StreamIdenTypeList containing the Active Destination MAC and VLAN Stream identification type (46.2.3). If the user's data frame uses either IPv4-tuple or IPv6-tuple, the CB-StreamIdenTypeList shall contain the IP Stream identification type. These InterfaceCapabilities specify that the end station supports the IEEE 802.1CB stream identification functions that transform between the user's identification and the corresponding network identification.
- 3) When the externalControl attribute is FALSE (12.32.4.1), if the Talker's DataFrameSpecification TLV is missing from Talker Advertise, the Nearest Bridge shall fail the Stream reservation. The fully distributed model does not specify support for stream transformation in end station. To fail the Stream reservation, the Nearest Bridge shall change Talker Advertise to Talker Failed and report Failure Code=22 (Table 46-16).
- 4) The CNC shall allocate a multicast MAC address for the network identification and use MRP External Control to declare an MSRP attribute containing a InterfaceConfiguration sub-TLV (35.2.2.10.11) with configuration values for IEEE802-MacAddresses and IEEE802-VlanTag. These configuration values provide the network identification for the end station's transformation. For an end station acting as Talker, the Nearest Bridge includes InterfaceConfiguration in the declared Listener Ready or Listener Ready Failed. For an end station acting as Listener, the Nearest Bridge includes InterfaceConfiguration in the declared Talker Advertise.
- 5) When the Stream is withdrawn (i.e., MRP Leave of Talker Advertise), the CNC can free the multicast MAC address for use by subsequent Streams.

#### c) Stream Transformation in Bridge

When Stream transformation (46.1.4) is performed in the Bridge, the end station relies on the CNC to configure the Bridge to perform all transformation. The user identification (i.e., DataFrameSpecification) is provided to the CNC through the use of MRP External Control (12.32.4) in the Nearest Bridge (8.6.3). The CNC uses management to configure IEEE 802.1CB features in the Nearest Bridge to transform the Stream between user and network identification. This methodology requires the following:

- 1) The Talker's DataFrameSpecification TLV provides unique user identification of the Stream, but that user identification does not meet the requirements for no stream transformation [item a) in 35.2.2.10.5]. If the destination address alone does not distinguish the Stream from other Streams and non-TSN traffic, other elements of the DataFrameSpecification shall be unique. For example, if the data frame is untagged with unicast DestinationMacAddress and unicast DestinationIpAddress, a unique DestinationPort can distinguish the Stream.
- 2) When the externalControl attribute is FALSE (12.32.4.1), since the Talker's DataFrameSpecification TLV does not meet the requirements for no stream transformation [item a) in 35.2.2.10.5], the Nearest Bridge shall fail the Stream reservation. The fully distributed model does not specify support for stream transformation in Bridge. To fail the Stream reservation, the Nearest Bridge shall change Talker Advertise to Talker Failed and report Failure Code=22 (Table 46-16).
- 3) If the CNC determines that the Nearest Bridge does not support IEEE Std 802.1CB, it shall use MRP External Control to declare an MSRP attribute containing a StatusInfo sub-TLV (35.2.2.10.9) with Failure Code=23 (Table 46-16). For an end station acting as Talker, the Nearest Bridge declares Listener Asking Failed. For an end station acting as Listener, the Nearest Bridge declares Talker Failed.
- 4) If the CNC determines that the Nearest Bridge does not support the IEEE 802.1CB stream identification types for the DataFrameSpecification, it shall use MRP External Control to declare an MSRP attribute containing a StatusInfo sub-TLV (35.2.2.10.9) with Failure Code=24 (Table 46-16). For an end station acting as Talker, the Nearest Bridge declares Listener Asking Failed. For an end station acting as Listener, the Nearest Bridge declares Talker Failed.
- 5) If the CNC successfully configures the IEEE 802.1CB stream identification types for the DataFrameSpecification, it shall use MRP External Control to declare a successful MSRP attribute (assuming no other failures). For an end station acting as Talker, the Nearest Bridge declares Listener Ready or Listener Ready Failed. For an end station acting as Listener, the Nearest Bridge declares Talker Advertise.
- 6) When the Stream is withdrawn (i.e., MRP Leave of Talker Advertise), the CNC can free the multicast MAC address for use by subsequent Streams. The CNC can also remove IEEE 802.1CB configurations for the withdrawn Stream.

### 35.2.2.10.6 TrafficSpecification and TSpecTimeAware

The TrafficSpecification group and optional TSpecTimeAware group are specified in 46.2.3.5.

The TrafficSpecification shall consist of a required TrafficSpecification TLV, followed by an optional TSpecTimeAware TLV.

1 Figure 35-11 specifies the encoding of the value for the TrafficSpecification TLV.

|                       | Octet | Length |
|-----------------------|-------|--------|
| Interval              | 1     | 4      |
| MaxFramesPerInterval  | 5     | 2      |
| MaxFrameSize          | 7     | 2      |
| TransmissionSelection | 9     | 1      |

**Figure 35-11—Value of TrafficSpecification TLV**

2 Figure 35-12 specifies the encoding of the value for the TSpecTimeAware TLV. The presence of the optional  
3 TSpecTimeAware TLV is handled as specified in 46.2.3.5 for the presence of the TSpecTimeAware group.

|                        | Octet | Length |
|------------------------|-------|--------|
| EarliestTransmitOffset | 1     | 4      |
| LatestTransmitOffset   | 5     | 4      |
| Jitter                 | 9     | 4      |

**Figure 35-12—Value of TSpecTimeAware TLV**

4 The semantics of the MaxFramesPerInterval element of the enhanced TrafficSpecification TLV are the same  
5 as the semantics of the MaxIntervalFrames of the original TSpec structure (35.2.2.8.4). The semantics of the  
6 MaxFrameSize element of the enhanced TrafficSpecification TLV are the same as the semantics of the  
7 MaxFrameSize of the original TSpec structure (35.2.2.8.4).

8 A Talker that assumes usage of the fully distributed model should use TrafficSpecification as follows:

- 9 a) Set the Interval element of the TrafficSpecification TLV to the classMeasurementInterval (34.3) of  
10 the stream's SR class (35.2.2.9.2).
- 11 b) Set the TransmissionSelection element to the value 1 for use of the credit-based shaper (8.6.8.2).
- 12 c) Do not use the TSpecTimeAware TLV.

13 When the externalControl attribute is FALSE (12.32.4.1), if the Talker's TrafficSpecification TLV does not  
14 meet the preceding recommendations a) through c), a Bridge may fail the Stream reservation. Bridges using  
15 the fully distributed model are not required to support Talker-specific intervals or shaping beyond those of  
16 MSRPv0. To fail the Stream reservation, the Bridge shall change Talker Advertise to Talker Failed and  
17 report Failure Code=25 (Table 46-16).

18 NOTE—In IEEE Std 802.1BA [B11], the AccumulatedLatency computation assumes consistent use of the credit-based  
19 shaper at the classMeasurementInterval for the Talker and all Bridges using the SR class. This assumption aligns with  
20 the preceding recommendations. The Talker's TrafficSpecification specifies the interval, shaping, and/or scheduling of  
21 the Talker only, and TrafficSpecification does not change as it propagates through Bridges. Therefore, when MRP  
22 External Control is not in use, in order to support TrafficSpecifications beyond those of IEEE Std 802.1BA, each Bridge  
23 must be able to 1) distinguish whether the Port registering Talker Advertise is connected directly to the Talker (i.e., end  
24 station) or another Bridge, to determine where TrafficSpecification impacts the AccumulatedLatency, and 2) understand  
25 the shaping and scheduling used in each Bridge in the path from Talker to the current Bridge since that also impacts  
26 AccumulatedLatency. Specifications for these tasks are not provided in this standard.

### 1 35.2.2.10.7 UserToNetworkRequirements

2 The UserToNetworkRequirements group is specified in 46.2.3.6.

3 Figure 35-13 specifies the encoding of the value for the UserToNetworkRequirements TLV.

|                  | Octet | Length |
|------------------|-------|--------|
| NumSeamlessTrees | 1     | 1      |
| MaxLatency       | 2     | 4      |

**Figure 35-13—Value of UserToNetworkRequirements TLV**

4 UserToNetworkRequirements does not exist in the original Attribute Types (MSRPv0).  
5 UserToNetworkRequirements provides an optional mechanism for the Stream's Talker and/or Listeners to  
6 specify requirements to the network.

7 As specified in the MSRP structure definition (35.2.2.10.1), the UserToNetworkRequirements TLV may be  
8 used for either Talker or Listener attributes.

9 If UserToNetworkRequirements.MaxLatency is greater than zero, when an MSRP Participant detects that  
10 the AccumulatedLatency (35.2.2.10.10) of the Stream is greater than  
11 UserToNetworkRequirements.MaxLatency, the Stream's status is reported as failed (35.2.4.6).

12 If UserToNetworkRequirements.MaxLatency is zero (or UserToNetworkRequirements is not provided),  
13 when an MSRP Participant detects that the AccumulatedLatency of the Stream is greater than the initial  
14 AccumulatedLatency when the Stream was successfully configured, the Stream's status is reported as failed.  
15 This technique is compatible with MSRPv0 (35.2.2.8.6).

16 As specified in 46.2.3.6 and 35.2.4.6, UserToNetworkRequirements.MaxLatency specified by a Talker  
17 applies to all Listeners of the stream. UserToNetworkRequirements.MaxLatency specified by a Listener  
18 applies to that Listener alone.

19 Additional specifications for UserToNetworkRequirements.MaxLatency are provided in 35.2.6.

20 A Talker that assumes usage of the fully distributed model should use UserToNetworkRequirements as  
21 follows:

22 a) Set the NumSeamlessTrees element to one.

23 When the externalControl attribute is FALSE (12.32.4.1), if the Talker's UserToNetworkRequirements TLV  
24 does not meet the preceding recommendation a), a Bridge may fail the Stream reservation. Bridges using the  
25 fully distributed model are not required to support configuration of seamless redundancy. To fail the  
26 Stream reservation, the Bridge shall change Talker Advertise to Talker Failed and report Failure Code=25  
27 (Table 46-16).

28 NOTE—NumSeamlessTrees greater than one is intended for use with MRP External Control (i.e., externalControl  
29 TRUE), which passes SRP attributes to a CNC, and the CNC configures Bridges for seamless redundancy (e.g.,  
30 IEEE Std 802.1CB or IEC 62439-3:2016 [B6]). When MRP External Control is not in use, in order to support  
31 NumSeamlessTrees greater than one, each Bridge must be able to either 1) determine that seamless redundancy has  
32 already been configured for all Bridges between the Talker and its Listeners or 2) solicit such configuration from an  
33 external entity. Specifications for these tasks are not provided in this standard.

### 35.2.2.10.8 InterfaceCapabilities

The InterfaceCapabilities group is specified in 46.2.3.7.

Figure 35-14 specifies the encoding of the value for the InterfaceCapabilities TLV. NumITL represents the number of elements in the CB-StreamIdenTypeList. NumSTL represents the number of elements in the CB-SequenceTypeList.

|                                                                       |       |                          |
|-----------------------------------------------------------------------|-------|--------------------------|
| TLV Length: $3 + (4 \times \text{NumITL}) + (4 \times \text{NumSTL})$ | Octet | Length                   |
| reserved                                                              | 1     | 7 bits                   |
| VlanTagCapable                                                        | 1     | 1 bit                    |
| NumITL                                                                | 2     | 1                        |
| NumSTL                                                                | 3     | 1                        |
| CB-StreamIdenTypeList                                                 | 4     | $4 \times \text{NumITL}$ |
| CB-SequenceTypeList                                                   | 4     | $4 \times \text{NumITL}$ |

**Figure 35-14—Value of InterfaceCapabilities TLV**

InterfaceCapabilities does not exist in the original Attribute Types (MSRPv0). InterfaceCapabilities provides an optional mechanism for stream transformation as specified in 35.2.2.10.5.

The InterfaceCapabilities TLV is used only for negotiation between an end station and the neighboring MRP Participant on the link. The InterfaceCapabilities TLV shall be removed from the MSRP FirstValue prior to propagation with MAP (35.2.4).

### 35.2.2.10.9 StatusInfo

The StatusInfo group is specified in 46.2.5.1.

Figure 35-15 specifies the encoding of the value for the StatusInfo TLV.

|                |       |        |
|----------------|-------|--------|
|                | Octet | Length |
| TalkerStatus   | 1     | 1      |
| ListenerStatus | 2     | 1      |
| FailureCode    | 3     | 1      |

**Figure 35-15—Value of StatusInfo TLV**

The semantics of the FailureCode element of the enhanced StatusInfo TLV are the same as the semantics of the Failure Code of the original FailureInformation structure (35.2.2.8.7), and both use the same Table 46-16 for values.

The original Attribute Types (MSRPv0) did not provide a FailureCode from a Listener. The enhanced StatusInfo provides a mechanism for a Listener to provide a FailureCode as status to the Talker.

The StatusInfo in the Talker attribute is used to communicate status information to Listeners. The StatusInfo in the Listener attribute is used to communicate status information to the Talker. In SRP, status flows in one direction. Unless stated otherwise in these specifications, elements of StatusInfo are not copied from a Talker attribute to a Listener attribute, or vice versa.

A StatusInfo TLV for Declaration Type (35.2.1.3) of Talker Advertise shall use a TalkerStatus of Ready.

A StatusInfo TLV for Declaration Type of Talker Failed shall use a TalkerStatus of Failed.

A StatusInfo TLV for Declaration Type of Listener Asking Failed shall use a ListenerStatus of Failed.

A StatusInfo TLV for Declaration Type of Listener Ready shall use a ListenerStatus of Ready.

A StatusInfo TLV for Declaration Type of Listener Ready Failed shall use a ListenerStatus of PartialFailed.

For Talker and Listener attributes, the value for the FailureCode element is specified in Table 46-16.

Refer to 35.2.4.4.6 for information on merging nonzero FailureCode values from multiple Listeners.

NOTE—MSRPv1 adds new values for FailureCode (Table 46-16) that did not exist in MSRPv0 (i.e., 20 and higher).

MSRPv0 participants that register Talker Failed with these values are expected to handle the failure without complete understanding of the cause.

### 35.2.2.10.10 AccumulatedLatency

The AccumulatedLatency group is specified in 46.2.5.2.

Figure 35-16 specifies the encoding of the value for the AccumulatedLatency TLV.

|                    | Octet | Length |
|--------------------|-------|--------|
| AccumulatedLatency | 1     | 4      |

**Figure 35-16—Value of AccumulatedLatency TLV**

The semantics of the enhanced AccumulatedLatency TLV are the same as the semantics of the original Accumulated Latency structure (35.2.2.8.6).

The original Attribute Types (MSRPv0) failed the Stream when Accumulated Latency increased beyond its initial value. In addition to supporting that mechanism by default, the enhanced AccumulatedLatency (MSRPv1) provides an optional mechanism to fail the Stream when AccumulatedLatency exceeds specified UserToNetworkRequirements for MaxLatency (35.2.2.10.7).

### 35.2.2.10.11 InterfaceConfiguration

The InterfaceConfiguration group is specified in 46.2.5.3.

The encoding of the value for the InterfaceConfiguration TLV consists of one or more interface configurations. Each interface configuration consists of a single InterfaceID TLV (35.2.2.10.4), followed by a list of configuration values for that interface.

The values in each InterfaceID shall match one of the InterfaceID entries in the Talker/Listener EndStationInterfaces group.

The list of configuration values uses zero or more of the following TLVs:

- IEEE802-MacAddresses TLV (35.2.2.10.5)
- IEEE802-VlanTag TLV (35.2.2.10.5)
- IPv4-tuple TLV (35.2.2.10.5)
- IPv6-tuple TLV (35.2.2.10.5)
- TimeAwareOffset TLV with a value as specified in Figure 35-17

|                 |                 |       |        |
|-----------------|-----------------|-------|--------|
| Group length: 4 |                 | Octet | Length |
|                 | TimeAwareOffset | 1     | 4      |

**Figure 35-17—Value of TimeAwareOffset TLV**

InterfaceConfiguration does not exist in the original Attribute Types (MSRPv0). InterfaceConfiguration provides an optional mechanism for stream transformation as specified in 35.2.2.10.5.

The InterfaceConfiguration TLV is used only for negotiation between an end station and the neighboring MRP Participant on the link. The InterfaceConfiguration TLV shall be removed from the MSRP FirstValue prior to propagation with MAP (35.2.4).

### 35.2.2.10.12 FailedInterfaces

The FailedInterfaces group is specified in 46.2.5.4.

The FailedInterfaces TLV may be contained within the Talker or Listener attribute. When a failure occurs in network configuration (i.e., nonzero FailureCode in StatusInfo TLV), FailedInterfaces provides a list of one or more physical interfaces (distinct points of attachment) in the failed Bridge or end station. Each entry in the list is sufficient to locate the interface in the physical topology.

The Value of the FailedInterfaces TLV consists of a sequence of zero or more TLV entries, and each TLV entry uses the InterfaceID TLV specified in 35.2.2.10.4.

The semantics of the enhanced FailedInterfaces TLV is similar to the system identifier of the original FailureInformation structure (35.2.2.8.7), but with enhanced ability to identify more than one failed interface.

The FailedInterfaces TLV is associated with the single FailureCode in the StatusInfo TLV, and it is not used to communicate multiple failures.

Elements of FailedInterfaces are not copied from a Talker attribute to a Listener attribute, or vice versa.

## 35.2.3 Provision and support of Stream registration service

### 35.2.3.1 Initiating MSRP registration and deregistration

MSRP utilizes the following five declaration types (35.2.1.3) to communicate: Talker Advertise, Talker Failed, Listener Ready, Listener Ready Failed, and Listener Asking Failed.

When a Port's *neighborProtocolVersion* is 0x00, declarations shall use only the original Attribute Types (35.2.2.8). When a Port's *neighborProtocolVersion* is 0x01 or higher, declarations shall use either the original Attributes Types or the enhanced Attributes Types (35.2.2.10).

An end station behaving as a Talker will send a Talker Advertise declaration to inform the network about the characteristics of the Stream it can provide. Bridges register this declaration, update some of the information contained within the Talker declaration, and forward it out the nonblocked (35.1.3.1) Ports on the Bridge. If *talkerPruning* is enabled and the Bridge has the Stream's destination\_address registered on one or more Ports (e.g., using MMRP) it shall only forward the declarations out those Ports. Eventually the Talker declaration will be registered by other end stations.

1 If *talkerPruning* is enabled and the Stream's *destination\_address* is not registered on any Ports the Talker  
2 declaration shall not be forwarded (35.2.4.3.2). When the *talkerPruning* parameter is disabled (false) for the  
3 Bridge, each Port provides a *talkerPruningPerPort* parameter to control MAC address pruning for that Port  
4 (35.2.4.3.3).

5 If *talkerVlanPruning* is enabled (35.2.4.3.4), the Bridge will limit the Talker declarations to Ports that have  
6 the Stream's VLAN identifier [item b) in 35.2.2.8.3] registered as a member in the VLAN Registration  
7 Entries (8.8).

8 An end station behaving as a Listener will receive the Talker Advertise declaration and register it. If the  
9 Listener is interested in receiving that Stream it will send a Listener Ready declaration back toward the  
10 Talker. The Bridge's MSRP MAP function will use the StreamID (35.2.2.8.2, 35.2.2.10.2) to associate the  
11 Listener Ready with the Talker Advertise and forward the Listener Ready declaration only on the Port that  
12 registered the Talker Advertise. This is referred to as Listener Pruning since the declarations are not  
13 forwarded out any other Ports. The Bridge will also reserve the required bandwidth and configure its queues  
14 and the FDB.

15 If any Bridge along the path from Talker to Listener does not have sufficient bandwidth or resources  
16 available its MSRP MAP function will change the Talker Advertise declaration to a Talker Failed  
17 declaration before forwarding it. Similarly a Listener Ready declaration will be changed to a Listener  
18 Asking Failed declaration if there is not sufficient bandwidth or resources available. This way both the  
19 Talker and Listener will know whether the reservation was successful.

20 In the case where there is a Talker attribute and Listener attribute(s) registered within a Bridge for a  
21 StreamID and a MAD\_Leave.request is received for the Talker attribute, the Bridge shall act as a proxy for  
22 the Listener(s) and automatically generate a MAD\_Leave.request back toward the Talker for those Listener  
23 attributes. This is a special case of the behavior described in 35.2.4.4.1.

24 Finally, there is the Listener Ready Failed declaration. This is used when there are two or more Listeners for  
25 a Stream. To simplify the explanation assume there are only two Listeners and one has sufficient bandwidth  
26 back to the Talker (signified by a Listener Ready), and the other does not (signified by a Listener Asking  
27 Failed). At some point in the network topology there will be a single Bridge that will receive the Listener  
28 Ready on one port from the first Listener and the Listener Asking Failed on another port from the second  
29 Listener. That Bridge's MSRP MAP function will merge (35.2.4.4.3) those two declarations into a single  
30 Listener Ready Failed declaration that will be forwarded to the Talker. When the Talker receives the Listener  
31 Ready Failed it will know there are one or more Listeners that want the Stream and can receive it, and there  
32 are one or more Listeners that want the Stream but have insufficient bandwidth or resources somewhere  
33 along the path to receive it. The Talker may still send the Stream, but it will realize that not all Listeners are  
34 going to receive it.

35 MSRP provides a set of Service Primitives that control the declarations of the attributes defined previously.  
36 The primitives associated with the Talker application entities are summarized in Table 35-8. Listener  
37 application entities have a corresponding set of primitives summarized in Table 35-9.

**Table 35-8—Summary of Talker primitives**

| Name              | Request    | Indication |
|-------------------|------------|------------|
| REGISTER_STREAM   | 35.2.3.1.1 | —          |
| DEREGISTER_STREAM | 35.2.3.1.3 | —          |
| REGISTER_ATTACH   | —          | 35.2.3.1.6 |
| DEREGISTER_ATTACH | —          | 35.2.3.1.8 |

**Table 35-9—Summary of Listener primitives**

| Name              | Request    | Indication |
|-------------------|------------|------------|
| REGISTER_STREAM   | —          | 35.2.3.1.2 |
| DEREGISTER_STREAM | —          | 35.2.3.1.4 |
| REGISTER_ATTACH   | 35.2.3.1.5 | —          |
| DEREGISTER_ATTACH | 35.2.3.1.7 | —          |

**1 35.2.3.1.1 REGISTER\_STREAM.request**

2 A Talker application entity shall issue a REGISTER\_STREAM.request to the MSRP Participant to initiate  
3 the advertisement of an available Stream.

4 A Talker may choose to enter a nonzero value in the Accumulated Latency that indicates the amount of  
5 latency in nanoseconds that a Stream will encounter before being passed to the MAC Service interface.

6 On receipt of a REGISTER\_STREAM.request the MSRP Participant shall issue a MAD\_Join.request  
7 service primitive (10.2, 10.3). The attribute\_type (10.2) parameter of the request shall carry the appropriate  
8 Talker Attribute Type (35.2.2.4), depending on the Declaration Type and *neighborProtocolVersion*. The  
9 attribute\_value (10.2) parameter shall carry the values from the REGISTER\_STREAM.request primitive.

10 REGISTER\_STREAM.request (

11 StreamID,

12 Declaration Type,

13 DataFrameParameters,

14 TSpec,

15 Data Frame Priority,

16 Rank,

17 Accumulated Latency,

18 FailureInformation

19 )

### 1 **35.2.3.1.2 REGISTER\_STREAM.indication**

2 A REGISTER\_STREAM.indication notifies the Listener application entity that the referenced Stream is  
3 being advertised by a Talker somewhere on the attached network.

4 On receipt of a MAD\_Join.indication service primitive (10.2, 10.3) with an attribute\_type of Talker  
5 Advertise, Talker Failed, or Talker Enhanced (35.2.2.4), the MSRP application shall issue a  
6 REGISTER\_STREAM.indication to the Listener application entity. The REGISTER\_STREAM.indication  
7 shall carry the values from the attribute\_value parameter.

```
8     REGISTER_STREAM.indication (
9         StreamID,
10        Declaration Type,
11        DataFrameParameters,
12        TSpec,
13        Data Frame Priority,
14        Rank,
15        Accumulated Latency,
16        FailureInformation
17    )
```

### 18 **35.2.3.1.3 DEREGISTER\_STREAM.request**

19 A Talker application entity shall issue a DEREGISTER\_STREAM.request to the MSRP Participant to  
20 remove the Talker's advertisement declaration, and thus remove the advertisement of a Stream, from the  
21 network.

22 On receipt of a DEREGISTER\_STREAM.request the MSRP Participant shall issue a MAD\_Leave.request  
23 service primitive (10.2, 10.3) with the attribute\_type set to the Declaration Type currently associated with  
24 the StreamID. The attribute\_value parameter shall carry the StreamID and other values that were in the  
25 associated REGISTER\_STREAM.request primitive.

```
26     DEREGISTER_STREAM.request (
27         StreamID
28     )
```

### 29 **35.2.3.1.4 DEREGISTER\_STREAM.indication**

30 A DEREGISTER\_STREAM.indication notifies the Listener application entity that the referenced Stream is  
31 no longer being advertised by a Talker.

32 On receipt of a MAD\_Leave.indication service primitive (10.2, 10.3) with an attribute\_type of Talker  
33 Advertise, Talker Failed, or Talker Enhanced (35.2.2.4), the MSRP application shall issue a  
34 DEREGISTER\_STREAM.indication to the Listener application entity.

```
35     DEREGISTER_STREAM.indication (
36         StreamID
37     )
```

### 38 **35.2.3.1.5 REGISTER\_ATTACH.request**

39 A Listener application entity shall issue a REGISTER\_ATTACH.request to the MSRP Participant to request  
40 attachment to the referenced Stream.

1 On receipt of a REGISTER\_ATTACH.request the MSRP Participant shall issue a MAD\_Join.request  
2 service primitive (10.2, 10.3). The attribute\_type parameter of the request shall carry the appropriate  
3 Listener Attribute Type (35.2.2.4), depending on *neighborProtocolVersion*. The attribute\_value shall contain  
4 the StreamID and the Declaration Type.

```
5     REGISTER_ATTACH.request    (  
6                               StreamID,  
7                               Declaration Type  
8                               )
```

#### 9 **35.2.3.1.6 REGISTER\_ATTACH.indication**

10 A REGISTER\_ATTACH.indication notifies the Talker application entity that the referenced Stream is being  
11 requested by one or more Listeners.

12 On receipt of a MAD\_Join.indication service primitive (10.2, 10.3) with an attribute\_type of Listener  
13 (35.2.2.4), the MSRP application shall issue a REGISTER\_ATTACH.indication to the Talker application  
14 entity. The REGISTER\_ATTACH.indication shall carry the values from the attribute\_value parameter.

```
15     REGISTER_ATTACH.indication (  
16                               StreamID,  
17                               Declaration Type  
18                               )
```

#### 19 **35.2.3.1.7 DEREGISTER\_ATTACH.request**

20 A Listener application entity shall issue a DEREGISTER\_ATTACH.request to the MSRP Participant to  
21 remove the request to attach to the referenced Stream.

22 On receipt of a DEREGISTER\_ATTACH.request the MSRP Participant shall issue a MAD\_Leave.request  
23 service primitive (10.2, 10.3) with the attribute\_type set to the appropriate Listener Attribute Type  
24 (35.2.2.4). The attribute\_value parameter shall carry the StreamID and the Declaration Type currently  
25 associated with the StreamID.

```
26     DEREGISTER_ATTACH.request (  
27                               StreamID  
28                               )
```

#### 29 **35.2.3.1.8 DEREGISTER\_ATTACH.indication**

30 A DEREGISTER\_ATTACH.indication notifies the Talker application entity that the referenced Stream is no  
31 longer being requested by any Listeners.

32 On receipt of a MAD\_Leave.indication service primitive (10.2, 10.3) with an attribute\_type of Listener  
33 (35.2.2.4), the MSRP application shall issue a DEREGISTER\_ATTACH.indication to the Talker application  
34 entity. The DEREGISTER\_ATTACH.indication shall contain the StreamID.

```
35     DEREGISTER_ATTACH.indication (  
36                               StreamID  
37                               )
```

## 1 35.2.4 MSRP Attribute Propagation

2 There is no MSRP MAP function for Domain attributes. MSRP simply declares the characteristics of the SR  
3 classes that are supported on the Bridge Port regardless of what has been learned from Domain registrations  
4 on other Bridge Ports. Registration of the neighbor's Domain attribute determines the value of the  
5 *SRPDomainBoundaryPort* and *neighborProtocolVersion* variables (35.2.1.4).

6 This clause describes the following:

- 7 a) Rules for combining and propagating Listener attributes toward the associated Talker
- 8 b) How MSRP adjusts the Talker and Listener attributes before propagating them
- 9 c) How MSRP translates Attribute Types when propagating from a ProtocolVersion (35.2.2.1) on a  
10 registering Port to a different ProtocolVersion on declaring Ports.

11 Unless stated otherwise, Talker and Listener attributes are propagated as described in 10.3.

12 In principle, the MAP performs MSRP Attribute Propagation when any of the following conditions occur:

- 13 d) A *MAD\_Join.indication* adds a new attribute to MAD (with the *new* parameter, 10.2, set to TRUE).
- 14 e) A *MAD\_Leave.indication* is issued by the MAD.
- 15 f) An internal application declaration or withdrawal is made in a station.
- 16 g) When the bandwidth of the underlying media changes (see *bandwidthAvailabilityChanged*  
17 notification in 34.3.3).
- 18 h) A Port becomes an SRP domain core port (3.270).
- 19 i) If *talkerPruning* (35.2.4.3.2) or *talkerPruningPerPort* (35.2.4.3.3) is enabled and there is a change in  
20 the MAC Address Registration Entries (8.8.4) of a Port.
- 21 j) If *talkerVlanPruning* (35.2.4.3.4) is enabled and there is a change in the VLAN Registration Entries  
22 on a Port (8.8).
- 23 k) A Port changes its *neighborProtocolVersion* parameter (35.2.1.4(j)).

24 The MSRP MAP function is responsible for adjusting and propagating Talker and Listener attributes  
25 throughout the bridged network. It also updates the Dynamic Reservation Entries (8.8.7) to specify which  
26 Streams shall be filtered and which shall be forwarded, along with updating the associated *streamAge*  
27 [item c) in 35.2.1.4]. The bandwidth associated with those Streams is reported to the queuing algorithms via  
28 the *operIdleSlope(N)* parameter [item d) in 34.3] on a per-port per-traffic class basis.

29 Streams of higher importance are given available bandwidth before streams of lower importance.

30 If insufficient bandwidth or resources are available the streams *destination\_address* will be filtered and the  
31 failure will be noted in the Talker and Listener attributes declared from that Bridge.

32 A port shall only forward MSRP declarations for SR classes it supports. This will eliminate unnecessary  
33 priority remapping for traffic related to unsupported SR classes.

34 The following subclauses describe what the MSRP MAP function shall accomplish.

### 35 35.2.4.1 Stream importance

36 MSRP utilizes the stream Rank [item b) in 35.2.2.8.5, 35.2.2.10.3] to decide which stream is more important  
37 than another.

1 In the case where two streams have the same Rank, the *streamAge* will be compared. If the Ranks are  
2 identical and the *streamAges* are identical the StreamIDs (35.2.2.8.2, 35.2.2.10.2) will be compared and the  
3 numerically lower StreamID is considered to be more important.

#### 4 **35.2.4.2 Stream bandwidth calculations**

5 As referenced in Table 35-5, the bandwidth requirements of a Stream include more than just the amount  
6 specified in the REGISTER\_STREAM.request (35.2.3.1.1). SRP shall add the *perFrameOverhead* (34.4)  
7 associated with the media attached to the port.

8 If this port is on a Shared Media (35.1.1) the bandwidth requirements may need to be further increased. For  
9 example, a Stream transmitted from one station to another may have to be sent across the media twice. One  
10 time from the Talker station to the DMN, and a second time from the DMN to the Listener station. In this  
11 case the bandwidth requirements would need to be doubled.

12 The *totalFrameSize* for a stream on an outbound Port is therefore the sum of the following three amounts  
13 (doubled if each frame is transmitted on the media twice):

- 14 a) *MaxFrameSize* [item a) in 35.2.2.8.4].
- 15 b) *perFrameOverhead* (34.4) associated with the media attached to the port.
- 16 c) One (1) additional octet to account for slight differences (up to 200 ppm) in the class measurement  
17 interval between neighboring devices.

18 Multiply *totalFrameSize* by *MaxIntervalFrames* [item b) in 35.2.2.8.4] to arrive at the associated bandwidth  
19 (in bits per second), which is then used to update *operIdleSlope(N)* as shown in Table 35-14.

20 Streams that are in the Listener Ready or Listener Ready Failed state reduce the amount of bandwidth  
21 available to other Streams. Streams that have no Listeners, or the Listeners are in the Asking Failed state, do  
22 not reduce available bandwidth for other Streams since the Stream data will not be flowing through this  
23 outbound Port. These details are considered when calculating how many Streams can flow through a  
24 particular Port. The total amount of bandwidth available to a particular traffic class on a Port is represented  
25 by *deltaBandwidth(N)* [item b) in 34.3]. Subclauses 34.3.1 and 34.3.2 describe the relationship of available  
26 bandwidth between traffic classes.

#### 27 **35.2.4.3 Talker attribute propagation**

28 Table 35-10 describes the propagation of Talker attributes for a StreamID from one port of a Bridge to  
29 another. If no Talker attributes are registered for a StreamID then no Talker attributes for that StreamID will  
30 be declared on any other port of the Bridge. If a Talker Failed is registered then it will be propagated as a  
31 Talker Failed out all other nonblocked (35.1.3.1) ports on the Bridge.

32 Talker Advertise registrations require further processing by the MAP function. MAP will analyze available  
33 bandwidth and other factors to determine if the outbound port has enough resources available to support the  
34 Stream. MAP will also verify *msrpMaxFanInPorts*, if nonzero, will not be exceeded. If there are sufficient  
35 resources and bandwidth available MAP will declare a Talker Advertise. Otherwise, MAP will declare a  
36 Talker Failed on the outbound port and add appropriate FailureInformation.

37 If the outbound Port is an SRP domain boundary port for a given SR class, then for that SR class, the MAP  
38 function shall operate such that any Talker Advertise declaration for that SR class that would otherwise  
39 propagate through that Port is converted to a Talker Failed declaration with a failure code of 8 (Table 46-16),  
40 meaning “Egress Port is not AVB-capable.” The consequence of this behavior is that stream reservations can  
41 be established only in circumstances where the Talker and the Listener(s) for the stream are located within  
42 the same SRP domain.

**Table 35-10—Talker attribute propagation per port**

|          |               | Talker |                                      |               |
|----------|---------------|--------|--------------------------------------|---------------|
|          |               | (none) | Advertise                            | Failed        |
| Listener | (none)        | (none) | Talker Advertise or<br>Talker Failed | Talker Failed |
|          | Ready         | (none) | Talker Advertise or<br>Talker Failed | Talker Failed |
|          | Ready Failed  | (none) | Talker Advertise or<br>Talker Failed | Talker Failed |
|          | Asking Failed | (none) | Talker Advertise or<br>Talker Failed | Talker Failed |

### 1 35.2.4.3.1 ProtocolVersion Translation

2 Ports with *neighborProtocolVersion* [item j) in 35.2.1.4] of 0x00 shall use only the original Attribute Types  
3 (35.2.2.4) of Talker Advertise and Talker Failed. Ports with *neighborProtocolVersion* of 0x01 or higher shall  
4 use either the original Attribute Types or the enhanced Attribute Type of Talker Enhanced.

5 In order to propagate an enhanced Attribute Type (e.g., registered from a Port with *neighborProtocolVersion*  
6 of 0x01) to an original Attribute Type (e.g., declared to a Port with *neighborProtocolVersion* of 0x00), fields  
7 of the attribute's FirstValue shall be translated as specified in Table 35-11.

8 NOTE—Original Attribute Types always propagate without translation, even if *neighborProtocolVersion* is 0x01 or  
9 higher.

**Table 35-11—Translation of Talker attributes**

| Enhanced field                                                            | Original field                              | Enhanced to original translation                                                                                                             |
|---------------------------------------------------------------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| StreamID,<br>MacAddress                                                   | StreamID,<br>MAC Address                    | No change: Copy the field's contents from<br>enhanced to original without change.                                                            |
| StreamID,<br>UniqueID                                                     | StreamID,<br>Unique ID                      | No change: Copy the field's contents from<br>enhanced to original without change.                                                            |
| StreamRank, Rank                                                          | PriorityAndRank, Rank                       | No change: Copy the field's contents from<br>enhanced to original without change.                                                            |
| EndStationInterfaces                                                      | —                                           | Not propagated: This TLV is not propagated<br>through MAP, so translation is not applicable.                                                 |
| DataFrameSpecification,<br>IEEE802-MacAddresses,<br>DestinationMacAddress | DataFrameParameters,<br>destination_address | No change: Copy the field's contents from<br>enhanced to original without change.                                                            |
| DataFrameSpecification,<br>IEEE802-MacAddresses,<br>SourceMacAddress      | —                                           | Lost: The declaration type does not change (i.e.,<br>fail), because MSRPv0 does not use the source<br>MAC address for Stream identification. |
| DataFrameSpecification,<br>IEEE802-VlanTag,<br>PriorityCodePoint          | PriorityAndRank,<br>Data Frame Priority     | No change: Copy the field's contents from<br>enhanced to original without change.                                                            |

**Table 35-11—Translation of Talker attributes (continued)**

| Enhanced field                                        | Original field                          | Enhanced to original translation                                                                                                                                                                                      |
|-------------------------------------------------------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| TrafficSpecification,<br>Interval                     | —                                       | Lost: If this field does not match the default classMeasurementInterval (34.3) of the stream's SR class, a Talker Advertise declaration is converted to a Talker Failed declaration with a failure code of 20.        |
| TrafficSpecification,<br>MaxFramesPerInterval         | TSpec,<br>MaxIntervalFrames             | No change: Copy the field's contents from enhanced to original without change.                                                                                                                                        |
| TrafficSpecification,<br>MaxFrameSize                 | TSpec,<br>MaxFrameSize                  | No change: Copy the field's contents from enhanced to original without change.                                                                                                                                        |
| TrafficSpecification,<br>TransmissionSelection        | —                                       | Lost: If this field is not one, a Talker Advertise declaration is converted to a Talker Failed declaration with a failure code of 20.                                                                                 |
| TrafficSpecification,<br>TSpecTimeAware TLV           | —                                       | Lost: If this TLV is present, a Talker Advertise declaration is converted to a Talker Failed declaration with a failure code of 20.                                                                                   |
| UserToNetworkRequirements,<br>NumSeamlessTrees        | —                                       | Lost: If this field is not one, a Talker Advertise declaration is converted to a Talker Failed declaration with a failure code of 20.                                                                                 |
| UserToNetworkRequirements,<br>MaxLatency              | —                                       | Lost: If this field is not zero, a Talker Advertise declaration is converted to a Talker Failed declaration with a failure code of 20.                                                                                |
| InterfaceCapabilities                                 | —                                       | Not propagated: This TLV is not propagated through MAP, so translation is not applicable.                                                                                                                             |
| StatusInfo, TalkerStatus                              | —                                       | No change: This field determines the original Attribute Type to declare (Talker Advertise or Talker Failed).                                                                                                          |
| StatusInfo, ListenerStatus                            | —                                       | No change: This field is set according to the ListenerStatus that the Bridge last propagated in the Listener attribute of the Stream. If no Listener attribute has been propagated, this field is set to zero (None). |
| StatusInfo, FailureCode                               | FailureInformation,<br>Failure Code     | For Talker Failed, this field has no change (i.e., copy from enhanced to original).<br>For Talker Advertise, this field is lost, but the declaration type does not change (i.e., fail).                               |
| AccumulatedLatency                                    | AccumulatedLatency,<br>AL               | No change: Copy the field's contents from enhanced to original without change.                                                                                                                                        |
| InterfaceConfiguration                                | —                                       | Not propagated: This TLV is not propagated through MAP, so translation is not applicable.                                                                                                                             |

**Table 35-11—Translation of Talker attributes (continued)**

| Enhanced field                     | Original field                           | Enhanced to original translation                                                                                                                                                                            |
|------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FailedInterfaces,<br>MacAddress    | FailureInformation,<br>system identifier | No change: This field applies to Talker Failed only. The most significant 16 bits of system identifier are set to zero, and the MacAddress is copied to the least significant 48 bits of system identifier. |
| FailedInterfaces,<br>InterfaceName | FailureInformation                       | Lost: This field applies to Talker Failed only.                                                                                                                                                             |

### 35.2.4.3.2 Talker Pruning

The *talkerPruning* parameter (35.2.1.4) is disabled by default, and Talker declarations are sent out all nonblocked Ports. If *talkerPruning* is enabled and the destination\_address [item a) in 35.2.2.8.3] of the Stream is found in the MAC Address Registration Entries (8.8.4) for the Port, the declaration shall be forwarded. If the destination\_address is not found the declaration shall be blocked and no Talker declaration of any type shall be forwarded.

### 35.2.4.3.3 Talker Pruning Per Port

When the *talkerPruning* parameter is disabled (false) for the Bridge, each Port may provide a *talkerPruningPerPort* parameter (35.2.1.4) to control MAC address pruning for that Port.

When the *talkerPruningPerPort* feature is provided, all *talkerPruningPerPort* parameters are disabled by default.

When *talkerPruning* is enabled (true), the *talkerPruningPerPort* parameters are ignored.

Each *talkerPruningPerPort* parameter controls MAC address pruning for that Port when *talkerPruning* is disabled (false). If *talkerPruningPerPort* is disabled for the Port, Talker declarations are forwarded on that Port regardless of the destination\_address [item a) in 35.2.2.8.3] of the Stream. If *talkerPruningPerPort* is enabled for the Port and the destination\_address of the Stream is found in the MAC Address Registration Entries (8.8.4) for the Port, the declaration shall be forwarded. If *talkerPruningPerPort* is enabled for the Port and the destination\_address of the Stream is not found in the MAC Address Registration Entries for the Port, the declaration shall be blocked, and no Talker declaration of any type shall be forwarded.

### 35.2.4.3.4 Talker VLAN Pruning

The *talkerVlanPruning* parameter (35.2.1.4) may be provided on the Bridge in order to limit the Talker declarations to Ports that have the Stream's vlan\_identifier [item b) in 35.2.2.8.3] registered as a member in the VLAN Registration Entries (8.8).

When the *talkerVlanPruning* feature is provided, it is disabled (false) by default.

When *talkerVlanPruning* is disabled (false), the MAP context for MSRP propagates Talker declarations according to the VLAN spanning tree (35.1.3.1), regardless of the registration of the Stream's vlan\_identifier in the Filtering Database (8.8.10). This allows potential Listeners to receive Talker declarations prior to registering the VLAN with MVRP.

1 When *talkerVlanPruning* is enabled (true), in addition to propagating along the VLAN spanning tree, the  
2 MAP context for MSRP filters propagation according to the registration of the Stream's *vlan\_identifier* in  
3 the Filtering Database (8.8.10). If *talkerVlanPruning* is enabled and registration of the Stream's  
4 *vlan\_identifier* on a Port is not member (Registration Forbidden, Not Registered, or No Dynamic  
5 Registration Entry Present), MSRP shall not propagate the declaration on that Port. This propagation is  
6 effectively the same as propagation for the Stream's data frames. Potential Listeners can join the VLAN  
7 dynamically with MVRP in order to receive Talker declarations for that *vlan\_identifier* (35.1.2.1).

8 The *talkerVlanPruning* parameter filters by VLAN, and it operates independently from the parameters that  
9 filter by MAC address (*talkerPruning* and *talkerPruningPerPort*).

#### 10 **35.2.4.4 Listener attribute propagation**

11 Listener Attributes, unlike Talker Attributes, can be merged (35.2.4.4.3) from several Listeners on different  
12 ports into a single Listener declaration. There are two steps involved:

- 13 a) Processing of incoming Listener attribute registration on a port based upon the status of the  
14 associated Talker attribute registration,
- 15 b) Merging all the individual ports Listener attributes gathered in step 1, above, into a single Listener  
16 attribute to be declared on the nonblocked (35.1.3.1) outbound port which has the associated Talker  
17 registration. If no Talker attribute is registered within the Bridge for the StreamID associated with  
18 the Listener, the Listener attribute will not be propagated.

##### 19 **35.2.4.4.1 Incoming Listener attribute processing**

20 Table 35-12 describes how Listener attributes are propagated from the incoming ports.

**Table 35-12—Incoming Listener attribute propagation per port**

|          |               | Talker |                        |                        |
|----------|---------------|--------|------------------------|------------------------|
|          |               | (none) | Advertise              | Failed                 |
| Listener | (none)        | (none) | (none)                 | (none)                 |
|          | Ready         | (none) | Listener Ready         | Listener Asking Failed |
|          | Ready Failed  | (none) | Listener Ready Failed  | Listener Asking Failed |
|          | Asking Failed | (none) | Listener Asking Failed | Listener Asking Failed |

21 If no Listener attributes are registered on a particular port then no Listener attribute will be propagated to the  
22 Listener attribute merging (35.2.4.4.3) from that port.

23 If a Listener Asking Failed is registered on a port then it will be propagated as a Listener Asking Failed and  
24 merged with other Listener Attributes from other ports.

25 If no Talker attributes are associated with the Listener attribute, the Listener attribute will not be propagated.

26 If a Talker Failed is registered on another port for the associated Listener Ready or Listener Ready Failed  
27 then a Listener Asking Failed will be propagated and merged with other Listener attributes from other ports.

28 If a Talker Advertise is registered on another port for the StreamID associated with a Listener Ready or  
29 Listener Ready Failed then that Listener attribute will be forwarded as-is and merged with Listener  
30 Attributes from other ports.

#### 1 35.2.4.4.2 Updating Queuing and Forwarding information

- 2 When Incoming Listener attribute processing (35.2.4.4.1) has been completed for a port the Dynamic  
3 Reservation Entries (8.8.7) shall be updated as shown in Table 35-13.

**Table 35-13—Updating Dynamic Reservation Entries**

|          |               | Talker     |            |           |
|----------|---------------|------------|------------|-----------|
|          |               | (none)     | Advertise  | Failed    |
| Listener | (none)        | (no entry) | Filtering  | Filtering |
|          | Ready         | Filtering  | Forwarding | Filtering |
|          | Ready Failed  | Filtering  | Forwarding | Filtering |
|          | Asking Failed | Filtering  | Filtering  | Filtering |

- 4 The *operIdleSlope(N)* [item d) in 34.3] shall be updated as shown in Table 35-14, dependent on the change  
5 to the Dynamic Reservation Entries. MSRP MAP processing can occur at any time (35.2.4), resulting in a  
6 change to which Streams are filtered and to which streams are forwarded. These changes in bandwidth  
7 requirements shall be reflected in the *operIdleSlope(N)* variable. Streams that have had their bandwidth  
8 removed shall decrease *operIdleSlope(N)*. Streams that have just been allocated bandwidth shall increase  
9 *operIdleSlope(N)*.

**Table 35-14—Updating *operIdleSlope(N)***

|                                                    |            | Dynamic Reservation Entries prior to MSRP MAP running |                                  |                                  |
|----------------------------------------------------|------------|-------------------------------------------------------|----------------------------------|----------------------------------|
|                                                    |            | (none)                                                | Filtering                        | Forwarding                       |
| Dynamic Reservation Entries after MSRP MAP running | (none)     | (no change)                                           | (no change)                      | Decrease <i>operIdleSlope(N)</i> |
|                                                    | Filtering  | (no change)                                           | (no change)                      | Decrease <i>operIdleSlope(N)</i> |
|                                                    | Forwarding | Increase <i>operIdleSlope(N)</i>                      | Increase <i>operIdleSlope(N)</i> | (no change)                      |

- 10 NOTE—The order of operations is important when updating the Dynamic Reservation Entries and the *operIdleSlope(N)*  
11 in order not to allow any associated streaming frames to be dropped. If the bandwidth utilization of a port is going to be  
12 increased (i.e., a Stream is going to be forwarded) the *operIdleSlope(N)* is updated before the Dynamic Reservation  
13 Entries. If the bandwidth utilization of a port is going to be decreased (i.e., a Stream is going to be filtered) the Dynamic  
14 Reservation Entries are updated before the *operIdleSlope(N)*.

### 35.2.4.4.3 Merge Listener Declarations

Listener Registrations with the same StreamID shall be merged into a single Listener Declaration that will be declared on the port with the associated Talker registration. If no such Talker registration exists the Listener attribute is not declared. When this Declaration is sent,

- a) The Direction (35.2.1.2) is Listener.
- b) The Declaration Type (35.2.1.3) is determined according to Table 35-15.
- c) The StreamID (35.2.2.8.2) is that of the Listener Registrations.

**Table 35-15—Listener Declaration Type Summation**

| First Declaration Type | Second Declaration Type       | Resultant Declaration Type |
|------------------------|-------------------------------|----------------------------|
| Ready                  | none or Ready                 | Ready                      |
|                        | Ready Failed or Asking Failed | Ready Failed               |
| Ready Failed           | any                           | Ready Failed               |
| Asking Failed          | Ready or Ready Failed         | Ready Failed               |
|                        | none or Asking Failed         | Asking Failed              |

### 35.2.4.4.4 ProtocolVersion Translation

Ports with *neighborProtocolVersion* [item j) in 35.2.1.4] of 0x00 shall use only the original Attribute Type (35.2.2.4) of Listener. Ports with *neighborProtocolVersion* of 0x01 or higher shall use either the original Attribute Type or the enhanced Attribute Type of Listener Enhanced.

In order to propagate an enhanced Attribute Type (e.g., registered from a Port with *neighborProtocolVersion* of 0x01) to an original Attribute Type (e.g., declared to a Port with *neighborProtocolVersion* of 0x00), fields of the attribute's FirstValue shall be translated as specified in Table 35-16.

NOTE—Original Attribute Types always propagate without translation, even if *neighborProtocolVersion* is 0x01 or higher.

### 35.2.4.4.5 Merge MaxLatency

When more than one Listener provides the UserToNetworkRequirements TLV, multiple values of MaxLatency shall be merged by using the largest MaxLatency value in that set of multiple values. This ensures that Bridges closer to the Talker support the most flexible requirement for any Listener. The requirements of an individual Listener continue to be met in Bridges closer to that Listener.

### 35.2.4.4.6 Merge Listener Failures

As specified in 35.2.4.4.3, it is possible for a Bridge to merge failed Declaration Types for Listeners (e.g., Ready Failed with Asking Failed). Each failed Declaration Type uses a nonzero FailureCode (35.2.2.10.9) and a FailedInterfaces TLV associated with that FailureCode.

When merging failures, the FailedInterfaces TLV shall always be transferred with its corresponding StatusInfo TLV since the FailureCode is associated with the FailedInterfaces.

**Table 35-16—Translation of Listener attributes**

| Enhanced field                              | Original field        | Enhanced to original translation                                                                                                                                                                                |
|---------------------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| StreamID, MacAddress                        | StreamID, MAC Address | No change: This field determines the original Attribute Type to declare (Talker Advertise or Talker Failed).                                                                                                    |
| StreamID, UniqueID                          | StreamID, Unique ID   | No change: This field determines the original Attribute Type to declare (Talker Advertise or Talker Failed).                                                                                                    |
| EndStationInterfaces                        | —                     | Not propagated: This TLV is not propagated through MAP, so translation is not applicable.                                                                                                                       |
| UserToNetworkRequirements, NumSeamlessTrees | —                     | Lost: If this field is not one, a Listener Ready or Listener Ready Failed declaration is converted to a Listener Asking Failed declaration.                                                                     |
| UserToNetworkRequirements, MaxLatency       | —                     | Lost: If this field is not zero, a Listener Ready or Listener Ready Failed declaration is converted to a Listener Asking Failed declaration.                                                                    |
| InterfaceCapabilities                       | —                     | Not propagated: This TLV is not propagated through MAP, so translation is not applicable.                                                                                                                       |
| StatusInfo, TalkerStatus                    | —                     | No change: This field is set according to the TalkerStatus that the Bridge last propagated in the Talker attribute of the Stream. If no Talker attribute has been propagated, this field is set to zero (None). |
| StatusInfo, ListenerStatus                  | —                     | No change: This field determines the original FourPackedType (35.2.2.10) to declare.                                                                                                                            |
| StatusInfo, FailureCode                     | —                     | Lost: The declaration type does not change (i.e., fail).                                                                                                                                                        |
| InterfaceConfiguration                      | —                     | Not propagated: This TLV is not propagated through MAP, so translation is not applicable.                                                                                                                       |

1 When merging a Ready Failed declaration with an Asking Failed declaration, the StatusInfo and  
2 FailedInterfaces shall be transferred from the Asking Failed declaration. When merging failed declarations  
3 with the same Declaration Type, the StatusInfo and FailedInterfaces shall be transferred from the declaration  
4 with the Failure Code of the lowest numeric value. When merging failed declarations with the same  
5 Declaration Type and Failure Code, the decision of which failure to transfer is left to the Bridge's  
6 implementation.

### 7 35.2.4.5 MAP Context for MSRP

8 MSRPDU's can carry information about Streams in multiple VLANs, which in an MST environment, can be  
9 in different spanning tree instances. Queue resources, however, are allocated and used according to priority  
10 parameters, not according to VID. Furthermore, on a shared medium, Streams can use the shared medium  
11 even on VLANs that are blocked on the Bridge's Port to that shared medium (e.g., consider an IEEE 802.11  
12 AP that transmits frames between two stations that are on a VLAN that is blocked on the AP). Therefore,  
13 there is a single context for MSRP Attribute Propagation that includes all Bridge Ports. The Declarations are  
14 filtered according to the requirements of 35.2.4 and its subclauses and according to the state of the spanning  
15 tree per 35.1.3.1.

16 All MSRPDU's are transmitted as untagged frames.

#### 1 **35.2.4.6 MaxLatency Comparison**

2 The comparison for UserToNetworkRequirements.MaxLatency greater than zero determines whether to fail  
3 the Stream due to AccumulatedLatency (35.2.2.8.6, 35.2.2.10.10) that exceeds the requirement specified by  
4 Talkers and/or Listeners. The comparison is performed separately for the Talker and each Listener.

5 For the Talker, the UserToNetworkRequirements.MaxLatency from the Talker is compared to  
6 AccumulatedLatency for all Listeners of the Stream. For example, if the Bridge forwards the Stream to three  
7 Ports (three Listeners registered), the Talker's UserToNetworkRequirements.MaxLatency is compared to  
8 three values of AccumulatedLatency. For any of the comparisons, if any Listener's AccumulatedLatency is  
9 greater than the Talker's UserToNetworkRequirements.MaxLatency, the Talker fails the MaxLatency  
10 comparison.

11 If the Talker fails the MaxLatency comparison and the Declaration Type of the Talker is Advertise, the  
12 Bridge shall change Talker Advertise to Talker Failed and report Failure Code=21 (Table 46-16).

13 For the Listener, the UserToNetworkRequirements.MaxLatency from the Listener is compared to  
14 AccumulatedLatency for the corresponding Listener. If the Listener's AccumulatedLatency is greater than  
15 the Listener's UserToNetworkRequirements.MaxLatency, the Listener fails the MaxLatency comparison.

16 If the Listener fails the MaxLatency comparison, the Bridge shall change Listener Ready to Listener Asking  
17 Failed for the failed Listener and report Failure Code=21. The Listener Asking Failed is merged with  
18 declarations of other Listeners to determine the resultant Declaration Type to the Talker (35.2.4.4.3).

19 In the fully distributed model (46.1.3.1), the comparison for the Talker's  
20 UserToNetworkRequirements.MaxLatency is performed in each Bridge in the path from the Talker to each  
21 Listener, in the same direction as AccumulatedLatency. In the fully distributed model, the comparison for  
22 the Listener's UserToNetworkRequirements.MaxLatency is performed in each Bridge in the path from the  
23 Listener to each Talker, using the AccumulatedLatency from the Talker's attribute.

24 In the centralized network/distributed user model (46.1.3.2), the comparison for the Talker's and Listener's  
25 UserToNetworkRequirements.MaxLatency is performed in the CNC, using the capabilities of each Bridge  
26 as learned through remote management (e.g., Bridge Delay of 12.32.1). When the CNC detects failure of the  
27 MaxLatency comparison, Failure Code 21 is declared to the Talker and Listener as specified in item a) in  
28 35.2.2.10.

#### 29 **35.2.5 Operational reporting and statistics**

##### 30 **35.2.5.1 Dropped Stream Frame Counter**

31 An implementation may support the ability to maintain a per-port per-traffic class count of data stream  
32 frames that are dropped for any reason. These are not MRP frames, but the data stream frames that flow  
33 between Talker and Listener(s) through the reservations established by MSRP.

#### 34 **35.2.6 Encoding**

35 If an MSRP message is received from a Port with an event value specifying the JoinIn or JoinMt message,  
36 and if the StreamID (35.2.2.8.2, 35.2.2.10.2), and Direction (35.2.1.2) all match those of an attribute already  
37 registered on that Port, and the Attribute Type (35.2.2.4) or FourPackedEvent (35.2.2.7.2) has changed, then  
38 the Bridge should behave as though an rLv! event (with immediate leavetimer expiration in the Registrar  
39 state table) was generated for the MAD in the Received MSRP Attribute Declarations before the rJoinIn! or  
40 rJoinMt! event for the attribute in the received message is processed. This allows an Applicant to indicate a

1 change in a stream reservation, e.g., a change from a Talker Failed to a Talker Advertise registration, without  
2 having to issue both a withdrawal of the old attribute, and a declaration of the new. A Listener attribute is  
3 also updated this way, for example, when changing from a Listener Ready to a Listener Ready Failed.

4 NOTE—This rule ensures that there is at most one Listener Declaration or one Talker Declaration for any given value of  
5 StreamID on any given port. In the unlikely situation where a Talker Advertise and a Talker Failed are received for the  
6 same Stream on the same port, the Talker Failed declaration takes precedence.

7 The following examples will help clarify the intent of this subclause. The first example describes the  
8 behavior when one attribute (Talker Advertise) is replaced by another (Talker Failed). The second example  
9 describes the behavior when the MSRP FourPackedEvents changes with a single Listener attribute.

10 This example illustrates processing of Talker Declaration changes. Assume a Bridge is receiving Talker  
11 Advertise declarations on an inbound Port. An emergency situation occurs and a 911 call is being placed via  
12 an entirely different Stream. The bandwidth that was available for the first Stream is now no longer available  
13 so the Bridge begins receiving Talker Failed declarations for that original stream. The MAP function realizes  
14 the Talker declaration has changed for the Stream and generates an internal leave event for the Talker  
15 Advertise and a join event for the Talker Failed. This behavior guarantees there will not be a declaration for  
16 a Talker Advertise and a Talker Failed for a single Stream existing within the Bridge at the same time.

17 As another example assume the same situation has occurred as described in the example above (a 911 call).  
18 For this scenario consider the Listener declarations flowing in the opposite direction. When there was  
19 bandwidth available the Bridge was declaring a Listener Ready, which was then changed to a Listener  
20 Asking Failed as soon as the 911 call came through. The other Bridge receiving these Listener declarations  
21 realized that the Listener attribute MSRP FourPackedEvents had changed and acted as if the Listener  
22 declaration had been withdrawn and replaced by the updated Listener declaration.

### 23 **35.2.7 Attribute value support requirements**

24 Implementations of MSRP shall maintain state information for all attribute values that support the Stream  
25 registrations (35.2.2.8, 35.2.2.10).

26 Implementations of MSRP shall be capable of supporting any attribute value in the range of possible values  
27 that can be registered using Stream registrations; however, the maximum number of attribute values for  
28 which the implementation is able to maintain current state information is an implementation decision, and  
29 may be different for Talker attributes and Listener attributes. The number of values that the implementation  
30 can support shall be stated in the PICS.

## 36. Priority-based Flow Control (PFC)

This clause specifies the operation of PFC (see 36.1) and the architecture of Priority-based Flow Control in a PFC-aware system (see 36.2).

The models of operation in this clause provide a basis for specifying the externally observable behavior of PFC and are not intended to place additional constraints on implementations; these can adopt any internal model of operation compatible with the externally observable behavior specified.

### 36.1 PFC operation

#### 36.1.1 Overview

Operation of PFC is limited to a data center environment. PFC enables to not discard frames due to congestion for protocols that require this property. However, PFC can cause congestion spreading behavior; therefore, it is intended for use on networks of limited extent. When PFC is used, deployment of congestion notification (see Clause 30) can reduce the frequency with which PFC is invoked.

PFC is a function defined only for a pair of full duplex MACs (e.g., IEEE 802.3 MACs operating in point-to-point full-duplex mode) connected by one point-to-point link. Use of PFC on shared media such as EPON is out of the scope of this standard. Figure 36-1 shows an example of PFC peering when IEEE 802.3 point-to-point full-duplex MACs are used.

Figure 36-1—PFC peering

1 PFC allows link flow control to be performed on a per-priority basis. In particular, PFC is used to inhibit  
2 transmission of data frames associated with one or more priorities for a specified period of time. PFC can be  
3 enabled for some priorities on the link and disabled for others.

4 Given that BPDUs, for example, are sent untagged and can bypass the output queues, it is strongly  
5 recommended for the default priority of a port to not have PFC enabled.

6 NOTE—The LLC-SAP of a Bridge Port can host a management protocol stack that uses PFC-enabled priorities, and  
7 these management frames can bypass the output queues. In this situation PFC can fail to provide insurance against these  
8 frames overflowing the buffer in the remote station of the link.

### 9 36.1.2 PFC primitives

10 PFC is invoked through the M\_CONTROL PFC primitives (11.4 of IEEE Std 802.1AC-2016 [B10]). A  
11 system client wishing to inhibit transmission of data frames on certain priorities from the remote system on  
12 the link generates an M\_CONTROL.request primitive specifying the following:

- 13 a) The globally assigned 48-bit multicast address 01-80-C2-00-00-01.
- 14 b) The PFC opcode (i.e., 01-01).
- 15 c) A request\_operand\_list with two operands indicating, respectively, the set of priorities addressed  
16 and the lengths of time for which it wishes to inhibit data frame transmission of the corresponding  
17 priorities.

18 NOTE—By definition, a point-to-point full-duplex link comprises exactly two stations, thus there is no ambiguity  
19 regarding the destination station's identity. The use of a well-known multicast address does not require a station to know,  
20 and maintain knowledge of, the individual 48-bit address of the other station.

21 As specified in IEEE Std 802.3, when PFC is enabled on a port for at least one priority over an IEEE 802.3  
22 link layer, the IEEE Std 802.3 PAUSE mechanism is not used for that port.

23 As a result of the processing of the PFC M\_CONTROL.request, the peering PFC station receives a PFC  
24 M\_CONTROL.indication primitive.

25 The parameters of the PFC M\_CONTROL.indication are as follows:

- 26 d) The PFC opcode (i.e., 01-01).
- 27 e) A indication\_operand\_list with two operands indicating, respectively, the set of priorities addressed  
28 and the lengths of time for which data frame transmission of the corresponding priorities has to be  
29 inhibited.

30 The request\_operand\_list of a PFC M\_CONTROL.request and the indication\_operand\_list of a PFC  
31 M\_CONTROL.indication are composed of the following operands:

- 32 f) priority\_enable\_vector: a 2-octet field, with the most significant octet being reserved (i.e., set to zero  
33 on transmission and ignored on receipt). Each bit of the least significant octet indicates if the  
34 corresponding field in the time\_vector parameter is valid. The bits of the least significant octet are  
35 named e[0] (the LSB) to e[7] (the MSB). Bit e[n] refers to priority n. For each e[n] bit set to one, the  
36 corresponding time[n] value is valid. For each e[n] bit set to zero, the corresponding time[n] value is  
37 invalid.
- 38 g) time\_vector: a list of eight 2-octet fields, named time[0] to time[7]. The eight time[n] values are  
39 always present regardless of the value of the corresponding e[n] bit. Each time[n] field is a 2-octet,  
40 unsigned integer containing the length of time for which the receiving station is requested to inhibit  
41 transmission of data frames associated with priority n. The field is transmitted most significant octet  
42 first, and least significant octet second. The time[n] fields are transmitted sequentially, with time[0]  
43 transmitted first and time[7] transmitted last. Each time[n] value is measured in units of  
44 pause\_quanta, equal to the time required to transmit 512 bits of a frame at the data rate of the MAC.  
45 Each time[n] field can assume a value in the range of 0 to 65 535 pause\_quanta.

### 36.1.3 Detailed specification of PFC operation

#### 36.1.3.1 Processing PFC M\_CONTROL.requests

Invoking the PFC M\_CONTROL.request results in the invocation of the appropriate link layer service request. For IEEE 802.3 link layers the PFC M\_CONTROL.request is mapped to a PFC MA\_CONTROL.request (IEEE Std 802.1AC). If PFC is not enabled for priority  $n$ , then PFC requests with  $e[n]$  set to one and  $time[n]$  different than zero (see 36.1.2) should not be generated.

NOTE—In the IEEE 802.1Q architecture frames coming from the LLC, including BPDUs, bypass the priority queues and therefore are not subject to PFC. However, in some implementations frames coming from the LLC can pass through the priority queues. In this case, it is not recommended to enable PFC for the priority to which BPDUs are assigned (usually priority 7).

#### 36.1.3.2 Processing PFC M\_CONTROL.indications

The PFC Receiver entity (see 36.2.2) maintains and makes available to Transmission Selection the vector of the  $Priority\_Paused[n]$  variables, indicating the state of each of the eight priorities. Each  $Priority\_Paused[n]$  variable is a boolean. When  $Priority\_Paused[n]$  is FALSE, priority  $n$  is not in paused state. When  $Priority\_Paused[n]$  is TRUE, priority  $n$  is in paused state.

Figure 36-2 shows the PFC state diagram for priority  $n$ . If PFC is not enabled for priority  $n$ , then the PFC state diagram does not apply to priority  $n$  and  $Priority\_Paused[n]$  is FALSE.

Figure 36-2—PFC Receiver state diagram for priority  $n$

Upon receipt of a PFC M\_CONTROL.indication, the PFC Receiver programs up to eight separate timers, each associated with a different priority, depending on the  $priority\_enable\_vector$ . For each bit in the  $priority\_enable\_vector$  that is set to one, the corresponding timer value is set to the corresponding time value in the  $time\_vector$  parameter.  $Priority\_Paused[n]$  is set to TRUE when the corresponding timer value (i.e.,  $priority\_timer[n]$ ) is nonzero.  $Priority\_Paused[n]$  is set to FALSE when the corresponding timer value (i.e.,  $priority\_timer[n]$ ) counts down to zero. A time value of zero in the  $time\_vector$  parameter has the same effect as the timer having counted down to zero. If PFC is not enabled for priority  $n$  and a PFC indication is received with  $e[n]$  set to one, then the  $time[n]$  parameter is ignored (i.e., the primitive is processed as if  $e[n]$  was set to zero).

NOTE—A  $priority\_enable\_vector$  with all bits set to zero is legal and equivalent to a no-op.

### 1 36.1.3.3 Timing considerations

2 For effective flow control on a point-to-point full-duplex link, it is necessary to place an upper bound on the  
3 length of time that a device can transmit data frames after receiving a PFC M\_CONTROL.indication with  
4 e[n] set to one in the priority\_enable\_vector and a nonzero time[n] in the time\_vector operands.

5 If MACsec is not supported, a queue shall go into paused state in no more than 614.4 ns since the reception  
6 of a PFC M\_CONTROL.indication that paused that priority. This delay is equivalent to 12 pause quanta  
7 (i.e., 6144 bit times) at the speed of 10 Gb/s, 48 pause quanta (i.e., 24 576 bit times) at the speed of 40 Gb/s,  
8 and 120 pause quanta (i.e., 61 440 bit times) at the speed of 100 Gb/s.

9 If MACsec is used, a queue shall go into paused state in no more than 614.4 ns + ‘SecY transmit delay’ (see  
10 IEEE Std 802.1AE) since the reception of a PFC M\_CONTROL.indication that paused that priority. The  
11 ‘SecY transmit delay’ is defined as the wire transmit time for a maximum sized MPDU + 4 times the wire  
12 transmit time for 64 octet MPDUs. For a 2000-byte frame the ‘SecY transmit delay’ is  $8 \times (2000 + 20) + 8 \times$   
13  $4 \times (64 + 12 + 4 + 20) = 19\,360$  bit times.

14 NOTE 1—19 360 bit times is an appropriate value for ‘SecY transmit delay’ for speeds up to 10 Gb/s. Support for the  
15 speeds of 40 Gb/s and 100 Gb/s can require a higher value.

16 If MACsec is supported but not used, the delay computation has to take into account the MACsec Bypass  
17 Capability (MBC) bit in the PFC configuration TLV of DCBX (D.2.10), that indicates if the link peer needs  
18 the extra time for MACsec. If the MBC bit is set to zero, the maximum PFC delay is 614.4 ns. If the MBC  
19 bit is set to one, the maximum PFC delay is 614.4 ns + ‘SecY transmit delay’.

20 NOTE 2—In addition to the above delays, system designers should take into account the delay of the PHY and of the  
21 link segment when designing devices that implement the PFC operation to ensure frames are not lost due to congestion  
22 (see Annex O for additional discussion on this topic).

## 23 36.2 PFC-aware system queue functions

24 Figure 36-3 illustrates the architecture of the queue functions of a PFC-aware system when Link  
25 Aggregation is not used. These functions offer a service to higher layers that utilizes a single instance of the  
26 ISS or EISS to connect to the lower layers. In Figure 36-3, two major blocks are outlined with dotted  
27 boundaries:

- 28 a) The PFC Initiator block, in the right of Figure 36-3 (see 36.2.1)
- 29 b) The outbound queue block, in the left of Figure 36-3 (see Figure 22-2)

30 The remaining entities illustrated in Figure 36-3, other than the PFC Receiver entity, are part of the  
31 IEEE 802.1 architecture and are not further discussed here.

### 32 36.2.1 PFC Initiator

33 The PFC Initiator entity generates M\_CONTROL PFC requests using the M\_CONTROL.request primitive  
34 (see 36.1.3.1) when appropriate (e.g., when an input buffer reaches a certain threshold).

### 35 36.2.2 PFC Receiver

36 The PFC Receiver entity processes the M\_CONTROL.indication primitives as specified in 36.1.3.2. In  
37 addition, the PFC Receiver maintains and makes available to Transmission Selection the vector of the  
38 Priority\_Paused[n] variables, indicating the state of each of the eight priorities.

1 The PFC Receiver entity acts per physical port. When Transmission Selection is running above Link  
2 Aggregation, each PFC Receiver entity processes the M\_CONTROL.indication primitives as specified in  
3 36.1.3.2, and maintains and makes available to Transmission Selection the vector of the Priority\_Paused[n]  
4 variables, indicating the state of each of the eight priorities of that physical link, as shown in Figure 36-  
5 4.

**Figure 36-3—PFC-aware system queue functions**

Figure 36-4—PFC-aware system queue functions with Link Aggregation

## 1 37. Enhanced Transmission Selection (ETS)

### 2 37.1 Overview

3 This clause provides definitions and an operational model for priority processing and bandwidth allocation  
4 in end stations and Bridges in a Data Center Bridging (DCB) environment. Using Priority-based processing  
5 and bandwidth allocations, different traffic classes with different types of traffic such as LAN, Storage  
6 Networking, Clustering, and management can be configured to provide bandwidth allocation, or best effort  
7 transmit characteristics.

8 In order to accomplish this, the following are provided:

- 9 a) A set of bandwidth configuration parameters that are used to configure the percentage of bandwidth  
10 assigned to each traffic class.
- 11 b) A set of characteristics that an ETS enabled transmitter is required to follow.
- 12 c) A means of communicating priority-to-traffic class allocations to neighboring systems (DCBX; see  
13 Clause 38).

#### 14 37.1.1 Relationship to other transmission selection algorithms

15 If ETS is used in conjunction with the strict priority and credit-based shaper algorithms, then attention  
16 should be paid to assignment of traffic classes as specified in 34.5.

### 17 37.2 ETS configuration parameters

18 The following ETS configuration parameters exist for each ETS enabled port:

- 19 a) *numTrafficClassesSupported*: Indicates the number of traffic classes supported by a port. This value  
20 has a minimum of 3 (see 37.3) and a maximum of 8.
- 21 b) *TCPriorityAssignment(P)*: For each supported priority, P, the traffic class to which that priority P is  
22 assigned (see 37.1.1). A traffic class only operates with the ETS algorithm if it is assigned to do so  
23 by the Transmission Selection Algorithm Table (see 8.6.8); i.e., the entry in the table for that traffic  
24 class is assigned the value 2 (see Table 8-6).
- 25 c) *TCBandwidth(N)*: For each traffic class N, the percentage of the available bandwidth assigned to  
26 that traffic class. The total for all traffic classes is equal to 100% (see 37.3).

27 Configuration of ETS parameters shall be done via DCBX (see Clause 38).

### 28 37.3 ETS algorithm

29 The ETS algorithm provides allocation of bandwidth to traffic classes. The algorithm allows bandwidth  
30 intensive and loss sensitive traffic to share the network while allowing coexistence with low latency traffic  
31 using the strict priority and credit-based shaper algorithms. Since there are a number of variants of  
32 bandwidth sharing algorithms (such as weighted round robin) that provide appropriate bandwidth sharing, a  
33 detailed algorithm is not specified. Any algorithm is allowed as long as it meets the specified performance  
34 requirements.

35 NOTE 1—The ETS algorithm is used to determine when an ETS traffic class has a frame available to transmit. The  
36 determination of which frame in the traffic class to send can be done in an implementation specific manner, subject to  
37 the ordering requirements in 8.6.6.

38 For the purposes of the ETS algorithm, Available Bandwidth is defined as the link bandwidth remaining  
39 after traffic classes not assigned to Transmission selection algorithm 2, and Vendor Specific (see Table 8-6)  
40 are serviced. The effect of Vendor Specific algorithms to Available Bandwidth is outside the scope of this  
41 standard.

1 The ETS algorithm shall provide the ability to configure traffic classes to share bandwidth according to the  
2 following:

- 3 a) Allow one or more priorities to be assigned to a traffic class.  
4 NOTE 2—All priorities within a traffic class typically share similar traffic handling requirements (e.g., loss and  
5 bandwidth).
- 6 b) Allow bandwidth to be configured for each traffic class with a granularity of 1%. The configured  
7 bandwidth indicates the percentage of Available Bandwidth that can be used by the traffic class  
8 when all other traffic classes are consuming their configured bandwidth.
- 9 c) For traffic classes for which the transmission selection algorithm is ETS (i.e., Transmission selection  
10 algorithm 2 in Table 8-6), select frames for transmission from the traffic class queues such that the  
11 bandwidth consumed by the traffic class approaches its percentage of Available Bandwidth. The  
12 traffic class consumes less than its percentage of Available Bandwidth when the offered load for that  
13 traffic class is less than its percentage of Available Bandwidth, in that case the remainder of its  
14 percentage of Available Bandwidth can be used by other traffic classes. A traffic class can consume  
15 more than its percentage of Available Bandwidth when the offered load of other traffic classes  
16 results in those traffic classes consuming less than their percentage of Available Bandwidth.  
17 Allocation of any excess Available Bandwidth is implementation specific.
- 18 d) When all traffic classes are offered enough load to consume their share of available bandwidth, and  
19 there is no offered load in the traffic classes using transmission selection algorithms other than ETS,  
20 the bandwidth received from an ETS traffic class shall deviate from its allocation by no more than  
21 10% of the available bandwidth when measured over a period of 10 000 000 bit times using  
22 maximum sized frames during a time period when no PFC frames are received (i.e., no congestion).  
23 NOTE 3—The measurement window is derived from an approximate number of bits in 500 frames (i.e., 500  
24 frames × 2000 bytes per frame × 8 bits per byte rounded up to 10 000 000).  
25 NOTE 4—Allowed deviation of ± 10% allows for variations of traffic (e.g., burstiness) over the specified  
26 measurement window and provides balance between precision and implementation flexibility.
- 27 e) At least 3 traffic classes shall be supported per port. A minimum of 3 traffic classes allows a  
28 minimum configuration such that one ETS traffic class contains priorities that have PFC enabled,  
29 one ETS traffic class contains priorities that have PFC disabled, and one traffic class using strict  
30 priority.

## 31 **37.4 Legacy configuration**

32 Subclause 8.6.8 specifies strict priority scheduling as default behavior. This can be achieved by configuring  
33 the Transmission selection algorithm value for a traffic class to 0 (see Table 8-6).

34 Subclause 8.6.6 specifies the default priority to traffic class mapping. There is no change to such mapping  
35 when ETS is used.

## 1 38. Data Center Bridging eXchange protocol (DCBX)

### 2 38.1 Overview

3 This clause details the DCBX, which is used by DCB devices to exchange configuration information with  
4 directly connected peers. The protocol may also be used for misconfiguration detection and for  
5 configuration of the peer.

6 This standard describes the base protocol, which comprises state machines and TLVs for capability  
7 exchange. For each feature that is supported by DCBX, the attributes that are to be exchanged specify the  
8 following:

- 9 a) The attributes to be exchanged
- 10 b) How the attributes are used for detecting misconfiguration
- 11 c) What action needs to be taken when a misconfiguration is detected

12 The information listed above is specified for the following:

- 13 d) ETS
- 14 e) PFC
- 15 f) Application Priority TLV
- 16 g) Application VLAN TLV

### 17 38.2 Goals

18 The goals of DCBX are as follows:

- 19 a) Discovery of DCB capability in a peer port; for example, it can be used to determine if two link peer  
20 ports support PFC.
- 21 b) DCB feature misconfiguration detection: DCBX can be used to detect misconfiguration of a feature  
22 between the peers on a link. Misconfiguration detection is feature-specific because some features  
23 allow asymmetric configuration.
- 24 c) Peer configuration of DCB features: DCBX can be used by a device to perform configuration of  
25 DCB features in its peer port if the peer port is willing to accept configuration.

### 26 38.3 Types of DCBX attributes

27 Three types of DCBX attributes are exchanged:

- 28 a) Informational attributes (see 38.3.1)
- 29 b) Asymmetric attributes (see 38.4.1)
- 30 c) Symmetric attributes (see 38.4.2)

#### 31 38.3.1 Informational attributes

32 Informational attributes are exchanged via LLDP without any participation in a DCBX state machine.

### 33 38.4 DCBX and LLDP

34 DCBX uses Link Layer Discovery Protocol (LLDP) (see IEEE Std 802.1AB) to exchange attributes between  
35 two link peers. LLDP is a unidirectional protocol. It advertises connectivity and management information  
36 about the local station to adjacent stations on the same IEEE 802 LAN.

1 DCB exchanged attributes are packaged into Organizationally Specific TLVs. The OUI used for the DCBX  
2 TLV is the IEEE 802.1 OUI (i.e., 00-80-C2).

3 DCBX state machine transitions are based on the DCBX objects in the LLDP MIB module. Operation of the  
4 DCBX state machine may affect the values of the DCBX objects in the LLDP MIB module.

5 A port capable of any DCB feature shall have the capability for DCBX to be administratively disabled. The  
6 default state for DCBX is enabled.

7 DCBX is expected to operate over a point-to-point link. If multiple LLDP peer ports running DCBX are  
8 detected, then DCBX should behave as if the peer port's DCBX TLVs are not present until the multiple  
9 LLDP peer port condition is no longer present. However, a transition in LLDP peer port may occur in some  
10 circumstances (e.g., such as a transition from system boot to system operation). Therefore, when it is  
11 detected that the number of peer ports running DCBX exceeds 1 for a period longer than the longest TTL of  
12 any of the peers, a multi-peer condition is detected. During the time when the multi-peer condition has not  
13 been detected the DCBX data from the most recent DCBX peer shall be used. An LLDP peer port is  
14 identified by a concatenation of the chassis ID and port ID values transmitted in the LLDPDU. A DCBX  
15 peer port is a LLDP peer port that is sending DCBX TLVs.

16 DCBX defines two different types of attribute passing mechanisms:

- 17 a) Asymmetric: the passing of a attribute from one port to its peer port. In this case, the desired  
18 configuration for the peer may not match the local configuration.
- 19 b) Symmetric: the passing of a attribute from one port to its peer port with objective of both ports  
20 utilizing the same attribute value.

### 21 **38.4.1 Asymmetric attribute passing**

#### 22 **38.4.1.1 Overview**

23 Two types of TLV are passed for Asymmetric attribute Passing:

- 24 a) Configuration TLV: Provides current operational state and Willing bit. The received Willing bit is  
25 not used by the state machine, but instead provided to higher layers to provide an indication of the  
26 expected behavior of the remote port. The presence of the willing bit set to 1 indicates to the remote  
27 port that the local port is willing to accept a configuration for the specific attribute for which the  
28 willing bit is set.
- 29 b) Recommendation TLV: Provides recommendation for the operational state of remote port.  
30 Transmitted only if the local port is configured to make recommendations in which case it is  
31 transmitted in all LLDPDUs. Transmitted regardless of the “willingness” of the remote port.

32 NOTE—An implementation is allowed to send a recommendation TLV or a configuration TLV or both.

#### 33 **38.4.1.2 Asymmetric state variables**

34 **LocalWilling:** Indicates that the local port has been administratively configured to accept recommendations.  
35 This value is included in the Willing bit of Configuration TLVs transmitted by this port. A local port may be  
36 configured as not Willing.

37 **OperParam:** The current operational value of the attribute on the local port. This value is included as the  
38 attribute in the Configuration TLVs.

39 **LocalAdminParam:** The administratively configured value for the attribute. This becomes the operational  
40 value of the attribute by default, and the operational value may be overridden if the local port accepts a  
41 recommendation from the remote port.

1 **RemoteParam:** The attribute received in the last Recommendation TLV. This variable is set to NULL if the  
2 remote LLDP database contains no Recommendation TLV.

3 **DCBXMapping:** A function that maps the received parameters to the capabilities of the receiving port.

### 4 38.4.1.3 Asymmetric state machine

5 The Asymmetric state machine is depicted in Figure 38-1.

Figure 38-1—DCBX Asymmetric state machine

### 6 38.4.2 Symmetric attribute passing

#### 7 38.4.2.1 Overview

8 For Symmetric attribute passing one type of TLV is used:

- 9 a) Configuration TLV. This TLV always carries the current local operational state and a Willing (W)  
10 bit.

11 A port that sets the W bit is considered Willing. A Willing port shall set its operational attribute to that  
12 indicated in the received TLV if the received TLV has the W bit set to zero. If both the local port and remote  
13 port are willing, then the attribute values of the port with the lower numerical MAC address shall take  
14 precedence.

#### 15 38.4.2.2 Symmetric state variables

16 **LocalWilling:** Indicates that the local port has been administratively configured to accept the attribute from  
17 the remote port. This value is included in the Willing bit of DCBX TLVs transmitted by this port.

18 **RemoteWilling:** rwTrue indicates that the Willing bit was set in the last TLV received. rwFalse indicates  
19 that the Willing bit was not set in the last TLV received. This variable is set to rwNull if the remote LLDP  
20 database contains no Willing bit.

21 **LocalMAC:** The MAC address of the local port.

22 **RemoteMAC:** The MAC address of the remote port.

23 **OperParam:** The current operational value of the attribute on the local port. This value is included as the  
24 attribute in the DCBX TLV.

25 **RemoteParam:** Contains the value of the last attribute (i.e., the operational value of the remote port)  
26 received in the TLV. This variable is set to NULL if the remote LLDP database contains no TLV.

1 **LocalAdminParam:** The administratively configured value for the attribute. This becomes the operational  
2 value of the attribute by default, and may be overridden if the local port accepts the attribute from the remote  
3 port.

4 **DCBXMapping:** A function that maps the received parameters to the capabilities of the receiving port.

### 5 38.4.2.3 Symmetric state machine

6 The Symmetric state machine is depicted in Figure 38-2.

**Figure 38-2—Symmetric state machine**

7 NOTE—Through observation of the states and state variables it is possible to determine that the state machine is in the  
8 process of passing attributes. This knowledge may be useful for clients of DCBX. For example, a client may wish to  
9 delay use of the link while the DCBX state machine is in the process of passing and possibly setting attributes. A  
10 “Pending” indication indicating that the state machine is in this process may be created by the following equations:

11 Pending = RemoteParam == NULL  
12 || !LocalWilling && RemoteWilling == rwTrue && OperParam != RemoteParam;

## 1 39. Multiple I-SID Registration Protocol (MIRP)

2 MIRP defines an MRP application (10.1) that provides the ability to flush learned MAC Address Entries  
3 held in the FDB of an I-component on a per-I-SID basis. MIRP makes use of MRP Attribute Declaration  
4 (MAD) and MRP Attribute Propagation (MAP), which provide the common state machine descriptions and  
5 the common attribute propagation mechanisms defined for use in MRP-based applications. The MRP  
6 architecture, MAD, and MAP are defined in Clause 10.

7 In a PBBN, the assignment of S-VIDs and I-SIDs to VIPs is often fixed, and the overhead of signaling the  
8 creation of Dynamic VLAN Registration Entries among I-components is undesirable. It can nevertheless be  
9 necessary to signal the need to flush the I-components' FDBs of learned MAC address information. For  
10 example, one could configure a point-to-point service that is dual-homed (has two I-components) at each  
11 end of the service, only two of which (one at each end) are active at any one time. A failure that causes one  
12 I-component to take over from the other requires that the active I-component at the other end of the service  
13 forget its associations of C-MAC addresses to the failed I-component's B-MAC address. Therefore, the  
14 MIRP application supports the Registration Fixed (New propagated), instead of the Registration Fixed (New  
15 ignored), value in the Registrar Administrative Controls.

16 The function of MIRP can be performed by MVRP. However, in an I-component with one S-VID per VIP  
17 requires 4094 MVRPDUs, one for each VIP, to signal a simultaneous topology change on all 4094 S-VIDs,  
18 whereas it can signal those same topology changes with a single Multiple I-SID Registration Protocol Data  
19 Unit (MIRPDU) through the PIP.

### 20 39.1 MIRP overview

21 MIRP is an extension of MVRP (11.2) for use in I-components and B-components. The extensions in both  
22 I-components and B-components are as follows:

- 23 a) The attribute values carried by the MIRPDUs are 24-bit I-SID values, rather than 12-bit VIDs in an  
24 MVRPDU.
- 25 b) A MIRP Participant can only be a New-Only Participant (10.6), so the Registrar Administrative  
26 Controls can take only the value, Registration Fixed (New propagated).
- 27 c) MIRP uses the Nearest Customer Bridge group address (Table 8-1) or the Default Backbone  
28 Destination from the CBP's Backbone Service Instance table (6.11) instead of an MRP Application  
29 address from Table 10-1, so a Provider Bridge forwards frames containing MIRPDUs normally,  
30 while a Customer Bridge filters them.

31 In an I-component only, the extensions are as follows:

- 32 d) A VIP in an I-component can be attached to an MVRP Participant or to a MIRP Participant, but not  
33 to both.
- 34 e) An MVRP to MIRP attributes translation function (39.2.1.1) enables interoperability between the  
35 MVRP and MIRP Participants in the I-component.
- 36 f) There is only one MIRP Participant and one instance of the MIRP application per PIP.

37 In a B-component only, the extensions are as follows:

- 38 g) MIRP Participants are placed on zero or more CBPs, and on at most one non-CBP Port in the  
39 B-component.
- 40 h) MAP (10.3) operates among MIRP MAD components only, using 24-bit MIRP I-SID values.

41 Figure 39-1 illustrates the architecture of MVRP and MIRP in an I-component. The arrows showing the  
42 relationship between the MVRP or MIRP applications and the FDB in the MAC Relay Entity have been  
43 omitted from Figure 39-1, but these relationships are the same as those shown in Figure 11-1.

**Figure 39-1—Operation of MIRP in an I-component**

- <sup>1</sup> The architecture of MIRP in a B-component is illustrated in Figure 39-2. One management Port and one  
<sup>2</sup> CBP are shown, although any number of CBPs can be supported. (See 39.2.2 for an alternate model.)

**Figure 39-2—Operation of MIRP in a B-component**

### 1 39.1.1 Behavior of I-components

2 Since PBBs are insulated from C-MAC addresses by the I-TAG, MVRP Participants in I-components are  
3 peers of MVRP Participants in other I-components, and not with MVRP Participants attached to PNP in  
4 B-components or BCBs. In the case that an I-component is configured for some number of VIPs, each  
5 serving some number of VLANs, a single MIRPDU transmitted or received over the PIP takes the place of  
6 the individual MVRPDUs that would otherwise be transmitted or received over those VIPs.

7 An I-component supporting MIRP shall:

- 8 a) Implement the MIRP application as indicated in 39.2;
- 9 b) Implement an MVRP/MIRP attributes translation function as indicated in 39.2.1.1; and
- 10 c) Support operation only as an MRP New-Only Participant (10.6).

### 11 39.1.2 Behavior of B-components

12 As illustrated in Figure 39-2, there are any number of MIRP Participants in a B-component, each on a CBP,  
13 and each containing an instance of the MIRP application and a MIRP MAD, with the MADs interacting via  
14 MAP. In addition, at most one MIRP Participant is attached to a Port that is not a CBP. This port can be a  
15 PNP, or a Management Port with no attachment to an external LAN. The latter case is shown in Figure 39-2.

16 A B-component supporting MIRP shall:

- 17 a) Implement the MIRP application as indicated in 39.2; and
- 18 b) Support operation as an MRP New-Only Participant (10.6).

## 19 39.2 Definition of the MIRP application

### 20 39.2.1 Definition of MRP elements

#### 21 39.2.1.1 S-VID and I-SID mapping in an I-Component

22 MVRP MAP (11.2.1, 10.3) propagates information among the MVRP MADs and the MIRP MAD. But,  
23 since MVRP MADs support 12-bit VID values, and the MIRP MAD supports 24-bit I-SID values, a  
24 translation function is required to map the VIP-ISID to or from S-VIDs statically configured on the VIP.

- 25 c) When a “new” MIRP declaration is received on a given VIP as a result of receiving an MIRPDU  
26 from the attached LAN (MAD\_Join.indication), the MAD\_Join.request with the *new* parameter set  
27 that is generated by the MIRP MAD is translated to a MAD\_Join.request for each S-VLAN with a  
28 Static VLAN Registration Entry of Registration Fixed (New propagated) on that VIP. When any  
29 MIRP declaration with the *new* parameter is received on a given VIP as a result of a request from  
30 MAP (MAD\_Join.request) for any S-VLAN with a Static VLAN Registration Entry of Registration  
31 Fixed (New propagated) on that VIP, it is translated to a MAD\_Join.request for that VIP’s I-SID  
32 with the *new* parameter set. All other requests are discarded.

33 NOTE—If many S-VLANs are configured per VIP, then using an MVRP New-Only Participant (11.2.6) offers more  
34 detailed control of MAC address flushing than does MIRP, at some cost in bandwidth and processing effort.

#### 35 39.2.1.2 I-SID translation in a B-component

36 If a Backbone Service Instance table (6.11) on a CBP implements the Local Service Instance Identifier  
37 (Local-SID) field, the attribute values encoded in MIRPDUs by the MIRP Participants in CBPs shall be  
38 Local-SID values. The attribute values transferred by MAP in the B-component and encoded in MIRPDUs  
39 by the MIRP Participant on a non-CBP Port shall be Backbone-SID values.

### 1 39.2.1.3 MAP Context for MIRP

2 The MIRP MAP Context identifies the set of Ports that form the applicable topology for the propagation of  
3 the MIRPDUs among the MIRP Participants. Within a single I-component, the MIRP Participants on PIPs  
4 behave as independent end stations from an I-SID registration perspective and correspondingly there is no  
5 further propagation of the MIRPDUs. As described in 39.2.1.1, the S-VID/I-SID translation function allows  
6 the MIRP MADs to communicate with MVRP MADs. Thus, New messages can propagate throughout a  
7 concatenated network of PBNs (via MVRP) and PBBNs (via MIRP).

8 Within a single B-component, there may be multiple MIRP MAP Contexts. The reason for having separate  
9 MIRP MAP Contexts is to collect and distribute MIRP information bound for or received from MIRPDUs  
10 that use different combinations of B-VIDs and MAC addresses, as chosen by the network administrator via  
11 managed objects (12.16.1). A Port in a B-component supporting a MIRP Participant, either an  
12 administratively chosen PNP or Management Port, or a CBP, can participate in more than one MIRP  
13 Context. The Ports of a B-component comprising a given MIRP Context is a PNP or Management Port, plus  
14 the set of CBPs on the B-component for which the following are true:

- 15 a) The CBP is in the Member set (8.8.9) for the B-VID.
- 16 b) If the MIRPDU destination\_address for the CBP is the Default Backbone Destination address, the  
17 FDB does not filter that B-VID and MAC address on the Port.

18 In a B-component, the parameters controlling MIRPDU addressing (39.2.1.6) control the number of MIRP  
19 MAP Contexts as follows:

- 20 c) If a single destination\_address and B-VID are used for all MIRPDUs [item a) in 39.2.1.6] then there  
21 is a single MIRP MAP Context.
- 22 d) If the Nearest Customer Bridge group address (Table 8-1) used with a B-VID from a Backbone  
23 Service Instance table [item b) in 39.2.1.6], then there is a separate MIRP MAP Context for each  
24 B-VID that appears in the CBP Backbone Service Instance table (6.11) of any CBP with a  
25 configured MIRP Participant.
- 26 e) If the Default Backbone Destination option for the MIRPDU destination\_address is used [item c) in  
27 39.2.1.6], then there is a separate MIRP MAP Context for each combination of Default Backbone  
28 Destination and B-VID in the CBP Backbone Service Instance table (6.11) of any CBP with a  
29 configured MIRP Participant.

30 The MIRP Participant on a CBP propagates information for a particular I-SID between the CBP MIRP  
31 MAD and the appropriate MIRP MAP Context, as determined by the CBP's Backbone Service Instance  
32 table and the addressing selection parameters (39.2.1.6). Thus, a CBP MIRP MAD may exchange requests  
33 and indications with multiple MIRP MAP Contexts.

34 NOTE 1—MIRPDUs cannot pass through the CBP functions (6.11) because they have no I-TAG. Readers can see from  
35 Figure 39-2 and Figure 39-3 that this isolates the MIRPDUs exchanged among PNPs, Management Ports (and CBPs in  
36 Figure 39-3) over the backbone from the MIRPDUs exchanged over the various I-component-to-CBP links.

37 NOTE 2—See 39.2.2 for an alternate model for MIRP operation in a B-component and the MIRP MAP Context.

### 38 39.2.1.4 MAP Context identification for MIRP

39 In an I-component, there is only one MAP Context.

40 In a B-component, the vlan\_identifier and destination\_address of an MIRPDU received on a PNP or  
41 Management Port serve to identify the MIRP MAP Context as defined in 39.2.1.3. In a CBP, the MIRP MAP  
42 Context used to propagate information is determined by CBP Backbone Service Instance table (6.11) entry  
43 for each I-SID value propagated. An MIRPDU that corresponds to no MAP Context configured on the  
44 receiving B-component is discarded.

### 1 39.2.1.5 MIRP application addressing in an I-component

2 The source MAC address for an MIRPDU is the MAC address of the PIP.

3 The destination MAC address for an MIRPDU transmitted from a PIP shall be the Nearest Customer Bridge  
4 group address, (01-80-C2-00-00-00, see Table 8-1).

5 MIRPDUs transmitted and received on a PIP carry no VLAN tag and have no `vlan_identifier`.

6 NOTE—An MIRPDU transmitted by a PIP needs no B-TAG because it is connected to a CBP (see Figure 25-4) that  
7 either has an MIRP Participant to receive the untagged MIRPDU, or if not, discards the MIRPDU (39.2.1.3).

### 8 39.2.1.6 MIRP application addressing in a B-component

9 The source MAC address for an MIRPDU is the MAC address of the Port from which it is transmitted.

10 For a MIRP Participant attached to a CBP, the destination MAC address for an MIRPDU transmitted shall  
11 be the Nearest Customer Bridge group address, (01-80-C2-00-00-00, see Table 8-1). MIRPDUs shall be  
12 transmitted from a CBP without a VLAN tag.

13 For the MIRP Participant attached to a PNP or Management Port, there are three choices, selectable via  
14 managed variables [see item k) in 12.16.1.1.3], for the destination MAC address and B-VLAN on  
15 transmitted MIRPDUs:

- 16 a) The `destination_address` is the Nearest Customer Bridge group address (Table 8-1), and the  
17 `vlan_identifier` is the MIRP B-VID [item c) in 12.16.1.2.2].
- 18 b) The `destination_address` is the Nearest Customer Bridge group address (Table 8-1), and the  
19 `vlan_identifier` is a B-VID from the CBPs' Backbone Service Instance tables (6.11).
- 20 c) The `destination_address` is a Default Backbone Destination from the CBPs' Backbone Service  
21 Instance tables (6.11), and the `vlan_identifier` is a B-VID from those tables.

22 In case b) or case c), it is possible that different CBPs in the serving I-SIDs in the same MIRP MAP Context  
23 (39.2.1.3) can be configured differently. For each I-SID value's message in the MIRPDU, the MIRP  
24 Participant on the PNP or Management Port uses the Backbone Service Instance table from the CBP with the  
25 lowest numerical Port Number to determine the {`destination_address`, `vlan_identifier`} pair to use for that  
26 I-SID value.

27 A separate MIRPDU is transmitted for each separate MIRP MAP Context. If multiple {`destination_address`,  
28 `vlan_identifier`} pairs are generated by different I-SIDs within a single MIRP MAP Context, then the MIRP  
29 Participant shall transmit at least one MIRPDU for each distinct pair.

30 NOTE 1—The network administrator can use the `destination_address` and `vlan_identifier` configuration choice to  
31 optimize either for the fewest transmitted MIRPDUs by using case a), for the fewest unnecessarily addressed  
32 I-components by using case c), or for a balance of these two conflicting optimizations by using b).

33 NOTE 2—If different B-components in a single PBBN are configured differently for MIRP application addressing, then  
34 MIRPDUs can be lost or misinterpreted, because the different B-components can classify MIRPDUs in different MAP  
35 Contexts.

36 NOTE 3—See 39.2.2 for an alternate model for MIRP operation in a B-component and MIRPDU addressing.

### 37 39.2.1.7 MIRP application EtherType

38 The EtherType used for MIRPDUs shall be the MIRP EtherType identified in Table 10-2.

### 39 39.2.1.8 MIRP ProtocolVersion

40 The ProtocolVersion for the version of MIRP defined in this standard takes the hexadecimal value 0x00.

### 1 39.2.1.9 MIRP AttributeType definitions

2 MIRP defines a single Attribute Type (10.8.2.2) that is carried in MRP exchanges, as follows:

3 Attributes identified by the I-SID Vector Attribute Type are instances of VectorAttributes (10.8.1), used to  
4 identify a sequence of values of I-SIDs. The value of AttributeType used to identify the I-SID Vector  
5 Attribute Type in MRPDUs (10.8.2.2) shall be 1.

### 6 39.2.1.10 MIRP FirstValue definitions

7 The FirstValue field in instances of the I-SID Vector Attribute Type shall be encoded in MRPDUs (10.4) as  
8 three octets, taken to represent an unsigned binary number, and equal to the value of the VIP-ISID parameter  
9 for the VIP.

10 The range of permitted I-SID values that can be encoded in the FirstValue fields in MIRP is restricted to  
11 those not listed in Table 9-3.

### 12 39.2.1.11 Administrative controls

13 MIRP supports only the Registration Fixed (New propagated) value of the Registrar Administrative  
14 Controls (10.7.2) and this value cannot be manipulated by management. Therefore, the MRP Registrar  
15 Administrative Control (12.7.7.1, 12.7.7.2) can only take the value New propagated.

16 The provision of static control over the ability of Applicant state machines to participate in protocol  
17 exchanges is achieved by means of the Applicant Administrative Control parameters associated with the  
18 operation of MRP (10.7.3). Where management capability is implemented, the Applicant Administrative  
19 Control parameters can be applied and modified by means of the management functionality defined in 12.9.

20 The management controls in Clause 12 operate per Bridge Port, but a MIRP Participant is attached to a PIP,  
21 which is not a Bridge Port. Therefore, if MIRP is enabled on any VIP on a PIP, then the MIRP Participant is  
22 enabled on that PIP. If MIRP is disabled on all of the VIPs on a PIP, then the MIRP Participant on the PIP is  
23 disabled.

24 The choice of destination\_address and vlan\_identifier used in an MIRPDU from a B-component are made  
25 by an enumerated configuration parameter [item d) in 12.16.1.2.2] and a B-VLAN configuration parameter  
26 [item c) in 12.16.1.2.2].

### 27 39.2.2 Alternate MIRP model for B-components

28 An alternate model for the operation of MIRP in a B-component is illustrated in Figure 39-3. This model is  
29 perfectly interoperable with that presented in 39.2.1 and Figure 39-2, is indistinguishable in terms of  
30 required protocol behavior from that model, and thus can be used to implement MIRP. In this alternate  
31 model, there is a pair of communicating MIRP Participants in each CBP, separate from a similar pair in  
32 every other CBP, with no MIRP Participant on any PNP or management Port. The LAN-facing MIRP  
33 Participant (the right-hand MIRP Participant in Figure 39-3) corresponds to the CBP MIRP Participant  
34 described in 39.2.1. The Relay-facing MIRP Participant (the left-hand MIRP Participant in Figure 39-3) is  
35 attached to the EISS Connectivity (39.2.2.1). Its functions correspond to those of the MIRP Participant on a  
36 PNP or Management Port in 39.2.1 and Figure 39-2.

37 NOTE 1—Because the CBP functions (6.11) do not pass frames without I-TAGs, the Relay-facing MIRP Participant can  
38 exchange MRPDUs only through the MAC Relay Entity, and the LAN-facing MIRP Participant only through the LAN.

39 NOTE 2—The only difference between the models in Figure 39-2 and Figure 39-3 that is visible to an observer external to  
40 the B-component is that the alternate model can issue MRPDUs with different source\_address parameters, while the  
41 PNP model issues all MRPDUs with the same source\_address. Since MRP and MIRP make no use of that parameter,  
42 this difference does not affect the operation of the protocol.

### **1 39.2.2.1 EISS Connectivity**

4 Each EM\_UNITDATA.indication provided by the lower EISS access point (Figure 39-3) shall result in a  
5 corresponding EM\_UNITDATA.indication with identical parameters at each of the access points supporting  
6 the MAC Relay and Higher Layer Entities. (Only one such Higher Layer Entity is shown in Figure 39-3.)  
7 Each EM\_UNITDATA.request from the EISS access point supporting the MAC Relay Entity shall result in  
8 a corresponding EM\_UNITDATA.indication with identical parameters at each of the access points for the  
9 Higher Layer Entities, and a corresponding EM\_UNITDATA.request with identical parameters at the lower  
10 access point. Each EM\_UNITDATA.request from an ISS access point supporting a Higher Layer Entity  
11 shall result in a corresponding EM\_UNITDATA.indication with identical parameters at the access points for  
12 the MAC Relay Entity, and at other access points for Higher Layer Entities, and a corresponding  
13 EM\_UNITDATA.request with identical parameters at the access point for the LAN.

### 17 39.2.2.2 Alternate MIRP MAP Context

### 20 39.2.2.3 Alternate MIRPDU addressing

26 NOTE—The model in Figure 39-3 results in the CBPs communicating MIRP information via MIRPDUs, instead of via  
27 the MIRP MAP, as in Figure 39-2, and all of those MIRPDUs would be output to the rest of the PBBN, as well.

### 1 39.2.3 Use of “new” declaration capability

2 MIRP supports the Registration Fixed (New propagated) value for the Registrar Administrative Controls for  
3 a Port in a Static VLAN Registration Entry. MIRP will accept and propagate a New Message received on  
4 that Port for that VLAN and propagate it to all other Ports.

5 When any MIRP declaration marked as “new” is received on a given VIP, either as a result of receiving an  
6 MIRPDU from the attached LAN (MAD\_Join.indication), or as a result of receiving a request from the  
7 MAP (via the S-VID/I-SID translation function [39.2.1.1]) for the MIRP Application (MAD\_Join.request),  
8 any entries in the I-component’s FDB for that Port and for the VLANs corresponding to the attribute value in  
9 the MAD\_Join primitive are removed.

### 10 39.2.4 Attribute value support requirements

11 Implementations of MIRP shall be capable of supporting all attribute values in the range of possible values  
12 that can be registered using MIRP. An I-component shall be capable of maintaining current state information  
13 for at least 4094 attributes in the range of possible values. A CBP implementation shall support the full  
14 range of attribute values that are supported, in turn, by its Backbone Service Instance table.

### 15 39.2.5 MRP Message filtering

16 A MIRP Participant operates in Registration Fixed (New propagated) mode only. Therefore, any MIRP  
17 Message for an attribute that is not a VIP-ISID (for an I-component) or a Local-SID or Backbone-SID (for a  
18 CBP) is ignored by a MIRP Participant.

## 40. Edge Virtual Bridging (EVB)

Figure 40-1 provides an overview of the EVB architecture. An end station that supports the attachment of one or more virtual stations is said to be an EVB station. Each virtual station has at least one Virtual Station Interface (VSI). Each virtual station communicates with other virtual stations or other stations on the Bridged Network via the edge relay (ER) to which it is attached (see 3.85).

**Figure 40-1—EVB architecture overview**

An ER supports local relay among virtual stations and/or relay between a virtual station and other stations on the Bridged Network through an EVB Bridge. When forwarding of frames from one DRP to one or more other DRPs associated with the same ER (i.e., local relay) is not supported, then forwarding of traffic from one DRP to one or more other DRPs is performed by the EVB Bridge, utilizing reflective relay (8.6.1).

Connection between a DRP and a virtual station is achieved via a VSI. Traffic from a VSI traverses an internal LAN connecting the DRP to the virtual station. The operation of an ER does not result in any modifications to relayed frames over and above the normal tagging and untagging functions of a VLAN Bridge. ERs do not participate in, or affect, spanning tree operation; it is therefore necessary that the logical connectivity maintained within the station is always loop-free (5.24.1).

Figure 40-1 shows a 2-port ER within the EVB station; this illustrates the fact that even where a single VSI is supported by an S-channel, an ER is present in order to provide C-tagging, reserved address filtering (per Table 8-1) and support for the VSI Discovery and Configuration Protocol (VDP, Clause 41), the Edge Control Protocol (ECP), the EVB TLV (D.2.12), and LLDP (IEEE Std 802.1AB).

Each VSI instance is assigned a VSI manager ID, VSI Type Identifier (VTID), and VSI Instance Identifier (VSIID). VDP associates a VSI instance and its related VID(s), MAC address(es), GroupID(s), VSI manager ID, VTID,<sup>49</sup> and VSIID with an SBP. Similarly, VDP de-associates a VSI instance from an SBP.

VDP can also be used to associate a single VTID with, or de-associate a single VTID from the SBP. In this case, the VSI instance does not contain any MAC addresses, VIDs, or Group IDs, and uses the wildcard VID format (41.2.9.1). Only the most recent associate command is used to configure the VTID for the SBP.

<sup>49</sup> The meaning of the VTID is decided by local system and network management.

1 An ER supports relaying of frames associated with one or more VSIs. In order to achieve this, an ER can  
2 support two types of operation. In the first type, referred to as virtual edge bridge (VEB), traffic transferred  
3 from one DRP to another DRP of the same ER is forwarded directly by that ER. In the second type, referred  
4 to as VEPA, traffic transferred from one DRP to another DRP of the same ER is forwarded onto a single  
5 URP beyond the ER to the EVB Bridge. In this case, the EVB Bridge's SBP is enabled with reflective relay  
6 (40.4, 8.6.1); this allows the frame to be reflected back to the same ER from which it was received by the  
7 EVB Bridge. The ER can then forward the frame to the destination. Thus, in the second mode, all traffic  
8 transits the EVB Bridge's SBP and is subject to, for example, filtering or policing behavior associated with  
9 the EVB Bridge.

10 NOTE—Connection between an EVB Bridge and an ordinary end station takes place via a C-VLAN Bridge Port, not an  
11 SBP.

12 An S-channel is a point-to-point S-VLAN that spans a pair of Port-mapping S-VLAN components (22.6.4)  
13 and can be used to interconnect an ER and the C-VLAN component of an EVB Bridge. Multiple S-channels  
14 can share the use of a LAN. The use of multiple S-channels allows the EVB station to support multiple ERs.  
15 The endpoint of an S-channel is known as an S-channel Access Port (CAP); frames are S-tagged on entry to,  
16 and are untagged on exit from, the S-VLAN component through a CAP.

17 EVB TLVs (D.2.12) exchanged via LLDP allow an EVB station and an EVB Bridge to exchange  
18 information related to the use of reflective relay and other operational parameters. Each ER has an LLDP  
19 database at its URP. Each ER can also have an LLDP database at each DRP.

20 Each URP and each SBP has an instance of ECP (Clause 43) used to support the VDP. These instances of  
21 ECP use the Nearest Customer Bridge address as the destination for frames exchanged between the URP and  
22 SBP. VDP TLVs are packed into PDUs that are handed to ECP for delivery. ECP provides reliable delivery  
23 of VDP PDUs.

## 24 **40.1 EVB architecture without S-channels**

25 Figure 40-2 illustrates the relationship of the EVB entities to the Bridge architecture when no S-channels are  
26 supported and no Port-mapping S-VLAN components are implemented. In this configuration, the EVB  
27 station and EVB Bridge may exchange an S-channel Discovery and Configuration Protocol (CDCP) TLV  
28 over the Nearest non-TMPR Bridge address indicating that the S-VLAN component is not present. If the  
29 CDCP TLV managed object does not exist in the LLDP database, then the transmitting station or Bridge is  
30 assumed to not support S-channels. A URP or an SBP can send a CDCP TLV. If the EVB station supports  
31 the CDCP TLV then the nearest non-TMPR LLDP database is located at the URP. If the EVB Bridge  
32 supports the CDCP TLV then the nearest non-TMPR LLDP database is located at the SBP.

1

Figure 40-2—EVB architecture without S-channels

## 2 40.2 EVB architecture with S-channels

3 Figure 40-3 shows the relationship of the EVB entities to the Bridge architecture when S-channels are  
4 supported. In this configuration, the EVB station and Bridge build nearest non-TPMR LLDP databases at  
5 their Uplink Access Ports (UAPs) and use them to exchange CDCP TLVs. Both the EVB station and EVB  
6 Bridge set the SComp parameter in the CDCP TLV to TRUE indicating they have an S-VLAN component.  
7 The CDCP operating on the CDCP TLVs exchanged by LLDP is used to configure the S-channels.

Figure 40-3—EVB architecture with S-channel

1 EVB stations and EVB Bridges use Port-mapping S-VLAN components (5.6, 22.6.4) to instantiate S-  
2 channels. Each S-channel connects a CAP on the EVB station to a CAP on the EVB Bridge. The CAP on an  
3 EVB station connects to a single URP on an ER via an internal LAN. The CAP on an EVB Bridge connects  
4 to a single SBP on the C-VLAN component via an internal LAN. There is a 1:1 relationship between a CAP  
5 and an SBP of the EVB Bridge, and a 1:1 relationship between a CAP and a URP of the EVB station. S-  
6 channel support allows the EVB station and EVB Bridge to support multiple ERs on a LAN. Each S-channel  
7 is associated with the URP of a distinct ER.

8 Figure 40-4 shows the relationship between S-channels and CAPs and the positioning of a station's internal  
9 and external LANs. When S-channels are supported, each physical LAN can be used to support multiple S-  
10 channels identified on the LAN by S-tagging. The S-channels are supported by one Port-mapping S-VLAN  
11 component for each UAP. Each Port-mapping S-VLAN component within an EVB station can be identified  
12 by its single UAP. A CAP is uniquely identified by the combination of the UAP of the S-VLAN component  
13 and the S-VID of the S-channel. Each CAP attaches by internal C-tagged LANs to a single URP or SBP. The  
14 C-VLANs carried over each S-channel are determined by configuration of the EVB station and of the C-  
15 VLAN component within the EVB Bridge.

**Figure 40-4—EVB components and internal LANs with S-channels**

16 NOTE—As a result of normal Bridge behavior described in 6.9, the priority carried in the C-TAG is regenerated at the  
17 CAP to form the S-TAG priority.

18 The C-VLAN component of the EVB Bridge is a standard C-VLAN component (5.5) that additionally  
19 supports reflective relay (40.4, 8.6.1), the EVB LLDP TLV, and VDP.

1 When a UAP table entry (12.26.4.1) is created, a Port-mapping S-VLAN component is instantiated and the  
2 following actions are taken automatically:

- 3 a) The UAP is configured to perform as follows:
  - 4 1) Admit all frames (6.9).
  - 5 2) Have a PVID parameter equal to the default S-channel S-VID (6.9, 40.3).
  - 6 3) Be included in the member set for the default S-channel S-VID (8.8.10).
  - 7 4) Be a member of the untagged set for the default S-channel S-VID (8.8.2).
  - 8 5) Be included in the member set for all S-VIDs of active S-channels.
- 9 b) An S-channel Interface table entry is created if one does not already exist for the default S-channel.  
10 This table provides the equivalent functionality of the following:
  - 11 1) Creating a CAP for the default S-channel.
  - 12 2) Configuring the CAP to accept only un-S-tagged frames (6.9).
  - 13 3) Setting the member set for the default S-channel's S-VID to include the CAP.
  - 14 4) Setting the CAP's PVID to the default S-channel's S-VID.
  - 15 5) Adding the CAP to the default S-channel S-VID's untagged set.
  - 16 6) Setting filters on the CAP for the Nearest Bridge and Nearest non-TPMR Bridge group MAC  
17 addresses.
  - 18 7) In the case of an EVB Bridge allocating (or creating) an SBP on the C-VLAN component  
19 attached to the CAP by an internal LAN.
- 20 c) An instance of LLDP is started on the UAP transmitting a local database on the Nearest Non-TPMR  
21 Bridge Address and including the CDCP TLV.
- 22 d) CDCP is started on the UAP and configured with the parameters specified when the UAP was  
23 created.
  - 24 1) If the CDCP role is "B," then CDCP will wait for new S-channel creation requests. As new  
25 requests are found, CDCP creates new S-channel interface table entries for each new S-channel  
26 and deletes entries when S-channels are removed.
  - 27 2) If the CDCP role is "S," then CDCP uses the S-channel interface table to create the list of S-  
28 channel Identifiers (SCIDs) for the S-channels it is requesting from the "B" side.

### 29 **40.3 Asymmetric EVB architecture without S-channels**

30 Figure 40-5 and Figure 40-6 illustrate the relationship of the EVB entities to the Bridge architecture when  
31 S-channels are supported by only one side at a time; either the EVB Bridge or EVB station, but not both  
32 simultaneously. In these configurations, the EVB entity with S-channel support will advertise it has an  
33 S-VLAN component by building a nearest non-TPMR LLDP databases at its UAP and including the CDCP  
34 TLV with the parameter SComp set to TRUE. The EVB entity without S-channel support may advertise a  
35 Nearest non-TPMR Bridge LLDP database with the CDCP TLV indicating an SComp parameter set to  
36 FALSE. CDCP is assumed not to be supported by the peer EVB entity until a CDCP TLV has been received.

37 Each Port-mapping S-VLAN component within an EVB entity supports an internal default S-channel  
38 identified by S-VID 1 and uses it to pass untagged frames to its UAP. This default S-channel is always  
39 present in the entity supporting an S-VLAN component. In the asymmetric configurations, frames from the  
40 system without S-channel support are carried over the default S-channel within the system that has  
41 S-channel support.

1

Figure 40-5—EVB architecture without S-channels, with EVB Bridge S-VLAN component

2

Figure 40-6—EVB architecture without S-channels, with EVB station S-VLAN component

## 1 40.4 EVB status parameters

2 In EVB Bridges and EVB Stations, an **EVBMode** parameter is associated with each port that provides EVB  
3 functionality. The parameter represents the EVB status of the port.

4 The **EVBMode** parameter determines whether EVB functionality is supported, and in what mode. The  
5 parameter can take one of the following values:

- 6 a) **EVB Bridge.** The port supports the functionality of an EVB Bridge.
- 7 b) **EVB station.** The port supports the functionality of an EVB station.
- 8 c) **Not Supported.** The port does not support EVB functionality. This value is assumed if the EVB  
9 status parameters are not implemented.
- 10 d) **NVO3 Mode.** The port supports the revised EVB functionality to be used in an NVO3 Split-NVE  
11 scenario.

### 12 40.4.1 EVBMode = Not supported

13 If the value of the **EVBMode** parameter is **Not Supported**, then no further status parameters are available,  
14 EVB functionality is not supported, and the operation of the service associated with the port follows the  
15 normal forwarding rules for a Bridge.

### 16 40.4.2 EVBMode = EVB Bridge

17 If the value of the **EVBMode** parameter is **EVB Bridge**, then further parameters are available, as follows:

- 18 a) **reflectiveRelayCapable.** If this parameter is TRUE, then the active topology enforcement function  
19 is capable of performing reflective relay, as specified in 8.6.1; if FALSE, the active topology  
20 enforcement function is not capable of performing reflective relay.

21 NOTE 1—The value of the reflectiveRelayCapable parameter is an inherent property of the implementation  
22 and is not subject to administrative control.

- 23 b) **operReflectiveRelayControl.** If this parameter is TRUE, then reflective relay is enabled; if FALSE,  
24 reflective relay is disabled.

25 NOTE 2—Reflective relay is enabled if a remote EVB station has requested that it be provided (as determined  
26 by protocol exchanges between the EVB station and EVB Bridge) and the EVB Bridge is capable of providing  
27 it, or disabled if the EVB station has not requested that it be provided or the EVB Bridge is not capable of  
28 providing it.

### 29 40.4.3 EVBMode = EVB station

30 If the value of the **EVBMode** parameter is **EVB station**, then further parameters are available, as follows:

- 31 a) **adminReflectiveRelayRequest.** This parameter can take one of two values:
  - 32 1) **TRUE.** The attached EVB Bridge is requested to enable Reflective relay.
  - 33 2) **FALSE.** The attached EVB Bridge is requested to disable Reflective relay.

34 NOTE 1—The value of adminReflectiveRelayRequest is used in the EVB TLV exchanges described in D.2.12  
35 to indicate to an attached EVB Bridge that the EVB station needs reflective relay to be provided. A given EVB  
36 station is not required to support both possible values of adminReflectiveRelayRequest.

- 37 b) **operReflectiveRelayStatus.** This parameter can take one of three values:
  - 38 1) **TRUE.** The EVB Bridge has enabled reflective relay.
  - 39 2) **FALSE.** The EVB Bridge has disabled reflective relay.
  - 40 3) **Unknown.** It is not known whether the EVB Bridge has enabled reflective relay.

41 NOTE 2—The value of operReflectiveRelayStatus indicates whether the EVB Bridge has enabled reflective  
42 relay, or whether the EVB Bridge status is not currently known, as determined by protocol exchanges between  
43 the EVB station and EVB Bridge. The EVB Bridge status can be unknown during initialization or until the  
44 protocol exchanges have completed.

#### 1 40.4.4 EVBMode = NVO3 Mode

2 If the value of the **EVBMode** parameter is **NVO3 Mode**, then further parameters are available in 40.5.

### 3 40.5 EVB Status Parameter for NVO3 Mode Support

4 In an NVO3 Split-NVE scenario, tNVE is located in a station that may not be an EVB Station and nNVE is  
5 located in a bridge or router that may not be an EVB Bridge. Hence tNVE and nNVE will be used to refer to  
6 EVB Station and EVB Bridge revised to support NVO3.

7 The parameters of the EVB TLV provide the required parameter list. EVB TLV (Annex D) and status  
8 parameters are amended to support NVO3.

9 When **EVBMode** is set to **NVO3 Mode**, an **NVERole** parameter is to be further inspected. The parameter  
10 represents the NVE role of the port.

#### 11 40.5.1 NVERole = nNVE

12 If the value of the **NVERole** parameter is **nNVE**, then further parameters are available, as follows:

13 a) **reflectiveRelayCapable**. This parameter is FALSE in NVO3 as tNVE has no requirement to  
14 support reflective relay.

15 NOTE 1—The value of the reflectiveRelayCapable parameter is an inherent property of the implementation  
16 and is not subject to administrative control.

17 b) **operReflectiveRelayControl**. If this parameter is TRUE, then reflective relay is enabled; if FALSE,  
18 reflective relay is disabled. In an NVO3 scenario, it is always FALSE since tNVE will not request  
19 reflective relay to be enabled.

20 NOTE 2—Reflective relay is enabled if a remote EVB station has requested that it be provided (as determined  
21 by protocol exchanges between the EVB station and EVB Bridge) and the EVB Bridge is capable of providing  
22 it, or disabled if the EVB station has not requested that it be provided or the EVB Bridge is not capable of  
23 providing it.

24 c) **BGID**. This parameter is set to TRUE, which indicates that the nNVE wishes to control VID  
25 assignments and use the GroupID in VDP exchanges.

26 NOTE 3—GroupID in VDP is equivalent to VNI ID in NVO3, which is a mandatory parameter to be supported.  
27 Both bridge and station sides support it.

#### 28 40.5.2 NVERole = tNVE

29 If the value of the **EVBMode** parameter is **tNVE**, then further parameters are available, as follows:

30 a) **adminReflectiveRelayRequest**. This parameter is set to FALSE, which indicates the attached  
31 nNVE is requested to disable reflective relay.

32 b) **operReflectiveRelayStatus**. This parameter can be FALSE or Unknown.

33 NOTE 1—The value of operReflectiveRelayStatus indicates whether the nNVE has enabled reflective relay, or  
34 whether the nNVE status is not currently known, as determined by protocol exchanges between the tNVE and  
35 nNVE. The nNVE status can be unknown during initialization or until the protocol exchanges have completed.  
36 However The nNVE status cannot be reflective relay enabled.

37 c) **SGID**. This parameter is set to TRUE, which indicates that the tNVE can support the use of the  
38 GroupID.

39 NOTE 2—GroupID in VDP is equivalent to VNI ID in NVO3, which is a mandatory parameter to be supported.  
40 Both bridge and station sides should support it.

## 41. VSI Discovery and Configuration Protocol (VDP)

VDP associates (registers) a VSI instance with an Station-facing Bridge Port (SBP) of an EVB Bridge. VDP simplifies and automates virtual station configuration by enabling the movement of a VSI instance (and its related VSI Type information) from one virtual station to another or from one EVB Bridge to another. VDP supports VSI discovery and configuration across a channel interconnecting an EVB station and an EVB Bridge. VDP TLVs are exchanged between the station and the Bridge in support of this protocol.

This clause defines the VDP TLV structure and state machines.

When VDP is used between EVB Station and EVB Bridge, VDP uses ECP (Clause 43) as a transport protocol for VDP TLV exchanges. When ECP is used as a transport protocol for VDP, ECP uses the Nearest Customer Bridge group MAC address (Table 8-1) as the destination address for ECPDUs. Three VDP TLVs are defined as follows:

- a) The VSI manager ID TLV (41.1). There is a single instance of this TLV in any ECPDU that carries VDP, and it appears as the first TLV in the ECPDU.
- b) The VDP association TLV (41.2). One or more of these TLVs can appear in any ECPDU, following the VSI manager ID TLV.
- c) The organizationally defined TLV (41.3).

NOTE 1—If there are multiple VSI managers, then their TLVs are transmitted in separate ECPDUs.

NOTE 2—Beyond the requirement stated, that the VSI manager ID TLV appears as the first TLV in ECPDUs carrying VDP, there are no further constraints placed upon how an implementation chooses to pack VDP TLVs into an ECPDU.

NOTE 3—VDP TLVs are not LLDP TLVs, and the TLV type values used in VDP TLVs are assigned from a distinct number space from those used in LLDP TLVs.

When VDP is used between tNVE and nNVE in an NVO3 Split-NVE scenario, VDP may use ECP (Clause 43) as a transport protocol for VDP TLV exchanges. When ECP is used as a transport protocol for VDP in NVO3, ECP uses a specific unicast MAC address or the Nearest Customer Bridge group MAC address (Table 8-1) as the destination address for ECPDUs. The VDP TLVs used between a tNVE and nNVE are as follows:

- d) The VDP association TLV (41.2). One or more of these TLVs can appear in any ECPDU or other transport protocol.
- e) The organizationally defined TLV (41.3).

### 41.1 VSI manager ID TLV definition

Figure 41-1 illustrates the format of the VSI manager ID TLV.

**Figure 41-1—VSI manager ID TLV**

The VSI manager ID TLV field definitions are contained in 41.1.1 through 41.1.3.

### 41.1.1 TLV type

The TLV type field takes the value shown in Table 41-1 for VSI manager ID.

**Table 41-1—VDP TLV types**

| TLV type                                | Value           |
|-----------------------------------------|-----------------|
| Pre-Associate                           | 0x01            |
| Pre-Associate with resource reservation | 0x02            |
| Associate                               | 0x03            |
| De-associate                            | 0x04            |
| VSI manager ID                          | 0x05            |
| Organizationally defined TLV            | 0x7F            |
| Reserved for future standardization     | 0x00, 0x06–0x7E |

### 41.1.2 TLV information string length

This field contains the length of the TLV information string, which is 16 octets.

### 41.1.3 VSI Manager ID

Identifies the database that should be accessed to get the VSI Type. The value 0 means that the station does not know what VSI Manager ID to use, indicating that the Bridge should select a default value. Any other value is interpreted as an IPv6 address, as defined in IETF RFC 4291.

## 41.2 VDP association TLV definitions

Figure 41-2 illustrates the format of the VDP association TLV.

**Figure 41-2—VDP association TLV**

The VDP association TLV field definitions are contained in 41.2.1 through 41.2.9. The semantics of the VDP association TLV types are defined in 41.2.10.

When the VDP association TLV is sent as a response, the Status field indicates the outcome of the requested operation, and the remaining fields are populated using the information provided in the request or information provided by the EVB Bridge.

### 41.2.1 TLV type

The TLV type field identifies the type of the VDP association TLV, and can take any of the values shown in Table 41-1 for pre-associate, pre-associate with resource reservation, associate, or de-associate.

### 41.2.2 TLV information string length

This field contains the length of the TLV information string, calculated as  $23 + M$  octets, where  $M$  is the number of octets in the filter info field (41.2.9).

### 41.2.3 Status

The Status field contains a 4-bit error type, encoded in bits 1–4, and four individual Boolean flags, encoded in bits 5–8.

For all requests, the error type field is reserved for future standardization; it is transmitted as 0x0 and is ignored on receipt.

For all requests, the Boolean flags are interpreted as shown in Table 41-2.

**Table 41-2—Flag values in VDP requests**

| Name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Bit position | Interpretation                                                                                                                                                                                                                                                                                                                                        |       |       |                |   |   |                                                     |   |   |                                                              |   |   |                                                          |   |   |          |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------|----------------|---|---|-----------------------------------------------------|---|---|--------------------------------------------------------------|---|---|----------------------------------------------------------|---|---|----------|
| M-bit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Bit 5        | Indicates that the user of the VSI (e.g., the virtual station) is migrating (M-bit = 1) or provides no guidance on the migration of the user of the VSI (M-bit = 0). The M-bit is used as an indicator relative to the VSI to which the user is migrating.                                                                                            |       |       |                |   |   |                                                     |   |   |                                                              |   |   |                                                          |   |   |          |
| S-bit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Bit 6        | Indicates that the VSI user (e.g., the virtual station) is suspended (S-bit = 1) or provides no guidance about whether the user of the VSI is suspended (S-bit = 0). A keep-alive Associate request with S-bit = 1 can be sent when the VSI user is suspended. The S-bit is used as an indicator relative to the VSI that the user is migrating from. |       |       |                |   |   |                                                     |   |   |                                                              |   |   |                                                          |   |   |          |
| Req/Ack                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Bit 7        | Set to 0 to indicate that the TLV contains a request.                                                                                                                                                                                                                                                                                                 |       |       |                |   |   |                                                     |   |   |                                                              |   |   |                                                          |   |   |          |

| 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 1            | Reserved                                                                                                                                                                                                                                                                                                                                              |       |       |                |   |   |                                                     |   |   |                                                              |   |   |                                                          |   |   |          |

For all responses, the value of the error type indicates the outcome of the request, as shown in Table 41-3, and the Boolean flags are interpreted as shown in Table 41-4.

**Table 41-3—Error types in VDP responses**

| Name                                                                                                               | Value   | Interpretation                                                                        |
|--------------------------------------------------------------------------------------------------------------------|---------|---------------------------------------------------------------------------------------|
| Success                                                                                                            | 0x0     | The VDP Request was successfully completed by the Bridge.                             |
| Invalid Format                                                                                                     | 0x1     | The VDP TLV format is invalid.                                                        |
| Insufficient Resources                                                                                             | 0x2     | The Bridge does not have enough resources to complete the VDP operation successfully. |
| Unable to contact VSI manager                                                                                      | 0x3     | The Bridge was unable to contact the VSI manager.                                     |
| Other failure                                                                                                      | 0x4     | The operation failed for some other reason.                                           |
| Invalid VID, GroupID, or MAC address                                                                               | 0x5     | The operation failed because the VID, GroupID, or MAC address was invalid.            |
| Reserved                                                                                                           | 0x6–0xF | Reserved for future standardization.                                                  |
| NOTE—“Success” is only interpreted as success by the state machines if all of the flag bits (Table 41-4) are zero. |         |                                                                                       |

**Table 41-4—Flag values in VDP responses**

| Name       | Bit position | Interpretation                                                                                                               |
|------------|--------------|------------------------------------------------------------------------------------------------------------------------------|
| Hard error | Bit 5        | Set to 1 to indicate that the operation failed, and if the same operation is re-tried, it is likely to fail in the same way. |
| Keep       | Bit 6        | Set to 1 to indicate that the command was rejected and the state prior to the requested command has been kept.               |
| Req/Ack    | Bit 7        | Set to 1 to indicate that the TLV contains a response.                                                                       |
| Reserved   | Bit 8        | Reserved for future standardization.                                                                                         |

#### 1 41.2.4 VSI Type ID (VTID)

2 The VTID is an integer value used to identify a VSI Type.

3 NOTE—One VTID could describe the VSI Type configuration of multiple VSIs. A VTID is only unique per VSI  
4 manager ID.

#### 5 41.2.5 VSI Type Version

6 The VSI Type Version is an integer identifier that allows a VSI Manager Database to contain multiple  
7 versions of a given VSI Type.

#### 8 41.2.6 VSIID format

9 The VSIID format field defines the format of the VSIID field that follows it (41.2.7). The possible values of  
10 VSIID format are as shown in Table 41-5.

**Table 41-5—VSIID format values**

| Name     | Description                                                                      | Value                      |
|----------|----------------------------------------------------------------------------------|----------------------------|
| IPv4     | An IPv4 address, encoded as specified in IETF RFC 4291.                          | 0x01                       |
| IPv6     | An IPv6 address, encoded as specified in IETF RFC 4291.                          | 0x02                       |
| MAC      | An IEEE 802 MAC address (6 octets), with 10 leading octets containing all zeros. | 0x03                       |
| Local    | The interpretation of the VSIID is locally defined.                              | 0x04                       |
| UUID     | A Universally Unique Identifier (UUID) as specified in IETF RFC 4122.            | 0x05                       |
| Reserved | Reserved for future standardization.                                             | 0x00,<br>0x06 through 0xFF |

#### 1 41.2.7 VSIID

2 The VSIID is an identifier for the VSI instance. A VSIID is generated when a VSI instance is created. The  
3 VSIID remains constant during virtual station migration. The format of the VSIID is determined by the  
4 VSIID format field (41.2.6). In cases where the format uses an identifier value that has fewer than 16 octets,  
5 the VSIID field is packed out to 16 octets with leading octets containing zeros.

#### 6 41.2.8 Filter Info format

7 The Filter Info format field determines the format of the Filter Info field (41.2.9). The Filter Info formats  
8 defined by this standard are shown in Table 41-6.

**Table 41-6—Filter Info format values**

| Format                              | Value                   |
|-------------------------------------|-------------------------|
| VID (41.2.9.1)                      | 0x01                    |

## 1 41.2.9 Filter Info field

2 The Filter Info field contains information from which a filter can be constructed. The filter is a set of VID  
3 values or a set of MAC/VID values. The MAC address in a MAC/VID value is an individual MAC address.  
4 The filter is applied to traffic transiting ports that do not have direct knowledge of the associated VSI, such  
5 as an EVB SBP, in order to identify the traffic associated with a particular VSI. This allows such ports to  
6 apply a VSI Type to the traffic of an individual VSI. Other devices that have direct knowledge of the traffic  
7 associated with a VSI, for example devices that form a 1:1 relationship between a port and VSI, simply  
8 provide this information via management interfaces.

9 The Filter Info field can also contain information that is not part of the filter. In particular, the Filter Info  
10 field can contain GroupID values. Like the VID, the GroupID identifies a VLAN. When the number of  
11 VLANs in the network is less than 4095, each VLAN can be assigned a VID value that is global within the  
12 network. When the number of VLANs in the network exceeds 4094, a globally-scoped VID can no longer be  
13 used to uniquely identify each VLAN. Instead, overlapping VIDs may be used in different regions of the  
14 network, and a per-region mapping between the global VLAN and the region-specific VID is maintained. In  
15 this case, the VLAN is uniquely and globally identified by a GroupID.

16 When VLANs are identified by GroupID, the station has knowledge of the GroupID but it does not, in  
17 general, know the corresponding VID to be used by traffic associated with the VLAN. The Bridge is aware  
18 of, or can obtain knowledge of, the VID associated with the specified GroupID. Thus, the station can send  
19 GroupID values to the Bridge via the Filter Info field of the VDP Request. The Bridge can map GroupID  
20 values to local VID values. The VID is included in the filter constructed by the Bridge and is returned with  
21 its corresponding GroupID to the station via the VDP Response.

22 In the NVO3 Split-NVE scenario, the VNI ID is carried in the lower 3 octets of the GroupID. The upper octet of the  
23 GroupID should be all zeros.

24 NOTE 1—The mechanism by which the EVB Bridge determines the GroupID to local VID associations is outside the  
25 scope of this standard.

26 Additionally, the Filter Info field of a VDP TLV in a VDP Response can specify a Priority Code Point (PCP)  
27 value associated with any, or all, of the VID values carried by that VDP Response. The PCP value, if  
28 specified, is used by the EVB station as the default PCP value associated with the VSI and VID. The Filter  
29 Info field contains a PCP Significant (PS) bit associated with each PCP field, indicating whether the PCP  
30 field carries a PCP value (binary 1) or does not carry a PCP value (binary 0). If the PCP field carries a PCP  
31 value, then the EVB station can adopt that value as the default PCP value associated with the VSI and VID.  
32 When sending data frames associated with a given VSI and VID, the EVB station can determine the PCP  
33 value associated with each frame by using an algorithm local to the EVB station. For example, the PCP  
34 value can be based on the identity of an application associated with the frame as determined by examining  
35 higher layer information. For any given frame, it is possible that the algorithm does not provide a specific  
36 value of PCP. In such cases, the PCP field is assigned the value of the default PCP associated with the VSI  
37 and VID.

38 NOTE 2—Specification of a PCP value in the VDP Response does not imply that all frames sent by the EVB station,  
39 associated with the VSI and VID, carry the specified PCP. It implies only that, if the EVB station has no other  
40 information regarding the PCP value that should appear in that particular frame, then the specified default PCP value is  
41 used.

### 1 41.2.9.1 VID Filter Info format

2 The VID Filter Info format specifies that the Format Info field contains a set of VID values to be associated  
3 with the VSI instance (41.2.7). Figure 41-3 illustrates the VID Filter Info format.

**Figure 41-3—VID Filter Info format**

4 The number of VID values in the sequence is specified by the Number of entries field.

5 The VID field can specify the null VID (see Table 9-2). When the null VID is specified, it is the only VID  
6 specified in the Filter Info field (i.e., the Number of entries field is assigned the value 0x0001). Use of the  
7 null VID indicates that the set of VID values associated with the VSI is supplied by the Bridge. The Bridge  
8 can obtain VID values from the VSI Type whose identity is specified by the VSI Type information in the  
9 VDP Request. The set of VID values is returned to the station via the VDP Response.

10 NOTE—In the case that more than one VID is assigned, the policy that determines how the VIDs are used is outside the  
11 scope of this standard.

12 The Filter Info field can specify the wildcard VID (see Table 9-2). When the wildcard VID is specified, it is  
13 the only VID specified in the Filter Info field (i.e., the Number of entries field is assigned the value 0x0001).  
14 Use of the wildcard VID value indicates that the VSI Type specified by the VDP Request is designated as  
15 the channel VSI Type applied to the EVB SBP associated with the S-channel.

### 16 41.2.9.2 MAC/VID Filter Info format

17 The MAC/VID Filter Info format indicates that the Format Info field specifies a sequence of MAC/VID  
18 value pairs to be associated with the VSI instance (41.2.7). Figure 41-4 illustrates the MAC/VID Filter Info  
19 format of the Filter Info field.

**Figure 41-4—MAC/VID filter format**

20 The number of MAC/VID pair values is specified by the field Number of Filter Info entries. Each MAC/  
21 VID pair value carries a 6-octet individual MAC address and a 2-octet VID value.

22 The Filter Info field can specify the null VID for any entry. Use of the null VID indicates that the VID value  
23 is supplied by the Bridge.

### 24 41.2.9.3 GroupID/VID Filter Info format

25 The GroupID/VID Filter Info format indicates that the Format Info field specifies a sequence of GroupID/  
26 VID pairs to be associated with the VSI instance (41.2.7).

27 Figure 41-5 illustrates the GroupID/VID Filter Info format of the Filter Info field.

**Figure 41-5—GroupID/VID filter format**

1 The number of GroupID/VID pairs is specified by the Number of entries field.

2 The null VID (see Table 9-2) can be used in a GroupID/VID pair when the GroupID/VID filter format is  
3 specified in the VDP Request. In this case, the Bridge is expected to supply the corresponding local VID  
4 value in the VDP Response. For this purpose, the Bridge maintains, or has access to, the mapping between  
5 GroupID and local VID.

#### 6 41.2.9.4 GroupID/MAC/VID Filter Info format

7 The GroupID/MAC/VID Filter Info format indicates that the Filter Info field specifies a sequence of  
8 GroupID/MAC/VID triples to be associated with the VSI instance (41.2.7). Figure 41-6 illustrates the  
9 GroupID/MAC/VID Filter Info format of the Filter Info field.

**Figure 41-6—GroupID/MAC/VID filter format**

10 The number of GroupID/MAC/VID triples is specified by the value of the Number of entries field. The null  
11 VID (see Table 9-2) can be used in a GroupID/MAC/VID triple when the GroupID/MAC/VID filter format  
12 is specified in the VDP Request. In this case, the Bridge is expected to supply the corresponding local VID  
13 value in the VDP Response. For this purpose, the Bridge maintains, or has access to, the mapping between  
14 GroupID and local VID.

#### 15 41.2.9.5 GroupID/VID/IPv4 Filter Info format

16 The GroupID/VID/IPv4 Filter Info format indicates that the Format Info field specifies a sequence of  
17 GroupID/VID/IPv4 triples to be associated with the VSI instance (41.2.7).

18 Figure 41-7 illustrates the GroupID/VID/IPv4 Filter Info format of the Filter Info field.

**Figure 41-7—GroupID/VID/IPv4 filter format**

1 The number of GroupID/VID/IPv4 triples is specified by the Number of entries field.

2 The null VID (see Table 9-2) can be used in a GroupID/VID/IPv4 triple when the GroupID/VID/IPv4 filter  
3 format is specified in the VDP Request. In this case, the Bridge is expected to supply the corresponding local  
4 VID value in the VDP Response. For this purpose, the Bridge maintains, or has access to, the mapping  
5 between GroupID and local VID.

#### 6 41.2.9.6 GroupID/MAC/VID/IPv4 Filter Info format

7 The GroupID/MAC/VID/IPv4 Filter Info format indicates that the Format Info field specifies a sequence of  
8 GroupID/MAC/VID/IPv4 values to be associated with the VSI instance (41.2.7).

9 Figure 41-8 illustrates the GroupID/MAC/VID/IPv4 Filter Info format of the Filter Info field.

**Figure 41-8—GroupID/MAC/VID/IPv4 filter format**

10 The number of GroupID/MAC/VID/IPv4 values is specified by the Number of entries field. The null VID  
11 (see Table 9-2) can be used in a GroupID/MAC/VID/IPv4 value when the GroupID/MAC/VID/IPv4 filter  
12 format is specified in the VDP Request. In this case, the Bridge is expected to supply the corresponding local  
13 VID value in the VDP Response. For this purpose, the Bridge maintains, or has access to, the mapping  
14 between GroupID and local VID.

#### 15 41.2.9.7 GroupID/VID/IPv6 Filter Info format

16 The GroupID/VID/IPv6 Filter Info format indicates that the Format Info field specifies a sequence of  
17 GroupID/VID/IPv6 triples to be associated with the VSI instance (41.2.7).

18 Figure 41-9 illustrates the GroupID/VID/IPv6 Filter Info format of the Filter Info field.

**Figure 41-9—GroupID/VID/IPv6 filter format**

19 The number of GroupID/VID/IPv6 triples is specified by the Number of entries field.

20 The null VID (see Table 9-2) can be used in a GroupID/VID/IPv6 triple when the GroupID/VID/IPv6 filter  
21 format is specified in the VDP Request. In this case, the Bridge is expected to supply the corresponding local  
22 VID value in the VDP Response. For this purpose, the Bridge maintains, or has access to, the mapping  
23 between GroupID and local VID.

#### 1 41.2.9.8 GroupID/MAC/VID/IPv6 Filter Info format

2 The GroupID/MAC/VID/IPv6 Filter Info format indicates that the Format Info field specifies a sequence of  
3 GroupID/MAC/VID/IPv6 values to be associated with the VSI instance (41.2.7).

4 Figure 41-10 illustrates the GroupID/MAC/VID/IPv6 Filter Info format of the Filter Info field.

**Figure 41-10—GroupID/MAC/VID/IPv6 filter format**

5 The number of GroupID/MAC/VID/IPv6 values is specified by the Number of entries field. The null VID  
6 (see Table 9-2) can be used in a GroupID/MAC/VID/IPv6 value when the GroupID/MAC/VID/IPv6 filter  
7 format is specified in the VDP Request. In this case, the Bridge is expected to supply the corresponding local  
8 VID value in the VDP Response. For this purpose, the Bridge maintains, or has access to, the mapping  
9 between GroupID and local VID.

#### 10 41.2.10 VDP TLV type and status semantics

11 The following subclauses define the semantics associated with each VDP TLV type.

##### 12 41.2.10.1 Pre-Associate

13 The Pre-Associate TLV type is used to pre-associate a VSI instance with a Bridge Port. The Bridge validates  
14 the request (see below) and returns a failure Status in case of errors. Successful pre-association does not  
15 imply that the VSI Type will be applied to any traffic flowing through the VSI. The pre-associate enables  
16 faster response to an associate by allowing the Bridge to obtain the VSI Type prior to an association.

17 The station can send a Pre-Associate TLV to roll back the station and bridge from associated to pre-associate  
18 status.

19 NOTE—If the VSI Type changes without a corresponding change to its version, then inconsistent behavior can result.

##### 20 41.2.10.2 Pre-Associate with Resource Reservation

21 Pre-Associate with Resource Reservation involves the same steps as Pre-Associate (41.2.10.1), but on  
22 successful pre-association also reserves resources in the Bridge to prepare for a subsequent Associate  
23 request.

24 The station can send Pre-Associate with a Resource Reservation TLV to roll back the station and bridge  
25 from associated to pre-associate with Resource Reservation status.

##### 26 41.2.10.3 Associate

27 The Associate TLV Type creates and activates an association between a VSI instance and a Bridge Port. The  
28 Bridge allocates any required Bridge resources for the referenced VSI. The Bridge activates the  
29 configuration for the VTID. This association is then applied to the traffic flow to/from the VSI instance.

30 NOTE—~~This standard does not specify how~~ ~~The mechanism used by~~ a Bridge to determine the required resources  
31 ~~associated with a VTID is outside the scope of this standard.~~

1 For a given VSIIID, a station may issue an Associate without having previously issued a Pre-Associate or  
2 Pre-Associate with Resource Reservation. During normal operations a VSI instance is associated on only  
3 one port. During network transitions (e.g., virtual station migration) a VSI instance might be associated with  
4 more than one port.

5 If a Pre-Associate or a Pre-Associate with Resource Reservation had previously been received for a given  
6 VSI instance, the Bridge establishes the association and allocates resources based only on the information  
7 contained in the Associate TLV. Any resources that had been reserved in order to satisfy a previous Pre-  
8 Associate with Resource Reservation, and that are not required in order to establish the association as  
9 specified in the Associate, are released.

#### 10 41.2.10.4 De-Associate

11 The de-associate TLV Type is used to remove an association between a VSI instance and a Bridge Port. Pre-  
12 Associated and Associated VSIs can be de-associated. De-associate releases any resources that were  
13 reserved as a result of prior Associate or Pre-Associate operations for that VSI instance.

14 A de-associate can be initiated either by the station or the Bridge. In the latter case, the Bridge sends a de-  
15 associate TLV as if it was a response to a request from the station.

16 NOTE 1—A Bridge could, for example, issue a de-associate as a consequence of changes in the Bridge’s status or  
17 configuration.

18 NOTE 2—The result of the above semantics is that a de-associate can be initiated at any time and by either party.

### 19 41.3 Organizationally defined TLV definitions

20 Figure 41-11 illustrates the format of the organizationally defined TLV.

**Figure 41-11—Organizationally defined TLV**

21 The organizationally defined TLV field definitions are contained in 41.3.3 and 41.3.4.

#### 22 41.3.1 TLV type

23 The TLV type field takes the value shown in Table 41-1 for the organizationally defined TLV.

#### 24 41.3.2 TLV information string length

25 This field contains the length of the TLV information string, which is 3 + N octets, where N is the number of  
26 octets in the organizationally defined information field (41.3.4).

#### 27 41.3.3 Organizationally unique identifier (OUI) or Company ID (CID)

28 Identifies the organization that is responsible for defining the content of the organizationally defined  
29 information field (41.3.4). The value of the OUI/CID field is an OUI (see IEEE Std 802) or a CID assigned  
30 to that organization by the IEEE registration authority.

#### 1 **41.3.4 Organizationally defined information**

2 The content and interpretation of this field is specified by the organization that owns the OUI or CID value  
3 contained in the OUI/CID field (41.3.3).

#### 4 **41.4 Validation rules for VDP TLVs**

5 The following rules apply to the validation of received ECPDUs that carry VDP TLVs:

- 6 a) If the first TLV in the ECPDU is not a VSI manager ID TLV (41.1), then the entire ECPDU is  
7 discarded without further processing.
- 8 b) If the ECPDU contains a TLV of a type that is not recognized by the implementation, then that TLV  
9 is discarded and is ignored by the VDP state machines.
- 10 c) If a TLV extends past the physical end of the ECPDU, then that TLV is discarded.

#### 11 **41.5 VDP state machines**

12 The station VDP state machine is defined in 41.5.3. A station that supports VDP shall support one instance  
13 of the station VDP state machine for each active VSI.

14 The Bridge VDP state machine is defined in 41.5.2. A Bridge that supports VDP shall support one instance  
15 of the Bridge VDP state machine for each active VSI.

##### 16 **41.5.1 State machine conventions**

17 The notational conventions used in the specification of VDP are as stated in Annex E.

## 1 41.5.2 Bridge VDP state machine

2 The Bridge VDP state machine shall implement the function defined in Figure 41-12 and the attendant  
3 definitions in 41.5.4 through 41.5.7.

Figure 41-12—Bridge VDP state machine

### 1 41.5.3 Station VDP state machine

2 The station VDP state machine shall implement the function defined in Figure 41-13 and the attendant  
3 definitions in 41.5.4 through 41.5.7.

NOTE - The ".Except" notation used in some exit conditions is described in 41.5.6.  
In this state machine, "ExceptStatus.ExceptVidZero.ExceptPsZero" has been abbreviated to "ExceptStatusVidPs".

Figure 41-13—Station VDP state machine

#### 1 **41.5.4 VDP state machine timers**

2 A set of timers is used by the VDP state machines; these operate as countdown timers (i.e., they expire when  
3 their value reaches zero). These timers are 32-bit countdown timers. They:

- 4 a) Have a resolution of ten microseconds, with a tolerance of  $\pm 20\%$ .
- 5 b) Are started by loading an initial integer value,  $n$ , where  $0 < n \leq 2^{31}$ .
- 6 c) Are decremented by one per timer tick, as long as  $n > 0$ ; the interval between timer ticks is the same  
7 as the timer resolution.
- 8 d) Represent the remaining time in the period.

9 NOTE—Where timers are used in the VDP state machines to initiate keep-alive messages, it is recommended that a  
10 small random component is added to the timer interval in order to avoid the possibility that timers associated with  
11 different VSIs become synchronized.

##### 12 **41.5.4.1 waitWhile**

13 An instance of the waitWhile timer exists for each instance of the station VDP state machine (41.5.3) and for  
14 each instance of the Bridge VDP state machine (41.5.2).

#### 15 **41.5.5 VDP state machine variables and parameters**

##### 16 **41.5.5.1 bridgeExit**

17 A Boolean signal from the Bridge. When TRUE, this variable indicates that the Bridge VDP state machine  
18 should exit.

##### 19 **41.5.5.2 newCmd**

20 This variable is set to TRUE by the system to indicate to the state machine that there is a command ready to  
21 be transmitted. The state machine sets newCmd FALSE when that command has been processed and is  
22 ready to process a further command.

##### 23 **41.5.5.3 NULL**

24 A null value. If NULL is assigned to a TLV variable, it indicates that the variable contains no TLV.

##### 25 **41.5.5.4 operCmd**

26 The command TLV (the TLV that carried the current operating command—associate, pre-associate, or de-  
27 associate), at the station or Bridge, or NULL if there is no current operating command.

##### 28 **41.5.5.5 reinitKeepAlive**

29 The value used to initialize the waitWhile timer (41.5.4.1) by the station VDP state machine in order to  
30 determine when to transmit a keep alive message. This value is derived from the value of the management  
31 variable `urpVdpOperReinitKeepAlive` (12.26.5), which is type `timer_exp`, by using  
32 `urpVdpOperReinitKeepAlive` as an exponent of 2. The variable `urpVdpOperReinitKeepAlive` is the larger of  
33 the values proposed by the station and Bridge.

34 The default value used by the station for `urpVdpOperReinitKeepAlive` is an exponent value of 20,  
35 representing a timer interval of about 10.5 s.

#### 1 **41.5.5.6 resourceCmdResult**

2 This variable is used to record the result of a resourceCmd() procedure call (41.5.7.2). The possible result  
3 values are as follows:

- 4 a) Success
- 5 b) timeOut
- 6 c) Fail (insufficient resources)
- 7 d) Fail (invalid format)
- 8 e) Fail (other)

#### 9 **41.5.5.7 resourceWaitDelay**

10 The value used to initialize the waitWhile timer (41.5.4.1) by the Bridge VDP state machine when the state  
11 machine is waiting for a response. This value is derived from the values of the management variable  
12 sbpVdpOperRsrcWaitDelay (12.26.2), which is type timer exp, by using sbpVdpOperRsrcWaitDelay as an  
13 exponent of 2. The variable sbpVdpOperRsrcWaitDelay is the larger of the values proposed by the EVB  
14 station and EVB Bridge.

15 The default value used by the station and Bridge for sbpVdpOperRsrcWaitDelay is an exponent value of 20,  
16 representing a timer interval of about 10.5 s.

#### 17 **41.5.5.8 Resp**

18 A response TLV returned from the procedure resourceCmd() (41.5.7.2). Resp can be set to NULL prior to  
19 issuing resourceCmd(). The variable is always non-NULL when resourceCmd() completes.

#### 20 **41.5.5.9 respWaitDelay**

21 The value used to initialize the waitWhile timer (41.5.4.1) by the station VDP state machine when the state  
22 machine is waiting for a response. This value is derived from the values of the management variables  
23 urpVdpOperRsrcWaitDelay (12.26.5), ecpOperAckTimerInit (12.27) and ecpOperMaxRetries (12.27). The  
24 value is expressed in units of VDP timer tics of 10 usec by the following equation:

$$25 \quad \text{respWaitDelay} = 1.5 \times (2^{\text{urpVdpOperRsrcWaitDelay}} + (2 + 2 \times \text{maxRetries} + 1) \times \text{ackTimerInit})$$

26 NOTE 1—The factor of 1.5 allows for a 20% tolerance in the timer values.

27 where maxRetries is the ECP state machine variable that is ecpVdpOperMaxRetries and ackTimerInit is the  
28 ECP state machine variable that is 2ecpOperAckTimerInit. The values of urpVdpOperRscWaitDelay,  
29 ecpOperAckTimerInit, and ecpOperMaxRetries that are used are the larger of the values proposed by the  
30 station and Bridge.

31 The default value used by the station and Bridge is about 17.4 s. The default value for  
32 urpVdpOperRscWaitDelay is an exponent of 20 representing a timer interval of about 10.5 s and for  
33 ecpOperAckTimerInit is an exponent of 14 representing a timer interval of about 164 ms. The default value  
34 of the ECP state machine variable ackTimerInit is 16,384 ECP/VDP timer tics. The default value for  
35 ecpOperMaxRetries and the ECP state machine variable maxRetries is 3.

36 NOTE 2—The factor of 1.5 allows for a 20% tolerance in the timer values.

#### 37 **41.5.5.10 rxCmd**

38 The last received command TLV, or NULL if no command TLV has been received. The rxCmd variable is  
39 updated only if it is NULL.

#### 1 41.5.5.11 rxResp

2 The last received response TLV. The rxResp variable contains the last received Resp TLV at the station or  
3 NULL. RxResp is NULL if no TLVs have been received or if the variable has been cleared by the state  
4 machine.

5 NOTE—It is possible to have a race condition when clearing rxResp since it can be updated asynchronously if the  
6 Bridge issues an unsolicited DEASSOC command. If the race condition occurs, the de-associate will occur as a result of  
7 the station timer expiring.

#### 8 41.5.5.12 sysCmd

9 A command TLV from the system or hypervisor, or NULL if there is no pending command. The VDP state  
10 machine is ready to accept a new command when the value of sysCmd is NULL.

#### 11 41.5.5.13 toutKeepAlive

12 The value used to initialize the waitWhile timer (41.5.4.1) by the Bridge VDP state machine in order to  
13 determine when to expect to receive a keep alive message. This variable is derived from the values of the  
14 management variables sbpVdpOperReinitKeepAlive (12.26.2), ecpOperAckTimerInit (12.27), and  
15 ecpOperMaxRetries (12.27). The value is expressed in units of VDP timer tics of 10 usec by the following  
16 equation:

$$17 \quad \text{toutKeepAlive} = 1.5 \times (2^{\text{sbpVdpOperReinitKeepAlive}} + (2 + 2 \times \text{maxRetries} + 1) \times \text{ackTimerInit})$$

18 NOTE—The factor of 1.5 allows for a 20% tolerance in the timer values.

19 Where maxRetries is the ECP state machine variable that is ecpVdpOperMaxRetries and ackTimerInit is the  
20 ECP state machine variable that is  $2^{\text{ecpOperAckTimerInit}}$ . The values of sbpVdpOperReinitKeepAlive,  
21 ecpOperAckTimerInit, and ecpOperMaxRetries that are used are the larger of the values proposed by the  
22 EVB station and EVB Bridge.

23 The default value used by the station and Bridge is about 17.4 s. The default for  
24 sbpVdpOperReinitKeepAlive is an exponent of 20 representing a timer interval of about 10.5 s and for  
25 ecpOperAckTimerInit is an exponent of 14 representing a timer interval of about 164 ms. The default value  
26 of the ECP state machine variable ackTimerInit is 16,384 ECP/VDP timer tics. The default value for  
27 ecpOperMaxRetries and the ECP state machine variable maxRetries is 3.

#### 28 41.5.5.14 vsiState

29 The current association state of the VDP state machine. This variable may take the values DEASSOC (de-  
30 associated), PREASSOC (pre-associated), PREASSOCR (pre-associated with resource reservation), or  
31 ASSOC (associated).

#### 32 41.5.6 Command-Response TLV field references in state machines

33 The state machines can make use of the value of individual fields within the value of a TLV by using the  
34 following notation:

35 Tlv-variable-name.Field-name

36 In practice, only the following two Field-names are used in the state machines:

- 37 a) TLVtype, which references the TLV type field of the TLV (41.2.1)
- 38 b) Keep, which references the Keep bit of the Status field in the TLV (41.2.3)

1 So, for example, a reference in the state diagram to sysCmd.Keep is a reference to the Keep bit of the Status  
2 field of the TLV value contained in the sysCmd variable.

3 The state machines also make use of the ability to compare TLV values for equality or inequality while  
4 ignoring a specific field, using the following notation:

5       Tlv-variable-name.ExceptField-name

6 This is interpreted as meaning “The value of the TLV contained in the Tlv-variable-name variable, ignoring  
7 the value of Field-Name in the comparison.”

8 The reserved Field-name “VidZero” is used to specify that if any VID in the Filter Info field (41.2.9.1)  
9 contains zero, then that VID is ignored in the comparison. The reserved Field-name “PsZero” is used to  
10 specify that if PS in the Filter Info field contains zero, then the PS and PCP are both ignored in the  
11 comparison.

12 Multiple fields can be excepted by concatenating ExceptField-name items with a separating period.

13 The value of the Flag bits (Table 41-2 and Table 41-4) are always ignored in field comparison operations.

#### 14 **41.5.7 VDP state machine procedures**

##### 15 **41.5.7.1 buildDea()**

16 The buildDea() procedure builds a DEASSOCIATE TLV for the VSI as the return parameter.

##### 17 **41.5.7.2 resourceCmd(rxCmd, delay)**

18 This procedure makes a resource request from the Bridge, waits for a response, builds a response TLV and  
19 places it in the variable Resp. The response values reflect the requested resource action (PREASSOC,  
20 ASSOC, or DEASSOC), conditioned by return variable resourceResult, which is set to NULL before calling  
21 the resourceCmd procedure and set to one of the following values by the procedure:

- 22 a) SUCCESS
- 23 b) KEEP
- 24 c) DEASSOCIATE
- 25 d) TIMEOUT

26 The response constructed by the procedure in the Resp variable can be PREASSOC, ASSOC, or DEASSOC  
27 with a Status, keep indicator and hard error indicator. For a successful completion the procedure will copy  
28 the rxCmd parameter into the Resp variable. If the Bridge is selecting VIDs based on GroupIDs, then the  
29 procedure also replaces zero VIDs with valid VIDs.

30 The delay parameter specifies how long the procedure should wait for a response. If the delay is exceeded,  
31 no response is received, and the VSI is not associated, then the procedure returns a value of TIMEOUT. If  
32 the delay is exceeded, no response is received and the VSI is associated, then the procedure returns a value  
33 of KEEP along with a Resp equal to the rxCmd parameter. If the delay is not exceeded, then the procedure  
34 returns SUCCESS, KEEP, or DEASSOCIATE depending on the response received along with the rxCmd in  
35 the Resp and the Status set as follows:

##### 36 e) **DEASSOC:**

37       The procedure returns DEASSOCIATE along with Resp.Status set to Success.

- 1 f) **PREASSOC:**
- 2 1) If the request can be satisfied, the procedure returns SUCCESS along with Resp.Status set to
- 3 Success.
- 4 2) If the request cannot be satisfied, the procedure returns DEASSOCIATE along with
- 5 Resp.Status set to a code other than Success and the Resp.hard set to TRUE if a retry will not
- 6 change the situation or FALSE if a retry might change the situation.
- 7 g) **PREASSOCR:**
- 8 1) If the request can be satisfied, and the resources requested are available and reserved for this
- 9 VSI, the procedure returns SUCCESS along with the Resp.Status set to Success.
- 10 2) If the request cannot be satisfied, or the resources are unavailable or not reserved for this VSI,
- 11 the procedure returns DEASSOCIATE along with the Resp.Status code other than Success and
- 12 the Resp.hard set to TRUE if a retry will not change the situation or FALSE if a retry might
- 13 change the situation.
- 14 h) **ASSOC:**
- 15 1) If the request can be satisfied, and the resources requested are available and enabled for this
- 16 VSI, the procedure returns SUCCESS along with the Resp.Status set to Success.
- 17 2) If the request cannot be satisfied, or the resources are unavailable or not reserved for this VSI,
- 18 and the VSI is not currently Associated, the procedure returns DEASSOCIATE along with the
- 19 Resp.Status code other than Success and the Resp.hard set to TRUE if a retry will not change
- 20 the situation or FALSE if a retry might change the situation.
- 21 3) If the request cannot be satisfied, or the resources are unavailable or not reserved for this VSI,
- 22 and the VSI is currently Associated, the procedure returns KEEP along with the Resp.Status
- 23 code other than Success and the Resp.hard set to TRUE if a retry will not change the situation
- 24 or FALSE if a retry might change the situation.

25 NOTE—A de-associate can happen at any time, initiated by either party to an association.

#### 26 **41.5.7.3 resourceFree()**

27 The resourceFree() procedure frees all resources associated with this VSI.

#### 28 **41.5.7.4 TxTlv(tlv)**

29 The TxTlv() procedure causes the TLV passed in the tlv parameter to be transmitted.

## 1 42. S-Channel Discovery and Configuration Protocol (CDCP)

2 This clause provides an overview, detailed semantics, and state machines for CDCP.

### 3 42.1 CDCP discovery and configuration

4 CDCP is used to configure S-channels (see 40.2). S-channels are implemented in stations and Bridges using  
5 a Port-mapping S-VLAN component (22.6.4). Figure 40-1 illustrates the use of S-channels.

6 When the Port-mapping S-VLAN components used to create S-channels exist, they can exchange  
7 un-S-tagged frames that are assigned to S-VID 1 and are considered to be assigned to the default S-channel,  
8 which has an S-channel Identifier (SCID) of 1. The default S-channel is always un-S-tagged even when  
9 S-channels are enabled.

10 NOTE 1—SCIDs are locally assigned identifiers.

11 The S-channel configuration is determined by the Bridge's capabilities and by requests made using CDCP  
12 described in this clause. The station requests S-channels using CDCP. CDCP in turn uses an LLDP TLV  
13 exchange to coordinate the creation and deletion of S-channels. The LLDP database used by CDCP is  
14 addressed using the Nearest non-TPMR Bridge address. The Port-mapping S-VLAN component filters both  
15 the Nearest Bridge and the Nearest non-TPMR Bridge addresses on all ports and passes the Nearest  
16 Customer Bridge address.

17 The SCID value 1 and S-VID value 1 are always reserved for the exclusive use as the un-S-tagged default  
18 S-channel. CDCP reports the default S-channel in the CDCP TLV as the first SCID, S-VID pair (i.e., <1,1>).  
19 The Bridge shall not assign this S-VID except to the default S-channel.

20 NOTE 2—For the default S-channel, any QoS information that is necessary is extracted from the PCP bits of the C-tag.

### 21 42.2 CDCP state machine overview

22 CDCP requires each side of the configuration be assigned a role as a Bridge or a station. This is done by  
23 setting the AdminRole variable. In most cases the station or Bridge role will not be settable, though the  
24 protocol allows for systems that can take either role. For CDCP to configure an S-channel, one side takes the  
25 station role and the other side takes the Bridge role. If both sides of the LAN have equipment configured as  
26 stations or as Bridges the protocol will not configure S-channels.

27 NOTE—The role adopted by a given system can be fixed if the system is only capable of operating in a given role.

28 The CDCP state machine (Figure 42-1) operates on data contained in LLDP MIBs that is updated as a result  
29 of the reception of CDCP TLVs, exchanged using LLDP operating on the Nearest non-TPMR Bridge  
30 address. The structure of CDCP TLVs is defined in D.2.13.

31 The configuration proceeds by the Bridge providing the best match it can to the station's requested channels  
32 and configuration. The station makes the resource request, the Bridge responds with its best matching  
33 resources, the station then goes operational and reports its running configuration to the Bridge, and finally  
34 the Bridge goes operational with the running configuration of the station.

35 In the event the station wishes to change its configuration it alters the request in its CDCP TLV and then  
36 follows the same process as previously stated. If the 'B' loses its ability to support the current configuration  
37 it can alter the current configuration in its CDCP TLV at which time the station drops down to the resources  
38 supplied by the Bridge.

## 42.3 CDCP configuration state machine

The notational conventions used in the specification of CDCP are as stated in Annex E.

In an implementation that supports the station role, the CDCP configuration state machine shall implement the function specified by the state diagram in Figure 42-1 and the attendant definitions in 42.4 and 42.5.

Figure 42-1—CDCP state machine—Station role

1 In an implementation that supports the Bridge role, the CDCP configuration state machine shall implement  
2 the function specified by the state diagram in Figure 42-2 and the attendant definitions in 42.4 and 42.5.

Figure 42-2—CDCP state machine—Bridge role

3 42.4 CDCP configuration variables

4 42.4.1 AdminChnCap

5 The administratively configured value for the Number of Channels supported parameter. This value is  
6 included as the ChnCap parameter in the CDCP TLV.

## 1 42.4.2 AdminRole

2 The administratively configured value for the local port's role parameter. The value of AdminRole is not  
3 reflected in the CDCP TLV. The AdminRole can take the value S or B; the value determines which of the  
4 CDCP state machines is instantiated. If AdminRole is S, the Station role state machine (Figure 42-1) is  
5 instantiated. If AdminRole is B, the Bridge role state machine (Figure 42-2) is instantiated. S indicates the  
6 sender is unwilling to accept S-channels configuration (mode, number of channels supported, channel index)  
7 from its neighbor and that the sender is willing to accept S-VID assignments from the neighbor. Stations  
8 usually take the S role. B indicates the sender is willing to accept S-channels configuration (mode, number  
9 of channels supported, channel index) from its neighbor and that the sender is willing do the best it can to fill  
10 the S-VID requests from the neighbor. Bridges usually take the B role.

## 11 42.4.3 AdminSVIDWants

12 The administratively configured value for (SCID, S-VID) pairs wanted by a station; it is not used by a  
13 Bridge. The first value is always the pair (1, 1) for the default S-channel assignment. The S-channel numbers  
14 may be any valid number in the range 0–167. A 0 S-channel number indicates reserved space in the TLV. If  
15 the S-VID value is 0 it means the station is requesting any available S-VID. S-VID value 1 is reserved for  
16 exclusive use for the default S-channel S-VID. No other values of the SVID are permitted. The  
17 AdminSVIDWants parameter is used to form the (SCID, S-VID) pairs in the CDCP TLV. This list is formed  
18 from the EVB station's S-channel interface table (12.26.4) and is used to build the EVB Bridge's S-channel  
19 interface table.

## 20 42.4.4 LastLocalSVIDPool

21 A temporary copy of the LocalSVIDPool.

## 22 42.4.5 LastRemoteSVIDList

23 Temporary local copy of the RemoteSVIDList. This variable is not included in the CDCP TLV. The  
24 LastRemoteSVIDList has the same syntax as RemoteSVIDList.

## 25 42.4.6 LastSVIDWants

26 A local temporary copy of the AdminSVIDWants.

## 27 42.4.7 LocalSVIDPool

28 The set of S-VIDs and Bridge Ports available for S-channel assignment. These are determined by both  
29 administrative resource assignments and by resource availability. The OperSVIDList for a B role is drawn  
30 from the LocalSVIDPool.

## 31 42.4.8 OperChnCap

32 The current value for the ChnCap parameter. This value is included as the ChnCap parameter in the local  
33 CDCP TLV. The range for this variable is 1–167.

## 34 42.4.9 OperRole

35 The current operational value of the Role parameter in the local port. This value is included as the Role  
36 parameter in the CDCP TLV and may take values S or B as described for AdminRole.

#### 1 **42.4.10 OperSVIDList**

2 The current value for (SCID, S-VID) assignments. This is the list of (SCID, S-VID) pairs included in the  
3 local CDCP TLV. The total size of the list cannot exceed 167 pairs. The list always includes the default  
4 S-channel pair (1,1). The valid range for each S-channel of this list is from 1–167. The valid range for each  
5 S-VID in the list is from 0 to 0xffe. For the S role a S-VID of 0 indicates a request for a channel. For the B  
6 role an S-VID of 0 indicates a non-configured channel.

#### 7 **42.4.11 RemoteChnCap**

8 The current value for the ChnCap parameter. This value is included as the ChnCap parameter in the remote  
9 CDCP TLV. NULL means no remote CDCP TLV exists in the local LLDP database. The range for this  
10 variable is 1–167.

#### 11 **42.4.12 RemoteRole**

12 Indicates the value in the remote CDCP TLV role field. rrNull indicates either the TLV was not present in the  
13 last LLDPDU or that no LLDPDUs have been received. rwS and rwB indicate that the Role field was set in  
14 the CDCP TLV received and that it had a value of S or B, respectively, as described for the AdminRole  
15 variable.

#### 16 **42.4.13 RemoteSVIDList**

17 The current value for (SCID, S-VID) assignments. This is the list of (SCID, S-VID) pairs included in the  
18 remote CDCP TLV. NULL means no remote CDCP TLV exists in the local LLDP database. If the list is  
19 empty but the CDCP TLV is present, its value is NONE. The total size of the list cannot exceed 167 pairs.  
20 The valid range for each S-channel of this list is from 1–167. The valid range for each S-VID in the list is  
21 from 0 to 0xffe. When the S-VID is value is 0 the S-VID is not configured. For the S role, a S-VID of 0  
22 indicates a request for a channel. For the B role, an S-VID of 0 indicates a non-configured channel. The  
23 RemoteSVIDList is reflected within the EVB Bridge in the S-channel interface table (12.26.4).

#### 24 **42.4.14 schState**

25 The current running state of the S-channel. The values for this variable are NOTRUNNING or RUNNING.  
26 This variable can be read using the management functionality defined in Clause 12.

### 27 **42.5 CDCP configuration procedures**

#### 28 **42.5.1 SetSVIDRequest (OperRole, AdminSVIDWants, OperSVIDList)**

29 This function creates the OperSVIDList placed in the Local LLDP database, as follows:

- 30 a) If the OperRole for the equipment is B, then the OperSVIDList remains unchanged.
- 31 b) If the OperRole for the equipment is S, the function compares the AdminSVIDWants with the  
32 OperSVIDList and amends the OperSVIDList, as follows:
  - 33 1) All active S-channels in the OperSVIDList that are in the AdminSVIDWants are kept active,  
34 and in addition, any channels not currently in the OperSVIDList are requested by including  
35 them in the OperSVIDList along with a 0 S-VID number. The OperSVIDList S-channel order  
36 is changed to match the AdminSVIDWants.
  - 37 2) Any S-channels in the OperSVIDList that are not in AdminSVIDWants are made inactive and  
38 are removed from the OperSVIDList.

## 1 42.5.2 RxSVIDConfig (OperSVIDList, LastRemoteSVIDList)

2 This function creates the OperSVIDList placed in the Local LLDP database for an S role port.

3 The function compares the AdminSVIDWants with the LastRemoteSVIDList. For each AdminSVIDWants  
4 S-channel with an S-VID assignment in the LastRemoteSVIDList, a (SCID, S-VID) pair is generated in the  
5 OperSVIDList. For each AdminSVIDWants S-channel without an S-VID assignment in the  
6 LastRemoteSVIDList, a (SCID,0) pair is generated in the OperSVIDList. The OperSVIDList S-channel  
7 order is set to match the AdminSVIDWants.

## 8 42.5.3 TxSVIDConfig (OperChnCap, RemoteChnCap, LastLocalSVIDPool, 9 RemoteSVIDList, OperSVIDList)

10 This function creates the OperSVIDList placed in the Local LLDP database for a B role port.

11 First the function takes the smaller of the OperChnCap and RemoteChnCap and truncates the  
12 RemoteSVIDList to the smaller of the two.

13 A new OperSVIDList is created as follows:

- 14 a) For each S-channel in the RemoteSVIDList with a (SCID, S-VID) pair in the OperSVIDList, the  
15 (SCID, S-VID) remains unchanged unless the S-VID is no longer part of the LastLocalSVIDPool. If  
16 the S-VID is no longer in the pool, a new one is selected if available. If no S-VID is available, the  
17 (SCID, S-VID) pair will be deleted from the OperSVIDList.
- 18 b) For each S-channel in the OperSVIDList without a (SCID, SVID) pair in the RemoteSVIDList, the  
19 (SCID, SVID) pair will be deleted from the OperSVIDList.
- 20 c) For a (SCID, SVID) pair in the remote list, where the S-VID is zero, an S-VID is assigned if it is  
21 available and the pair is inserted in the OperSVIDList. If an S-VID is not available, the pair is not  
22 inserted in the OperSVIDList.
- 23 d) For a (SCID, SVID) pair in the remote list, where the S-VID is nonzero, there is no effect on the  
24 OperSVIDList.

## 43. Edge Control Protocol (ECP)

This clause provides an overview, detailed semantics, and state machines for ECP.

### 43.1 ECP operation

Figure 43-1 depicts, at a high level, ECP operation. In step 1, the upper layer protocol (ULP) passes an outgoing ULP Data Unit (ULPDU) to ECP by invoking a transmit request procedure. In step 2, the ULPDU, which for some ULPs (e.g., VDP) may contain a set of ULP TLVs, is transmitted and an ECP low-level acknowledgment (ACK) timer is set. The frame is not yet deleted from the transmit buffer until an ACK (L-ACK in the diagram) is received for that ECPDU. In step 3, the arriving ECP frame is received into a receive buffer, where it is held until it is removed by an ECP indication procedure that passes the ULP Data Unit to the associated upper-level protocol. In step 4, when the receive buffer is emptied, a L-ACK is sent to the sender. In step 5, if the L-ACK is received before the L-ACK timer expires, then the transmit buffer is cleared and ECP can process another ULPDU through the ECP procedure. However, if the L-ACK timer expires before the L-ACK is received, then the frame in the transmit buffer is re-sent and the L-ACK timer is re-initialized. This timeout and re-sending can occur up to a maximum number of retries determined by the value of the *maxRetries* parameter of the transmit state machine. If this number of retries is reached and there is still no response, then the transmit buffer is cleared, a failure counter is incremented, and the transmit state machine is then ready to process another ULPDU. There is no indication to the ULP that a transmission failure has occurred; it is the ULP's responsibility both to detect the failure condition and to recover from it in an appropriate way.

Figure 43-1—Example ECP exchange

ECP is intended to operate between two peers over an IEEE 802 LAN. ECP delivers the following service characteristics:

- Reliable delivery of ULPDUs, resilient against frame loss. The value of the *maxRetries* parameter determines the number of sequential lost frames that the protocol can sustain.
- Delivery of ULPDUs to the recipient ULP in the order that they were transmitted by the sending ULP.
- Delivery of a single copy of each ULPDU to the recipient.
- Flow control that provides protection against buffer overrun on the receive side.

## 1 43.2 Edge Control Sublayer Service (ECSS)

2 Two service primitives model the hand-off of data units between the ULP and ECP:  
3 ECP\_UNITDATA.request and ECP\_UNITDATA.indication.

4 ECP\_UNITDATA.request (ulptype, ulpdu)

5 The ECP\_UNITDATA.request primitive is invoked by the ULP to notify ECP that a ULDPDU is ready to be  
6 transmitted. The **ulpdu** parameter is the ULDPDU that the ULP wishes to transmit. The **ulptype** parameter  
7 identifies the type of the ULP (see 43.3.3).

8 NOTE—For example, for VDP the ULDPDU consists of a set of VDP TLVs passed to ECP for transmission. The  
9 maximum size of the ULDPDU, and therefore the set of TLVs that it can contain, is determined by the maximum SDU  
10 size supported by the underlying MAC (see 6.5.8).

11 ECP\_UNITDATA.indication (ulptype, ulpdu)

12 The ECP\_UNITDATA.indication is invoked by ECP to indicate a ULDPDU has been received and is  
13 available for ULP processing. The **ulpdu** parameter is the ULDPDU that has been received. The **ulptype**  
14 parameter identifies the type of the ULP, as indicated in the received ECPDU (see 43.3.3).

## 15 43.3 ECP state machines

### 16 43.3.1 State machine conventions

17 The notational conventions used in the specification of ECP are as stated in Annex E.

### 18 43.3.2 Overview

19 There are two state machines used by each ECP instance: the ECP transmit state machine (43.3.4) and the  
20 ECP receive state machine (43.3.5). A Bridge Port that supports ECP shall support one instance of the ECP  
21 transmit state machine and one instance of the ECP receive state machine.

22 Initialization of the transmit and receive state machines occurs when portEnabled (43.3.7.5) is FALSE, or  
23 when a BEGIN global event occurs. The transmit state machine transmits an ECPDU in response to an  
24 ECP\_UNITDATA.request from the ULP that indicates there is a PDU ready to be transmitted. The PDU is  
25 transmitted with a sequence number that is used by the (remote) receive state machine in a responding ACK  
26 ECPDU. If no ACK with the correct sequence number is received within a defined time period, and if the  
27 maximum number of retries has not been reached, the transmit state machine retransmits the ECPDU. If the  
28 maximum number of retries is exceeded, or if an ACK is received that matches the last sequence number  
29 sent, then the transmit state machine increments the sequence number and waits for the next  
30 ECP\_UNITDATA.request.

31 NOTE—The sequence number for the first ECPDU transmitted after a state machine initialization (which occurs when  
32 BEGIN is TRUE or portEnabled [43.3.7.5] is FALSE) is an implementation choice; for example, it could be a pre-  
33 determined number, a random number, or it could continue the sequence from the last sequence number used.

34 When the first ECPDU is received following initialization, the receive state machine initializes its local  
35 record of the last sequence number received to be one less than the sequence number in the received  
36 ECPDU. This record of the last sequence number received allows the state machine to detect whether the  
37 received ECPDU has been received already (current and last sequence numbers match) or this is a new  
38 ECPDU (current and last sequence numbers differ). In both cases, the receive state machine sends an ACK  
39 ECPDU, using the current sequence number. In the case that the received ECPDU is new, the last received  
40 sequence number is updated to reflect the sequence number of the received ECPDU, and an  
41 ECP\_UNITDATA.indication is sent to the ULP to pass the contents of the ECPDU to the service user.

### 43.3.3 Edge Control Protocol Data Unit (ECPDU)

This subclause specifies the format of a ECPDU, along with the header that is added to and removed from ECP frames by the ECP function. The ECP header allows each ECPDU from the sender to be identified through a sequence number, which the receiver acknowledges by sending a ECP Acknowledgment frame. The format of the ECPDU is illustrated in Figure 43-2.

**Figure 43-2—ECPDU structure**

The destination address of the Ethernet frame that contains a ECPDU is specified by the ULP. The address used is either an individual MAC address or one of the reserved addresses specified in Table 8-1.

The source address shall be the individual MAC address of the sending station or port.

The fields of the ECPDU are defined in the following subclauses.

#### 43.3.3.1 EtherType

A 16-bit field that contains the EtherType assigned for use by ECP (89-40).

#### 43.3.3.2 Version

A 4-bit field that identifies the protocol version. The version shall be 0x01.

#### 43.3.3.3 Operation type

A 2-bit field that identifies the operation type as follows:

- a) ECP request (0x0)
- b) ECP acknowledgment (0x1)

#### 43.3.3.4 Subtype

A 10-bit field that defines the ULP type included in the PDU. For ACKs the subtype is ignored at the station.

The subtype used by VDP is as shown in Table 43-1.

**Table 43-1—ECP subtypes**

| Use                                               | Reference        | Subtype          |
|---------------------------------------------------|------------------|------------------|
| VDP                                               | Clause 41        | 0x0001           |
| Port Extender Control and StatusProtocol (PE CSP) | IEEE Std 802.1BR | 0x0002           |
| Link-local Registration Protocol (LRP)            | IEEE Std 802.1CS | 0x0003           |
| Reserved for future standardization               | —                | All other values |

### 43.3.3.5 Sequence Number

A 2-octet field that identifies the sequential order of the PDU, with respect to other ECPDUs. The starting sequence number can start anywhere for the first ECPDU, but the sequence number for each subsequent new request ECPDU is incremented by 1 modulo 65536.

NOTE—The sequence numbers used by each instance of the ECP transmit state machine are independent of each other.

### 43.3.3.6 ULDPDU

This field contains an upper layer protocol data unit (ULPDU) if the operation type in the Mode field is ECP request; the field is absent if the operation type is ECP acknowledgment.

### 43.3.4 ECP transmit state machine

The ECP transmit state machine shall implement the function specified by the state diagram in Figure 43-3 and the attendant definitions in 43.3.6 through 43.3.8.

Figure 43-3—ECP transmit state machine

### 43.3.5 ECP receive state machine

The ECP receive state machine shall implement the function specified by the state diagram in Figure 43-4 and the attendant definitions in 43.3.6 through 43.3.8.

Figure 43-4—ECP receive state machine

### 43.3.6 ECP state machine timers

A set of timers is used by the ECP state machines; these operate as countdown timers (i.e., they expire when their value reaches zero). These timers are based on the Timer Exp data type (12.3). They:

- Have a resolution of ten microseconds, with a tolerance of  $\pm 20\%$ .
- Are started by loading an initial integer value,  $n$ , where  $0 < n \leq 2^{31}$ .
- Are decremented by one per timer tick, as long as  $n > 0$ ; the interval between timer ticks is the same as the timer resolution.
- Represent the remaining time in the period.

#### 1 **43.3.6.1 ackTimer**

2 The ackTimer is used to determine how long the transmit state machine will wait for an acknowledgment  
3 PDU to be received before it either retries a transmission or aborts a transmission due to too many retries.  
4 This timer is initialized using the value of ackTimerInit determined as stated in D.2.12.6.

#### 5 **43.3.7 ECP state machine variables and parameters**

##### 6 **43.3.7.1 ackReceived**

7 This Boolean variable is set to TRUE when an ECPDU is received with a MODE field indicating that the  
8 PDU is an ACK. The variable is set FALSE by the ECP transmit state machine once the ACK has been  
9 processed.

##### 10 **43.3.7.2 ec pduReceived**

11 This Boolean variable is set to TRUE when an ECPDU is received with a MODE field indicating that the  
12 PDU is a request. The variable is set FALSE by the ECP receive state machine once the request has been  
13 processed and the ACK has been sent.

##### 14 **43.3.7.3 lastSeq**

15 This integer variable is used to record the previous received sequence number.

##### 16 **43.3.7.4 maxRetries**

17 This integer variable defines the maximum number of times that the ECP transmit state machine will retry a  
18 transmission if no ACK is received. The default value of maxRetries is 3; this variable can be changed by  
19 management as documented in 12.26.2. The value is derived from ecOperMaxRetries (Table 12-31).

##### 20 **43.3.7.5 portEnabled**

21 This Boolean variable is set to the value of the MAC\_Operational parameter (IEEE Std 802.1AC) for the  
22 Port.

##### 23 **43.3.7.6 requestReceived**

24 This Boolean variable is set to TRUE when a ULP issues an ECP\_UNITDATA.request primitive. The  
25 variable is set FALSE by the state machine once the request has been processed.

##### 26 **43.3.7.7 retries**

27 This integer variable counts the number of transmission retries that have been made for the current ECPDU.

##### 28 **43.3.7.8 seqECPDU**

29 This integer variable is used to record the sequence number contained in the most recent received request  
30 ECPDU.

##### 31 **43.3.7.9 sequence**

32 This integer variable is used to record the current sequence number that is used in transmitted request  
33 ECPDUs.

1 **43.3.7.10 txErrors**

2 This integer variable is used to count the number of times that the ECP transmit state machine has  
3 retransmitted an ECPDU.

4 **43.3.8 ECP state machine procedures**

5 **43.3.8.1 inc(counter)**

6 This procedure increments the counter variable by 1 modulo 65 536.

7 **43.3.8.2 transmitECPDU()**

8 This procedure causes an ECPDU to be transmitted, using the PDU structure defined in 43.3.3. The  
9 sequence number field is set to the least significant 16 bits of the current sequence number contained in the  
10 sequence variable (43.3.7.9). The mode field is set to ECP request. The ULPDU field is set to the value of  
11 the ulpdu parameter of the request primitive. The subtype field is set to the value of the ulptype parameter of  
12 the request primitive.

13 **43.3.8.3 invokeIndication()**

14 This procedure causes an ECP\_UNITDATA.indication primitive to be invoked in order to pass the contents  
15 of an incoming ECPDU to the ECP service user. The ulptype parameter carries the value of the ULP type  
16 carried in the ECPDU. The ulpdu parameter carries the value of the ULPDU field of the ECPDU.

17 **43.3.8.4 sendAck()**

18 This procedure causes an ECPDU to be transmitted, using the PDU structure defined in 43.3.3. The  
19 sequence number field is set to the least significant 16 bits of the sequence number contained in the  
20 seqECPDU variable (43.3.7.8). The mode field is set to ECP acknowledgment. The ULPDU field is absent.  
21 The subtype field is set to the value of the ulptype parameter of the received request ECPDU.

22 **43.3.8.5 seqNum(pdu-type)**

23 This procedure returns an integer value equal to the value of the most recently received request ECPDU  
24 (pdu-type = reqECPDU) or acknowledgment ECPDU (pdu-type = ackECPDU).

25

## 1 44. Equal Cost Multiple Paths (ECMP)

2 SPB supports two approaches to spreading traffic load. The first approach, ECT VLANs, spreads traffic by  
3 assigning each service instance to a VLAN configured to use one of the supported SPT Sets. This approach  
4 is applicable to both SPBV and SPBM. Each Base VID is assigned to an ECT-ALGORITHM (tie-breaker)  
5 that defines the SPT Set for that VLAN, and different ECT Algorithms may thus be used to select different  
6 shortest paths in the SPT Region. In case of a PBBN, each I-SID is assigned to a Base VID. This approach  
7 can spread traffic load while maintaining traffic path congruence in each VLAN.

8 The second approach, ECMP, spreads traffic by employing multiple equal cost paths with a single VID. This  
9 approach is applicable only to SPBM. Unicast frame filtering dynamically selects a next hop from the set of  
10 equal cost next hops for the frame's destination MAC address. Multicast frame filtering is controlled by  
11 selecting a multicast routing mode and a tie-break mask for each backbone service instance and advertising  
12 that selection in ISIS-SPB. Multicast filtering entries for the backbone service instance are generated by  
13 calculations that select a multicast tree from the set of Equal Cost Trees (ECTs) in the SPT Region based on  
14 the advertised multicast mode and tie-break mask.

### 15 44.1 SPBM ECMP

#### 16 44.1.1 ECMP Operation

17 SPBM ECMP provides a mechanism to spread traffic load across a set of equal cost shortest paths in an SPT  
18 Region using a single VID. Rather than using one equal cost tie-breaking function to create a single SPT for  
19 all individual addresses, ECMP uses a hash function to spread individual address forwarding over a set of  
20 equal cost forwarding ports.

21 If flow filtering (44.2) is not supported, the ECMP ECT Algorithm selects one port from the set of equal cost  
22 forwarding ports for each individual address (44.1.2) and creates a Dynamic Filtering Entry for the address  
23 indicating the selected port.

24 If flow filtering (44.2) is supported, a set of equal cost forwarding ports may be recorded in the FDB in a  
25 Dynamic Filtering Entry (8.8.3). During unicast frame filtering the MAC Relay Entity selects one  
26 forwarding port from the applicable set using a dynamic port selection process (44.2.3).

27 The individual address forwarding port selection processes, both with and without flow filtering, are  
28 designed to:

- 29 a) Spread traffic (i.e., make varied choices) for different flows traversing the SPT Region, and
- 30 b) Maintain frame ordering for each flow by making the same choice for all frames belonging to any  
31 single flow.

32 ECMP is supported by Dynamic Filtering Entries in the FDB and, optionally, the flow filtering tag (F-TAG,  
33 44.2.1) that carries Flow Hash and TTL information. The flow hash serves both to distinguish frames  
34 belonging to different flows and to identify frames that belong to (or may belong to) the same flow. The flow  
35 hash is used as input to the dynamic port selection process to support the design goals noted above. The TTL  
36 is used to mitigate traffic loops, if they happen to occur (44.2.4).

37 While unicast frames are spread across equal cost paths, multicast frames cannot be treated this way. Instead  
38 multicast traffic load is spread by assigning a multicast mode and tie-breaker to each group address. This  
39 selection enables the use of varied SPTs for each group address or set of group addresses. The default ECMP  
40 ECT Algorithm selects a source rooted SPT for each node that may transmit multicast traffic. This default

1 source rooted SPT is used for all group addresses assigned to that node. Finer grained control of multicast  
2 load spreading is done by selecting a multicast mode and tie-break mask for a particular I-SID. This  
3 selection governs the multicast routing used for that I-SID's assigned group address. The selectable  
4 multicast modes include the following:

- 5 c) Source rooted SPT
- 6 d) Shared tree
- 7 e) Head-end replication

8 Up to 16 source rooted SPTs can be supported per node by using one of 16 different tie-break masks in  
9 calculating the SPT. During SPT calculation the tie-break mask is used to select one from the set of equal  
10 cost parents (neighbor nodes closer to the root) for each node (28.9). The default multicast treatment is  
11 equivalent to using a tie-break mask of zero. An I-SID on a CBP can be assigned to a specific SPT by  
12 configuring the Tie-Break Mask for that I-SID [item h) in 12.25.6.1.2 and item h) in 28.12.10].

13 To reduce the amount of multicast forwarding state required, shared (spanning) trees are supported. Up to 16  
14 shared trees can be configured using the 16 tie-break masks. For shared trees the tie-break mask is used both  
15 to select a shared tree root Bridge and to select from the set of equal cost parents for each node in the tree.  
16 The shared tree root for a given tie-break mask is determined by selecting the best (least) masked Bridge ID  
17 (i.e., the Bridge ID value masked using the tie-break mask). The SPT calculation from the shared tree root  
18 also uses the tie-break mask to select between equal cost parents (again selecting the least masked Bridge  
19 ID). Each I-SID on a CBP can be assigned to a shared tree by setting a shared tree transmit indicator bit and  
20 configuring the tie-break mask to identify the shared tree (28.12.10). All CBPs for a given I-SID that  
21 transmit on a shared tree use the same group address (Figure 27-6), and share the forwarding state for this  
22 address in the FDB.

23 It is possible to avoid using group addresses altogether and handle multicast frames by head-end replication.  
24 An I-SID on a CBP using head-end replication sends a unicast frame to each destination instead of sending a  
25 group addressed frame. If an I-SID is using head-end replication it is configured to indicate no multicast  
26 transmission from that CBP. In this case no group address forwarding state will be installed for that I-SID's  
27 assigned address at that CBP (28.9). An I-SID using head-end replication at a CBP should nevertheless  
28 indicate that it wishes to receive multicast frames since other CBPs supporting the same I-SID may still use  
29 multicast.

30 NOTE—ISIS-SPB does not check for the use of the same tree type for all endpoints of an I-SID, but use of different tree  
31 types within a single I-SID is not recommended.

#### 32 **44.1.2 ECMP ECT Algorithm**

33 The content of FDB entries for individual addresses in ECMP depends on whether flow filtering (44.2) is  
34 supported by a Bridge.

35 If flow filtering is not supported or the ECT-ALGORITHM value indicates no flow filtering (Table 44-1),  
36 then for each individual address the ECMP ECT Algorithm selects one port from the set of equal cost  
37 forwarding ports using a form of the FNV non-cryptographic hash algorithm and creates a Dynamic  
38 Filtering Entry (8.8.3) indicating that port as forwarding. The forwarding port is selected by the following  
39 process:

1 For a set of  $\kappa$  equal cost forwarding Ports, let  $P$  be an ordered list of the forwarding Ports sorted from  
2 greatest to least neighbor SPB System Identifier and  $P_i$  be the  $i$ th Port in  $P$ . Thus  $P_0$  is the Port whose  
3 neighbor has the greatest SPB System Identifier and  $P_{\kappa-1}$  is the Port whose neighbor has the least SPB  
4 System Identifier. The following algorithm is used to select a value for  $i$  for the individual MAC address,  
5 thus selecting Port  $P_i$  to be the forwarding port:

- 6 a) Set a 32-bit variable *bestHash32* to 0xFFFFFFFF.
- 7 b) Set  $i$  to 0 (zero).
- 8 c) For each  $n$  in  $0..k-1$ , (in order) perform the following steps:
  - 9 1) Set a 32-bit variable *hash32* to 0x811C9DC5.
  - 10 2) For each octet  $O_j$  (extended to 32 bits with leading 0's) in the Bridge's SPB System Identifier  
11 (8.13.8), starting with the least significant octet (octet 5) and progressing to the most significant  
12 octet (octet 0), set *hash32* to  $((\text{hash32 XOR } O_j) \times 0x01000193)$ .
  - 13 3) For each octet  $O_j$  (extended to 32 bits with leading 0's) in the neighbor SPB System Identifier  
14 for Port  $P_n$ , starting with the least significant octet (octet 5) and progressing to the most  
15 significant octet (octet 0), set *hash32* to  $((\text{hash32 XOR } O_j) \times 0x01000193)$ .
  - 16 4) For each octet  $O_j$  (extended to 32 bits with leading 0's) in the individual MAC address, starting  
17 with the least significant octet (octet 5) and progressing to the most significant octet (octet 0),  
18 set *hash32* to  $((\text{hash32 XOR } O_j) \times 0x01000193)$ .
  - 19 5) If  $\text{hash32} < \text{bestHash32}$ , set  $i$  to  $n$  and set *bestHash32* to *hash32*.

20 If flow filtering (44.2) is supported and the ECT-ALGORITHM value indicates flow filtering (Table 44-1),  
21 ISIS-SPB configures the Flow Filtering Control Table (44.2.2) for each port on which the ECMP SPBM  
22 VID is registered (27.13). For CBPs the Base VID is configured with both Flow Filtering and Flow Hash  
23 Generation enabled. For PNPs the Base VID is configured with Flow Filtering enabled and Flow Hash  
24 Generation disabled. For each individual address the ECMP ECT Algorithm calculates a Port Map  
25 specifying forwarding for a set of equal cost hops to that address and creates a corresponding Dynamic  
26 Filtering Entry (8.8.3). These Dynamic Filtering Entries are used in the dynamic selection of forwarding  
27 ports by the flow filtering process (44.2.3).

28 For each I-SID on a CBP transmitting multicast frames, the ECMP ECT Algorithm may calculate a source  
29 rooted SPT. If equal cost paths are found to any node on the tree, the path whose parent node (neighbor node  
30 toward the root) has the least Bridge Identifier is selected. A group MAC Address Registration Entry (8.8.4)  
31 is created for the I-SID's source rooted tree SPBM group MAC address (Figure 27-3) if the node performing  
32 the calculation is located between the source node and any multicast receiver(s) for the I-SID. The group  
33 MAC Registration Entry indicates forwarding for each port that leads to at least one multicast receiver for  
34 the I-SID on the calculated SPT (except the port from the source).

35 The ECMP ECT Algorithm supports two additional parameters that control multicast forwarding state  
36 calculation. First, a Tie-Break Mask value may be specified for an I-SID on a CBP [item i) in 28.12.10 and  
37 item h) in 12.25.6.1.2]. When a nonzero Tie-Break Mask is advertised, a 64-bit mask (formed by repeating  
38 the 4-bit Tie-Break Mask value in each nibble) is applied to (XORed with) each Bridge Identifier before  
39 selecting the lowest value as described in the SPT calculation in the paragraph above. Thus the default  
40 behavior described above is equivalent to using a Tie-Break Mask of zero. This parameter enables up to 16  
41 different SPTs to be calculated from a given source node. Each I-SID on a CBP may be assigned  
42 independently to one of these 16 source trees.

43 The second parameter controlling multicast forwarding state calculation is the shared tree indicator. An  
44 I-SID on a CBP may be configured to use a shared tree instead of a source-specific SPT [item h) in 28.12.10  
45 and item g) in 12.25.6.1.2]. There may be up to 16 shared trees, corresponding to the 16 Tie-Break Mask  
46 values. Each shared tree is calculated by selecting a root Bridge using the least masked Bridge Identifier. If a  
47 node advertises a Bridge Priority for the given Tie-Break Mask (28.12.6.1) the advertised value is used  
48 instead of the normal Bridge Priority in forming its Bridge Identifier (before masking). In calculating the

1 SPT from the selected root, the same Tie-Break Mask is used to form masked Bridge Identifiers (using the  
2 normal Bridge Priority), and the least value of masked Bridge Identifier is used to choose between equal cost  
3 parents for any node. If an I-SID on a CBP is configured to use a shared tree, the group address used in the  
4 group MAC Address Registration Entry is constructed using the Tie-Break Mask and the I-SID (27.15,  
5 Figure 27-6). In this case the ECMP ECT Algorithm creates a group MAC Address Registration Entry if the  
6 node performing the calculation is between the CBP and any multicast receivers on the SPT calculated from  
7 the selected root node. The Port Map indicates forwarding for all Ports that lead from a multicast transmitter  
8 to at least one multicast receiver for the I-SID.

9 If an I-SID on a CBP does not indicate transmission of multicast frames (e.g., head-end replication is to be  
10 used instead), then no group MAC Address Registration Entry is configured for multicast from that CBP for  
11 that I-SID.

12 Table 44-1 shows the ECT-ALGORITHM values for the ECMP ECT Algorithm.

**Table 44-1—ECMP ECT-ALGORITHM values**

| ECT-ALGORITHM | ECMP behavior               |
|---------------|-----------------------------|
| 00-80-C2-11   | ECMP without flow filtering |
| 00-80-C2-12   | ECMP with flow filtering    |

### 13 **44.1.3 Loop prevention for ECMP**

14 Loop prevention for unicast ECMP operates as specified in Clause 13 with the extension of allowing  
15 multiple Root Ports in case of multiple equal cost paths in order to support the per frame tie-breaking of  
16 ECMP. The ECMP connectivity to a destination bridge comprises the shortest paths destined to that bridge  
17 when the topology is Agreed in the meaning of the Agreement Protocol. If a bridge is not the destination  
18 bridge, then the one or more ports that ISIS-SPB has calculated as respectively providing a shortest path to  
19 the destination is a Root Port in the ECMP connectivity. Each port, other than a Root Port, is a Designated  
20 Port if ISIS-SPB has calculated that the port provides a shortest path for frames forwarded from the attached  
21 bridge to the destination in the ECMP connectivity. With these extensions to the definitions of Port Roles,  
22 Clause 13 specifications apply to ECMP as well.

23 NOTE 1—Despite allowing more than one Root Port for an SPT Bridge, a single Root Port is enforced on a per-frame  
24 basis as ECMP operation ensures that a frame is forwarded through only one of the Root Ports towards the destination.

25 Loop prevention for the shared trees used for ECMP multicast operates as specified by Clause 13 for shared  
26 spanning trees except for that instead of a Spanning Tree Protocol Entity (STPE), it is ISIS-SPB that  
27 configures the per-tree Port States and Roles based on its calculations and the operation of the Agreement  
28 Protocol; furthermore, the Learning Process (8.7) neither creates nor deletes Dynamic Filtering Entries.

29 NOTE 2—The per-tree Port States and Roles do not belong to an MSTI having a distinct MSTID because an ECMP B-  
30 VID is assigned to the SPBM MSTI. The Port States and Roles are associated with a single SPT used as a shared  
31 spanning tree supporting bidirectional forwarding (not as a unidirectional tree as for SPB).

## 44.2 Support for Flow Filtering

Flow filtering support enables Bridges to distinguish frames belonging to different client flows and to use this information in the forwarding process. Information related to client flows may be used at the boundary of an SPT Domain to generate a flow hash value. The flow hash, carried in an F-TAG, serves to distinguish frames belonging to different flows and can be used in the forwarding process to distribute frames over equal cost paths. This provides for finer granularity load spreading while maintaining frame order for each client flow.

Flow filtering behavior is controlled by ISIS-SPB. To allow Bridges that support flow filtering to be used alongside Bridges that do not support flow filtering, ISIS-SPB requires that all Bridges at the SPT Domain boundary that advertise I-SIDs for an ECMP Base VID using flow filtering support F-TAG processing. Bridges that do not advertise I-SIDs for that Base VID are not required to support flow filtering. Therefore, network operators are able to upgrade selected bridges to support flow filtering and use flow filtering for selected VIDs without requiring the simultaneous upgrade of all bridges in the SPT Domain.

NOTE—Support for F-TAG processing is indicated in I-SID advertisements and so is only available via ISIS-SPB once I-SIDs are assigned to the Base-VID. A “dummy” ISID configuration can be used to discover via ISIS-SPB whether F-TAG processing is supported on a Bridge.

This clause specifies the following:

- A flow filtering tag (F-TAG) that carries a flow hash value (44.2.1).
- F-TAG processing on Bridge Ports (44.2.2).
- A forwarding process using the flow hash to select one forwarding port from a set of equal cost options (44.2.3).
- TTL loop mitigation (44.2.4).
- CFM for ECMP with flow filtering (44.2.5).
- Operation of bridged LANs with selective support for flow filtering (44.2.6).

### 44.2.1 Flow filtering tag (F-TAG)

An F-TAG is specified to carry additional information in support of flow filtering functions. The F-TAG comprises a Tag Protocol Identifier (TPID) (EtherType) and Tag Control Information (TCI).

**Table 44-2—F-TAG EtherType**

| Tag Type           | Name                                     | Value |
|--------------------|------------------------------------------|-------|
| Flow Filtering Tag | IEEE 802.1Q Flow Filtering Tag EtherType | 89-4B |

The F-TAG TCI field (Figure 44-1) is 4 octets in length and encodes priority, drop\_eligible, TTL, and flow hash information for a service primitive.

**Figure 44-1—Flow Filtering TCI format**

1 The F-TAG TCI contains the following fields:

- 2 a) *PCP (Priority Code Point)*—This 3-bit field encodes the priority and drop\_eligible parameters of  
3 the service request primitive associated with this frame using the same encoding as specified for  
4 VLAN tags in 6.9.3.
- 5 b) *DEI (Drop Eligible Indicator)*—This 1-bit field carries the drop\_eligible parameter of the service  
6 request primitive associated with this frame.
- 7 c) *Reserved*—This 6-bit field may be used for future format variations. The Reserved field contains a  
8 value of zero when the tag is encoded and is ignored when the tag is decoded.
- 9 d) *TTL (Time To Live)*—This 6-bit field holds a counter value that is decremented each time the F-TAG  
10 is read (44.2.2.1) and provides a mechanism to limit the number of network hops a frame may take.
- 11 e) *Flow Hash*—This 16-bit field carries a flow hash value used in the dynamic port selection process  
12 for ECMP (8.8.3).

#### 13 44.2.2 F-TAG processing

14 This standard specifies flow filtering behavior for SPBM ECMP (44.2). To support this behavior, a flow  
15 hash may be conveyed in a mac\_service\_data\_unit using an F-TAG (44.2.1). This clause specifies a Support  
16 for Flow Filtering shim that produces and processes F-TAG information. The shim has two EISS SAPs—a  
17 lower EISS toward a LAN and an upper EISS toward the MAC Relay Entity.

18 At the boundary of a flow filtering SPT Domain, for example, at CBPs, the flow hash is generated for  
19 EM\_UNITDATA.indication primitives. At intermediate ports, for example, PNPs, the F-TAG is generated  
20 using the flow hash in EM\_UNITDATA.request primitives or processed to retrieve the flow hash value from  
21 EM\_UNITDATA.indication primitives. The F-TAG also includes a TTL field, used for loop mitigation, and  
22 PCP and DEI fields that are processed by this shim.

23 Flow filtering support is governed by a Flow Filtering Control Table for each port containing an entry for  
24 each VID with the following fields:

- 25 a) Flow Filtering (enabled/disabled). This field indicates whether flow filtering behavior is enabled on  
26 the port for the VID. The default value is disabled.
- 27 b) Flow Hash Generation (enabled/disabled). This field indicates whether flow hash generation is  
28 enabled on the port for the VID. The default value is disabled.
- 29 c) TTL Value (1..63). This field is the initial TTL value for frames entering the flow filtering SPT  
30 Domain [item d) in 12.16.5.5.2]. The default value is 8.

31 The Flow Filtering Control Table is provisioned by ISIS-SPB (44.1.2). For flow filtering, a CBP will have  
32 both the Flow Filtering field and the Flow Hash Generation field set to enabled and the TTL Value field set  
33 to provide the initial time\_to\_live value for indication primitives. For flow filtering, a PNP will have the  
34 Flow Filtering field set to enabled and the Flow Hash Generation field set to disabled. The TTL Value field  
35 (initial TTL value) is not used on a PNP.

36 NOTE—Based on the description above, for flow filtering, the condition “Flow Hash Generation field indicates  
37 enabled” is equivalent to indicating a CBP, and the condition “Flow Hash Generation field indicates disabled” is  
38 equivalent to indicating a PNP.

#### 1 44.2.2.1 Data indications

2 On receipt of an EM\_UNITDATA.indication primitive from the lower EISS on a PNP, the received frame  
3 shall be discarded if:

- 4 a) For the `vlan_identifier` in the Flow Filtering Control Table, the Flow Filtering field indicates  
5 enabled, and the initial octets of the `mac_service_data_unit` do not contain a valid F-TAG; or
- 6 b) The value in the TTL field in the F-TAG is 0.

7 NOTE 1—A frame received with a TTL value of 0 will be discarded, i.e., not relayed, even if it is addressed to another  
8 port on the receiving Bridge.

9 Otherwise, an EM\_UNITDATA.indication primitive is invoked at the upper EISS with parameter values  
10 determined from the received primitive based on the Flow Filtering Control Table for the received  
11 `vlan_identifier` as follows:

- 12 c) If the Flow Filtering field indicates disabled, the invoked primitive is identical to the received  
13 primitive.
- 14 d) If the Flow Filtering field indicates enabled, the **`destination_address`**, **`source_address`**,  
15 **`vlan_identifier`**, and **`connection_identifier`** in the invoked primitive are identical to those  
16 parameters in the received primitive.
- 17 e) If the Flow Filtering field indicates enabled and the Flow Hash Generation field indicates disabled,  
18 the **`mac_service_data_unit`** in the invoked primitive is created by removing the F-TAG from the  
19 received **`mac_service_data_unit`**; otherwise, the **`mac_service_data_unit`** in the invoked primitive  
20 is identical to the received primitive.

21 The value of the **`flow_hash`** and **`time_to_live`** parameters are determined as follows:

- 22 f) If the Flow Hash Generation field indicates enabled, the value of `flow_hash` is generated from the  
23 received primitive (using a process selected by the implementation). `time_to_live` is set to the TTL  
24 Value from the Flow Filtering Control Table for the received `vlan_identifier`.

25 NOTE 2—Procedures for calculating the flow hash are not covered by this standard. The procedure is typically a  
26 protocol-dependent hash of the client protocol header being carried within the `mac_service_data_unit`.

27 NOTE 3—There is often a compromise between the speed of a hash calculation and the quality of value spreading. This  
28 standard makes no assurances regarding the quality of the distribution of `flow_hash` values.

- 29 g) If the Flow Hash Generation field indicates disabled, the value of `flow_hash` is taken from the Flow  
30 Hash field in the received F-TAG, and `time_to_live` is set to the TTL value in the received F-TAG  
31 decremented by 1.

32 The value of the **`drop_eligible`** and **`priority`** parameters are determined as follows:

- 33 h) If the **`mac_service_data_unit`** was tagged with an F-TAG, the value of the `drop_eligible` parameter  
34 and the received priority value are decoded as described in 6.9.3, using the PCP and DEI values  
35 from the F-TAG. Otherwise,
- 36 i) The received priority value and the `drop_eligible` parameter value are the values in the  
37 EM\_UNITDATA.indication.
- 38 j) The value of the priority parameter is then regenerated from the received priority, as specified in  
39 6.9.4.

#### 40 44.2.2.2 Data requests

41 On invocation of an EM\_UNITDATA.request primitive at the upper EISS, an EM\_UNITDATA.request  
42 primitive is invoked at the lower EISS, with parameter values determined based on the Flow Filtering  
43 Control Table for the received `vlan_identifier`.

44 If the Flow Filtering field indicates disabled or the Flow Hash Generation field indicates enabled, the  
45 invoked primitive is identical to the received primitive.

1 If the Flow Filtering field indicates enabled and the Flow Hash Generation field indicates disabled, all  
2 parameters in the invoked primitive match those in the received primitive except the `mac_service_data_unit`.  
3 The `mac_service_data_unit` in the invoked primitive is formed by inserting an F-TAG as the initial octets to  
4 the received `mac_service_data_unit`. The values of the **flow\_hash**, **time\_to\_live**, **priority**, and  
5 **drop\_eligible** parameters are used to determine the contents of the F-TAG, in accordance with 44.2.1.

#### 6 44.2.3 Forwarding process extension for flow filtering

7 Frame filtering (8.6.3) reduces the set of potential transmission ports in accordance with applicable FDB  
8 entries. When flow filtering is enabled, the ISIS-SPB control plane creates Dynamic Filtering Entries with  
9 multiple forwarding Ports in the Port Map when there are multiple equal cost hops to a given individual  
10 address. Frame filtering must select only one of these forwarding ports on which to transmit each frame with  
11 a matching destination\_address and VID.

12 Selection of one Port from a set indicated by the Port Map shall be performed using a form of the FNV non-  
13 cryptographic hash algorithm as follows:

14 For a Port Map specifying  $\kappa$  ποτεντιαλ φορωαρδινγ Πορτσ, λετ Π βε αν ορδερεδ λιστ οφ ποτεντιαλ  
15 φορωαρδινγ Πορτσ σορτεδ φρομ γρεατεστ το λεαστ νειγηβορ ΣΠΒ Σψστεμ Ιδεντιφιερ ανδ Πι βε τη

23 τηε μοστ σιγνιφιχαντ οχτετ (οχτετ 0), σετ ηαση32 το ((ηαση32 ΞΟΡ Οφ) × 0ξ01000193).
- 24 γ) Φορ εαχη οχτετ Οφ (εξτενδεδ το 32 βιτσ ωιτη λεαδινγ 0□σ) ιν τηε φλω\_ηαση παραμετερ,  
25 σταρτινγ ωιτη τηε λεαστ σιγνιφιχαντ οχτετ (οχτετ 4 οφ Φιγυρε 44–1) and progressing to the  
26 most significant octet (octet 3 of Φιγυρε 44–1), σετ ηαση32 το ((ηαση32 ΞΟΡ Οφ) ×  
27 0ξ01000193).
- 28 δ) Σετ α 16–βιτ παριαβλε ηαση16 το ((ηαση32 ανδ 0ξ0000ΦΦΦΦ) ΞΟΡ (ηαση32 /  
29 0ξ00010000)).
- 30 ε) Σετ ι το (ηαση16 μοδ κ), σελεχτινγ Πορτ Πι.

#### 31 44.2.4 TTL Loop mitigation

32 The F-TAG contains a TTL field whose value is decremented each time a frame is forwarded by an SPT  
33 Bridge supporting flow filtering [item g) in 44.2.2]. A frame is filtered (discarded) if it is received with a  
34 TTL value of 0. This mechanism mitigates the impact of looping frames by limiting the number of hops  
35 these frames may travel in the network. This method of loop mitigation protects network resources by  
36 ensuring frames are forwarded at most a fixed number of times.

37 NOTE—The TTL carried in the F-TAG is decremented for all frames; however, the Flow Hash is applicable only to  
38 unicast frames. The Flow Hash has no effect on the filtering of group addressed frames.

#### 39 44.2.5 CFM for ECMP with flow filtering

40 CFM as specified in Clause 18 through Clause 22 provides capabilities useful in detecting, isolating, and  
41 reporting connectivity faults. SPBM MAs (27.18) can be used with an ECMP VID and provide most of the  
42 necessary CFM functionality. One additional MA type is specified for ECMP, the ECMP path MA, because  
43 an SPBM path MA can test only one path between a pair of endpoints.

1 An ECMP path MA is used to continuously test multiple paths between two endpoints. This type of MA has  
2 only two MEPs at two SPT Region boundary ports. The MA is identified by a TE-SID comprising an ESP in  
3 each direction between the two endpoints. An ECMP path MEP cycles through a set of flow hash values  
4 intended to direct the CCM frames along (and thus test) different paths to the other MEP in the MA. Each  
5 flow hash is used in multiple consecutive CCM frames so that a fault on a particular path will be detected  
6 and reported back via an RDI signal. This standard does not specify the mechanisms that would be necessary  
7 to support Loopback and Linktrace on an ECMP path MA since full Loopback and Linktrace coverage can  
8 be provided by an SPBM VID MA. Therefore, there are no MHFs associated with an ECMP path MA.

#### 9 44.2.5.1 ECMP path MEP placement in a Bridge Port

10 Since ECMP path MEPs must only see traffic from one other endpoint, these MEPs need to be further  
11 differentiated by the TESI Multiplex Entity (6.19). This locates an ECMP path MEP so that it receives  
12 CCMs only from the other MEP in its MA. Figure 44-2 shows an example of ECMP path MEPs on a CBP.

Figure 44-2—SPBM VID MEP and ECMP path MEP placement in a CBP

#### 1 44.2.5.2 Continuity Check protocol in an ECMP path MA

2 The Continuity Check protocol is described in 20.1 and the corresponding state machines in Clause 20. The  
3 modifications required to realize ECMP path MAs include the following:

- 4 a) The MEP Continuity Check Initiator state machine adds three variables for controlling ECMP path  
5 testing (20.10.4, 20.10.5, 20.10.6) and shares two of these with the Remote MEP state machine  
6 (Figure 20-1).
- 7 b) The destination\_address parameter is set to the individual MAC address of the other MEP in the MA  
8 [item a) in 20.11.1].
- 9 c) The flow\_hash parameter is set to one of the values to be tested, and the time\_to\_live parameter is  
10 set as specified in item e) in 20.11.1.
- 11 d) The MEP Continuity Check initiator state machine is modified to support a cycle of path tests for an  
12 ECMP path MEP (20.12).
- 13 e) The Remote MEP state machine is modified to track a cycle of path test RDI values and report  
14 rMEPlastRDI as set if any RDI has been seen in the last path test cycle for an ECMP path MEP  
15 (20.19.2, 20.20).

16 NOTE—In an ECMP path MEP testing a set of paths, the RDI signal reflects back the state of far end CCM reception.  
17 Using the current CCM sending cycle position (pathN), the CCM sending rate, and the path round trip delay, one can  
18 calculate roughly the position in the sending cycle corresponding to a received RDI. This approach makes minimal  
19 changes to the CCM state machines at the CCM sending MEP and no changes at the CCM receiving MEP. It is subject to  
20 some ambiguity based on differences in path delay, the sending rate, and cycle length. In the case of ambiguous results,  
21 further testing would be required to identify a faulty path.

22 SPBM MAs may also implement the following enhancements to the Continuity Check protocol:

- 23 f) The procedure MEPprocessEqualCCM() on ECMP path MEPs does not include the check of the  
24 MAID on received CCMs [item b) in 20.17.1].

25 All other Continuity Check processes are the same as those for a VID-based MA.

#### 26 44.2.6 Operation with selective support for flow filtering

27 When adding new capabilities to a network, it is desirable to make changes incrementally rather than  
28 perform a wholesale upgrade (e.g., incur a “flag day” event). Flow filtering is optional functionality that can  
29 be used with selected Base-VIDs while not adversely affecting other services in the network. However, flow  
30 filtering changes frame encoding (i.e., adds new header information in an F-TAG) and therefore requires that  
31 a Base-VID using ECMP with flow filtering have all its boundary points capable of processing the F-TAG.  
32 To enable incremental incorporation of flow filtering, ISIS-SPB requires F-TAG support for any Bridges  
33 with a CBP associated with a Base VID using ECMP with flow filtering while allowing other Bridges in the  
34 SPT region to operate without flow filtering support.

35 When the ECMP ECT-ALGORITHM value indicates support for flow filtering (Table 28-1), an I-SID  
36 cannot be configured to use a Base VID using ECMP with flow filtering unless the Bridge supports flow  
37 filtering (12.16.5.2). Requiring all Bridges advertising service instances using ECMP with flow filtering to  
38 support F-TAG processing provides for proper handling of F-tagged frames at the boundary of the SPT  
39 Domain.

40 Within the SPT Domain, it is possible to use Bridges that support the ECMP ECT Algorithm but do not  
41 support flow filtering (i.e., do not recognize F-TAGs). In this case, the ECMP ECT Algorithm (28.9) selects  
42 one port from the set of equal cost forwarding ports for each individual address and creates a Dynamic  
43 Filtering Entry for the address indicating the selected port.

44 NOTE—Bridges that do not support flow filtering should not change PCP and DEI values for frames carrying F-TAGs  
45 as this may not provide the desired behavior. If the PCP and DEI values are changed in the VLAN tag only, the PCP and  
46 DEI values carried in the F-TAG will be reasserted when the F-TAG is next processed.

<sup>1</sup> These ECMP behaviors enable incremental upgrade of edge bridges to support flow filtering and selective  
<sup>2</sup> use of this capability with I-SIDs registered only at these upgraded edge bridges. ECMP operation with  
<sup>3</sup> selective support for flow filtering enables incremental introduction of flow filtering capabilities into an  
<sup>4</sup> existing network and earlier introduction of flow filtering support for selected services.

## 1 45. Path Control and Reservation (PCR)

2 This clause specifies IS-IS extensions to provide the following:

- 3 a) Establishment of explicit trees for frame forwarding in an SPT Region (45.1),
- 4 b) Use of IS-IS to communicate bandwidth assignments made by the Path Computation Element (PCE)  
5 (45.2), and
- 6 c) Redundancy with the establishment of the corresponding trees (45.3).

7 The Path Control and Reservation (PCR) IS-IS extensions specified in this clause are compatible with ISIS-  
8 SPB specified in Clause 27 and Clause 28. Furthermore, IS-IS with PCR extensions (ISIS-PCR) relies on  
9 the SPB architecture and terminology; and ISIS-PCR also leverages some of the ISIS-SPB sub-TLVs (see,  
10 e.g., 5.5) as specified by this clause. This specification considers only point-to-point links for PCR although  
11 IS-IS also supports shared media LANs.

12 NOTE 1—ISIS-PCR does not require the implementation of the full ISIS-SPB protocol; but in addition to IS-IS, ISIS-  
13 PCR requires the support of the ISIS-SPB sub-TLVs listed in 5.5 (also listed as PCR-2–PCR-5 in A.43), whose use is  
14 specified by this clause. Nonetheless, if an SPT Bridge supports both ISIS-SPB and ISIS-PCR, then both of them are  
15 implemented by the same IS-IS Higher Layer Entity.

16 A VID can be associated with an explicit tree, i.e., with an explicit active topology within an SPT Region.  
17 The Base VID of the VLAN is then associated with explicit path control mode of IS-IS operation, i.e., ISIS-  
18 PCR. A VID can be associated with multiple explicit trees if the considerations explained in 45.1.4 are taken  
19 into account. VIDs controlled by ISIS-PCR do not participate in ECMP operation (Clause 44).

20 NOTE 2—A VLAN can provide a point-to-point, point-to-multipoint, or multipoint-to-point service using the  
21 multipoint-to-multipoint connectivity provided by an active topology. Similarly the Transmit and Receive IS-IS sub-  
22 TLV flags (28.12.10) of Edge Bridges allow an I-SID to use a multipoint-to-multipoint VLAN to provide point-to-point,  
23 point-to-multipoint, or multipoint-to-point service.

24 Path Computation Element (PCE) entities are external to the IS-IS protocol and fully or partially determine  
25 and describe each explicit tree to be established by ISIS-PCR throughout an SPT Region. There can be  
26 multiple PCEs in a region; nevertheless, any given explicit tree is under the control of one PCE. Explicit  
27 trees can be used, for example, for placing selected traffic on a precisely defined route, usually off the  
28 shortest path tree.

29 ISIS-PCR is able to record and communicate bandwidth assignments if instructed to do so by a PCE. ISIS-  
30 PCR can be used for bandwidth assignments only if MSRP is not used in the SPT Region. If ISIS-PCR  
31 communicates bandwidth assignments, then the tree descriptor assembled by the PCE also includes the  
32 details of the bandwidth assignment to be recorded by the Bridges. This mode of operation is expected to be  
33 used to divert traffic aggregates off their shortest path route, in order to avoid potential congestion on the  
34 default shortest path.

35 The redundancy provided by a physical topology can be leveraged by various resiliency schemes. A PCE  
36 can be used for the computation, and ISIS-PCR can be used for the establishment of the trees required for a  
37 given resiliency solution.

### 38 45.1 Explicit trees

39 This subclause specifies IS-IS extensions that provide explicit forwarding trees for data frames. An explicit  
40 tree is determined by a Path Computation Element (PCE) and is not required to follow the shortest path.  
41 PCE is defined by IETF RFC 4655 [B34]. A PCE is an entity that is capable of computing a topology for  
42 forwarding based on a network topology, its corresponding attributes, and potential constraints. A PCE  
43 explicitly describes a forwarding tree as specified in 45.1.9. Either a single PCE or multiple PCEs determine  
44 explicit trees for a region. Even if there are multiple PCEs in a region, each explicit tree is determined by  
45 only one PCE, which is referred to as the owner PCE of the tree. PCEs and ISIS-PCR can be used in  
46 combination with ISIS-SPB shortest path routing.

1 A PCE is a higher layer entity in an SPT Bridge or an end station. The PCE interacts with the active  
2 topology control protocol, i.e., with ISIS-PCR. The collaboration with ISIS-PCR can be provided by a Path  
3 Control Agent (PCA) on behalf of a PCE. Either the PCE or the corresponding PCA is part of the IS-IS  
4 Domain. If the PCE is not part of the IS-IS Domain, then the PCE has to be associated with a PCA that  
5 resides either in an SPT Bridge or in an end station directly connected to at least one Bridge of the SPT  
6 Region. The PCE or its PCA establishes IS-IS adjacency (45.1.7) in order to receive all the LSPs transmitted  
7 by the Bridges in the region. The PCE, either on its own or via its PCA, can control the establishment of  
8 explicit trees in that region by injecting an LSP conveying an explicit tree and thus instruct ISIS-PCR to set  
9 up the explicit tree determined by the PCE. Each PCE, whether located in a Bridge or end station, has access  
10 to the link state topology and resource information common throughout the region. If instructed to do so by  
11 a PCE, ISIS-PCR can also record and communicate bandwidth assignments, which can be applied only if  
12 MSRP is not used in the region. Different PCE and PCA locations are illustrated in Figure 45-1 and  
13 Figure 45-2.

**Figure 45-1—An SPT Region controlled by a single PCE**

14 NOTE 1—The operation details of the PCE are not specified by this standard. If the PCE is part of the IS-IS Domain,  
15 then the PCE uses IS-IS PDUs to communicate with the IS-IS Domain, and the PCE has a live IS-IS LSDB (i.e., the PCE  
16 implements the PCA functions, too). A PCE can instead communicate with the IS-IS Domain via a PCA, e.g., to retrieve  
17 the Link State Database (LSDB) or instruct the creation of an explicit tree. However, the means of communication  
18 between the PCE and the PCA is not specified by this standard. A PCE could operate on a network topology retrieved by  
19 other means, e.g., configuration, instead of retrieving it from a live IS-IS LSDB; which operation mode is not specified  
20 by this standard. Having no live LSDB, the PCE instructs its PCA to flood the LSP conveying the appropriate Topology  
21 sub-TLV.

22 ISIS-PCR implements Software Defined Networking (SDN) through hosting the PCE in an external agent,  
23 e.g., an SDN Controller. In this case IS-IS is the protocol used to control the Bridges by the SDN Controller;  
24 the explicit trees are programmed in the Bridges via IS-IS.

**Figure 45-2—An SPT Region controlled by multiple PCEs**

1 Figure 45-1 shows a region controlled by a single PCE residing in end station X connected to SPT Bridge  
2 11. The PCE has IS-IS adjacency established with SPT Bridge 11, i.e., the PCE is part of the IS-IS Domain.

3 The IS-IS Domain coincides with the SPT Region in Figure 45-1 and Figure 45-2; they comprise SPT  
4 Bridges 11, 44, 55, and 88 (Edge Bridges) and SPT Bridges 22, 33, 66, and 77 (Core Bridges). As shown in  
5 the figures, each SPT Bridge implements a Bridge Local Computation Engine (BLCE).

6 Figure 45-2 shows a region controlled by multiple PCEs. Some of the SPT Bridges implement a PCE in  
7 addition to their BLCE; PCE 1 and PCE 2 reside in SPT Bridge 11 and SPT Bridge 88, respectively. PCE 3  
8 resides in End Station Y. PCE 3 is not part of the IS-IS Domain; PCE 3 uses PCA 3 to instruct ISIS-PCR for  
9 the establishment of explicit trees and to retrieve link state data from the domain.

10 An Explicit Tree (ET) is an undirected loop-free topology, whose use is under the control of the owner PCE  
11 by means of associating VIDs and MAC addresses with it. As it is undirected, the ET contains no  
12 assumptions about the direction of any flows that use it; it can be used in either direction as specified by the  
13 VIDs and MAC addresses associated with it. It is the responsibility of the PCE to ensure reverse path  
14 congruency (3.222) and unicast multicast congruency (3.295) if that is required, e.g., making an explicit tree  
15 symmetric (3.273) by setting it up so that it is used in both directions between a pair of Bridges.

16 An explicit tree is either strict or loose. A strict explicit tree specifies all Bridges and paths it comprises. A  
17 loose tree specifies only the Bridges that have a special role in the tree, e.g., an Edge Bridge, and no path or  
18 path segment is specified between the Bridges, which are therefore loose hops even if Edge Bridges are  
19 adjacent neighbors. The special role of a hop can be an Edge Bridge, a root, a leaf, a Bridge to be avoided, or  
20 a transit hop in the case of a tree with a single leaf. The path for a loose hop is determined by the BLCE of  
21 the SPT Bridges. The shortest path is used for a loose hop unless specified otherwise by the descriptor  
22 (45.1.9) of the tree or by the corresponding ECT Algorithm (45.1.2).

1 NOTE 2—PCE and BLCE are architecturally different entities. A BLCE is implemented in each SPT Bridge, where the  
2 BLCE implements the SPF algorithm at the minimum and can also implement more complex path computation  
3 algorithms, e.g., for determining constrained or redundant trees. For instance, the BLCE of SPT Bridges supporting  
4 ISIS-SPB at least implements an all pairs shortest path algorithm in addition to SPF. Forwarding trees are computed by  
5 the BLCEs unless they are explicitly given. Conversely, a PCE can implement more complex computation algorithms,  
6 and its main task is to determine explicit trees even if the PCE resides in a Bridge.

7 NOTE 3—If shortest paths are used for loose hops, then there is no need for any computation in addition to SPB as ISIS-  
8 SPB performs all pairs shortest path computation.

9 A loose explicit tree is constrained if the tree descriptor includes one or more constraints, e.g., the  
10 administrative group to which the links of the tree have to belong. The BLCE of the SPT Bridges then  
11 performs constrained routing (CR) to determine a loose hop instead of shortest path routing. CR relies on  
12 distributed link state operation similarly to shortest path routing. CR essentially performs shortest path  
13 routing on the topology that contains only the links meeting the constraint(s); therefore, the applied path  
14 computation algorithm is also referred to as Constrained Shortest Path First (CSPF).

15 NOTE 4—If a tree is a strict explicit tree, then it is fully specified; therefore, no constraint is included in the tree  
16 descriptor (45.1.9) as no further computation is needed.

17 An explicit tree is specified by a Topology sub-TLV (45.1.9). The Topology sub-TLV associates one or more  
18 VIDs with an explicit tree. The Topology sub-TLV includes two or more Hop sub-TLVs (45.1.10), and a hop  
19 is specified by an IS-IS System ID. A strict tree is decomposed to branches, and each branch is specified by  
20 an ordered list of Hop sub-TLVs. A loose tree is not fully specified, but the Topology sub-TLV conveys  
21 some of its hops. The Hop sub-TLV of a loose hop can include a delay constraint [item h) in 45.1.10]. A  
22 Topology sub-TLV can also include further sub-TLVs to constrain (45.1.11, 45.1.12) loose hops. The  
23 Bridges involved in an explicit tree store the corresponding Topology sub-TLVs in their Explicit Tree  
24 Database (ETDB).

25 Explicit trees are propagated and set up by ISIS-PCR in an SPT Region. The PCE or its PCA assembles the  
26 Topology sub-TLVs (45.1.9) and then instructs ISIS-PCR to establish the tree. If the PCE resides in an SPT  
27 Bridge, then the PCE entity passes the Topology sub-TLV (45.1.9) to the ISIS-PCR entity, which shall then  
28 flood an LSP including the Topology sub-TLV throughout the SPT Domain. If the PCE resides in an end  
29 station, then either the PCE or its PCA adds the Topology sub-TLV (45.1.9) into an LSP, which is flooded  
30 throughout the SPT Domain. The Topology sub-TLV is flooded by the same techniques used for the SPB  
31 LSPs. The SPT Bridges then shall process the Topology sub-TLV (45.1.9) upon reception. If the Topology  
32 sub-TLV specifies one or more loose trees, then the path for the loose hops is determined by the BLCE of the  
33 SPT Bridges. The SPT Bridges then install the appropriate FDB entries (45.1.6) for frame forwarding along  
34 the tree described by the Topology sub-TLV (45.1.9) or the trees computed based on the Topology sub-TLV.  
35 Dynamic Filtering Entries are maintained by ISIS-PCR for the VID, MAC address tuples associated with  
36 an ET.

37 NOTE 5—Due to the LSP aging of IS-IS, the Topology sub-TLVs (45.1.9) have to be refreshed similar to other IS-IS  
38 TLVs in order to keep the integrity of the LSDB. The corresponding Dynamic Filtering Entries are also refreshed when a  
39 Topology sub-TLV is refreshed. Refreshing Topology sub-TLVs is the task of the entity being part of the IS-IS Domain,  
40 i.e., either the PCE or the PCA.

41 The owner PCE can withdraw an explicit tree by sending an updated LSP that does not include the Topology  
42 sub-TLV. If a Topology sub-TLV is removed from an LSP (or has been changed), so that (previous)  
43 Topology sub-TLV is no longer present (or has been changed) in the LSDB, then that (previous) Topology  
44 sub-TLV is implicitly withdrawn. ISIS-PCR then removes (or updates) the explicit tree.

45 ISIS-PCR provides precedence order among Topology sub-TLVs as specified in 45.2.3 if it is needed in a  
46 region with multiple PCEs.

## 1 45.1.1 Tree structures

2 Two types of tree structures can be used for explicit trees, as follows:

- 3 — Ad-hoc trees
- 4 — Template trees

5 Ad-hoc explicit trees do not follow any template; they can comprise any path. A particular explicit tree is  
6 defined, and a VID is assigned to the explicit tree. The administratively straightforward way to do this is to  
7 use a bidirectional VID for the explicit tree. This approach constructs a shared bidirectional (\*,G) tree  
8 joining all members of a group.

9 NOTE 1—A single common (\*,G) spanning tree can be constructed this way.

10 Alternatively, explicit trees can follow templates. It can be helpful to define a tree rooted on every Bridge,  
11 where each tree spans every Bridge of a domain and the complete set of trees, one rooted on each Bridge of  
12 a domain, are constructed consistently, so that collectively they form a single forwarding plane offering any-  
13 to-any connectivity within that domain. Such trees are used as a source rooted tree for multicast traffic  
14 emitted from a Bridge, and they are also used as a destination rooted tree for unicast traffic being sent to  
15 their Bridge. There is a fundamental constraint that has to be obeyed for all such structures individually in  
16 that plane. They have to be simply connected trees, with only one path from any point in the network domain  
17 to the root of the tree. If paths to the root cross at any point, or merge and subsequently diverge, a unicast  
18 forwarding inconsistency or an unwanted multicast frame replication point is created.

19 This connectivity style (i.e., a tree per Bridge per plane) is, for example, enforced by construction by  
20 Shortest Path Bridging. In SPB, a Base VID is associated with one of the standard symmetric ECT  
21 Algorithms (28.8), which identifies a plane. In SPBM, the individual trees within each Base VID are defined  
22 by the MAC address of the root Bridge; in SPBV each Bridge is allocated an individual SPVID to define its  
23 tree.

24 Any preferred algorithm can be used when performing explicit routing, and the required constraint can be  
25 replicated by maintaining the simply connected tree construct. Thus the template-tree-based approach  
26 constructs one or more explicitly routed forwarding planes with tree sets, one tree rooted on each Bridge  
27 within each plane.

28 In the case of a learning VLAN, a unidirectional VID can be assigned to each tree (similarly to the  
29 unidirectional SPVID model), so that each tree is independent and identifies its root Bridge. Shared VLAN  
30 Learning (3.247) takes place among the VIDs associated with the same explicit tree set, where reverse  
31 congruence (3.222) has to be enforced by the function that computes the explicit trees on a particular  
32 forwarding plane (Base VID).

33 In the case of a non-learning VLAN, the MAC of the root Bridge identifies the tree, and a single Base VID  
34 identifies the entire forwarding plane.

35 Care has to be taken when constructing multicast trees with multiple sources if the template tree approach is  
36 used. Source-specific multicast (S,G) has to be applied if multiple sources participate in a single multicast  
37 group. A separate source rooted tree is constructed for every source of the group, and the complete multicast  
38 structure is the superposition of all these separate source rooted trees. The multicast traffic of the different  
39 sources has to be distinguished either by a VID (as in SPBV) or by a source-specific Group MAC address  
40 (as in SPBM, see 27.15).

41 NOTE 2—There is no requirement here that the initial template construction actually generates spanning trees. If  
42 Bridges only initially require connectivity to a subset of the SPT Bridges of a region, only the relevant part of the  
43 template need initially be constructed. This leaves freedom to add hitherto unconnected Bridges by extension of trees  
44 using a preferred route at a later stage.

## 45.1.2 Explicit ECT Algorithms

Five explicit path control modes are specified by this standard; each of them is identified by a distinct ECT-ALGORITHM. Table 45-1 summarizes the ECT Algorithms that can be used for explicit trees. The ECT-ALGORITHMS specified by this standard for explicit trees are formed using OUI=00-80-C2 and Index values 0x17, 0x18, 0x19, and the range from 0x21 to 0x40. SPT Bridges that support PCR shall support the Strict Tree ECT Algorithm (00-80-C2-17) and may support the other ECT Algorithms of Table 45-1. VLANs under explicit path control are associated with one of the ECT Algorithms as specified by 45.1.3.

NOTE 1—The ECT-ALGORITHM is in fact the identifier of the method and the algorithm used to determine the active topology. Although the active topology specified by this clause is not an Equal Cost Tree, the terminology and the ECT Algorithm framework of Clause 27 and Clause 28 is kept. The Opaque ECT concept (28.6) is also supported for explicit path control, which can be used for further algorithms.

**Table 45-1—ECT-ALGORITHM values for explicit trees**

| ECT-ALGORITHM                  | Algorithm Name                                                     | Behavior                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00-80-C2-17                    | Strict Tree<br>(ST ECT Algorithm)                                  | A single strict explicit tree. No restoration or update is performed by IS-IS on its own; only the PCE can initiate the update of a strict ET.                                                                                                                                                                                                                                                                                 |
| 00-80-C2-21 ...<br>00-80-C2-30 | Loose Tree<br>(LT ECT Algorithm)                                   | A single loose explicit tree. The loose hops are computed by the BLCE of SPT Bridges applying constrained or shortest path routing. The loose hops are restored by IS-IS upon a topology change if loop-free paths are available. The Bridge Priority Mask to be used in the case of constrained or shortest paths is specified by Table 45-2.                                                                                 |
| 00-80-C2-31 ...<br>00-80-C2-40 | Loose Tree Set<br>(LTS ECT Algorithm)                              | A set of loose explicit trees. The set comprises an individual tree for each Edge Bridge included in the descriptor of the explicit tree, i.e., they are template trees. Each tree is computed by the BLCE of SPT Bridges applying constrained routing. These trees are restored by IS-IS upon a topology change. The Bridge Priority Mask to be used in the case of constrained or shortest paths is specified by Table 45-2. |
| 00-80-C2-18                    | Maximally Redundant<br>Trees<br>(MRT ECT Algorithm)                | Maximally Redundant Trees (MRTs) are loose trees for each MRT Root, which are computed together with the corresponding GADAG by the BLCE of SPT Bridges and cautiously restored by ISIS-PCR. If the topology view is identical throughout the SPT Domain, then IS-IS restores these trees one by one, only one of each redundant set at a time (45.3.3).                                                                       |
| 00-80-C2-19                    | Maximally Redundant<br>Trees with GADAG<br>(MRTG<br>ECT Algorithm) | Maximally Redundant Trees (MRTs) are loose trees for each MRT Root, which are computed by the BLCE of SPT Bridges based on the GADAG received from the single GADAG Computer. MRTs are cautiously restored by ISIS-PCR upon reception of a new GADAG from the GADAG Computer. IS-IS restores these trees one by one, only one of each redundant set at a time (45.3.4).                                                        |

The Strict Tree (ST) ECT Algorithm is used for a strict explicit tree. A strict ET is static as no other entity can update it but the tree owner PCE. In the case of a topology change, it is the task of the owner PCE to detect the topology change, e.g., based on the changes in the LSDB, and to update the strict trees if needed. In other words, the owner PCE computes the new tree, assembles its descriptor, and then instructs ISIS-PCR to install it. The use of VIDs for strict trees is described in 45.1.4, and redundant strict trees are explained in 45.3.2.

The Loose Tree (LT) ECT Algorithm is used for a single loose explicit tree. The path for loose hops is determined by the BLCE of the SPT Bridges; therefore, the Topology sub-TLV (45.1.9) specifying the tree has to indicate which hop is the root of the tree. The loose hops are maintained by IS-IS, i.e., restored upon a topology change if a loop-free path is available. If the tree computed by the BLCE visits the same Bridge twice (implying that a loop or hairpin has been created), then that loop or hairpin has to be pruned from the tree even if it contains a hop specified by the Topology sub-TLV. Constrained routing can be applied for the loose hops based on the attributes listed in 45.1.8. If a Bridge is not to be included is also a constraint, which can be specified by the Exclude flag [item c6) in 45.1.10] of a Hop sub-TLV (45.1.10) conveyed by the Topology sub-TLV specifying the tree.

The Loose Tree Set (LTS) ECT Algorithm is used if connectivity among the Edge Bridges specified by the Topology sub-TLV (45.1.9) is to be provided by a set of loose trees so that one tree is rooted at each Edge Bridge, i.e., the loose trees are template trees (45.1.1). The BLCEs of the SPT Bridges compute the loose trees, which are maintained by IS-IS, i.e., restored upon a topology change. Avoiding some bridges in these trees is a constraint, which can be specified by the Exclude flag [item c6) in 45.1.10]. Further constraints can be specified by the Topology sub-TLV based on the attributes listed in 45.1.8.

NOTE 2—A Loose Tree Set is similar to a Shortest Path Tree Set with the following differences: The trees of an LTS span only the Edge Bridges specified by the Topology sub-TLV; they do not span the entire SPT Region. Furthermore, constrained routing is applied instead of shortest path routing.

**Table 45-2—Bridge Priority Masking for the LT and LTS ECT Algorithms**

| ECT-ALGORITHM<br>(LT ECT Algorithm) | ECT-ALGORITHM<br>(LTS ECT Algorithm) | Algorithm<br>MASK |
|-------------------------------------|--------------------------------------|-------------------|
| 00-80-C2-21                         | 00-80-C2-31                          | 0x00              |
| 00-80-C2-22                         | 00-80-C2-32                          | 0xFF              |
| 00-80-C2-23                         | 00-80-C2-33                          | 0x88              |
| 00-80-C2-24                         | 00-80-C2-34                          | 0x77              |
| 00-80-C2-25                         | 00-80-C2-35                          | 0x44              |
| 00-80-C2-26                         | 00-80-C2-36                          | 0x33              |
| 00-80-C2-27                         | 00-80-C2-37                          | 0xCC              |
| 00-80-C2-28                         | 00-80-C2-38                          | 0xBB              |
| 00-80-C2-29                         | 00-80-C2-39                          | 0x22              |
| 00-80-C2-2A                         | 00-80-C2-3A                          | 0x11              |
| 00-80-C2-2B                         | 00-80-C2-3B                          | 0x66              |
| 00-80-C2-2C                         | 00-80-C2-3C                          | 0x55              |
| 00-80-C2-2D                         | 00-80-C2-3D                          | 0xAA              |
| 00-80-C2-2E                         | 00-80-C2-3E                          | 0x99              |
| 00-80-C2-2F                         | 00-80-C2-3F                          | 0xDD              |
| 00-80-C2-30                         | 00-80-C2-40                          | 0xEE              |

1 In the case of the LT and LTS ECT Algorithms, the symmetric shortest path tie-breaking specified in 28.5,  
2 28.6, 28.7, and 28.8 is used during shortest path computation to manipulate the lexicographic ordering of  
3 hops on a path after pruning the topology according to the constraints. The Bridge Priority Masks for the LT  
4 and LTS ECT Algorithms are shown in Table 45-2. The mask identification method specified for the  
5 Symmetric ECT Algorithms is used. The IEEE 802.1 OUI (00-80-C2) is used, Index values 0x21 through  
6 0x30 are used for the LT ECT Algorithm, and Index values 0x31 through 0x40 are used for the LTS ECT  
7 Algorithm as shown in Table 45-2.

8 The Maximally Redundant Trees (MRT) ECT Algorithm or the Maximally Redundant Trees with  
9 Generalized Almost Directed Acyclic Graph (GADAG) (MRTG) ECT Algorithm is used if maximally  
10 redundant loose explicit trees have to be maintained together. The use of the MRT ECT Algorithm and the  
11 MRTG ECT Algorithm is described in 45.3.3 and 45.3.4, respectively.

12 ISIS-PCR uses the link metrics specified by the SPB Link Metric sub-TLVs (28.12.7) if the LT, the LTS, the  
13 MRT, or the MRTG ECT Algorithm is used. The SPB Link Metric sub-TLV is used as specified in 28.12.7;  
14 therefore, the maximum metric value is used in cases where the metrics advertised by adjacent Bridges for a  
15 given link are different.

16 A topology change can cause the need for recomputing and updating multiple loose trees. If constrained  
17 routing based on available bandwidth (45.1.12) is used for multiple loose trees, then there can be a race  
18 hazard for the same resources if they are updated at the same time. Furthermore, the computation order can  
19 influence the trees. Therefore, ISIS-PCR applies the tie-breaking method specified in 45.2.3 in order to  
20 determine the computation order among the loose trees based on their descriptor Topology sub-TLV. If a  
21 Topology sub-TLV specifies multiple loose trees, e.g., LTS or MRTs, then the computation order of these  
22 trees follows the ascending order of the IS-IS System ID of the Bridges rooting the trees.

### 23 **45.1.3 ISIS-PCR VLAN configuration**

24 A VLAN provided by an explicit tree controlled by IS-IS is associated with IS-IS by means of allocating the  
25 VLAN's Base VID to the appropriate MSTID, i.e., either to the SPBM-MSTID or to the SPBV-MSTID. The  
26 explicit path control mode is then selected by associating the Base VID with the corresponding explicit ECT  
27 Algorithm.

28 The Base VID of VLANs controlled by IS-IS is allocated either to the SPBM-MSTID (0xFFC) or to the  
29 SPBV-MSTID (0xFFD) as specified in 27.4, which also applies to VLANs under explicit path control via  
30 IS-IS. If multiple VIDs belong to a VLAN under explicit path control, then each VID has to be allocated to  
31 the same MSTID; otherwise, the explicit trees do not get installed for the VLAN.

32 The exact active topology enforcement method applied for the VLAN is determined by the ECT Algorithm  
33 (28.8) with which the VLAN is associated. Explicit path control mode is configured by means of associating  
34 the Base VID with one of the ECT Algorithms specified in 45.1.2. The association of the VLAN with the  
35 ECT Algorithm shall be provided by the SPB Base VLAN-Identifiers sub-TLV (28.12.4).

36 Each VID belongs only to one PCE, which is the owner PCE that has full control on the use of the VID. The  
37 VIDs of a PCE are to be configured at the PCE. If multiple PCEs try to use the same VID, then ISIS-PCR  
38 provides the precedence as specified in 45.2.3.

39 An IS-IS controlled VLAN is a non-learning VLAN if the VLAN's Base VID is allocated to the SPBM-  
40 MSTID (0xFFC). MAC addresses are distributed explicitly for non-learning VIDs by IS-IS. The M flag is  
41 set in the SPB Instance sub-TLV (28.12.5) for non-learning VLANs. If a non-learning VLAN is associated  
42 with a symmetric ECT Algorithm (28.8), then the VLAN is under SPBM control as specified by Clause 27  
43 and Clause 28 even if the VLAN is not a B-VLAN. If a non-learning VLAN is associated with one of the  
44 explicit ECT Algorithms (45.1.2), then it is under explicit path control as specified by this clause.

1 An IS-IS controlled VLAN is a learning VLAN if the VLAN's Base VID is allocated to the SPBV-MSTID  
2 (0xFFD). If a learning VLAN is supported by multiple VIDs, then Shared VLAN Learning (3.247) takes  
3 place among the VLAN's VIDs associated with the same shortest path or explicit tree set. The M flag is  
4 cleared in the SPB Instance sub-TLV (28.12.5) for learning VLANs. If a learning VLAN is associated with a  
5 symmetric ECT Algorithm (28.8), then the VLAN is under SPBV control as specified by Clause 27 and  
6 Clause 28; correspondingly, SPVIDs can be auto-allocated to SPTs from the pool of SPVIDs, i.e., from the  
7 VIDs allocated to the SPVID-Pool-MSTID (0xFFFF) as specified by 27.4. If a learning VLAN is associated  
8 with one of the explicit ECT Algorithms (45.1.2), then it is under explicit path control as specified by this  
9 clause; and each VID of the VLAN is allocated to the SPBV-MSTID (0xFFD), i.e., none of the VLAN's  
10 VIDs is allocated automatically. When a VLAN is under explicit path control, it is the responsibility of the  
11 PCE to provide reverse congruent paths (3.222) so that Shared VLAN Learning (3.247) operates correctly.

12 NOTE 1—The learning VIDs used for explicit trees are not allocated to the SPVID-Pool-MSTID. Therefore, they are  
13 not taken from the SPVID pool; they are not Shortest Path VIDs even if conveyed by an SPVID field of an IS-IS sub-  
14 TLV. To emphasize, a learning VID is an SPVID only if it is taken from the SPVID pool.

15 The Topology sub-TLV (45.1.9) conveys only the VLAN's Base-VID for each ECT Algorithm. Further  
16 VIDs, if any, are associated with the VLAN and its Base VID by ISIS-SPB sub-TLVs as specified below.

17 If the ST ECT Algorithm (Table 45-1) is used for either a learning or a non-learning VLAN, then the VLAN  
18 is supported only by its Base VID. The VLAN's Base VID shall be associated with the ST ECT Algorithm  
19 in the SPB Base VLAN-Identifiers sub-TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5).

20 If the LT ECT Algorithm (Table 45-1) is used for either a learning or a non-learning VLAN, then the VLAN  
21 is supported only by its Base VID, which is associated with the LT ECT Algorithm in the SPB Base VLAN-  
22 Identifiers sub-TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5).

23 If the LTS ECT Algorithm (Table 45-1) is used for a non-learning VLAN, then the VLAN is supported only  
24 by its Base VID, which is associated with the LTS ECT Algorithm in the SPB Base VLAN-Identifiers sub-  
25 TLV (28.12.4) and in the SPB Instance sub-TLV (28.12.5).

26 NOTE 2—The use of the LTS ECT Algorithm for a non-learning VLAN is similar to SPBM (Clause 27 and Clause 28)  
27 operations, but constrained trees are used instead of SPTs. One VID is sufficient for the support of a set of constrained  
28 trees, which is specified as a set of loose explicit trees.

29 However, if the LTS ECT Algorithm (Table 45-1) is used for a learning VLAN, then the VLAN is supported  
30 by multiple VIDs because each tree of an LTS is required to have its own VID. The VLAN's Base-VID is  
31 associated with the LTS ECT Algorithm in the SPB Base VLAN-Identifiers sub-TLV (28.12.4) and in the  
32 SPB Instance sub-TLV (28.12.5). In addition to the Base VID, as many VIDs are needed to support the  
33 VLAN as the number of transmitter Edge Bridges specified by the Topology sub-TLV (45.1.9). The  
34 individual VID of a transmitter Edge Bridge is configured to support the VLAN at the given SPT Bridge.  
35 The VID to be used for the loose tree of a transmitter Edge Bridge is conveyed by the SPVID field of the  
36 VLAN ID Tuple of the corresponding Base VID in the SPB Instance sub-TLV (28.12.5) of the given Edge  
37 Bridge. The A flag of the given VLAN ID Tuple is cleared to indicate that auto-allocation is not used for the  
38 SPVID parameter. If no VID is configured for the loose tree in the SPB Instance sub-TLV of a transmitter  
39 Edge Bridge, then ISIS-PCR does not install the loose tree for that Edge Bridge. If the same local VID value  
40 is configured at multiple Bridges, then ISIS-PCR does not install the loose tree for either Bridge, and the  
41 conflict has to be resolved by operator action. Although the field is called SPVID, the VID it conveys is not  
42 a Shortest Path VID but a loose tree VID as indicated by the ECT Algorithm field of the given VLAN ID  
43 Tuple and by the VID to MSTID allocation.

44 NOTE 3—The use of the LTS ECT Algorithm for a learning VLAN is similar to SPBV (Clause 27 and Clause 28)  
45 operations, but with loose trees, i.e., constrained trees are used instead of SPTs. Therefore, each Bridge rooting a loose  
46 tree has to have its own VID for the support of a learning VLAN on that tree. The SPB Instance sub-TLV is used to bind  
47 the VIDs of the individual root Bridges to the Base VID; the SPVID parameter conveys the VID to be used for the loose  
48 tree rooted at the given Bridge. The VID is not a Shortest Path VID because it is used for a loose explicit tree as  
49 indicated by the ECT Algorithm parameter and by the VID to MSTID allocation.

1 If the MRT ECT Algorithm (Table 45-1, 45.3.3) or the MRTG ECT Algorithm (Table 45-1, 45.3.4) is used  
2 for a VLAN, then a distinct VID is required for the two MRTs: MRT-Blue and MRT-Red. In the case of a  
3 non-learning VLAN, a single VID is used for MRT-Blue of all MRT Roots, and another VID is used for all  
4 MRT-Reds. Two VIDs support a non-learning VLAN if the MRTs protect each other, whereas the VID of the  
5 SPT Set is also needed as the third VID if the MRTs protect SPTs. The MRT VIDs are also allocated to the  
6 SPBM-MSTID (0xFFC) in the case of a non-learning VLAN. However, each MRT Root has to be  
7 configured with its own unique VID-pair for its MRT-Blue and MRT-Red in the case of a learning VLAN,  
8 and all the MRT VIDs are allocated to the SPBV-MSTID (0xFFD). Independent VLAN Learning (3.104) is  
9 applied among the VIDs associated with MRTs. Twice as many MRT VIDs support a learning VLAN as  
10 MRT Roots, which are all the VIDs that are needed if the MRTs protect each other. The Shortest Path VIDs  
11 (real SPVIDs) of the SPTs are also needed in addition to the MRT VIDs for the support of a learning VLAN  
12 if the MRTs protect SPTs. As the two MRT algorithms differ only in GADAG handling, the VLAN  
13 configuration is the same for these two ECT Algorithms once the appropriate ECT-ALGORITHM value is  
14 used in the ECT Algorithm field of the IS-IS sub-TLVs. The VLAN's Base VID is associated with the MRT  
15 ECT Algorithm or with the MRTG ECT Algorithm in the SPB Base VLAN identifier sub-TLV (28.12.4).

16 The SPB Instance sub-TLV (28.12.5) provides the VIDs for MRT-Blue and MRT-Red and also associates  
17 them with the VLAN. The same VID values are used in the corresponding SPVID fields in the SPB Instance  
18 sub-TLV of all MRT Roots in the case of a non-learning VLAN; whereas the VID values in the SPVID  
19 fields are unique for each MRT Root in the case of a learning VLAN. The SPB Instance sub-TLV also  
20 specifies whether the MRTs are used to protect each other or whether they protect an SPT.

21 The SPB Instance sub-TLV (28.12.5) conveys three VLAN ID Tuples for the VLAN. The ECT Algorithm  
22 parameter of the second and the third VLAN ID Tuple is either the MRT ECT Algorithm or the MRTG ECT  
23 Algorithm, accordingly. If the MRTs are used to protect SPTs, then the ECT Algorithm parameter of the first  
24 VLAN ID Tuple specifies the ECT Algorithm to be used for shortest path computation, e.g., one of the  
25 standard symmetric ECT Algorithms (Table 45-1). The first VLAN ID Tuple also specifies the VID to be  
26 used for the shortest paths, which is the Base VID for a non-learning VLAN or the Shortest Path VID  
27 (allocated to the SPVID-Pool-MSTID) conveyed by the SPVID parameter for a learning VLAN. If the  
28 MRTs are used to protect each other, then the ECT Algorithm parameter of the first VLAN ID Tuple is the  
29 same as that of the second and the third VLAN ID Tuple. The second and the third VLAN ID Tuples  
30 associate the MRT VIDs with the Base VID. The SPVID parameter of the second VLAN ID Tuple provides  
31 the VID for MRT-Blue. The SPVID parameter of the third VLAN ID Tuple provides the VID for MRT-Red.  
32 In other words, the SPVID parameters of the second and third VLAN ID tuples convey the MRT VIDs, not  
33 Shortest Path VIDs. If ISIS-PCR detects that the same local MRT VID value is configured at multiple  
34 Bridges, then ISIS-PCR does not install the MRT for either Bridge, and the conflict has to be resolved by  
35 operator action.

36 If the MRTs are used to protect SPTs, then the MRT VIDs differ from the Base VID and also differ from  
37 Shortest Path VID conveyed by the SPVID parameter of a learning VLAN's first VLAN ID Tuple. In the  
38 case of non-learning VLANs, if the MRTs are used to protect each other, then the VLAN's Base VID is used  
39 as the VID for MRT-Blue; consequently, the SPVID parameter of the VLAN's second VLAN ID Tuple  
40 conveys the VLAN's Base VID. If the MRTs of a learning VLAN are used to protect each other, then no  
41 Shortest Path VID is required for the VLAN; therefore, the SPVID parameter of the VLAN's first VLAN ID  
42 Tuple is not used but ignored. The use of the SPB instance sub-TLV for the MRT and MRTG ECT  
43 Algorithms is illustrated in Figure 45-3.

44 NOTE 4—The SPVID parameter conveys only a Shortest Path VID if the ECT Algorithm parameter of the given VLAN  
45 ID Tuple identifies shortest path operations and the VID is allocated to the SPVID-Pool-MSTID. The SPVID parameter  
46 is not a Shortest Path VID if the ECT Algorithm parameter identifies explicit path control, i.e., taken from Table 45-1,  
47 which is also indicated by the fact that the VID is not allocated to the SPVID-Pool-MSTID.

48 An I-SID of a PBBN shall be associated with an explicit tree by the SPBM Service Identifier and Unicast  
49 Address sub-TLV (28.12.10) by means of associating the I-SID with a Base VID that is allocated to one of  
50 the explicit ECT Algorithms of Table 45-1.

|                 | Parameter                    | Value                                                     |                                |                         |                                |

Figure 45-3—The use of the SPB Instance sub-TLV for MRT

#### 1 45.1.4 Use of VIDs for strict explicit trees

2 The use of a distinct VID for each explicit tree does not scale in some cases. A more flexible and scalable  
3 method of VID assignment is available for explicit trees. This subclause explains the rules to be observed  
4 and suggests two schemes for the use of VIDs for strict explicit trees, i.e., for VIDs associated with the ST  
5 ECT Algorithm (Table 45-1). Nonetheless, ensuring that VIDs associated with strict explicit trees actually  
6 follow these rules in order to provide unambiguous and loop-free frame forwarding is the responsibility of  
7 the network administrator and the owner PCE controlling the VID; this standard provides no method for  
8 policing this. As each VID belongs to a single owner PCE, a VID can be used only for multiple explicit trees  
9 that are controlled by the same PCE.

10 NOTE 1—Use of VIDs associated with MRTs is explained in 45.3.3.

11 Ensuring unambiguous filtering entries and providing forwarding to the appropriate destination are the  
12 fundamental requirements to be met when assigning VIDs with explicit trees.

13 For unicast frames, there has to be a single egress port for each Individual MAC, VID tuple in each SPT  
14 Bridge. In other words, different explicit trees associated with the same bidirectional VID within an SPT  
15 Domain are not allowed to have any SPT Bridges in common when MAC learning is being used.  
16 Unidirectional VIDs or bidirectional non-learning VIDs associated with different explicit trees to a  
17 particular destination can have common SPT Bridges along the merged segments of those explicit trees as  
18 long as every such tree uses a single egress port for each unicast destination in every Bridge.

19 NOTE 2—A VID can be unidirectional by means of asymmetric use, e.g., as explained in F.1.3 or like an SPVID  
20 (3.257). Also, a bidirectional non-learning VID is in fact used in unidirectional fashion with respect to any given  
21 destination MAC address.

22 For multicast frames, it has to be ensured that each member of the multicast group receives only a single  
23 copy of a particular frame, even if there are multiple potential sources within a group.

24 Congruency (3.222), if required, has to be enforced by the PCE. In the case of unidirectional VIDs, the same  
25 path has to be used for both directions between a source and destination pair in order to provide reverse path  
26 congruency, essential when MAC learning is employed. Unicast and multicast traffic have to be placed on  
27 the same tree in order to provide unicast multicast congruency.

28 The tree structures explained in 45.1.1 can be applied for strict explicit trees, and VIDs can be used on top of  
29 these strict trees as follows.

30 An ad-hoc explicit tree (45.1.1) with a bidirectional VID provides a shared bidirectional (\*,G) tree joining  
31 all members of a group. This structure minimizes VID consumption (as a local instance-by-instance  
32 optimization) compared to cases when each member has its own VID. On the other hand, there is the  
33 constraint that trees using the same VID are not allowed to touch or cross; hence the number of explicit trees  
34 is limited by the available VID space.

35 The template tree (45.1.1) approach constructs one or more explicitly routed forwarding planes with tree  
36 sets, one tree rooted on each Bridge within each plane. In the case of learning VIDs, each tree is associated  
37 with a unidirectional VID, and Shared VLAN Learning (3.247) takes place among the VIDs of a tree set. In  
38 the case of non-learning VIDs, the MAC of the root Bridge identifies the tree; therefore, one VID (the Base  
39 VID) is enough for an entire plane. Furthermore, source-specific multicast (S,G) has to be applied if  
40 multiple sources participate in a single multicast group as explained in 45.1.1. The desired connectivity can  
41 be then laid for VIDs associated with strict template trees with the complete assurance that the required  
42 simply connected tree constraint is obeyed.

43 The efficiency of the template trees approach can be improved substantially in terms of the usage of local  
44 VIDs if Edge Bridges “inherit” the tree and VID rooted at their directly connected Core Bridge. This is  
45 possible because a loop or forwarding ambiguity cannot be created in a single Ethernet hop; to guarantee  
46 this, multi-homed Edge Bridges have to be always configured as non-transit Bridges.

## 1 45.1.5 MAC addresses and ISIS-PCR

2 Propagation of MAC address information by IS-IS is required for explicit trees in order to create Dynamic  
3 Filtering Entries for VID, MAC tuples, except for learning VIDs. The SPBV MAC Address sub-TLV  
4 (28.12.9) shall be used for the advertisement of both Individual and Group MAC Addresses for S-VLANs  
5 and C-VLANs associated with explicit trees. The VLAN's VID is conveyed by Octets 3 and 4 of the SPBV  
6 MAC Address sub-TLV. This local VID (if required) and the VLAN's Base VID are allocated either to the  
7 SPBV-MSTID (for learning VIDs) or to the SPBM-MSTID (for non-learning VIDs); furthermore, the Base  
8 VID is allocated to one of the explicit ECT Algorithms (Table 45-1) as explained in 45.1.2 in more detail.

9 NOTE 1—Multiple SPBV MAC Address sub-TLVs are used if different MAC addresses are mapped to different VIDs  
10 at an SPT Bridge, i.e., MAC addresses associated with an SPT Bridge are not bound together.

11 The SPBM Service Identifier and Unicast Address sub-TLV (28.12.10) shall be used to associate Individual  
12 addresses with an I-SID; Octets 3 through 8 of the sub-TLV convey an Individual B-MAC address. Thus, the  
13 SPT Bridges populate their FDB with the Individual MAC addresses according to their T/R flags for the B-  
14 VLANs allocated to the SPBM-MSTID and associated with explicit path control.

15 Either a Group MAC address associated with an I-SID is source specific, or it is the Backbone Service  
16 Instance Group address (26.4). If Octets 3 through 8 of any SPBM Service Identifier and Unicast Address  
17 sub-TLV convey the null value throughout the SPT Domain, then the Backbone Service Instance Group  
18 address corresponding to the given I-SID is to be used for all multicast sources in (\*,G) mode on one simple  
19 explicit tree. If no SPBM Service Identifier and Unicast Address sub-TLV with null value in its B-MAC  
20 address field is present in the SPT Domain, then the source-specific group addressing specified in 27.15 has  
21 to be applied, exactly as used for SPBM. In the source-specific case, the SPB Instance sub-TLV (28.12.5)  
22 shall be used to propagate the SPSourceID (27.10) of the Bridges that are Edge Bridges of the explicit tree  
23 and can be a source of the multicast traffic. In order to avoid forwarding anomalies, source-specific group  
24 addressing has to be used if there are multiple multicast sources for a given I-SID using the same B-VID and  
25 the template tree model (45.1.4) is followed, i.e., multiple trees are used.

26 NOTE 2—Multiple SPBM Service Identifier and Unicast Address sub-TLVs are used if different MAC addresses are  
27 mapped to different I-SIDs at an SPT Bridge, i.e., MAC addresses associated with an SPT Bridge are not bound together.

## 28 45.1.6 Filtering Database entries for explicit trees

29 The Topology sub-TLV (45.1.9) provides the information needed for ISIS-PCR to create the appropriate  
30 Dynamic VLAN Registration Entries, i.e., it provides the explicit tree, the VIDs associated with the tree, and  
31 the direction of the directed VIDs.

32 The per Bridge association of a MAC address with a VID is provided by the SPBV MAC Address sub-TLV  
33 (28.12.9) as described in 45.1.5. Based on the Topology sub-TLVs and SPBV MAC Address sub-TLVs,  
34 ISIS-PCR can create the VID, MAC tuple Dynamic Filtering Entries for VLANs associated with explicit  
35 trees.

36 The association of a B-VID with an explicit tree is provided by the Topology sub-TLV (45.1.9), and the per  
37 Bridge association of an I-SID to a B-VID is provided by the SPBM Service Identifier and Unicast Address  
38 sub-TLV (28.12.10), which also provides the association of a B-MAC to an I-SID as described in 45.1.5.  
39 The SPBM Service Identifier and Unicast Address sub-TLVs also make it clear whether source-specific  
40 group addressing is to be used. If that is the case, then the SPB Instance sub-TLVs (28.12.5) provide the  
41 SPSourceIDs (27.10) that are needed for the creation of the automatically generated Group MAC addresses  
42 of the I-SID as described in 45.1.5. Based on these sub-TLVs, ISIS-PCR can create the B-VID, B-MAC  
43 tuple Dynamic Filtering Entries for I-SIDs associated with explicit trees.

### 1 45.1.7 ISIS-PCR support

2 ISIS-PCR and PCEs are configured to use one of the Group addresses from Table 8-17 to establish  
3 adjacencies and exchange PDUs. ISIS-PCR running on C-VLAN components use the Customer Bridge  
4 address. ISIS-PCR running on S-VLAN components use the Provider Bridge address. ISIS-PCR running on  
5 B-VLAN components can use the Provider Bridge Address or one of the existing IS-IS addresses.

6 The use of the ISIS-PCR adjacency between Bridges is contingent on the Bridges inclusion within the same  
7 SPT Region and thus requires that they have an MCID and Auxiliary MCID (13.8, 28.12.2) where at least  
8 one matches on every adjacency in the Region (8.9.4, 13.8). MCID and Auxiliary MCID enable migration of  
9 the MCID definition allowing these Bridges to operate as one SPT Region under certain small changes. The  
10 operational set of Base VLANs has to be consistent during migration. The MCID and the Auxiliary MCID  
11 are exchanged in IS-IS Hello PDUs, which also include the SPB Base VLAN-Identifiers sub-TLV (28.12.4).  
12 ISIS-PCR adjacencies are formed and maintained as specified by 28.2, i.e., in exactly the same way as ISIS-  
13 SPB adjacencies. Either a PCE hosted by an end station has a PCA that is part of the IS-IS Domain, or the  
14 PCE forms and maintains an ISIS-PCR adjacency between the PCE and the SPT Bridge to which the end  
15 station is attached.

16 Management of explicit trees also requires the following:

- 17 a) Management of the PCR objects (12.26)
- 18 b) Administrative agreement on the MCID Configuration Name and Revision Level (Clause 28)

19 NOTE—The addresses used by IS-IS PDUs and the operations with respect to IS-IS adjacencies are the same for ISIS-  
20 PCR and ISIS-SPB. This subclause (45.1.7) simply reiterates provisions of Clause 27 and Clause 28 (see 27.2, 28.2).

### 21 45.1.8 Attributes for path computation

22 More attributes than the link metric are needed for PCEs or BLCEs in order to be able to determine paths  
23 that meet the requirements. Extended link attributes are specified by the Traffic Engineering (TE) extensions  
24 for IS-IS in IETF RFC 5305. The TE information is flooded in LSPs by IS-IS and it is stored in the Traffic  
25 Engineering Database (TED). The TED contains the topology and the resource information of the IS-IS  
26 Domain.

27 SPT Bridges may support the Extended IS Reachability TLV (type 22) specified in IETF RFC 5305, which  
28 provides the following link attribute IS-IS sub-TLVs:

- 29 a) Administrative Group (color, resource class) (sub-TLV type 3)
- 30 b) Maximum Link Bandwidth (sub-TLV type 9)
- 31 c) Maximum Reservable Link bandwidth (sub-TLV type 10)
- 32 d) Unreserved Bandwidth (sub-TLV type 11)
- 33 e) Traffic Engineering Default Metric (sub-TLV type 18)

34 SPT Bridges may support the following IS-IS TE Metric Extension link attribute sub-TLVs specified in  
35 IETF RFC 7810:

- 36 f) Unidirectional Link Delay (sub-TLV type 33)
- 37 g) Min/Max Unidirectional Link Delay (sub-TLV type 34)
- 38 h) Unidirectional Delay Variation (sub-TLV type 35)
- 39 i) Unidirectional Link Loss (sub-TLV type 36)
- 40 j) Unidirectional Residual Bandwidth (sub-TLV type 37)
- 41 k) Unidirectional Available Bandwidth (sub-TLV type 38)
- 42 l) Unidirectional Utilized Bandwidth (sub-TLV type 39)

1 The IS-IS TE Metric Extensions sub-TLVs are conveyed by IS-IS Extended IS Reachability TLV (type 22).  
2 The bandwidth already allocated determines the Residual Bandwidth and the Available Bandwidth. When  
3 they are used in a Bridged Network, reservations performed by MSRP or bandwidth assignments recorded  
4 by ISIS-PCR are taken into account to determine these sub-TLVs.

5 NOTE—The Residual Bandwidth and the Unreserved Bandwidth sub-TLVs can be used concurrently; see  
6 IETF RFC 7810.

7 If Shared Risk Link Group (SRLG) information is to be applied, then the SRLG TLV (type 138) of IETF  
8 RFC 5307 may be used as specified here. Figure 45-4 shows the format of the SRLG TLV.

|                        | Octet                        | Length                              |
|------------------------|------------------------------|-------------------------------------|
| Type (138)             | 1                            | 1                                   |
| Length                 | 2                            | 1                                   |
| System ID              | 3–8                          | 6                                   |
| Pseudonode num         | 9                            | 1                                   |
| Flag                   | 10                           | 1 bit                               |
| reserved               | 10                           | 7 bits                              |
| Link Local Identifier  | 11–14                        | 4                                   |
| Link Remote Identifier | 15–18                        | 4                                   |
| SRLG <i>l</i>          | Shared Risk Link Group Value | 19–22 4                             |
| ...                    |                              |                                     |
| SRLG <i>n</i>          | Shared Risk Link Group Value | (4 <i>n</i> +15)–(4 <i>n</i> +18) 4 |

**Figure 45-4—Shared Risk Link Group (SRLG) TLV**

9 The SRLG parameters are encoded as follows:

- 10 m) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 138.
- 11 n) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field, which is the  
12 number of SRLG Values multiplied by 4 plus 16 bytes.
- 13 o) System ID (48 bits). Octets 3 through 8 convey the 6-byte IS-IS System Identifier of the adjacent  
14 neighbor.
- 15 p) Pseudonode num (8 bits). Octet 9 conveys the pseudonode number if the neighbor is connected  
16 through a shared media.
- 17 q) Flag (1 bit). Octet 10 conveys a flag, which is encoded as a bit in a single octet. A flag is set if the bit  
18 takes the value 1; otherwise, it is reset. The Flag of Octet 10 indicates whether an IP address is used  
19 to identify the link. It is not an IP address in the case of ISIS-PCR, i.e., the link is unnumbered.  
20 Therefore, the flag is reset in an SPT Domain, i.e., each bit of Octet 10 takes value 0.
- 21 r) reserved (7 bits). Seven bits of Octet 10 are reserved for future use, transmitted as 0, and ignored on  
22 receipt.
- 23 s) Link Local Identifier (32 bits). Octets 11 through 14 convey the local identifier of the interface,  
24 which is an Extended Local Circuit ID as specified by IETF RFC 5303.
- 25 t) Link Remote Identifier (32 bits). Octets 15 through 18 convey the identifier of the remote interface,  
26 which is a Neighbor Extended Local Circuit ID as specified by IETF RFC 5303.
- 27 u) Shared Risk Link Group Value (32 bits). Octets 4*n*+15 through 4*n*+18 convey the value assigned to  
28 SRLG *n* to which the link belongs. The same SRLG value is used for all links that share a resource  
29 whose failure affects each link of the group. A link can belong to multiple SRLGs; therefore,  
30 multiple Shared Risk Link Group Values can be present in the same SRLG TLV.

## 45.1.9 Topology sub-TLV

The variable-length Topology sub-TLV shall be used to describe an explicit tree. The Topology sub-TLV may be also used for describing a Generalized Almost Directed Acyclic Graph (GADAG) as explained in 45.3.4 in detail. The Topology sub-TLV is carried in an MT-Capability TLV (type 144) in a Link State PDU. A Topology sub-TLV specifying an explicit tree conveys one or more Base VIDs and two or more Hop sub-TLVs (45.1.10) and can convey further sub-TLVs (45.1.11, 45.1.12) to constrain loose hops. The Topology sub-TLV also specifies the algorithm to be used for constrained routing. Figure 45-5 shows the format of the Topology sub-TLV.

|                         |                     | Octet                               | Length  |         |
|-------------------------|---------------------|-------------------------------------|---------|---------|
|                         | Type (21)           | 1                                   | 1       |         |
|                         | Length              | 2                                   | 1       |         |
|                         | Number of Base VIDs | 3                                   | 1       |         |
| Base VID Tuple <i>l</i> | reserved            | 4                                   | 4 bits  | 0 or    |
|                         | Base VID            | 4–5                                 | 12 bits | 16 bits |
|                         | ...                 |                                     |         |         |
| Base VID Tuple <i>n</i> | reserved            | (2 <i>n</i> +2)                     | 4 bits  | 0 or    |
|                         | Base VID            | (2 <i>n</i> +2)–<br>(2 <i>n</i> +3) | 12 bits | 16 bits |
| sub-TLV <i>l</i>        | sub-TLV             |                                     |         |         |
|                         | ...                 |                                     |         |         |
| sub-TLV <i>m</i>        | sub-TLV             |                                     |         |         |

**Figure 45-5—Topology sub-TLV**

The parameters of explicit trees are encoded by the Topology sub-TLV as follows:

- Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 21.
- Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field.
- Number of Base VIDs (8 bits). Octet 3 conveys the number of Base VIDs carried in the Topology sub-TLV. Its minimum value is 1 if the Topology sub-TLV specifies an active topology. Its value can be 0 if the Topology sub-TLV specifies only a GADAG.
- reserved (4 bits). Four bits of Octet 2*n*+2 are reserved for future use, transmitted as 0, and ignored on receipt.
- Base VID (12 bits). Octet 2*n*+2 and Octet 2*n*+3 convey the *n*th Base VID parameter. The Base VID parameter provides the Base VID of the VLAN that is associated with the explicit tree. Multiple Base VIDs can be associated with the same explicit tree.

Some of the explicit ECT Algorithms (45.1.2) require further VIDs, in addition to the Base VID, which are associated with the VLAN by using the SPB Instance sub-TLV as specified in 45.1.3.

By default, each Edge Bridge is both transmitter and receiver for all VIDs associated with an explicit tree. Different behavior can be specified in the Hop sub-TLV (45.1.10) of the Edge Bridge.

If VIDs of a learning VLAN associated with the LTS ECT Algorithm (Table 45-1) are conveyed by the Topology sub-TLV, then the default behavior for each Edge Bridge is that it is the only transmitter on its own VID and a receiver on the VIDs of all the other Edge Bridges. For such a learning VLAN, a per Bridge local VID is announced by a transmitter Edge Bridge via the SPB Instance sub-TLV (28.12.5) as specified in 45.1.3. If no VID is allocated to the Edge Bridge, then it is not a transmitter but only a receiver.

A Topology sub-TLV specifying a GADAG can have zero Base VID parameters. In this case, the given GADAG has to be applied for each VLAN associated with the MRTG ECT Algorithm.

- f) sub TLVs. The rest of the octets convey further sub-TLVs that specify the hops of the topology and can also specify constraints, bandwidth assignment, and timestamp as specified in the following subclauses.

A topology is specified by a list of Hop sub-TLVs (45.1.10), and a hop is specified by an IS-IS System ID. An ill-formed Topology sub-TLV, e.g., specifying an invalid strict tree or having a conflict in its specification, is ignored; no tree is installed but a management report is generated.

The Topology sub-TLV specifies a strict tree by decomposing the tree to branches. Each branch is a point-to-point path specified by an ordered list of hops where the end of each branch is a leaf. Each element of a branch is the direct link between adjacent neighbor Bridges whose Hop sub-TLV is next to each other in the Topology sub-TLV. The first hop of the Topology sub-TLV is the root; hence, the first branch originates from the root. The rest of the branches fork from another branch. The first hop of a branch is a Bridge that is already part of a former branch, and the last hop is a leaf Bridge. Therefore, the hop after a leaf hop is the beginning of a new branch, if any. A hop of a branch is created if and only if the Bridge specified for that hop is directly connected to the preceding Bridge of the same branch. The order of the branches does not matter within the Topology sub-TLV, but the first branch begins with the root. Figure 45-6 shows an example for the specification of a strict tree.

**Figure 45-6—A strict tree and its descriptor Topology sub-TLV**

The Topology sub-TLV of a loose tree does not provide any path or path segment, but the hops that are to participate. The root is the first hop. The leaves of a single loose tree are also specified. Hop sub-TLVs can be included in a Topology sub-TLV to specify Bridges that have to be avoided. If the Topology sub-TLV specifies only a single leaf, then one or more transit hops can be specified by the Topology sub-TLV to direct the path along a sequence of Bridges, specified by the order of hops. If Bridges whose respective Hop sub-TLVs are adjacent to each other in the Topology sub-TLV but are not topology neighbors, then it is a loose hop. If a Topology sub-TLV conveys one or more loose hops, then that sub-TLV defines a loose explicit tree, and each hop is considered as a loose hop. If a loose tree specified by a Topology sub-TLV would create a loop or hairpin, then the loop is pruned, and the remaining hops are installed. An example for the specification of a single loose tree is shown in Figure 45-7, where Bridge 77 is the root; Bridges 11, 44, 55,

1 and 88 are leaves; and Bridge 22 is excluded from the tree. Bridges 11, 44, 55, and 88 are the Edge Bridges.  
2 Bridges 11, 44, 55, 77, and 88 are part of the tree because each of them has its special role as specified by the  
3 Topology sub-TLV. Conversely, the role of Bridges 33 and 66 is determined by the BLCE of the SPT  
4 Bridges only when the tree is computed after the reception of the Topology sub-TLV.

**Figure 45-7—Topology sub-TLV of a loose tree**

5 If the Base VIDs of the Topology sub-TLV are associated with the LTS ECT Algorithm or the MRT ECT  
6 Algorithm, then the Hop sub-TLVs conveyed by the Topology sub-TLV belong to Edge Bridges or Bridges  
7 to be excluded [item c6) in 45.1.10]. The BLCEs compute the loose trees, e.g., MRTs, so that they span the  
8 Edge Bridges and are rooted at an Edge Bridge.

9 The Topology sub-TLV specifies a GADAG if the Base VIDs conveyed by the Topology sub-TLV are  
10 associated with the MRTG ECT Algorithm (Table 45-1). The Topology sub-TLV specifies a GADAG by  
11 directed ear decomposition. A directed ear is a directed point-to-point path whose end points can coincide,  
12 but no other element of the path is repeated in the ear. Each ear is specified by an ordered list of hops, and  
13 that order of hops is according to the direction of the arcs in the GADAG. There are no leaves in a GADAG;  
14 hence, the Leaf flag is used to ease the parsing of the Topology sub-TLV and to mark the end of a topology  
15 block (3.281). The sequence of ears in the Topology sub-TLV is such that the end points of an ear belong to  
16 former ears. The GADAG Root is not marked by any flag, but the GADAG Root is the first hop in the  
17 Topology sub-TLV; correspondingly the first ear starts and ends with the GADAG Root. MRT Roots are  
18 marked by the Root flag, and all other Edge Bridges are leaves of the MRTs. If no MRT Root is specified,  
19 then each SPT Root is also an MRT Root. An example GADAG is shown in Figure 45-13 (in 45.3.4).

20 Each Edge Bridge of an explicit tree is always specified in the Topology sub-TLV by the inclusion of the  
21 Hop sub-TLVs corresponding to the Edge Bridges. The Edge Bridges of a tree are identified by setting the  
22 Edge Bridge flag [item c3) in 45.1.10] in the appropriate Hop sub-TLVs.

23 If the explicit tree is loose, then Administrative Group (45.1.11) and Bandwidth Constraint (45.1.12) sub-  
24 TLVs can be also conveyed by the Topology sub-TLV. In that case, each path of the tree has to meet the  
25 constraints specified by these sub-TLVs.

1 If ISIS-PCR is used for recording bandwidth assignment, then the Topology sub-TLV conveys the  
2 Bandwidth Assignment sub-TLV (45.2.1), and it can also convey a Timestamp sub-TLV (45.2.2). If the  
3 assignment of the bandwidth indicated by the Bandwidth Assignment sub-TLV of the Topology sub-TLV  
4 would result in overbooking any link of the explicit tree, then bandwidth assignment is not performed, and a  
5 management report is generated. If such a Topology sub-TLV describes a new valid explicit tree, then the  
6 paths of the tree are installed, but no bandwidth assignment is performed by ISIS-PCR.

7 NOTE 1—The LSP ID can be also considered as an identifier of an explicit tree if an LSP describes only a single tree,  
8 i.e., includes a single Topology sub-TLV.

9 NOTE 2—Allocation of VIDs to individual Aggregation Links between adjacent IS-IS Systems has to be done by  
10 the explicit configuration of conversations in that LAG at the two Systems in accordance with IEEE Std 802.1AX.

#### 11 **45.1.10 Hop sub-TLV**

12 The Hop sub-TLV shall be used to specify a hop of a topology. Each Hop sub-TLV conveys an IS-IS System  
13 ID, which specifies a hop. A Hop sub-TLV is conveyed by a Topology sub-TLV (45.1.9). A strict explicit  
14 tree is decomposed to branches where each branch is a point-to-point path specified by an ordered list of  
15 Hop sub-TLVs as specified in 45.1.9 and illustrated in Figure 45-6. A hop of a branch is created if and only  
16 if the Bridge specified for that hop is directly connected to the preceding Bridge in the path. In other words,  
17 a point-to-point LAN is identified by the two Bridges it interconnects; and the LAN is part of the strict tree  
18 if and only if the Hop sub-TLVs of the two Bridges are next to each other in the Topology sub-TLV. A Hop  
19 sub-TLV can convey a Circuit ID in order to distinguish multiple links between adjacent neighbor Bridges.  
20 A Hop sub-TLV also specifies the role of a Bridge, e.g., if it is the root or an Edge Bridge. The Topology  
21 sub-TLV of a loose tree comprises only the Hop sub-TLVs of the Bridges that have special roles in the tree.  
22 The Hop sub-TLV may also specify a delay budget for a loose hop.

23 By default, the Edge Bridges both transmit and receive with respect to each VID associated with an explicit  
24 tree, except for an LTS associated with a learning VLAN [45.1.3, item e) in 45.1.9], which uses a  
25 unidirectional VID per Bridge. The Hop sub-TLV allows different configuration by means of the VID's  
26 Transmit (T) and Receive (R) flags conveyed in the sub-TLV. The VID and its T/R flags are present in the  
27 Hop sub-TLV only if the behavior of the Edge Bridges differs from the default [defined in item e) in 45.1.9].  
28 The T/R flags of an I-SID associated with an explicit tree in a PBBN are set in the SPBM Service Identifier  
29 and Unicast Address sub-TLV (28.12.10), which also provides the association of the I-SID with the B-VID.

30 Figure 45-8 shows the format of the variable-length Hop sub-TLV, which shall be conveyed by a Topology  
31 sub-TLV (45.1.9).

|               |                           | Octet                                                            | Length  |              |
|---------------|---------------------------|------------------------------------------------------------------|---------|--------------|
| Hop Flags     | Type (22)                 | 1                                                                | 1       | 8 bits       |
|               | Length                    | 2                                                                | 1       |              |
|               | Circuit                   | 3                                                                | 1 bit   |              |
|               | VID                       | 3                                                                | 1 bit   |              |
|               | Edge Bridge               | 3                                                                | 1 bit   |              |
|               | Root                      | 3                                                                | 1 bit   |              |
|               | Leaf                      | 3                                                                | 1 bit   |              |
|               | Exclude                   | 3                                                                | 1 bit   |              |
|               | reserved                  | 3                                                                | 2 bits  |              |
| VID Tuple $l$ | System ID                 | 4–9                                                              | 6       | 0 or 16 bits |
|               | Extended Local Circuit ID | 10–13                                                            | 0 or 4  |              |
|               | Number of VIDs            | 10 or 14                                                         | 0 or 1  |              |
|               | T                         | 11 or 15                                                         | 1 bit   |              |
|               | R                         | 11 or 15                                                         | 1 bit   |              |
|               | reserved                  | 11 or 15                                                         | 2 bits  |              |
|               | VID                       | 11–12 or 15–16                                                   | 12 bits |              |
| ...           |                           |                                                                  |         |              |
| VID Tuple $n$ | T                         | $(2n+9)$ or $(2n+13)$                                            | 1 bit   | 0 or 16 bits |
|               | R                         | $(2n+9)$ or $(2n+13)$                                            | 1 bit   |              |
|               | reserved                  | $(2n+9)$ or $(2n+13)$                                            | 2 bits  |              |
|               | VID                       | $(2n+9)$ – $(2n+10)$ or $(2n+13)$ – $(2n+14)$                    | 12 bits |              |
|               | Delay Constraint          | 10–15 or 14–19 or $(2n+13)$ – $(2n+16)$ or $(2n+17)$ – $(2n+20)$ | 0 or 6  |              |

**Figure 45-8—Hop sub-TLV**

1 The parameters of a hop are encoded as follows:

- 2 a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 22.
- 3 b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field.
- 4 c) Hop Flags (8 bits). Octet 3 conveys the Hop flags. The Circuit and the VID flags influence the  
5 length of the Hop sub-TLV. Table 45-3 summarizes the use of the flags in the case of the different  
6 explicit ECT Algorithms.
  - 7 1) Circuit flag (1 bit). The Circuit flag indicates whether the Extended Local Circuit ID parameter  
8 is present. If the flag is set, then an Extended Local Circuit ID is also included in the Hop sub-  
9 TLV.
  - 10 2) VID flag (1 bit). The VID flag indicates whether one or more VIDs are conveyed by the Hop  
11 sub-TLV. If the flag is set, then the Number of VIDs parameter is present and indicates how  
12 many VIDs are conveyed by the Hop sub-TLV. If the VID flag is reset, then neither the Number  
13 of VIDs parameter nor VIDs are present in the Hop sub-TLV.
  - 14 3) Edge Bridge flag (1 bit). The Edge Bridge flag indicates whether the given System is an Edge  
15 Bridge, i.e., transmitter and/or receiver. If the System is an Edge Bridge, then the Edge Bridge  
16 flag is set. The Edge Bridge flag indicates that FDB entries have to be installed for the given  
17 hop as specified by its SPBV MAC address sub-TLV or SPBM Service Identifier and Unicast  
18 Address sub-TLV.

**Table 45-3—Hop sub-TLV flags**

|               |                | Flag                                                                                          |                                                             |                                                           |                                               |
|---------------|----------------|-----------------------------------------------------------------------------------------------|-------------------------------------------------------------|-----------------------------------------------------------|-----------------------------------------------|
|               |                | Edge Bridge                                                                                   | Root                                                        | Leaf                                                      | Exclude                                       |
| ECT Algorithm | Strict Tree    | The Bridge is an Edge Bridge.                                                                 | The Bridge is the root of the tree. (first hop)             | The Bridge is a leaf of the tree. (always an Edge Bridge) | —                                             |
|               | Loose Tree     | The Bridge is an Edge Bridge. (set for every hop of multipoint trees except for exclude hops) | The Bridge is the root of the tree. (first hop)             | The Bridge is a leaf of the tree. (always an Edge Bridge) | The Bridge has to be excluded from the tree.  |
|               | Loose Tree Set | The Bridge is an Edge Bridge. (set for every hop of multipoint trees except for exclude hops) | The Bridge roots a tree. (every Bridge that is Edge Bridge) | —                                                         | The Bridge has to be excluded from each tree. |
|               | MRT            | The Bridge is an Edge Bridge.                                                                 | The Bridge is an MRT Root. (always an Edge Bridge)          | —                                                         | The Bridge has to be excluded from the MRTs.  |
|               | MRT with GADAG | The Bridge is an Edge Bridge.                                                                 | The Bridge is an MRT Root. (always an Edge Bridge)          | The Bridge is the end of a topology block.                | —                                             |

- 4) Root flag (1 bit). The Root flag indicates whether the given System is a root of the explicit tree specified by the Topology sub-TLV. If the System is a root of a tree, then the Root flag is set.

If the Topology sub-TLV specifies a single tree, i.e., the Base VIDs conveyed by the Topology sub-TLV are associated with either the ST ECT Algorithm or the LT ECT Algorithm, then the Root flag is set only for one of the Systems conveyed by the Topology sub-TLV. Furthermore, the first Hop sub-TLV of the Topology sub-TLV conveys the System that is the root of the tree. If the Topology sub-TLV specifies a Loose Tree Set, i.e., the Base VIDs conveyed by the Topology sub-TLV are associated with the LTS ECT Algorithm (Table 45-1), then the Root flag is set for each Edge Bridge as each of them roots a tree. The first Hop sub-TLV of the Topology sub-TLV conveys a root.

If the Topology sub-TLV is used for MRT operations, i.e., the Base VIDs conveyed by the Topology sub-TLV are associated with either the MRT ECT Algorithm or the MRTG ECT Algorithm (Table 45-1), then the Root flag is set for each MRT Root. If no MRT Root is specified by a Topology sub-TLV specifying a GADAG, then each SPT Root is an MRT Root as well.

If the Base VIDs conveyed by the Topology sub-TLV are associated with the MRTG ECT Algorithm (Table 45-1), then the Topology sub-TLV specifies a GADAG, and the very first Hop sub-TLV specifies the GADAG Root. There is no flag for indicating the GADAG Root.

- 5) Leaf flag (1 bit). The Leaf flag indicates whether the given System is a leaf of the explicit tree specified by the Topology sub-TLV. If the System is a leaf, then the Leaf flag is set.

The Leaf flag is used to mark a leaf of a tree only if the Topology sub-TLV specifies a single tree, i.e., the Base VIDs are associated with either the ST ECT Algorithm or the LT ECT Algorithm (Table 45-1).

The Leaf flag is not used for marking leaves if the ECT Algorithm produces multiple trees because a Bridge that is leaf in one tree can be the root of another tree.

- 1 The Leaf flag is used to indicate the end of a topology block (3.281) if the Topology sub-TLV  
2 specifies a GADAG; see item f) in 45.1.9 and see 45.3.4.
- 3 6) Exclude flag (1 bit). The Exclude flag indicates whether the given System has to be excluded  
4 from the topology. The Exclude flag and the Root flag cannot be set for a given hop at the same  
5 time.
- 6 7) reserved (2 bits). Two bits of Octet 3 are reserved for future use, transmitted as 0, and ignored  
7 on receipt.
- 8 d) System ID (48 bits). Octets 4 through 9 convey the 6-byte IS-IS System Identifier of the Bridge to  
9 which the Hop sub-TLV refers.
- 10 e) Extended Local Circuit ID (32 bits). Octets 10 through 13 convey the Extended Local Circuit ID as  
11 specified by IETF RFC 5303 if Extended Local Circuit ID is present in the Hop sub-TLV, as  
12 indicated by the Circuit flag.
- 13 Parallel links corresponding to different IS-IS adjacencies between a pair of neighbor SPT Bridges  
14 can be distinguished by means of the Extended Local Circuit ID. The Extended Local Circuit ID is  
15 conveyed by the Hop sub-TLV specifying the Bridge nearer to the root of the tree and identifies a  
16 circuit that attaches the given Bridge to its neighbor cited by the next Hop sub-TLV of the Topology  
17 sub-TLV. The Extended Local Circuit ID can be used only in strict trees.
- 18 f) Number of VIDs (8 bits). A single octet conveys the Number of VIDs parameter, which is Octet 10  
19 if the Extended Local Circuit ID parameter is absent whereas it is Octet 14 if the Extended Local  
20 Circuit ID parameter is present. If the Hop sub-TLV does not convey VIDs, then the Number of  
21 VIDs parameter is not present, as indicated by the VID flag.
- 22 g) VID and its T/R flags (14 bits). Two octets convey the VID and its T/R flags parameters. The first  
23 one is Octet  $2n+9$  and the second one is Octet  $2n+10$  if the Extended Local Circuit ID parameter is  
24 absent whereas the first one is Octet  $2n+13$  and the second one is Octet  $2n+14$  if the Extended Local  
25 Circuit ID parameter is present.
- 26 The VID and its T/R flags are present in the Hop sub-TLV only if the given Bridge is an Edge  
27 Bridge and it behaves differently from the default with respect to that particular VID. (The default  
28 behavior is defined in item e of the Topology sub-TLV (45.1.9).)
- 29 1) T flag (1 bit). This bit is the Transmit allowed flag for the VID following the flag.
- 30 2) R flag (1 bit). This bit is the Receive allowed flag, i.e., R flag for the VID following the flag.
- 31 3) reserved (2 bits). Two bits of the first Octet are reserved for future use, transmitted as 0, and  
32 ignored on receipt.
- 33 4) VID (12 bits). The VID can be a Base VID, an MRT VID, or a VID in support of a learning  
34 VLAN associated with the LTS ECT Algorithm.
- 35 h) Delay Constraint (48 bits). The last six octets specify a delay constraint if they convey a  
36 Unidirectional Link Delay sub-TLV [item f) in 45.1.8]. The delay constraint can be used in a  
37 Topology sub-TLV that specifies a single loose tree, i.e., the Base VIDs are associated with the LT  
38 ECT Algorithm (Table 45-1). If delay constraint is applied, then the loose hop has to fit in the delay  
39 budget specified by the Delay parameter of the Unidirectional Link Delay sub-TLV [item f) in  
40 45.1.8] conveyed by the Hop sub-TLV. If the Topology sub-TLV specifies a single leaf, then the path  
41 between the preceding Hop sub-TLV and the current Hop sub-TLV has to meet the delay budget. If  
42 the Topology sub-TLV specifies multiple leaves, then the path between the root and the current Hop  
43 sub-TLV has to meet the delay budget. If the tree is used as a reverse congruent tree, then the delay  
44 constraint applies in both directions. If the tree is used as a directed tree, then the delay constraint  
45 applies in the direction of the tree.

46 NOTE 1—The T and R flags can be used to establish asymmetric VLANs, e.g., for rooted-multipoint connectivity.

47 NOTE 2—The Root and Leaf flags specify the role of the Bridges only in the explicit tree, i.e., the active topology.  
48 Roots and leaves with respect to data traffic are specified by the T/R flags of VIDs and MAC addresses associated  
49 with the Edge Bridges. Roots and leaves of the active topology and data flows do not necessarily coincide, e.g., see  
50 Figure 45-7.

### 1 45.1.11 Administrative Group sub-TLV

2 The Administrative Group sub-TLV may be included in a Topology sub-TLV (45.1.9) in order to put a  
3 constraint on loose hops. In this case, each LAN included in a loose hop has to be a member of the  
4 Administrative Group(s) indicated by the Administrative Group sub-TLV. The format of the Administrative  
5 Group sub-TLV is specified by IETF RFC 5305 as shown in Figure 45-9. In other words, the same format is  
6 used for the constraint as for the TE attribute; therefore, their comparison is easy.

|                      | Octet | Length |
|----------------------|-------|--------|
| Type (3)             | 1     | 1      |
| Length (4)           | 2     | 1      |
| Administrative Group | 3–6   | 4      |

**Figure 45-9—Administrative Group sub-TLV**

7 The administrative groups are encoded as follows:

- 8 a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 3.
- 9 b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field. The value of  
10 the Length field is 4.
- 11 c) Administrative Group (32 bits). Octets 3 through 6 convey the Administrative Group parameter. It  
12 comprises 32 flags, and each flag belongs to a distinct group. Group membership is indicated by the  
13 flags set.

### 14 45.1.12 Bandwidth Constraint sub-TLV

15 The Bandwidth Constraint sub-TLV may be included in a Topology sub-TLV (45.1.9) in order to specify  
16 how much available bandwidth is to be provided by the tree. Each loose hop has to meet the bandwidth  
17 constraint. The bandwidth value of the constraint is a total value, or it refers only to a single PCP as specified  
18 by the sub-TLV. Figure 45-10 shows the format of the Bandwidth Constraint sub-TLV.

|                     | Octet | Length |
|---------------------|-------|--------|
| Type (23)           | 1     | 1      |
| Length (5)          | 2     | 1      |
| PCP                 | 3     | 3 bits |
| DEI                 | 3     | 1 bit  |
| PCP flag            | 3     | 1 bit  |
| reserved            | 3     | 3 bits |
| Available Bandwidth | 4–7   | 4      |

**Figure 45-10—Bandwidth Constraint sub-TLV**

19 The parameters of the bandwidth constraint are encoded as follows:

- 20 a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 23.
- 21 b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field, The value of  
22 the Length field is 5 bytes.
- 23 c) PCP (3 bits). Octet 3 conveys the PCP parameter, which determines the traffic class to which the  
24 Available Bandwidth parameter refers.
- 25 d) DEI (1 bit). Octet 3 also conveys the DEI parameter.
- 26 If the DEI parameter is clear, then the bandwidth constraint refers to committed information rate.
- 27 If the DEI parameter is set, then the bandwidth constraint refers to peak information rate.

- 1 e) PCP flag (1 bit). Octet 3 also conveys the PCP flag. If it is set, then the PCP parameter is taken into  
2 account.
- 3 f) reserved (3 bits). Three bits of Octet 3 are reserved for future use, transmitted as 0, and ignored on  
4 receipt.
- 5 g) Available Bandwidth (32 bits). Octets 4 through 7 convey the Available Bandwidth. The Available  
6 Bandwidth is specific to the traffic class identified by the PCP parameter if the PCP flag is set;  
7 otherwise, it is total bandwidth. In line with the bandwidth parameters specified in IETF RFC 5305,  
8 the Available Bandwidth is encoded as a 32-bit IEEE floating point number, and the units are bytes  
9 (not bits!) per second. Thus, the Available Bandwidth constraint applied for a traffic class is easily  
10 comparable with the Unreserved Bandwidth stored in the TED for the given traffic class (see sub-  
11 TLV 11 specified by IETF RFC 5305).
- 12 The bandwidth constraint applies for both directions in the case of symmetric (3.273) explicit trees.  
13 Nevertheless, a VID associated with an explicit tree can be made unidirectional by means of the T/R  
14 flags belonging to the VID in the Hop sub-TLV (45.1.10) of the Edge Bridges. If all the VIDs of the  
15 Topology sub-TLV (45.1.9) are unidirectional and all belong to the traffic class identified by the  
16 PCP parameter of the Bandwidth Constraint sub-TLV, then it is enough to meet the bandwidth  
17 constraint in the direction applied for those VIDs.
- 18 NOTE—The peak information rate is the committed information rate plus the excess information rate.

## 19 45.2 Reservation

20 ISIS-PCR may be used for recording bandwidth assignment for explicitly placed data traffic in an SPT  
21 Region if MSRP is not used within the region. If MSRP is used in an SPT Region, then only MSRP  
22 performs reservations and IS-IS does not.

### 23 45.2.1 Bandwidth Assignment sub-TLV

24 ISIS-PCR can record bandwidth assignment for explicitly placed data traffic. ISIS-PCR can be used for  
25 recording bandwidth assignment only within an SPT Region where MSRP is not used.

26 If precedence order has to be determined among bandwidth assignments in an SPT Region with multiple  
27 PCEs, then ISIS-PCR provides it as specified in 45.2.3.

28 The Bandwidth Assignment sub-TLV can be used to define the amount of bandwidth whose assignment is to  
29 be recorded by ISIS-PCR at each hop of the explicit tree described by the corresponding Topology sub-TLV  
30 (45.1.9). The Bandwidth Assignment sub-TLV is conveyed by a Topology sub-TLV (45.1.9).

31 The Bandwidth Assignment sub-TLV is used by ISIS-PCR for the recording of bandwidth assignment for a  
32 traffic class. Figure 45-11 shows the format of the Bandwidth Assignment sub-TLV.

|            | Octet | Length |
|------------|-------|--------|
| Type (24)  | 1     | 1      |
| Length (5) | 2     | 1      |
| PCP        | 3     | 3 bits |
| DEI        | 3     | 1 bit  |
| Importance | 3     | 3 bits |
| reserved   | 3     | 1 bit  |
| Bandwidth  | 4–7   | 4      |

**Figure 45-11—Bandwidth Assignment sub-TLV**

1 The parameters for bandwidth assignment recorded by ISIS-PCR are encoded as follows:

- 2 a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 24.
- 3 b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field. The value of  
4 the Length field is 5.
- 5 c) PCP (3 bits). Octet 3 conveys the PCP parameter, which specifies the traffic class for which the  
6 bandwidth is to be assigned.
- 7 d) DEI (1 bit). Octet 3 also conveys the DEI parameter.  
8 If the DEI parameter is clear, then the bandwidth assignment is performed to provide committed  
9 information rate.  
10 If the DEI parameter is set, then the bandwidth assignment is performed to provide peak information  
11 rate.
- 12 e) Importance (3 bits). Octet 3 also conveys the Importance parameter for determining precedence  
13 order among bandwidth assignments within a PCP as specified in 45.2.3. A lower numerical value  
14 indicates a more important bandwidth assignment within a PCP. The default value of the Importance  
15 parameter is 7.
- 16 f) reserved (1 bit). One bit of Octet 3 is reserved for future use, transmitted as 0, and ignored on  
17 receipt.
- 18 g) Bandwidth (32 bits). Octets 4 through 7 convey the amount of bandwidth to be assigned for the  
19 traffic class identified by the PCP parameter. In line with the bandwidth values specified in IETF  
20 RFC 5305, the Bandwidth parameter is encoded as a 32-bit IEEE floating point number, and the  
21 units are bytes (not bits!) per second.  
22 The bandwidth assignment applies for both directions in the case of symmetric (3.273) explicit trees.  
23 Nevertheless, a VID associated with an explicit tree can be made unidirectional by means of the T/R  
24 flags belonging to the VID in the Hop sub-TLV (45.1.10) of the Edge Bridges. If all the VIDs having  
25 the same PCP in the Topology sub-TLV (45.1.9) are unidirectional, then the bandwidth is assigned  
26 only in the direction applied for those VIDs.

27 If bandwidth is to be assigned both for committed information rate and for peak information rate, then the  
28 Topology sub-TLV conveys two Bandwidth Assignment sub-TLVs: one with DEI cleared and another with  
29 DEI set.

## 30 45.2.2 Timestamp sub-TLV

31 The Timestamp sub-TLV may be included in a Topology sub-TLV (45.1.9) in order to provide precedence  
32 order among equally important bandwidth assignments within a PCP as specified in 45.2.3. Figure 45-12  
33 shows the format of the Timestamp sub-TLV.

|            | Octet | Length |
|------------|-------|--------|
| Type (25)  | 1     | 1      |
| Length (4) | 2     | 1      |
| Time       | 3–6   | 4      |

**Figure 45-12—Timestamp sub-TLV**

1 The timestamp represents a positive time with respect to the Precision Time Protocol (PTP) epoch, and it is  
2 encoded as follows:

- 3 a) Type (8 bits). Octet 1 conveys the type of the sub-TLV, and its value is 25.
  - 4 b) Length (8 bits). Octet 2 conveys the total number of bytes contained in the Value field. The value of  
5 the Length field is 4.
  - 6 c) Time (32 bits). Octets 3 through 6 convey the time in units of seconds with respect to the PTP epoch.
- 7 NOTE—The Timestamp sub-TLV carries the seconds portion of PTP as specified by IEEE Std 1588 [B17]. The  
8 epoch is 1970-01-01 00:00:00 TAI (i.e., the PTP time does not include leap seconds).

### 9 **45.2.3 Precedence ordering**

10 The PCEs are collectively responsible for making a consistent set of bandwidth assignments when ISIS-PCR  
11 is used for recording bandwidth allocations. Despite that responsibility, if precedence ordering is required  
12 among bandwidth assignments, then ordering based on the following parameters has to be applied:

- 13 1) PCP parameter of Bandwidth Assignment Sub-TLV
- 14 2) Importance parameter of Bandwidth Assignment Sub-TLV
- 15 3) Timestamp sub-TLV (if present in the Topology sub-TLV)

16 A bandwidth assignment takes precedence if it has higher PCP, or higher Importance within a PCP, or earlier  
17 timestamp in the case of equal Importance within a PCP. A bandwidth assignment associated with a  
18 timestamp takes precedence over a bandwidth assignment without timestamp when PCP and Importance of  
19 different bandwidth assignments are both equal.

20 If resolution is not possible based on the above parameters or they are not available, e.g., each bandwidth  
21 assignment lacks timestamp or the precedence order has to be determined for the use of a VID, then the item  
22 is granted to the PCE whose LSP has the numerically least LSP ID.

## 23 **45.3 Redundancy**

24 This subclause specifies IS-IS extensions in support of redundancy schemes, i.e., protection and restoration  
25 for data flows.

26 Local protection for unicast data flows based on loop-free alternates is described in 45.3.1.

27 Protection schemes are often based on two or more redundant trees, or if that is not possible, then on  
28 maximally redundant trees. Maximally Redundant Trees (MRTs) can be used either in a static fashion or  
29 with cautious restoration for ISIS-PCR. This subclause specifies how MRTs are installed and maintained  
30 leveraging the tools provided by 45.1. The use of static MRTs is described in 45.3.2. Setting up and  
31 maintaining MRTs with cautious restoration is described in 45.3.3 and 45.3.4.

### 32 **45.3.1 Loop-free alternates for unicast data flows**

33 Downstream Loop-Free Alternates (LFAs) provide a simple redundancy scheme, which may be supported  
34 by ISIS-SPB for unicast flows of an SPBM VLAN and for SPBV VLANs. A path toward an individual  
35 destination MAC address is downstream if it is ensured that the distance to the destination decreases at each  
36 hop along the path. Downstream paths are always loop-free alternates to each other with respect to an  
37 individual destination MAC address. Therefore, a downstream alternate path can be safely used for local  
38 protection as a loop-free backup path.

39 NOTE—The Alternate Ports of RSTP and MSTP leverage the loop-free alternate paths provided by the physical  
40 topology to the Root Bridge. In the case of spanning trees, ‘up’ or ‘upward’ to the Root is used to refer to the same  
41 direction as ‘downstream’ for destination rooted trees.

1 LFA can be provided for SPBV by SPTs (13.17, Clause 27, Clause 28). The LFA mechanism is the same for  
2 an SPT as for an MSTI where Alternate Ports leverage LFA paths.

3 Loop mitigation (6.5.4.2) may be relaxed in order to allow LFAs for unicast SPBM traffic. Ingress checking  
4 is modified and relaxed in order to allow the reception of a unicast frame from any SPT Bridge that is  
5 upstream with respect to the given individual destination MAC address. Thus, relaxed ingress checking  
6 implements a split horizon for loop mitigation by ensuring that a frame is admitted only if it is received from  
7 an SPT Bridge that is farther from the destination than the receiving SPT Bridge, which determines the valid  
8 set of ingress ports.

9 In the case of a failure at an SPT Bridge's Port or LAN on the shortest path toward individual MAC  
10 addresses, the SPT Bridge acts as a Point of Local Repair (PLR) and forwards frames through ports  
11 providing downstream LFA paths toward the given individual MAC addresses, if any.

12 An SPT Bridge updates its relaxed ingress checking after detecting a mismatch in the Agreement Digest. An  
13 ingress port is removed from the valid set of ingress ports with respect to a particular individual destination  
14 MAC address if a formerly upstream SPT Bridge is no longer farther from the destination than the given  
15 SPT Bridge. An LFA path is removed if the corresponding formerly downstream neighbor is not closer any  
16 more to the destination than the given SPT Bridge.

17 An SPT Bridge updates its LFA paths and relaxed ingress checking after finishing the updates of multicast  
18 states. If LFA paths with respect to an individual MAC address have been changed, then the new LFA paths  
19 are added. The valid set of ingress ports is extended with the new upstream Bridges with respect to an  
20 individual MAC address, if any.

### 21 **45.3.2 Static redundant trees**

22 The trees associated with the ST ECT Algorithm (00-80-C2-17, Table 45-1) are static in the sense that no  
23 entity other than the owner PCE can update them. In other words, ISIS-PCR only installs the strict trees and  
24 does not take any further action on them; i.e., ISIS-PCR neither restores them nor maintains them. In the  
25 case of a topology change, it is the task of the owner PCE to detect the topology change, e.g., based on the  
26 changes in its LSDB, and also update the strict trees if needed. This requires the owner PCE to compute the  
27 new tree and to assemble the corresponding new Topology sub-TLV (45.1.9). The PCE then sends the  
28 updated LSP conveying the new Topology sub-TLV, and ISIS-PCR updates the strict explicit tree. The  
29 owner PCE can withdraw an explicit tree by sending an updated LSP that does not include the Topology  
30 sub-TLV. If a Topology sub-TLV is removed from an LSP (or has been changed), so that (previous)  
31 Topology sub-TLV is no longer present (or has been changed) in the LSDB, then that (previous) Topology  
32 sub-TLV is implicitly withdrawn. ISIS-PCR then removes (or updates) the explicit tree.

33 NOTE 1—The PCE preferably does not initiate the update of explicit trees if there is any reason to suspect that the SPT  
34 Bridges of the SPT Region do not share a common view on network topology.

35 NOTE 2—The PCE can have a hot standby backup PCE in order to avoid a single point of failure.

36 Strict explicit trees can be used for Maximally Redundant Trees (MRTs), especially if more than two  
37 redundant trees are needed. Each tree is described by a distinct Topology sub-TLV (45.1.9). The VLAN  
38 configuration of strict trees is specified in 45.1.3.

39 The PCE or its PCA assembles and floods the corresponding Topology sub-TLVs (45.1.9); thus ISIS-PCR  
40 installs the explicit trees throughout the SPT Region as specified in 45.1. All of the maximally redundant  
41 trees are installed independently of each other, i.e., ISIS-PCR is not aware of any relationship between them.  
42 Maintaining the association among the redundant strict trees is not the responsibility of ISIS-PCR, but the  
43 entity that requests and uses them, e.g., the owner PCE and the management entity responsible for  
44 configuring the protection scheme in use. Therefore, no parameters for association of static explicit trees are  
45 present in the ISIS-PCR sub-TLVs.

46 NOTE 3—For instance, two static redundant trees can be used for CFM-based protection switching as specified in  
47 26.10, where the association and the use of the paths are provided. Static redundant trees can be also used for 1+1 types  
48 of protection schemes, where a copy of each data frame is forwarded on each of the redundant paths.

1 The algorithm used by the owner PCE for the computation of static redundant trees is not specified by this  
2 standard. Number  $K$ , the number of trees to be computed, is an input for the owner PCE. The Topology sub-  
3 TLVs (45.1.9) are the output of the owner PCE. Other outputs can include the number of common links and  
4 their identity.

### 5 **45.3.3 Maximally Redundant Trees (MRTs)**

6 SPT Bridges may support MRTs. The BLCE of SPT Bridges is also involved in the computation of MRTs.  
7 The MRTs can be, for example, used for point-to-multipoint protection if the MRTs are source rooted or for  
8 multipoint-to-point protection if the MRTs are destination rooted. The MRTs can be used to protect an SPT  
9 rooted at the MRT Root. The MRTs can be also used so that they protect each other, e.g., in a 1+1 type of  
10 protection scheme where data frames are sent on both MRTs. An MRT provides an undirected active  
11 topology just like an SPT or a spanning tree instance (which is also a shortest path tree rooted at the  
12 spanning tree root). Correspondingly, MRTs can be used for bidirectional or unidirectional traffic, as  
13 determined by the T/R parameters of the data traffic carried on the tree.

14 The MRT ECT Algorithm (00-80-C2-18, Table 45-1) is used for the establishment and maintenance of  
15 MRTs in a distributed fashion as specified by this subclause. The MRT Lowpoint Algorithm specified by  
16 IETF RFC 7811 has to be used for the computation of MRTs that span more than two Edge Bridges. If only  
17 two Edge Bridges are to be connected, then the algorithm specified in this subclause has to be used for path  
18 computation. The MRT Lowpoint Algorithm produces two MRTs for an MRT Root: MRT-Blue and MRT-  
19 Red. If the MRTs are used in a primary and backup fashion, then MRT-Blue is the primary and MRT-Red is  
20 the backup. The MRTs are cautiously restored after a topology change as described in this subclause.

21 NOTE 1—If more than two maximally redundant trees are required, then static redundant trees (45.3.2) have to be used.

22 When the MRT Lowpoint Algorithm is used by ISIS-PCR, then the input parameters of the  
23 Interface\_Compare function are as follows: The Interface\_compare\_metric is the SPB Link Metric  
24 (28.12.7), and the maximum metric value is used in cases where the metrics advertised by adjacent Bridges  
25 for a given link are different. The Interface\_compare\_unique\_node\_identifier is the 8-byte Bridge Identifier,  
26 which comprises a 6-byte IS-IS System Identifier and a 2-byte Bridge Priority.

27 The MRT Lowpoint Algorithm first computes the GADAG, and the computation requires the selection of the  
28 GADAG Root. The Bridge with the best Bridge Identifier is selected as the GADAG Root, where the  
29 numerically lower value indicates the better identifier. The manageable Bridge Priority component of the  
30 Bridge Identifier allows the configuration of the GADAG Root. The Bridge Priority is conveyed by Octets  
31 15 and 16 of the SPB Instance sub-TLV (28.12.5). Based on its LSDB, each SPT Bridge can locally  
32 determine which Bridge is the GADAG Root and then compute the GADAG. The MRTs are then computed  
33 based on the GADAG. Examples for a GADAG and two corresponding MRTs are shown in Figure 45-13  
34 and Figure 45-14, respectively. If tie-breaking is required among equal cost paths while the MRTs are  
35 computed, then the tie-breaking specified by the LowPATHID algorithm (28.7) has to be used. If MRTs  
36 support a VLAN having multiple multicast sources, then the BLCEs of the Bridges have to compute the  
37 MRTs of other Bridges in addition to their own MRTs due to the need to apply source-specific (S,G)  
38 multicast. This is similar to the application of All Pairs Shortest Path computation in ISIS-SPB. (See 45.1.1  
39 for further details on source-specific (S,G) multicast.)

40 The MRT Lowpoint Algorithm is specified in terms of determining next hop FDB entries toward a particular  
41 unicast destination. This generates a tree directed to the root, which is the destination. By inverting the  
42 direction of this destination rooted tree, a source rooted tree can be retrieved.

43 If MRTs are required for a VLAN so that each Bridge performs all the MRT computation steps on its own  
44 including GADAG computation, i.e., the MRT computation is fully distributed, then the VLAN has to be  
45 associated with the MRT ECT Algorithm (Table 45-1) as specified in 45.1.3.

1 Just using the MRT ECT Algorithm creates MRT-Blue and MRT-Red for each SPT Root, i.e., each SPT  
2 Root is also an MRT Root, and IS-IS maintains all the MRTs. Furthermore, the MRTs are spanning trees in  
3 this case, i.e., each Bridge of the SPT Region is included in both MRT-Blue and MRT-Red. This operation  
4 mode is selected by providing the VLAN configuration in the SPB Base VLAN Identifiers sub-TLV  
5 (28.12.4) and in the SPB Instance sub-TLV (28.12.5) as specified in 45.1.3. The Topology sub-TLV (45.1.9)  
6 is not used in this case, i.e., only ISIS-SPB sub-TLVs are used.

7 If the level of redundancy provided by each SPT Root also being an MRT Root is not required, then the  
8 MRT Roots can be specified by a Topology sub-TLV (45.1.9); this approach can be also applied when MRTs  
9 protect each other and SPTs are not used. The Topology sub-TLV describes loose explicit trees in this case,  
10 i.e., it specifies only the Edge Bridges that the MRTs are to span, and each Edge Bridge is a loose hop. An  
11 MRT Root is specified by setting the Root flag [item c4] in 45.1.10] in the corresponding Hop sub-TLV  
12 (45.1.10). An MRT Root is typically an Edge Bridge too. MRTs provide a path from each Edge Bridge to the  
13 MRT Root, i.e., each Edge Bridge is a leaf except for the MRT Root. If a Topology sub-TLV specifies  
14 multiple MRT Roots, then an Edge Bridge has different roles in the MRTs rooted at different Bridges.  
15 Therefore, the Leaf flag [item c5] in 45.1.10] is not used to mark leaves of MRTs. The Topology sub-TLV  
16 can include a hop with the Exclude flag [item c6] in 45.1.10] set for a Bridge that is to be avoided by the  
17 MRTs, in which case the Bridge is excluded from the GADAG, too. The Topology sub-TLV can convey one  
18 or more Base VIDs that are associated with the MRT ECT Algorithm. Whether the MRTs are unidirectional  
19 or bidirectional is determined by the T/R flags corresponding to the VIDs, I-SIDs, and MAC addresses  
20 associated with the given MRTs.

21 NOTE 2—For instance, if a VLAN is supported by ISIS-SPB in SPBM mode (Clause 27, Clause 28) and MRTs are used  
22 for the protection of SPTs, then only three VIDs are required to support the VLAN. The Base VID is used for all the  
23 SPTs. Another VID is used for all MRT-Blues, and a third VID is used for all MRT-Reds. The MRTs are then used as  
24 destination rooted trees for unicast traffic and as source rooted trees for multicast traffic just like the SPTs. The T/R  
25 parameters for the MRT VIDs are exactly the same as for the Base VID; therefore, IS-IS populates the FDBs for the  
26 MRTs the same way as for the SPTs, i.e., just uses the corresponding MRT VID instead of the Base VID.

27 If the Topology sub-TLV specifies only two Edge Bridges, then the following algorithm is used for the  
28 computation of the two maximally redundant paths instead of the MRT Lowpoint Algorithm. As they  
29 interconnect only two Edge Bridges, the MRTs are reverse path congruent maximally redundant paths in this  
30 case. According to the algorithm below, one of the two maximally redundant paths is the shortest path. The  
31 two paths are used to protect each other. A VLAN associated with maximally redundant paths has to be  
32 configured as specified in 45.1.3 for the MRT ECT Algorithm. The VID of MRT-Blue is used for the  
33 shortest path, and the VID of MRT-Red is used for the other path. The establishment of the redundant paths  
34 is initiated by the flooding of a Topology sub-TLV (45.1.9). The paths are then determined by the BLCE of  
35 the SPT Bridges and then installed by ISIS-PCR. The Topology sub-TLV can convey constraint sub-TLVs,  
36 which have to be also taken into account when determining the paths. The BLCEs perform the following  
37 path computation algorithm:

- 38 1) Prune the topology according to the constraints of the Topology sub-TLV (45.1.9), if any. The  
39 rest of the computation steps are performed on the pruned topology. If pruning splits the SPT  
40 Region, then the outcome can be that no path is available.
- 41 2) Run Dijkstra to get the (constrained) shortest path, which is the primary path.
- 42 3) Install the FDB entries corresponding to the VID of MRT-Blue along the primary path.
- 43 4) Update the network graph by the appropriate method as follows:  
44 a) Prune the links of the primary path if that does not partition the SPT Region.  
45 b) Otherwise, multiply by 1000 the link metric of the links taking part in the primary path.
- 46 5) Run Dijkstra to get the backup path.
- 47 6) Install the FDB entries corresponding to the VID of MRT-Red along the backup path.

48 It is recommended to use distinct VIDs for MRT-Blue and MRT-Red, which are loose trees and therefore  
49 computed by multiple entities. As a strict tree is controlled by a single PCE, it is easier to ensure  
50 unambiguous forwarding and allow the use of the same VID for different strict trees as described in 45.1.4  
51 than to do so for loose trees.

1 MRTs have to be restored cautiously after a topology change. The restoration should not be initiated if there  
2 is any reason to suspect that the SPT Bridges of the SPT Region do not share a common view on the network  
3 topology. BLCEs then perform path computation, and MRTs are updated as follows.

4 If MRTs are used for SPT protection, then MRTs are restored only after the restoration of the SPTs. Upon a  
5 failure event, Point of Local Repair (PLR) Bridges redirect data traffic to the MRT that is not affected by the  
6 failure, if any. As the topology change is announced by the corresponding LSPs, the SPT Bridges compute  
7 and install the new SPTs. If each SPT Bridge has installed the new SPT, then data traffic is directed back to  
8 the SPTs. After that, the new MRTs are computed and installed by the Bridges.

9 If MRTs support a non-learning VLAN, then the PLRs can redirect traffic by replacing the FDB entry  
10 belonging to the tree of normal operation (i.e., the SPT or an MRT) with the FDB entry belonging the  
11 protection tree (i.e., with MRT-Blue or MRT-Red) upon a failure event. If MRTs support a learning VLAN,  
12 then the PLRs can redirect traffic by updating VID translation at the Ingress Port from the VID of normal  
13 operation to the VID of the protection tree (i.e., to MRT-Blue or MRT-Red) upon a failure event.

14 If MRTs protect each other, then only one of the MRTs is restored at a time. Upon a failure event, PLR  
15 Bridges direct all data traffic to the MRT (e.g., MRT-Red) that is not affected by the failure. If a 1+1 type of  
16 protection scheme is used, then there is no need to react to a failure event as data frames are forwarded on  
17 both MRTs, i.e., there are no PLRs. When each SPT Bridge has the same view on the network topology  
18 again, then the SPT Bridges compute the new MRTs. The broken MRT (e.g., MRT-Blue) then is restored  
19 while the other MRT (e.g., MRT-Red) is not touched. If each SPT Bridge has installed the new MRT (e.g.,  
20 the new MRT-Blue), then data traffic is directed to this newly restored MRT. The SPT Bridges then install  
21 the other MRT (e.g., the new MRT-Red). The same restoration procedure is followed if both MRTs are  
22 affected by the failure so that MRT-Blue is restored first.

23 Loop prevention (6.5.4.1, 27.9) has to be applied for MRTs during the period when they are being restored  
24 by ISIS-PCR.

25 There is a non-zero probability of out-of-order frame delivery while ISIS-PCR restores loose explicit trees,  
26 e.g., MRTs. This probability is similar to the probability of out-of-order frame delivery while ISIS-SPB  
27 restores SPTs.

28 If there are two maximally redundant paths between a pair of Edge Bridges and only the backup path went  
29 down, then just Steps 4–6 of the above algorithm are performed again. If only the primary path went down,  
30 then data traffic takes the backup path, i.e., only the backup path is in use by the applied protection  
31 mechanism. The primary path is then updated according to Steps 1–3. No further steps are taken until the  
32 primary path is up again. The protection scheme can then revert to the primary path, and the backup path can  
33 be updated according to Steps 4–6. If both paths went down, then Steps 1–6 are performed again.

34 NOTE 3—The method to be used for verifying whether the SPT Bridges have a common view on the topology and  
35 whether SPTs and MRTs have been restored is left to the implementer and the network operator. A common method is to  
36 wait some time after the reception of the last LSP indicating a topology change. Alternatively, OAM can be used for  
37 instance.

#### 38 **45.3.4 MRTs with centralized GADAG computation**

39 The GADAG is identical for all the MRTs within a network domain, as a consequence of the use of the MRT  
40 Lowpoint Algorithm (IETF RFC 7811). The GADAG is computed by a single entity for VLANs associated  
41 with the MRTG ECT Algorithm (Table 45-1). This entity is referred to as the GADAG Computer and is  
42 either a PCE or the BLCE of the GADAG Root.

43 SPT Bridges may support the MRTG ECT Algorithm (00-80-C2-19, Table 45-1). MRTs are then computed  
44 by the SPT Bridges based on the GADAG provided by the GADAG Computer in a Topology sub-TLV  
45 (45.1.9). The GADAG and the MRTs are computed as specified by the MRT Lowpoint Algorithm

1 (IETF RFC 7811). The MRTs produced by the MRTG ECT Algorithm are cautiously restored after a failure  
2 event as described in this subclause. A VLAN is associated with the MRTG ECT Algorithm as specified in  
3 45.1.3 if MRTs with central GADAG computation are to be used for that VLAN.

4 The GADAG Root is determined based on the Bridge Identifier as described in 45.3.4, which also  
5 determines the sole SPT Bridge computing the GADAG if the GADAG Root is the GADAG Computer.  
6 Otherwise, the GADAG Computer PCE determines the GADAG Root, which also allows direct  
7 configuration of the GADAG Root.

8 The GADAG Computer performs the GADAG computation as specified by the MRT Lowpoint Algorithm  
9 (IETF RFC 7811). The GADAG Computer then encodes the GADAG in a Topology sub-TLV (45.1.9),  
10 which is then flooded throughout the domain. A GADAG is encoded in a Topology sub-TLV by means of  
11 directed ear decomposition as follows: A directed ear is a directed point-to-point path whose end points can  
12 coincide, but no other element of the path is repeated in the ear. Each ear is specified by an ordered list of  
13 hops, and that order of hops is according to the direction of the arcs in the GADAG. There are no leaves in a  
14 GADAG; hence, the Leaf flag [item c5] in 45.1.10] is used to ease the parsing of the Topology sub-TLV and  
15 to mark the end of a topology block (3.281). The sequence of ears in the Topology sub-TLV is such that the  
16 end points of an ear belong to former ears. The GADAG Root is not marked by any flag, but the GADAG  
17 Root is the first hop in the Topology sub-TLV; correspondingly the first ear starts and ends with the GADAG  
18 Root. MRT Roots are marked by the Root flag [item c4] in 45.1.10], and all other Edge Bridges are leaves of  
19 the given MRTs. If no MRT Root is specified, then each SPT Root is also an MRT Root. If a Bridge has to be  
20 excluded from the MRTs, then it is not part of the GADAG.

Figure 45-13—A GADAG and its descriptor Topology sub-TLV

Figure 45-13 shows the GADAG for the network topology depicted in Figure 45-1 and Figure 45-2 when SPT Bridge 11 is the GADAG Root. The graph shown in Figure 45-13 is in fact an ADAG, and removing the arc going from Bridge 33 to Bridge 11 (the GADAG Root) makes it a DAG. Figure 45-13 also shows the Topology sub-TLV that specifies the GADAG. The first directed ear starts and ends at the GADAG Root, i.e., Bridge 11. The second ear (Ear 2) starts at Bridge 22 and ends at Bridge 33. The third ear (Ear 3) comprises Bridges 66, 88, and 77. Each of the remaining arcs is an individual ear added by a pair of Hop sub-TLVs according to the direction of the arc. Bridges 11, 44, 55, and 88 are Edge Bridges. Bridge 55 is the only MRT Root.

The MRTs are then computed by the SPT Bridges as specified by the MRT Lowpoint Algorithm (IETF RFC 7811) based on the GADAG descriptor received from the GADAG Computer. Whether the MRTs are unidirectional or bidirectional is determined by the T/R flags corresponding to the VIDs, I-SIDs, and MAC addresses associated with the given MRTs. Figure 45-14 shows MRT-Blue and MRT-Red if the GADAG descriptor Topology sub-TLV of Figure 45-13 is used for MRT computation, i.e., SPT Bridge 55 is the only MRT Root. Figure 45-14 also shows that an Edge Bridge is not necessarily a leaf; see Bridge 11.

**Figure 45-14—MRT-Blue and MRT-Red for MRT Root 55**

The Topology sub-TLV specifying the GADAG can convey Base VIDs associated with the MRTG ECT Algorithm, which specifies the VLANs for which the GADAG is relevant. If there is no Base VID parameter in the Topology sub-TLV specifying a GADAG, then the given GADAG has to be used for all VLANs whose Base VID is associated with the MRTG ECT Algorithm.

A network topology can comprise multiple topology blocks (3.281), like the one illustrated in Figure 45-15, which comprises four blocks because each cut-link with the two Bridges at either end is a block. A GADAG is also shown in Figure 45-15. Note that two arcs with opposite direction represent a cut-link in a GADAG, e.g., see the cut-link between Bridges 75 and 77. The encoding starts with the block (ADAG) involving the GADAG Root as illustrated in Figure 45-15. The first hop in the Topology sub-TLV is the GADAG Root (Bridge 11 in this example). The ADAG of the first block is then described using the ear decomposition, as described above. In this example, the first block has been completely traversed at the second occurrence of Bridge 11 in the GADAG descriptor. The end of a block is indicated by setting the Leaf flag for the last hop

1 of the block, e.g., for the second occurrence of Bridge 11 in the example GADAG descriptor. The next  
2 Bridge that appears in the GADAG descriptor (Bridge 44 in this case) is the localroot for the Bridges in the  
3 next block. Continuing this process, the Leaf flag is set for the third occurrence of Bridge 44, the third  
4 occurrence of Bridge 75, and the third occurrence of Bridge 77, each indicating the end of a block.

### Figure 45-15—A GADAG for a topology with multiple blocks

1 If MRTs are used for SPT protection, then MRTs are restored only after the restoration of the SPTs. Upon a  
2 failure event, PLR Bridges redirect data traffic to the MRT that is not affected by the failure, if any. As the  
3 topology change is announced by the corresponding LSPs, SPT Bridges and the GADAG Computer become  
4 aware of the change. The SPT Bridges then compute and install the new SPTs. When each SPT Bridge has  
5 installed the new SPT, then data traffic is directed back to the SPTs. The GADAG Computer then computes  
6 the new GADAG and floods its descriptor. The SPT Bridges then compute and install the new MRTs if each  
7 SPT Bridge has already directed traffic back to the SPTs.

8 If MRTs protect each other, then only one of the MRTs is restored at a time. Upon a failure event, PLR  
9 Bridges direct all data traffic to the MRT that is not affected by the failure (e.g., MRT-Red). If a 1+1 type of  
10 protection scheme is used, then there is no need to react to a failure event as data frames are forwarded on  
11 both MRTs, i.e., there are no PLRs. When the GADAG Computer and the SPT Bridges have the same view  
12 on the network topology again, then the GADAG Computer computes the new GADAG and floods its  
13 descriptor. Upon reception of the Topology sub-TLV describing the new GADAG, the SPT Bridges compute  
14 the new MRTs. The broken MRT (e.g., MRT-Blue) then is restored while the other MRT (e.g., MRT-Red) is  
15 not touched. If each SPT Bridge has installed the new MRT (e.g., the new MRT-Blue), then data traffic is  
16 directed to this newly restored MRT. The SPT Bridges then install the other MRT (e.g., the new MRT-Red).  
17 The same restoration procedure is followed if both MRTs are affected by the failure so that MRT-Blue is  
18 restored first.

19 NOTE—The method to be used for verifying whether the SPT Bridges have a common view on the topology and  
20 whether SPTs and MRTs have been restored is left to the implementer and the network operator. A common method is to  
21 wait some time after the reception of the last LSP indicating a topology change. Alternatively, OAM can be used, for  
22 instance.

23

## **1 46. Time-Sensitive Networking (TSN) configuration**

2 Time-Sensitive Networking (TSN) is a collection of features in IEEE 802.1 standards that provide the  
3 following:

- 4 — Time synchronization among Bridges and end stations
- 5 — Significant reduction in frame loss due to faults in network equipment
- 6 — Significant reduction in, or the elimination of, frame loss due to egress Port congestion
- 7 — Bounded latency

8 This clause provides specifications for the configuration of TSN features in a network. The configuration  
9 process begins when Talkers and Listeners pass their requirements to the network and proceeds with the  
10 configuration of TSN features in Bridges along a tree from each Talker to its Listener(s).

### **11 46.1 Overview of TSN configuration**

#### **12 46.1.1 Streams, Talkers, and Listeners**

13 TSN configuration uses the concept of a Stream that is transmitted by a Talker to one or more Listeners. The  
14 Talkers and Listeners are located within end stations.

15 This clause specifies configuration information for Streams requested by Talkers and Listeners, or by  
16 network management entities acting on their behalf. Stream requirements are initially specified by, or for,  
17 Talker and Listener without detailed knowledge of the network. Network entities or administrators obtain  
18 these requirements, analyze the topology and capabilities of the Bridges, and configure Bridges to meet the  
19 requirements. The network returns the success or failure of each Stream's configuration to its Talker(s) and  
20 Listener(s).

#### **21 46.1.2 TSN configuration protocols**

22 A variety of protocols can be used for the exchange of configuration information (e.g., signaling protocols,  
23 remote network management protocols).

24 Specific TSN-capable products list the protocol that is supported as part of their conformance [e.g., 5.18.3,  
25 item c) in 5.29]. Each user/network protocol will specify a specific schema and/or encoding for the  
26 configuration information in 46.2. Examples of these protocols are described for each of the TSN  
27 configuration models in 46.1.3.

#### **28 46.1.3 TSN configuration models**

29 Three models for TSN user/network configuration are described. These models provide an architectural  
30 context for subsequent specifications. Each model specification shows the logical flow of configuration  
31 information between various entities in the network.

##### **32 46.1.3.1 Fully distributed model**

33 In the fully distributed model, the end stations that contain Talkers and Listeners communicate the user  
34 requirements directly to the neighboring Bridge. The network is configured in a fully distributed manner,  
35 without a centralized network configuration entity. The distributed network configuration is performed using  
36 a protocol that propagates configuration information along the active topology for the Stream (i.e., Bridges  
37 in the tree from Talker to Listeners).

1 As Stream requirements propagate through each Bridge, management of the Bridge's resources is effectively  
2 performed locally. This local management is limited to the information that the Bridge has knowledge of and  
3 does not necessarily include knowledge of the entire network.

4 Figure 46-1 provides a graphical representation of the fully distributed model.

**Figure 46-1—Fully distributed model**

5 In the figure, the solid arrows represent the protocol that is used to exchange information between Talkers/  
6 Listeners (users) and Bridges (network). This information is specified in 46.2.

7 In the figure, the dashed arrows represent the protocol that propagates information within the network. This  
8 protocol carries Stream configuration information (46.2) as well as additional information specific to  
9 network configuration.

10 The following TSN features can be configured by Bridges using this model:

- 11 a) Credit-based shaper algorithm (8.6.8.2) and its configuration (Clause 34)

12 The Stream Reservation Protocol (SRP) of Clause 35 can be used by Talkers and Listeners, and to propagate  
13 configuration information throughout the network of Bridges.

#### 14 **46.1.3.2 Centralized network/distributed user model**

15 Some TSN use cases are computationally complex. For example, for scheduled traffic (8.6.8.4),  
16 computation of the gate control list of each Port can take significant time. For such use cases, it is helpful to  
17 centralize the computation in a single entity (Bridge or end station), rather than perform the computation in  
18 all Bridges.

19 Some TSN use cases can benefit from a complete knowledge of all Streams in the network. For example, if  
20 the bandwidth for multiple Streams is greater than the available bandwidth along the shortest path between  
21 Talkers and Listeners, it is helpful to forward a subset of those Streams along a path other than the shortest.  
22 For these use cases, a centralized entity can gather information for the entire network in order to find the best  
23 configuration.

24 In the centralized network/distributed user model, end stations communicate their Talker/Listener  
25 requirements directly to the neighboring Bridge, just as in the fully distributed model. However, in the  
26 centralized network/distributed user model, a Centralized Network Configuration (CNC, 46.1.6) entity  
27 configures Bridges to pass Talker/ Listener Stream requirements directly to the CNC, rather than  
28 propagating that information along the path to be taken by Stream data. All configuration of Bridges for  
29 Streams is performed by this CNC using a remote network management protocol.

30 The CNC has a complete view of the physical topology of the network as well as the capabilities of each  
31 Bridge. This enables the CNC to centralize complex computations. The CNC can exist in either an end  
32 station or a Bridge.

1 Figure 46-2 provides a graphical representation of the centralized network/distributed user model.

**Figure 46-2—Centralized network/distributed user model**

2 In the figure, the solid arrows represent the protocol that is used to exchange Stream information between  
3 Talkers/Listeners (users) and Bridges (network). This information is specified in 46.2.

4 In the figure, the dashed arrows represent the protocol that transfers Stream configuration information  
5 between Bridges and the CNC. This information is specified in 46.2.

6 In the figure, dotted arrows represent the remote network management protocol. The CNC acts as the  
7 management client, and each Bridge acts as the management server. The CNC uses remote management to  
8 discover physical topology, retrieve Bridge capabilities, and configure TSN features in each Bridge. Talkers  
9 and Listeners are not required to participate in this remote network management protocol. The information  
10 carried by the remote network management protocol is specified in Clause 12.

11 NOTE 1—If the Talker/Listener protocol of the fully distributed model is selected to be the same as the Talker/Listener  
12 protocol of the centralized network/distributed user model, end stations can support both models without explicit  
13 knowledge of how the network is configured.

14 The following TSN features can be configured by the CNC using this model:

- 15 a) Credit-based shaper algorithm (8.6.8.2) and its configuration (Clause 34)
- 16 b) Frame preemption (6.7.2)
- 17 c) Scheduled traffic (8.6.8.4, 8.6.9)
- 18 d) Frame Replication and Elimination for Reliability (IEEE Std 802.1CB)
- 19 e) Per-Stream Filtering and Policing (8.6.5.1)
- 20 f) Cyclic queuing and forwarding (Annex T)

21 SRP (Clause 35) can be used as the Talker/Listener protocol (solid arrows of Figure 46-2). SRP's MRP  
22 External Control (12.32.4) feature can be used to exchange configuration information with the CNC  
23 component (dashed arrows of Figure 46-2). SRP exchanges configuration information using the TLV  
24 technique to reference elements in 46.2 (see 46.1.3.1). Examples of a remote network management protocol  
25 (dotted arrows of Figure 46-2) include Simple Network Management Protocol (SNMP), NETCONF (IETF  
26 RFC 6241 [B39]), and RESTCONF (IETF RFC 8040 [B47]).

27 NOTE 2—NETCONF and RESTCONF specify a startup datastore: nonvolatile configuration that is applied when the  
28 Bridge powers on. The startup datastore feature enables a CNC to configure Bridges and then remove itself from the  
29 network. SNMP does not specify a startup datastore feature. If SNMP is used by a CNC, this can be mitigated by a)  
30 using a proprietary (Bridge-specific) startup datastore feature or b) ensuring that the CNC is always active in the network  
31 in order to reconfigure Bridges that cycle power.

### 46.1.3.3 Fully centralized model

Many TSN use cases require significant user configuration in the end stations that act as Talkers and Listeners. For example, in many automotive and industrial control applications, the timing of physical inputs and outputs (I/Os) is determined by the physical environment under control, and the timing requirements for Streams are derived from that I/O timing. In some use cases, these I/O timing requirements can be computationally complex and involve detailed knowledge of the application software/hardware within each end station.

In order to accommodate this sort of TSN use case, the fully centralized model enables a Centralized User Configuration (CUC, 46.1.5) entity to discover end stations, retrieve end station capabilities and user requirements, and configure TSN features in end stations. The protocols that the CUC uses for this purpose are not specified in this standard.

From a network perspective, the primary difference between the fully centralized model and the centralized network/distributed user model is that all user requirements are exchanged between the CNC and CUC.

Figure 46-3 provides a graphical representation of the fully centralized model with multiple CUCs.

15

**Figure 46-3—Fully centralized model**

In the figure, the solid arrows represent the protocol that is used to exchange Stream information between the CUC and the CNC. This information is specified in 46.2.

In the figure, the dotted arrows represent the remote network management protocol. The CNC acts as the management client, and each Bridge acts as the management server. The CNC uses remote management to discover physical topology, retrieve Bridge capabilities, and configure TSN features in each Bridge. Talkers and Listeners are not required to participate in this remote network management protocol. The information carried by the remote network management protocol is specified in Clause 12.

In this fully centralized model, a protocol is used between the CUC and end stations (Talkers and Listeners) to retrieve end station capabilities and requirements and to configure the end stations.

1 The following TSN features can be configured by the CNC using this model:

- 2 a) Credit-based shaper algorithm (8.6.8.2) and its configuration (Clause 34)
- 3 b) Frame preemption (6.7.2)
- 4 c) Scheduled traffic (8.6.8.4, 8.6.9)
- 5 d) Frame Replication and Elimination for Reliability (IEEE Std 802.1CB)
- 6 e) Per-Stream Filtering and Policing (8.6.5.1)
- 7 f) Cyclic queuing and forwarding (Annex T)

8 YANG (IETF RFC 7950) is a data modeling language used to model configuration data and state data for  
9 remote network management protocols. The remote network management protocol uses a specific encoding  
10 such as XML or JSON. For a particular feature, a YANG module specifies the organization and rules for the  
11 feature's management data, and a mapping from YANG to the specific encoding enables the data to be  
12 understood correctly by both client (e.g., network manager) and server (e.g., Bridge).

13 In order to support the use of YANG-based protocols for the fully centralized model, 46.3 specifies a YANG  
14 module. The YANG module specifies a YANG typedef/grouping for each group of information in 46.2.

15 For an informative example workflow using the fully centralized model, refer to U.2.

#### 16 **46.1.4 Stream identification and transformation**

17 TSN configuration uses the concept of a Stream of data that is transmitted by a Talker to one or more  
18 Listeners.

19 In order to apply TSN behavior to a Stream (e.g., to reserve bandwidth), the network distinguishes Streams  
20 from each other and from non-TSN traffic (e.g., best-effort). Each frame of a Stream contains fields that  
21 uniquely identify the Stream.

22 The goal of TSN configuration is to allow Talkers and Listeners to use their existing transport layer and  
23 application layer protocols for data, rather than requiring a TSN-specific frame format. TSN achieves this  
24 goal by identifying each Stream using fields from well-established frame formats such as Transmission  
25 Control Protocol (TCP), User Datagram Protocol (UDP), and IEEE 802.1 (i.e., MAC addresses and VLAN  
26 identifier).

27 As the frames of each Stream cross the user/network boundary, the identification of the Stream in its frames  
28 can be different between the network and the user. For example, the user can use UDP without an awareness  
29 of VLAN IDs, but the network can require a specific VLAN ID in order to apply TSN features. In order to  
30 support this sort of difference in frame format, the TSN user/network configuration information (46.2)  
31 provides features to enable transformation of the Stream's identification at the user/network boundary. The  
32 user identification translates to/from the network identification at the boundary, either within the end station  
33 or a nearest Bridge. This transformation has the benefit of allowing the user's identification to match its  
34 higher layer application protocol and the network's identification to match the bridging technology.

Stream transformation can be accomplished using the functions specified in IEEE Std 802.1CB. The functions of IEEE Std 802.1CB can be implemented in the end station (Talker/Listener) or within the nearest Bridge. The descriptions in this clause focus on Stream transformation in the end station and use features of the TSN user/network configuration information (46.2).

NOTE 1—In this clause, Stream transformation refers to changes to the fields of a frame that identify the Stream. IEEE Std 802.1CB specifies Stream transformation for identification as well as for frame replication and elimination (redundancy).

NOTE 2—Stream transformation is an optional capability of end stations and Bridges. If stream transformation is not supported, the user's identification of the Stream must be the same as the network's identification, and the user must use an identification that is consistent with bridging as specified for TSN features in this standard (e.g., VLAN tag and group destination MAC address).

Figure 46-4 provides an example of Stream transformation in the Talker end station. Stream transformation in the Listener end station is similar. The example of Figure 46-4 assumes use of the centralized network/distributed user model (46.1.3.2). Use of the fully centralized model (46.1.3.3) is similar.

**Figure 46-4—Example of Stream transformation in Talker end station**

For Stream transformation in the end station, the end station's interface to the network can provide the transformation capability, acting as a network entity within the user's end station.

The identification of the Stream in the user originates from the User Application block, specified by the Talker as the DataFrameSpecification (46.2.3.4). The end station knows this user identification, but not the identification that the network requires. To negotiate the network identification, the Talker uses SRP to transmit InterfaceCapabilities (46.2.3.7) that describe its Stream transformation capabilities to the nearest Bridge. The Bridge uses MRP External Control (12.32.4) to send the InterfaceCapabilities to a CNC. The CNC consults its configuration of network identification and uses MRP External Control to send InterfaceConfiguration (46.2.5.3) along with successful Status (46.2.5) back to the Bridge. When the Bridge receives this information, it propagates back to the Talker using SRP. The InterfaceConfiguration provides the network identification, which the end station uses to perform Stream transformation for data frames.

NOTE 3—The network identification typically entails allocation of a group MAC address for the Stream. If a CNC is used, the CNC can allocate a group MAC address from a pool that it maintains.

Figure 46-5 provides an example of IEEE 802.1CB functions within the Stream Transformation block in the Talker end station. The example assumes that the user identification uses an Internet Protocol (IP) packet for identification and that the frame conveying the IP packet does not use the appropriate MAC address and VLAN tag for TSN features in Bridges (e.g., IP packet unicast destination MAC address, untagged). The IEEE 802.1CB function for IP Stream identification uses fields of the IP packet to identify the packet as a specific Stream. That stream identification is then applied to the IEEE 802.1CB function for Active Destination MAC and VLAN Stream identification to replace the destination MAC address and add a

1 VLAN tag for TSN Bridge features. The IP fields of the packet are not changed. The IEEE 802.1CB  
2 functions can be implemented in software (e.g., operating system driver) or in hardware.

**Figure 46-5—Example of IEEE 802.1CB functions in Talker end station**

3 Figure 46-6 provides a corresponding example of IEEE 802.1CB functions within the Stream  
4 Transformation block in the Listener end station. In this direction, the IEEE 802.1CB function for Active  
5 Destination MAC and VLAN Stream identification provides both functions. The IEEE 802.1CB function  
6 uses the group destination MAC address and VLAN tag of the received frame to identify a specific Stream.  
7 The IEEE 802.1CB function then transforms the destination MAC address and VLAN tag to restore the  
8 Stream's frame to its original format (as transmitted by the Talker).

**Figure 46-6—Example of IEEE 802.1CB functions in Listener end station**

#### 9 46.1.5 Centralized User Configuration

10 A Centralized User Configuration (CUC) delivers user requirements to the CNC. The CUC delivers  
11 information for configuring TSN features to end stations. It is a logical entity that can be located in any  
12 network system.

13 The CUC is responsible for:

- 14 a) Reconciling the requirements from Talkers and Listeners to Stream requirements, if necessary.
- 15 b) Sending the Stream requirements to the CNC.
- 16 c) Receiving the end station communication-configuration from the CNC.
- 17 d) Distributing the end station communication-configuration to Talkers and Listeners.

18 NOTE—The CNC is responsible for the assignment of a unique StreamID to each Stream. For this a remote procedure  
19 call (RPC) RequestFreeStreamId (46.2.7.5) is available so the CUC can request a free (i.e., available) StreamID from the  
20 CNC.

21 Stream requirements, in the context of the CUC, result from combining the Stream requirements of one  
22 Talker with the Stream requirements of one or multiple Listeners that, together, apply to form a Stream.  
23 Reconciling the requirements for the Stream does not change the parameters in the Stream request  
24 originating from the Talker or the Listener(s).

1 The end station communication-configuration that is received by the CUC from the CNC and then  
2 distributed to the Talkers and Listeners does not directly configure features on the end stations. It consists of  
3 configuration information that a CUC can provide for a Talker and Listeners to configure the Stream. An end  
4 station could, for example, make use of the information it receives in the communication-configuration from  
5 the CUC to configure an application in a way that ensures different Streams are sent by the application in a  
6 specific order that correlates with the expected Stream's transmission on the network.

7 A CUC affects only one Configuration Domain. Talkers and Listeners can only make use of the CUC to  
8 reconcile their Stream requirements into a Stream request, if they are part of the same Configuration  
9 Domain. If a Talker wants to communicate with one or more Listeners in a different Configuration Domain,  
10 this needs to be done through dedicated inter-domain communication mechanisms. Such inter-domain  
11 communication mechanisms are not specified by this standard.

12 The protocols that the CUC uses for communication with end stations are not specified by this standard. A  
13 CUC exchanges information with a CNC in order to configure TSN features on behalf of its end stations  
14 (46.2). The CUC can request computation of paths and configurations for Streams in the following ways:

- 15 e) Request computation of the paths and configurations for a set of Streams, using the protocol  
16 operation described in 46.2.7.1. The computation is performed by the CNC on the complete set of  
17 Streams of this request. This allows for optimized scheduling of Streams in the network.
- 18 f) Request computation of the paths and configurations for new or modified Streams, using the  
19 protocol operation described in 46.2.7.2. The computation is performed by the CNC on all Streams  
20 in a Configuration Domain that have a StreamStatus (46.2.3.8) of either planned or modified.
- 21 g) Request computation of the paths and configurations for all Streams of a CUC, using the protocol  
22 operation described in 46.2.7.3. The computation is performed by the CNC on all Streams in a  
23 Configuration Domain that belong to the CUC specified in the request.
- 24 h) Request the joining of a set of Listeners to an already existing Stream. The paths are extended to  
25 allow forwarding of the Stream to the new Listeners. Computation for the changes has to be  
26 triggered via RPC.
- 27 i) Request the removal of an existing Stream, using the protocol operation described in 46.2.8.1.
- 28 j) Request the removal of one or more Listeners from an existing Stream. Computation for the changes  
29 has to be triggered via RPC.

30 A CUC can be present for initial configuration, to manage changes to a running network, or both. Multiple  
31 CUCs can co-exist and operate in parallel in the same Configuration Domain as shown in Figure 46-3.

## 32 **46.1.6 Centralized Network Configuration**

33 The Centralized Network Configuration (CNC) is a logical entity that configures network resources on  
34 behalf of applications (users) and can be located in any station of a network.

35 The CNC is responsible for:

- 36 a) Receiving the Stream requirements for one or more Streams from the corresponding CUC.
- 37 b) Providing a way for a CUC to request a free StreamID.
- 38 c) Assigning a unique destination MAC address in the Configuration Domain it is responsible for to  
39 each of the requested Streams.
- 40 d) Computing paths for requested Streams.
- 41 e) Performing computation of scheduling and/or shaping configuration for the requested Streams.
- 42 f) Configuring the network devices to provide the required resources for the Streams (e.g. Filtering  
43 Database (8.8) entries, configuration of transmission gates, etc.), using remote management.

- 1 g) Providing the end station communication-configuration for the Streams to the corresponding CUC.
- 2 If the paths for the Streams impact existing Streams the CNC is also responsible for providing that
- 3 information to the CUCs that originally requested the impacted Streams.
- 4 h) Removing of Streams as requested by a CUC.
- 5 i) Discovering physical topology, using remote management.
- 6 j) Retrieving station capabilities, using remote management.

7 The CNC communicates with a CUC through the user/network configuration information specified in 46.2.  
8 It communicates with the stations using the managed objects defined in this and other IEEE 802.1 standards.  
9 There can only be one active CNC per Configuration Domain.

#### 10 **46.1.7 Configuration Domain**

11 A Configuration Domain is a set of stations that are under a common configuration and management  
12 scheme, and a single administration. The Configuration Domain provides boundary information for the  
13 common management scheme and to support the responsibilities of the CUC and CNC regarding Streams.  
14 Whether a CNC and one or more CUCs are present in a Configuration Domain depends on the TSN  
15 configuration model (46.1.3) that is used in the domain (e.g., whether the fully centralized model or a  
16 different configuration model is used). The CNC and the CUCs required for the configuration of a  
17 Configuration Domain affect only one Configuration Domain.

#### 18 **46.2 User/network configuration information**

19 User/network configuration information for the three TSN configuration models (46.1.3) is specified as  
20 follows. For the two distributed models, SRP specifies TLVs in 35.2.2.10 that reference information in 46.2.  
21 For the fully centralized model, the YANG module in 46.3 references information in 46.2.

22 Within this subclause, the word element refers to a single item of information used for TSN configuration.  
23 The word group refers to a collection of related elements. Groups are organized hierarchically, such that a  
24 group can be contained within another group. A single low-level group can be contained within multiple  
25 higher level groups. The dot-separated notation is used to refer to a specific element in text. For example,  
26 “Talker.StreamID.UniqueId” refers to the UniqueId element of the StreamID that is contained within the  
27 Talker group.

28 This subclause specifies each group in a table. Each row of the table specifies an element of the group. Each  
29 element’s row specifies its name, data type, and a reference to normative text that specifies its semantics  
30 (i.e., meaning). The data type of each element uses one of the values from 46.2.1. Other specifications such  
31 as conformance (i.e., required or optional), direction of transfer (i.e., user to network or network to user),  
32 default value, and range limitations are specified with normative text instead of with the table.

33 Each element name uses a camel-case naming convention (e.g., “MacAddress”) to align with naming  
34 conventions used in other clauses of IEEE Std 802.1Q. A specific protocol can use a different naming  
35 convention (e.g., 46.3) as long as the protocol’s name for the element can be associated with the element’s  
36 specification in 46.2.

#### 37 **46.2.1 Data types**

38 Data types in the tables include the following:

- 39 a) Boolean
- 40 b) int8, for a signed 8-bit integer
- 41 c) int16, for a signed 16-bit integer
- 42 d) int32, for a signed 32-bit integer

- 1 e) uint8, for an unsigned 8-bit integer
- 2 f) uint16, for an unsigned 16-bit integer
- 3 g) uint32, for an unsigned 32-bit integer
- 4 h) string
- 5 i) enumeration, for a collection of named values
- 6 j) rational, for a rational number consisting of a uint32 numerator and uint32 denominator
- 7 k) mac-address-type, for an IEEE 802 MAC address
- 8 l) ipv4-address-type, for an IPv4 address (IETF RFC 791)
- 9 m) ipv6-address-type, for an IPv6 address (IETF RFC 8200)
- 10 n) sequence of <X>, for a list of zero or more instances of data type <X> (e.g., sequence of uint32)

11 If the data type shown in the table is not from the preceding list, then the data type is specified in the  
12 normative text for the element.

### 13 46.2.2 Protocol integration

14 The TSN user/network configuration information consists of three high-level groups:

- 15 — **Talker:** Elements from user to network that specify the Talker for a single Stream.
- 16 — **Listener:** Elements from user to network that specify the Listener for a single Stream.
- 17 — **Status:** Elements from network to user that specify the status of the Stream's network configuration  
18 for a Talker or Listener. This group notifies the user when the Stream is ready for use (or a failure  
19 occurred).

20 A protocol that supports TSN user/network configuration information shall integrate the three groups using  
21 the specifications in this clause. The integration is provided in each protocol's specifications (not in this  
22 clause). For examples of such protocol integration, see Clause 35 and 46.3.

23 The StreamID of 46.2.3.1 uniquely identifies the Stream. The StreamID identifies configuration, not data, so  
24 it has no formal relation to the data frame encoding for the Stream.

25 TSN configuration can be viewed conceptually as a request/response exchange:

- 26 — Request: End station or CUC transmits a protocol message that contains a Talker or Listener group.
- 27 — Response: Bridge or CNC transmits a protocol message that contains a Status group.
- 28 NOTE—The Response can be unsolicited in order to update configuration, e.g., to address a change in the  
29 network.

30 The StreamID of each group correlates each request to its corresponding response, such that configuration of  
31 multiple Streams can overlap in time. For example, a possible sequence of messages is Talker request for  
32 StreamID 1, Talker request for StreamID 2, Listener request for StreamID 2, Status to Talker for StreamID 2,  
33 Status to Listener for StreamID 2, Listener request for StreamID 1, and so on.

34 For the fully distributed model (46.1.3.1), the Status response to a Talker is communicated in a message  
35 along with the Listener request(s). When there is more than one Listener per Stream, the Listener and Status  
36 groups must be merged as they propagate through Bridges to the Talker. The methodology for this merger is  
37 specified in the TSN configuration protocol (not in this clause).

38 For the fully centralized model (46.1.3.3), the CUC combines multiple Talker groups and Listener groups  
39 into a single transfer from CUC to CNC for computation together in the CNC. After the CNC computation is  
40 complete, a single transfer from CNC to CUC combines multiple Status groups. Each Status group can  
41 provide sub-groups for each Talker/Listener and merged groups for the entire Stream. The methodology for  
42 these combinations and mergers is specified in the TSN configuration protocol (not in this clause).

1 In addition to the request/response exchange, end stations can transmit Talker/Listener messages as  
2 advertisement (e.g., for a Talker to notify potential Listeners of its presence). The methodology for this  
3 advertisement is specified in the TSN configuration protocol (not in this clause).

4 For each Talker group and Listener group, there are two operations for each Stream:

- 5 — **Join:** Talker/Listener request to join the Stream and to configure network resources for this Stream's  
6 data transfer.
- 7 — **Leave:** Talker/Listener request to leave the Stream and to release the network resources for this  
8 Stream.

9 The groups in this clause specify requirements for the join and leave operation, but the encoding of the  
10 operation is not specified in this clause. Each TSN configuration protocol shall specify the encoding of the  
11 join/leave operation as part of its integration. For example, SRP specifications of this standard (Clause 35)  
12 encode the join/leave operation within the Multiple Registration Protocol (MRP) (Clause 10) that serves as  
13 its foundation.

14 The protocol message(s) that invoke the join or leave operation are not required to coincide with the protocol  
15 message(s) that contain the associated groups (Talker, Listener, or Status). Nevertheless, the groups specify  
16 elements that are required for a subsequent join or leave operation to be valid. For example, for the fully  
17 centralized model (46.1.3.3), the CUC can transfer a list of Talker/Listener groups to the CNC, followed by  
18 a separate protocol message with a join request that applies to the entire list. For the join request to succeed,  
19 each of the Talker/Listener groups contains the required elements. At a later time, the CUC can read the  
20 resulting list of Status groups from the CNC, which provides the response to the join.

#### 21 **46.2.2.1 DomainID**

22 DomainID uniquely identifies the Configuration Domain of a CUC, and the Streams associated with that  
23 CUC. DomainID is only used if the centralized network/distributed user model (46.1.3.2) or the fully  
24 centralized model (46.1.3.3) is used.

#### 25 **46.2.2.2 CucID**

26 CucID uniquely identifies a CUC within a Configuration Domain and is used in configuration models that  
27 include a CNC. It is used along with the DomainID to associate Streams with a CUC.

#### 28 **46.2.2.3 CncEnabled**

29 CncEnabled is used to enable or disable the CNC functionality of a station capable of acting as a CNC. If  
30 CncEnabled is set to TRUE the CNC functionality is enabled. If it is set to FALSE the CNC functionality is  
31 disabled. The default value for CncEnabled is FALSE.

#### 32 **46.2.3 Talker**

33 The Talker group specifies the following:

- 34 — Talker's behavior for Stream (how/when transmitted)
- 35 — Talker's requirements from the network
- 36 — TSN capabilities of the Talker's interface(s)

37 In the fully distributed model and the centralized network/distributed user model, this group originates from  
38 the Talker's end station. In the fully centralized model, this group originates from the CUC.

39 The Talker group contains the following groups:

- 1 — StreamID (46.2.3.1)
- 2 — StreamRank (46.2.3.2)
- 3 — EndStationInterfaces (46.2.3.3)
- 4 — DataFrameSpecification (46.2.3.4)
- 5 — TrafficSpecification (46.2.3.5)
- 6 — UserToNetworkRequirements (46.2.3.6)
- 7 — InterfaceCapabilities (46.2.3.7)
- 8 — StreamStatus (46.2.3.8)

9 For the join operation, the StreamRank and TrafficSpecification groups shall be included within the Talker  
10 group.

11 For the join operation, the UserToNetworkRequirements and InterfaceCapabilities groups may be included  
12 within the Talker group. If a group is omitted, the network uses the default values specified for elements of  
13 that group.

14 For the join operation, the DataFrameSpecification shall be included within the Talker group unless all of the  
15 following conditions apply:

- 16 a) The InterfaceCapabilities group is included.
- 17 b) InterfaceCapabilities.CB-StreamIdenTypeList includes the type for Active Destination MAC and  
18 VLAN Stream identification.

19 The preceding conditions enable the Talker and Listener to perform Stream transformation (46.1.4), and  
20 therefore the network does not need the user's data frame identification in DataFrameSpecification. The  
21 absence of the DataFrameSpecification group notifies the network that Stream transformation is performed  
22 in the end stations for this Stream.

23 For the join and leave operation, the StreamID group shall be included in the TSN user/network protocol in  
24 a location associated with the Stream (e.g., Talker group).

25 For the join and leave operation, EndStationInterfaces shall be included within the Talker group for the fully  
26 centralized model (46.1.3.3). For the join and leave operation, EndStationInterfaces should be included  
27 within the Talker group for the fully distributed model (46.1.3.1) or centralized network/distributed user  
28 model (46.1.3.2).

29 For the join and leave operation, StreamStatus shall be included.

### 30 **46.2.3.1 StreamID**

31 The StreamID group provides a unique identifier of the Stream's configuration and is used by protocols in  
32 the network to associate the user's Stream with TSN resources. The StreamID group is used by Talker,  
33 Listener, and Status groups.

34 The elements of the StreamID group are listed in Table 46-1.

**Table 46-1—StreamID elements**

| Name       | Data type        | Reference  |
|------------|------------------|------------|
| MacAddress | mac-address-type | 46.2.3.1.1 |
| UniqueID   | uint16           | 46.2.3.1.2 |

### 1 46.2.3.1.1 MacAddress

2 MacAddress is a 48-bit IEEE 802 MAC address associated with the Talker sourcing the Stream to the  
3 bridged network. The entire range of MAC addresses are acceptable.

4 NOTE 1—The MAC address component of the StreamID can, but does not necessarily, have the same value as the  
5 source\_address parameter of any frame in the actual data Stream. For example, the StreamID can be assigned by a TSN  
6 CUC (see 46.1.3.3), using a pool of MAC addresses that the TSN CUC maintains.

7 NOTE 2—If the MAC addresses used to construct StreamIDs are not unique within the network, duplicate StreamIDs  
8 can be generated, with unpredictable results.

### 9 46.2.3.1.2 UniqueID

10 UniqueID is used to distinguish between multiple Streams within the end station identified by MacAddress.

### 11 46.2.3.2 StreamRank

12 The StreamRank group provides the rank of this Stream relative to other Streams in the network. This rank is  
13 used to determine success/failure of Stream resource configuration and is unrelated to the Stream's data.

14 The elements of the StreamRank group are listed in Table 46-2.

**Table 46-2—StreamRank elements**

| Name | Data type | Reference  |
|------|-----------|------------|
| Rank | uint8     | 46.2.3.2.1 |

### 15 46.2.3.2.1 Rank

16 The Rank is used by the network to decide which Streams can and cannot exist when TSN resources reach  
17 their limit. If a Bridge's Port becomes oversubscribed (e.g., network reconfiguration, IEEE 802.11  
18 bandwidth reduction), the Rank is used to help determine which Streams can be dropped (i.e., removed from  
19 Bridge configuration).

20 The only valid values for Rank shall be zero and one. The configuration of a Stream with Rank zero is more  
21 important than the configuration of a Stream with Rank one. The Rank value of zero is intended for  
22 emergency traffic, and the Rank value of one is intended for non-emergency traffic.

23 NOTE—It is expected that higher layer applications and protocols can use the Rank to indicate the relative importance  
24 of Streams based on user preferences. Those user preferences are expressed by means beyond the scope of this standard.  
25 When multiple applications exist in a network (e.g., audio/video along with industrial control), it can be challenging for  
26 the varied applications and vendors to agree on multiple Rank values. To mitigate such challenges, this Rank uses a  
27 simple concept of emergency (zero) and non-emergency (one) that can be applied over all applications. For example, in  
28 a network that carries audio Streams for fire safety announcements, all applications are likely to agree that those Streams  
29 use Rank of zero.

### 30 46.2.3.3 EndStationInterfaces

31 The EndStationInterfaces group provides a list of one or more InterfaceID groups. Each InterfaceID group  
32 identifies a physical interface (distinct point of attachment) in the end station acting as a Talker/Listener.

33 Although many end stations contain a single interface, this list allows for multiple interfaces. Some TSN  
34 features allow a single Stream to span multiple interfaces (e.g., seamless redundancy).

<sup>1</sup> In centralized network models, EndStationInterfaces is used by the CNC to locate the interfaces of the  
<sup>2</sup> Talker/Listener in the topology.

<sup>3</sup> The InterfaceID group is used to identify a distinct point of attachment in EndStationInterfaces,  
<sup>4</sup> InterfaceConfiguration (46.2.5.3), and FailedInterfaces (46.2.5.4). In the context of EndStationInterfaces  
<sup>5</sup> and InterfaceConfiguration, each interface is located in an end station only. In the context of  
<sup>6</sup> FailedInterfaces, each interface can be located within an end station or a Bridge.

<sup>7</sup> The elements of the InterfaceID group are listed in Table 46-3.

**Table 46-3—InterfaceID elements**

| Name          | Data type        | Reference  |
|---------------|------------------|------------|
| MacAddress    | mac-address-type | 46.2.3.3.1 |
| InterfaceName | string           | 46.2.3.3.2 |

#### <sup>8</sup> **46.2.3.3.1 MacAddress**

<sup>9</sup> MacAddress is the MAC address (IEEE Std 802) of the interface in the station (end station or Bridge). This  
<sup>10</sup> MAC address uniquely identifies the station within the local network.

<sup>11</sup> MacAddress shall be included in the InterfaceID group.

<sup>12</sup> NOTE—This MAC address can be discovered in the physical topology using protocols such as IEEE Std 802.1AB  
<sup>13</sup> (LLDP). LLDP supports MAC address as a subtype for the station's Chassis ID and Port ID. If the station does not use  
<sup>14</sup> MAC address for its LLDP IDs, remote management can be used to associate this MacAddress to the values provided in  
<sup>15</sup> the LLDP IDs.

#### <sup>16</sup> **46.2.3.3.2 InterfaceName**

<sup>17</sup> InterfaceName is the name of the interface that is assigned locally by the station (end station or Bridge).

<sup>18</sup> InterfaceName may be included in the InterfaceID group.

<sup>19</sup> IEEE Std 802 recommends that each distinct point of attachment to an IEEE 802 network have its own  
<sup>20</sup> universal MAC address. If the identified station follows this IEEE 802 recommendation, the MacAddress  
<sup>21</sup> element uniquely identifies the interface as well as the station, and InterfaceName is not needed.

<sup>22</sup> If the MacAddress applies to more than one interface (distinct point of attachment) within the station,  
<sup>23</sup> InterfaceName provides a locally assigned name that can help to identify the interface.

<sup>24</sup> When YANG is used for management of the station, InterfaceName is the interface name that serves as the  
<sup>25</sup> key for the station's interface list (IETF RFC 7223 [B43]).

<sup>26</sup> NOTE 1—The TSN CNC is typically located in a different physical product than the station identified by this  
<sup>27</sup> InterfaceID. Since the InterfaceName is assigned locally by the identified station, it is possible that the station's product  
<sup>28</sup> will change InterfaceName in a manner that the TSN CNC cannot detect. For example, IETF RFC 7223 [B43] mentions  
<sup>29</sup> that the YANG interface name can change when a physical attachment point is inserted or removed.

<sup>30</sup> NOTE 2—This interface name can be discovered in the physical topology using protocols such as IEEE Std 802.1AB  
<sup>31</sup> (LLDP). LLDP supports interface name as a subtype for its Port ID. If the station does not use interface name for its  
<sup>32</sup> LLDP Port ID, remote management can be used to associate this InterfaceName to the values provided in the LLDP  
<sup>33</sup> Port ID.

#### 1 46.2.3.4 DataFrameSpecification

2 The DataFrameSpecification group specifies the frame that carries the Talker's Stream data. The network  
3 uses the specification to identify this Stream's frames as TSN in order to apply the required TSN  
4 configuration.

5 The DataFrameSpecification is based on the user's knowledge of the frame, without any network specifics.  
6 In other words, this specifies the frame that the Talker would use in the absence of TSN.

7 The DataFrameSpecification is provided as a list of fields that the user knows. Each field is provided as one  
8 of the following groups:

- 9 — IEEE802-MacAddresses (46.2.3.4.1)
- 10 — IEEE802-VlanTag (46.2.3.4.2)
- 11 — IPv4-tuple (46.2.3.4.3)
- 12 — IPv6-tuple (46.2.3.4.4)

13 The list of fields is ordered from start of frame to end of header. For example, if the Talker uses a VLAN-  
14 tagged Ethernet frame (not IP), the list consists of IEEE802-MacAddresses followed by IEEE802-VlanTag.  
15 For example, if the Talker uses a UDP/IPv4 packet without knowledge of the Ethernet header, the list  
16 consists of IPv4-tuple only.

17 This group is optional, and its absence indicates that Stream transformation is performed in the Talker and  
18 Listeners of this Stream (46.2.3).

##### 19 46.2.3.4.1 IEEE802-MacAddresses

20 The IEEE802-MacAddresses group specifies a pair of IEEE 802 MAC addresses for Stream identification.

21 The use of these fields for Stream identification corresponds to the managed objects for Stream  
22 identification in IEEE Std 802.1CB. If inconsistency arises between this specification and  
23 IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.

24 The elements of the IEEE802-MacAddresses group are listed in Table 46-4.

**Table 46-4—IEEE802-MacAddresses elements**

| Name                  | Data type        | Reference          |
|-----------------------|------------------|--------------------|
| DestinationMacAddress | mac-address-type | 46.2.3.4.1 item a) |
| SourceMacAddress      | mac-address-type | 46.2.3.4.1 item b) |

25 The elements of the IEEE802-MacAddresses group:

- 26 a) **DestinationMacAddress**—This field specifies a destination MAC address. An address of all 1's  
28 specifies that the destination MAC address is ignored for purposes of Stream identification.
- 29 b) **SourceMacAddress**—This field specifies a source MAC address. An address of all 1's specifies  
31 that the source MAC address is ignored for purposes of Stream identification.

##### 32 46.2.3.4.2 IEEE802-VlanTag

33 The IEEE802-VlanTag group specifies a customer VLAN Tag (C-TAG of Clause 9) for Stream  
34 identification.

- 1 The Drop Eligible Indicator (DEI) field is not relevant from the perspective of a TSN Talker/Listener.
- 2 The use of these fields for Stream identification corresponds to the managed objects for Stream  
3 identification in IEEE Std 802.1CB. If inconsistency arises between this specification and  
4 IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.
- 5 The elements of the IEEE802-VlanTag group are listed in Table 46-5.

**Table 46-5—IEEE802-VlanTag elements**

| Name              | Data type | Reference          |
|-------------------|-----------|--------------------|
| PriorityCodePoint | uint8     | 46.2.3.4.2 item a) |
| VlanId            | uint16    | 46.2.3.4.2 item b) |

- 6 The elements of the IEEE802-VlanTag group:
- 7 a) **PriorityCodePoint**—This field specifies the Priority Code Point (PCP) field of the VLAN tag. The  
9 value range is 0 to 7 inclusive. The PriorityCodePoint is not used to identify the Stream, but it does  
10 identify a traffic class (queue) in Bridges.
- 11 b) **VlanId**—This field specifies the VLAN ID (VID) field of the VLAN tag. The value range is 0 to  
13 4095 inclusive. If only the PriorityCodePoint is known, the VlanId is specified as 0.

#### 14 46.2.3.4.3 IPv4-tuple

- 15 The IPv4-tuple group specifies fields to identify an IPv4 (RFC791) Stream.
- 16 The use of these fields for Stream identification corresponds to the managed objects for Stream  
17 identification in IEEE Std 802.1CB. If inconsistency arises between this specification and  
18 IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.
- 19 The elements of the IPv4-tuple group are listed in Table 46-6.

**Table 46-6—IPv4-tuple elements**

| Name                 | Data type         | Reference          |
|----------------------|-------------------|--------------------|
| SourceIpAddress      | ipv4-address-type | 46.2.3.4.3 item a) |
| DestinationIpAddress | ipv4-address-type | 46.2.3.4.3 item b) |
| Dscp                 | uint8             | 46.2.3.4.3 item c) |
| Protocol             | uint16            | 46.2.3.4.3 item d) |
| SourcePort           | uint16            | 46.2.3.4.3 item e) |
| DestinationPort      | uint16            | 46.2.3.4.3 item f) |

- 20 The elements of the IPv4-tuple group:
- 21 a) **SourceIpAddress**—This field specifies the source IPv4 address. An address of all 0's specifies that  
23 the IP source address is ignored for purposes of Stream identification.

- 1 b) **DestinationIpAddress**—This field specifies the destination IPv4 address.
- 3 c) **Dscp**—This field specifies the Differentiated Services Code Point (DSCP) (IETF RFC 2474). A  
5 value of 64 decimal specifies that the DSCP is ignored for purposes of Stream identification.
- 6 d) **Protocol**—This field specifies the IPv4 Protocol (e.g., UDP). The special value of all 1's (FFFF  
8 hex) represents 'None', i.e., Protocol, SourcePort, and DestinationPort are ignored for purposes of  
9 Stream identification. For any value other than all 1's, the lower octet is used to match IPv4  
10 Protocol.
- 11 e) **SourcePort**—This field specifies the source port of the Protocol.
- 13 f) **DestinationPort**—This field specifies the destination port of the Protocol.

#### 15 46.2.3.4.4 IPv6-tuple

16 The IPv6-tuple group specifies fields to identify an IPv6 (RFC 8200) Stream.

17 The use of these fields for Stream identification corresponds to the managed objects for Stream  
18 identification in IEEE Std 802.1CB. If inconsistency arises between this specification and  
19 IEEE Std 802.1CB, IEEE Std 802.1CB takes precedence.

20 The elements of the IPv6-tuple group are listed in Table 46-7.

**Table 46-7—IPv6-tuple elements**

| Name                 | Data type         | Reference          |
|----------------------|-------------------|--------------------|
| SourceIpAddress      | ipv6-address-type | 46.2.3.4.3 item a) |
| DestinationIpAddress | ipv6-address-type | 46.2.3.4.3 item b) |
| Dscp                 | uint8             | 46.2.3.4.3 item c) |
| Protocol             | uint16            | 46.2.3.4.3 item d) |
| SourcePort           | uint16            | 46.2.3.4.3 item e) |
| DestinationPort      | uint16            | 46.2.3.4.3 item f) |

21 The elements of the IPv6-tuple group:

- 22 a) **SourceIpAddress**—This field specifies the source IPv6 address. An address of all 0's specifies that  
24 the IP source address is ignored for purposes of Stream identification.
- 25 b) **DestinationIpAddress**—This field specifies the destination IPv6 address.
- 27 c) **Dscp**—This field specifies the DSCP (IETF RFC 2474). A value of 64 decimal specifies that the  
29 DSCP is ignored for purposes of Stream identification.
- 30 d) **Protocol**—This field specifies the IPv6 Next Header (e.g., UDP). The special value of all 1's (FFFF  
32 hex) represents 'None', i.e., Protocol, SourcePort, and DestinationPort are ignored for purposes of  
33 Stream identification. For any value other than all 1's, the lower octet is used to match IPv6 Next  
34 Header.
- 35 e) **SourcePort**—This field specifies the source port of the Protocol.
- 37 f) **DestinationPort**—This field specifies the destination port of the Protocol.

### 46.2.3.5 TrafficSpecification

The TrafficSpecification group specifies how the Talker transmits frames for the Stream. This is effectively the Talker's promise to the network. The network uses this traffic specification to allocate resources and adjust queue parameters in Bridges.

The TrafficSpecification group consists of the following:

- a) Its required elements, listed in Table 46-8.

**Table 46-8—TrafficSpecification elements**

| Name                  | Data type | Reference  |
|-----------------------|-----------|------------|
| Interval              | rational  | 46.2.3.5.1 |
| MaxFramesPerInterval  | uint16    | 46.2.3.5.2 |
| MaxFrameSize          | uint16    | 46.2.3.5.3 |
| TransmissionSelection | uint8     | 46.2.3.5.4 |

- b) An optional TSpecTimeAware group, whose elements are listed in Table 46-9.

**Table 46-9—TSpecTimeAware elements**

| Name                   | Data type | Reference  |
|------------------------|-----------|------------|
| EarliestTransmitOffset | uint32    | 46.2.3.5.5 |
| LatestTransmitOffset   | uint32    | 46.2.3.5.6 |
| Jitter                 | uint32    | 46.2.3.5.7 |

The presence of TSpecTimeAware specifies that the Talker's traffic is synchronized to a known time on the network (e.g., using IEEE Std 802.1AS). The TSpecTimeAware group provides elements to specify the Talker's time-aware transmit to the network. The Talker and Listeners of a Stream are assumed to coordinate using user (application) mechanisms, such that each Listener is aware that its Talker transmits in a time-aware manner. If MaxFramesPerInterval is greater than one, the time-aware Talker shall transmit multiple frames as a burst within the Interval, with the minimum inter-frame gap allowed by the media.

NOTE—Although scheduled traffic (8.6.8.4) specifies a valid implementation of a time-aware Talker, the TSpecTimeAware group is intended to support alternate implementations of scheduling.

For informative examples using the TSpecTimeAware group of TrafficSpecification, refer to U.1.

#### 46.2.3.5.1 Interval

Interval specifies the period of time in which the traffic specification cannot be exceeded. The traffic specification is specified by MaxFramesPerInterval and MaxFrameSize.

The Interval is a rational number of seconds, defined by an unsigned 32-bit integer numerator and an unsigned 32-bit integer denominator.

1 If the TSpecTimeAware group is not present, the Interval specifies a sliding window of time. The Talker's  
2 transmission is not synchronized to a time on the network, and therefore the traffic specification cannot be  
3 exceeded during any Interval in time.

4 If the TSpecTimeAware group is present, the Interval specifies a window of time that is aligned with the  
5 time epoch that is synchronized on the network. For example, if IEEE Std 802.1AS is used with the PTP  
6 timescale, the first Interval begins at 1 January 00:00:00 TAI. If CurrentTime represents the current time,  
7 then the start of the next Interval (StartOfNextInterval) is:

8 
$$\text{StartOfNextInterval} = N \times \text{Interval}$$

9 where N is the smallest integer for which the relation:

10 
$$\text{StartOfNextInterval} \geq \text{CurrentTime}$$

11 would be TRUE.

#### 12 **46.2.3.5.2 MaxFramesPerInterval**

13 MaxFramesPerInterval specifies the maximum number of frame transmissions that the Talker can initiate in  
14 one Interval.

#### 15 **46.2.3.5.3 MaxFrameSize**

16 MaxFrameSize specifies maximum frame size that the Talker will transmit, excluding any overhead for  
17 media-specific framing (e.g., preamble, IEEE 802.3 header, Priority/VID tag, CRC, interframe gap). As the  
18 Talker or Bridge determines the amount of bandwidth to reserve on the egress Port (interface), it will  
19 calculate the media-specific framing overhead on that Port and add it to the number specified in the  
20 MaxFrameSize element.

#### 21 **46.2.3.5.4 TransmissionSelection**

22 TransmissionSelection specifies the algorithm that the Talker uses to transmit this Stream's traffic class. This  
23 algorithm is often referred to as the shaper for the traffic class.

24 The value for this element uses Table 8-6 (in 8.6.8). If no algorithm is known, the value zero (strict priority)  
25 can be used.

26 The Talker's shaping and scheduling of the Stream is considered to be on the user side of the user/network  
27 boundary, and this specifies the Talker's behavior to the network. In the fully distributed model, this value  
28 can be ignored by a Bridge, and it is not changed during propagation through the Bridge.

#### 29 **46.2.3.5.5 EarliestTransmitOffset**

30 EarliestTransmitOffset specifies the earliest offset within each Interval at which the Talker is capable of  
31 starting transmit of its frames. As part of the Status group, the network will return a specific  
32 TimeAwareOffset to the Talker (within the earliest/latest range), which the Talker uses to schedule its  
33 transmit.

34 EarliestTransmitOffset is specified as an integer number of nanoseconds.

35 The Talker's transmit offsets include EarliestTransmitOffset, LatestTransmitOffset, and the  
36 TimeAwareOffset returned to the Talker in the Status group. Each of the Talker's offsets is specified at the  
37 point when the message timestamp point of the first frame of the Stream in each Interval passes the reference  
38 plane marking the boundary between the network media and PHY. The message timestamp point is specified  
39 by IEEE Std 802.1AS for various media.

#### 1 46.2.3.5.6 LatestTransmitOffset

2 LatestTransmitOffset specifies the latest offset within the Interval at which the Talker is capable of starting  
3 transmit of its frames. As part of the Status group, the network will return a specific TimeAwareOffset to the  
4 Talker (within the earliest/latest range), which the Talker uses to schedule its transmit.

5 LatestTransmitOffset is specified as an integer number of nanoseconds.

#### 6 46.2.3.5.7 Jitter

7 Jitter specifies the maximum difference in time between the Talker's transmit offsets and the ideal  
8 synchronized network time (e.g., IEEE 802.1AS time). Jitter is specified as an unsigned integer number of  
9 nanoseconds.

10 The maximum difference means sooner or later than the ideal (e.g., transmit  $\pm 500$  ns relative to  
11 IEEE 802.1AS time results in Jitter of 500).

12 The ideal synchronized network time refers to time at the source (e.g., IEEE 802.1AS grandmaster). The  
13 Jitter does not include inaccuracies as time is propagated from the time source to the Talker because those  
14 inaccuracies are assumed to be known by the network and time synchronization is a network technology.  
15 The Jitter element is intended to specify inaccuracies in the Talker's implementation. For example, if the  
16 Talker's IEEE 802.1AS time is  $\pm 812$  ns relative to the grandmaster and the Talker schedules using a 100  $\mu$ s  
17 timer tick driven by IEEE 802.1AS time, Jitter is 50 000 (not 50 812).

18 The Talker's transmit offsets include EarliestTransmitOffset, LatestTransmitOffset, and the  
19 TimeAwareOffset returned to the Talker in the Status group.

#### 20 46.2.3.6 UserToNetworkRequirements

21 The UserToNetworkRequirements group specifies user requirements for the Stream, such as latency and  
22 redundancy.

23 The network (e.g., CNC) will merge all UserToNetworkRequirements for a Stream to ensure that all  
24 requirements are met.

25 The elements of the UserToNetworkRequirements group are listed in Table 46-10.

**Table 46-10—UserToNetworkRequirements elements**

| Name             | Data type | Reference  |
|------------------|-----------|------------|
| NumSeamlessTrees | uint8     | 46.2.3.6.1 |
| MaxLatency       | uint32    | 46.2.3.6.2 |

#### 26 46.2.3.6.1 NumSeamlessTrees

27 NumSeamlessTrees specifies the number of trees that the network will configure to deliver seamless  
28 redundancy for the Stream.

29 The value zero is interpreted as one (i.e., no seamless redundancy).

30 This requirement is provided from the Talker only. Listeners shall set this element to one.

1 From each Talker to a single Listener, the network configures a path that relays Stream data through Bridges.  
2 If the Talker has more than one Listener, the network configures a tree of multiple paths.

3 NumSeamlessTrees specifies the number of maximally disjoint trees that the network shall configure from  
4 the Talker to all Listeners. Each tree is disjoint from other trees, in that the network evaluates the physical  
5 topology to avoid sharing the same Bridge and links in each tree's paths. This computation of disjoint trees  
6 is maximal, in that shared Bridges and links are avoided to the maximum extent allowed by the physical  
7 topology. For example, if a single link exists from a Bridge to a Listener and NumSeamlessTrees is three,  
8 then all three trees will share that link to the Listener.

9 When NumSeamlessTrees is greater than one, the transfer of the Stream's data frames shall use a seamless  
10 redundancy standard, such as IEEE Std 802.1CB. When a link shared by multiple trees diverges to multiple  
11 disjoint links, the seamless redundancy standard replicates (i.e., forwards a distinct copy of each data frame  
12 to the disjoint trees). When disjoint trees converge to a single link, the seamless redundancy standard  
13 eliminates the duplicate copies of each data frame. Assuming that other sources of frame loss are mitigated  
14 (e.g., congestion), failure of a link or Bridge in one disjoint tree does not result in frame loss as long as at  
15 least one remaining disjoint tree is operational.

16 If the Talker sets this element to one, the network may make use of redundancy standards that are not  
17 seamless (i.e., failure of link results in lost frames), such as MSTP and IS-IS.

18 If the Talker sets this element to greater than one and seamless redundancy is not possible in the current  
19 network (no disjoint paths or no seamless redundancy standard in Bridges), the Status group returns a  
20 nonzero FailureCode (46.2.5.1).

21 If the UserToNetworkRequirements group is not provided within the Talker or Listener group, the network  
22 shall use the default value of one for this element.

### 23 **46.2.3.6.2 MaxLatency**

24 MaxLatency specifies the maximum latency from Talker to Listener(s) for a single frame of the Stream.

25 MaxLatency is specified as an integer number of nanoseconds.

26 Latency shall use the definition of 3.128, with additional context as follows: The "known reference point in  
27 the frame" is the message timestamp point specified in IEEE Std 802.1AS for various media (i.e., start of the  
28 frame). The "first point" is in the Talker at the reference plane marking the boundary between the network  
29 media and PHY (see IEEE Std 802.1AS). The "second point" is in the Listener at the reference plane  
30 marking the boundary between the network media and PHY.

31 When this requirement is specified by the Talker, it must be satisfied for all Listeners.

32 When this requirement is specified by the Listener, it must be satisfied for this Listener only.

33 If the UserToNetworkRequirements group is not provided within the Talker or Listener group, the network  
34 shall use the default value zero for this element.

35 The special value of zero represents usage of the initial value of Status.AccumulatedLatency as the  
36 maximum latency requirement. This effectively locks down the initial latency that the network calculates  
37 after successful configuration of the Stream, such that any subsequent increase in latency beyond that value  
38 causes the Stream to fail.

1 The assumption for when the “first point” occurs in the Talker depends on the presence of the  
2 TSpecTimeAware group in the Talker’s TrafficSpecification.

3 a) When TSpecTimeAware is not present:

4 1) The Talker is assumed to transmit at an arbitrary time (not scheduled).

5 b) When TSpecTimeAware is present:

6 1) The ‘first point’ is assumed to occur at the start of the Interval as if the Talker’s offsets  
7 (EarliestTransmitOffset and LatestTransmitOffset of 46.2.3.5) are both zero. The Talker’s  
8 offsets are not typically zero, but use of the start of Interval for purposes of MaxLatency allows  
9 the Listener(s) to schedule their application independently from the Talker’s offset  
10 configuration.

11 2) The Listener determines MaxLatency based on its scheduling of a read function in the  
12 application. Nevertheless, the time from frame reception (i.e., “second point”) to execution of  
13 the read function is in the user’s scope and therefore not included in MaxLatency.

14 3) MaxLatency can be set to a value greater than the Talker’s Interval in order to specify a longer  
15 latency requirement. For example, if the Talker’s Interval is 500  $\mu$ s and MaxLatency is 700  $\mu$ s,  
16 the Listener receives the frame no later than 200  $\mu$ s into the interval that follows the Talker’s  
17 Interval.

### 18 46.2.3.7 InterfaceCapabilities

19 The InterfaceCapabilities group specifies the network capabilities of all interfaces (Ports) contained in the  
20 EndStationInterfaces group.

21 The network may provide configuration of these capabilities in the InterfaceConfiguration group of the  
22 Status group.

23 NOTE—If an end station contains multiple interfaces with different network capabilities, each interface should be  
24 specified in a distinct Talker or Listener group (i.e., one interface in EndStationInterfaces). Use of multiple interface in  
25 EndStationInterfaces is intended for network capabilities that span multiple interfaces (e.g., seamless redundancy).

26 The elements of the InterfaceCapabilities group are listed in Table 46-11.

**Table 46-11—InterfaceCapabilities elements**

| Name                  | Data type          | Reference  |
|-----------------------|--------------------|------------|
| VlanTagCapable        | Boolean            | 46.2.3.7.1 |
| CB-StreamIdenTypeList | sequence of uint32 | 46.2.3.7.2 |
| CB-SequenceTypeList   | sequence of uint32 | 46.2.3.7.3 |

### 27 46.2.3.7.1 VlanTagCapable

28 When VlanTagCapable is true, the interface supports the ability to tag/untag frames using a Customer  
29 VLAN Tag (C-TAG of Clause 9) provided by the network.

30 For a Talker, the network’s tag replaces the tag specified by the DataFrameSpecification. If the  
31 DataFrameSpecification is untagged (no IEEE802-VlanTag group), the network’s tag is inserted in the frame  
32 as it passes through the interface.

1 For a Listener, the user's tag from the DataFrameSpecification replaces the network's tag as the frame  
2 passes through the interface. If the DataFrameSpecification is untagged (no IEEE802-VlanTag group), the  
3 network's tag is removed from the frame as it passes through the interface.

4 If the end station supports more than one interface (i.e., more than one entry in EndStationInterfaces),  
5 VlanTagCapable of true means that a distinct VLAN tag can be applied to each interface. The list of VLAN  
6 tags (one for each interface) can be provided by the network in InterfaceConfiguration.InterfaceList  
7 (IEEE802-VlanTag choice).

8 When VlanTagCapable is false, the interface does not support the capability to tag/untag frames using a  
9 Customer VLAN Tag (C-TAG of Clause 9) provided by the network.

10 If the InterfaceCapabilities group is not provided within the Talker or Listener group, the network shall use  
11 the default value of false for this element.

#### 12 **46.2.3.7.2 CB-StreamIdenTypeList**

13 CB-StreamIdenTypeList provides a list of the supported Stream Identification types as specified in IEEE Std  
14 802.1CB.

15 Each Stream Identification type is provided as a 32-bit unsigned integer. The upper 3 octets contain the OUI/  
16 CID, and the lowest octet contains the type number.

17 NOTE—If the Talker/Listener end system supports IEEE Std 802.1CB, Null Stream identification is required, and that  
18 Stream Identification type is included in this list. If the Talker/Listener end system does not support IEEE Std 802.1CB,  
19 this list is empty.

20 If the end station supports more than one interface (i.e., more than one InterfaceID in EndStationInterfaces),  
21 an empty CB-StreamIdenTypeList means that the end station is capable of transferring the Stream on any  
22 one of its interfaces (not all). When this is specified, the network shall decide which interface is best  
23 used for TSN purposes and communicate that decision by returning a single interface in  
24 InterfaceConfiguration.InterfaceList. The Talker/Listener uses this interface alone for the Stream.

25 If the InterfaceCapabilities group is not provided within the Talker or Listener group, the network shall use  
26 an empty list as the default value for this element.

#### 27 **46.2.3.7.3 CB-SequenceTypeList**

28 CB-SequenceTypeList provides a list of the supported Sequence Encode/Decode types as specified in  
29 IEEE Std 802.1CB.

30 Each sequence type is provided as a 32-bit unsigned integer. The upper 3 octets contain the OUI/CID, and  
31 the lowest octet contains the type number.

32 If the InterfaceCapabilities group is not provided within the Talker or Listener group, the network shall use  
33 an empty list as the default value for this element.

### 1 46.2.3.8 StreamStatus

2 StreamStatus is an enumeration specified in Table 46-12 that indicates the status of a Stream. The status is  
3 maintained by the CNC and is used to determine which Streams are computed by calling the RPC  
4 ComputePlannedAndModifiedStreams (46.2.7.2).

**Table 46-12—StreamStatus enumeration**

| Name       | Value | Description                                                                               |
|------------|-------|-------------------------------------------------------------------------------------------|
| Planned    | 0     | Stream has been requested but has not yet been configured.                                |
| Configured | 1     | Stream has been computed and configured.                                                  |
| Modified   | 2     | Stream has been configured but Stream parameters have been modified after configuration.. |

### 5 46.2.4 Listener

6 The Listener group specifies the following:

- 7 — Listener's requirements from the network
- 8 — TSN capabilities of the Listener's interface(s)

9 In the fully distributed model and the centralized network/distributed user model, this group originates from  
10 the Listener's end station. In the fully centralized model, this group originates from the CUC.

11 The Listener group contains the following groups:

- 12 — StreamID (46.2.3.1)
- 13 — EndStationInterfaces (46.2.3.3)
- 14 — UserToNetworkRequirements (46.2.3.6)
- 15 — InterfaceCapabilities (46.2.3.7)

16 For the join operation, the UserToNetworkRequirements and InterfaceCapabilities groups may be included  
17 within the Listener group. If a group is omitted, the network uses the default values specified for elements of  
18 that group.

19 For the join and leave operation, the StreamID group shall be included in the TSN user/network protocol in  
20 a location associated with the Stream (e.g., Listener group).

21 For the join and leave operation, EndStationInterfaces shall be included within the Listener group for the  
22 fully centralized model (46.1.3.3). For the join and leave operation, EndStationInterfaces should be included  
23 within the Listener group for the fully distributed model (46.1.3.1) or centralized network/distributed user  
24 model (46.1.3.2).

### 25 46.2.5 Status

26 The Status group provides the status of a Stream's configuration from the network to each user (Talker or  
27 Listener).

28 In the fully distributed model and the centralized network/distributed user model, this group is delivered to  
29 each Talker end station and Listener end station of the Stream. In the fully centralized mode, this group is  
30 delivered to the CUC.

1 The Status group contains the following groups:

- 2 — StreamID (46.2.3.1)
- 3 — StatusInfo (46.2.5.1)
- 4 — AccumulatedLatency (46.2.5.2)
- 5 — InterfaceConfiguration (46.2.5.3)
- 6 — FailedInterfaces (46.2.5.4)

7 The AccumulatedLatency and InterfaceConfiguration groups are distinct for each Talker or Listener, and  
8 therefore Status is distinct.

9 The protocol for TSN configuration shall specify that one Status group is received in response to the  
10 transmit of a Talker group or Listener group. This provides at least one response to each join or leave  
11 request.

12 StreamID (46.2.3.1) identifies the Stream for which status is provided.

13 StatusInfo (46.2.5.1) provides the status of the Stream's configuration in the network.

14 For the join and leave operation, the StreamID and StatusInfo groups shall be included in the TSN user/  
15 network protocol in a location associated with the Stream (e.g., Status group).

16 For the join operation, the AccumulatedLatency group shall be included within the Status group that is sent  
17 to a Listener. For the join operation, the AccumulatedLatency group may be included within the Status  
18 group that is sent to a Talker.

19 For the join operation, the InterfaceConfiguration group may be included within the Status group.  
20 InterfaceConfiguration provides configuration of the interfaces in a specific end station.

21 If a group is omitted, the network uses the default values specified for elements of that group.

22 When a failure occurs in network configuration, FailedInterfaces identifies one or more interfaces (Ports) on  
23 which the failure occurred. If the FailureCode of the StatusInfo group (46.2.5.1) is zero, the FailedInterfaces  
24 group shall not be included within the Status group. If the FailureCode is nonzero, the FailedInterfaces  
25 group may be included within the Status group.

26 When a Talker and at least one Listener have joined the stream and network resources are configured for the  
27 Stream (success or failure), the network shall transmit Status to the Talker and Listener(s). After the initial  
28 Status, upon any change in the status of the network configuration (e.g., new Listeners, change in  
29 FailureCode), the network shall transmit Status to the Talker and Listener(s). When the Stream does not have  
30 a Talker or a Listener, the network configuration is removed, and the network shall transmit a final Status to  
31 the remaining Talker and/or Listener(s). Beyond these requirements, additional transmit of Status is  
32 specified by the protocol that carries the Status group.

### 33 **46.2.5.1 StatusInfo**

34 The StatusInfo group provides information regarding the status of a Stream's configuration in the network.

<sup>1</sup> The elements of the StatusInfo group are listed in Table 46-13.

**Table 46-13—StatusInfo elements**

| Name           | Data type   | Reference  |
|----------------|-------------|------------|
| TalkerStatus   | enumeration | 46.2.5.1.1 |
| ListenerStatus | enumeration | 46.2.5.1.2 |
| FailureCode    | uint8       | 46.2.5.1.3 |

#### <sup>2</sup> **46.2.5.1.1 TalkerStatus**

<sup>3</sup> TalkerStatus provides the status of the network configuration for the Stream’s Talker.

<sup>4</sup> TalkerStatus uses the enumeration specified in Table 46-14.

**Table 46-14—TalkerStatus enumeration**

| Name   | Value | Description                |
|--------|-------|----------------------------|
| None   | 0     | No Talker detected.        |
| Ready  | 1     | Talker ready (configured). |
| Failed | 2     | Talker failed.             |

#### <sup>5</sup> **46.2.5.1.2 ListenerStatus**

<sup>6</sup> ListenerStatus provides the status of the network configuration for the Stream’s Listener(s). If there is more  
<sup>7</sup> than one Listener for the Stream, ListenerStatus provides the status of all Listeners.

<sup>8</sup> ListenerStatus uses the enumeration specified in Table 46-15.

**Table 46-15—ListenerStatus enumeration**

| Name          | Value | Description                                                                                            |
|---------------|-------|--------------------------------------------------------------------------------------------------------|
| None          | 0     | No Listener detected.                                                                                  |
| Ready         | 1     | All Listeners ready (configured).                                                                      |
| PartialFailed | 2     | One or more Listeners ready, and one or more Listeners failed. If Talker is ready, Stream can be used. |
| Failed        | 3     | All Listeners failed.                                                                                  |

### 1 **46.2.5.1.3 FailureCode**

2 If the Stream encounters a failure (TalkerStatus is Failed, or ListenerStatus is Failed, or ListenerStatus is  
3 PartialFailed), FailureCode provides a nonzero code that specifies the problem. If the Stream is configured  
4 without a failure, FailureCode is zero.

5 Table 46-16 specifies the nonzero values for FailureCode.

### 6 **46.2.5.2 AccumulatedLatency**

7 The AccumulatedLatency group provides the worst-case latency that a single frame of the Stream can encounter along  
8 its current path(s).

9 The elements of the AccumulatedLatency group are listed in Table 46-17.

**Table 46-16—TSN Failure Codes**

| Failure Code | Description of cause                      |
|--------------|-------------------------------------------|
| 1            | Insufficient bandwidth                    |
| 2            | Insufficient Bridge resources             |
| 3            | Insufficient bandwidth for traffic class  |
| 4            | StreamID in use by another Talker         |
| 5            | Stream destination_address already in use |

**Table 46-16—TSN Failure Codes (continued)**

| Failure Code | Description of cause                                                            |
|--------------|---------------------------------------------------------------------------------|
| 6            | Stream preempted by higher rank                                                 |
| 7            | Reported latency has changed                                                    |
| 8            | Egress Port is not AVB capable <sup>a</sup>                                     |
| 9            | Use a different destination_address (i.e., MAC DA hash table full)              |
| 10           | Out of MSRP resources                                                           |
| 11           | Out of MMRP resources                                                           |
| 12           | Cannot store destination_address (i.e., Bridge is out of MAC DA resources)      |
| 13           | Requested priority is not an SR Class (3.271) priority                          |
| 14           | MaxFrameSize [item a) in 35.2.2.8.4] is too large for media                     |
| 15           | msrpMaxFanInPorts [item f) in 35.2.1.4] limit has been reached                  |
| 16           | Changes in FirstValue, other than AccumulatedLatency, for a registered StreamID |
| 17           | VLAN is blocked or filtered on this egress Port <sup>b</sup>                    |
| 18           | VLAN tagging is disabled on this egress Port (untagged set)                     |
| 19           | SR class priority mismatch                                                      |
| 20           | Enhanced feature cannot be propagated to original Port                          |
| 21           | MaxLatency exceeded                                                             |
| 22           | Nearest Bridge cannot provide network identification for stream transformation  |
| 23           | Stream transformation not supported                                             |
| 24           | Stream identification type not supported for stream transformation              |
| 25           | Enhanced feature cannot be supported without a CNC                              |

<sup>a</sup> A device can use the IEEE Std 802.1AS asCapable variable to help determine if its neighboring device is AVB capable. If the asCapable variable is FALSE for a particular Port, then the neighboring device is not a time-aware system and therefore not AVB capable.

<sup>b</sup> This Failure Code is never declared in a Talker Failed message since Talker attributes are not propagated on egress Ports that have the associated VLAN blocked in the VLAN spanning tree (7.3) or filtered in VLAN Registration Entries (8.8). The Bridge can still be queried by other means to learn why the Talker attribute was not declared.

### 1 46.2.5.2.1 AccumulatedLatency

**Table 46-17—AccumulatedLatency elements**

| Name               | Data type | Reference  |
|--------------------|-----------|------------|
| AccumulatedLatency | uint32    | 46.2.5.2.1 |

2 The AccumulatedLatency element provides the worst-case maximum latency that a single frame of the  
3 Stream can encounter along its current path(s).

4 AccumulatedLatency is distinct for each Talker or Listener of the Stream.

5 When provided to a Listener, AccumulatedLatency is the worst-case maximum latency for that Listener  
6 only.

7 When provided to a Talker, AccumulatedLatency is the worst-case maximum latency for all Listeners (worst  
8 path).

9 AccumulatedLatency is specified as an integer number of nanoseconds.

10 AccumulatedLatency uses the same definition for latency as UserToNetworkRequirements.MaxLatency  
11 (46.2.3.6).

12 For a successful StatusInfo (46.2.5.1), the network returns a value less than or equal to  
13 UserToNetworkRequirements.MaxLatency.

14 If the TSpecTimeAware group is present in the TrafficSpecification group (46.2.3.5) of the Talker, the value  
15 is expressed as nanoseconds after the start of the Talker's Interval.

16 If the TSpecTimeAware group is not present in the TrafficSpecification group of the Talker, the value is  
17 expressed as nanoseconds after the Talker's transmit of any frame in the Stream, at any arbitrary time.

18 If UserToNetworkRequirements.NumSeamlessTrees is one, AccumulatedLatency shall provide the worst-  
19 case maximum latency for the current path from Talker to each Listener. If the path is changed (e.g., by a  
20 spanning tree protocol), AccumulatedLatency changes accordingly.

21 If UserToNetworkRequirements.NumSeamlessTrees is greater than one, AccumulatedLatency shall provide  
22 the worst-case maximum latency for all paths in use from the Talker to each Listener.

### 23 46.2.5.3 InterfaceConfiguration

24 The InterfaceConfiguration group provides configuration of interfaces in the Talker/Listener. This  
25 configuration assists the network in meeting the Stream's requirements. The InterfaceConfiguration meets  
26 the capabilities of the interface as provided in the InterfaceCapabilities group.

27 The InterfaceConfiguration group is distinct for each Talker or Listener of the Stream.

28 A distinct configuration is provided for each interface in the Talker/Listener (even if multiple interfaces use  
29 the same configuration). Each interface configuration consists of a single InterfaceID (46.2.3.3) group,  
30 followed by a list of configuration values for that interface.

1 The values in InterfaceID shall match one of the InterfaceID entries in the Talker/Listener  
2 EndStationInterfaces group.

3 The list of configuration values uses zero or more of the following groups:

- 4 — IEEE802-MacAddresses (46.2.5.3.1)
- 5 — IEEE802-VlanTag (46.2.5.3.2)
- 6 — IPv4-tuple (46.2.5.3.3)
- 7 — IPv6-tuple (46.2.5.3.4)
- 8 — TimeAwareOffset (46.2.5.3.5)

9 If the InterfaceConfiguration group is not provided within the Status group, the network shall assume zero  
10 configuration values as the default (no interface configuration).

#### 11 **46.2.5.3.1 IEEE802-MacAddresses**

12 The IEEE802-MacAddresses group provides the source and destination MAC addresses that apply to the  
13 network side of the user/network boundary.

14 NOTE 1—On the user side, the MAC addresses are in DataFrameSpecification.IEEE802-MacAddresses.

15 NOTE 2—The source MAC address of the network is typically the same as the user. The destination MAC address can  
16 be different. For example, the user can use an individual address, but the network can use a group (multicast) address.

17 This group uses the specifications from DataFrameSpecification.IEEE802-MacAddresses (46.2.3.4.1).

18 This configuration value is not provided unless IEEE Std 802.1CB is supported and a value for Active  
19 Destination MAC and VLAN Stream identification is provided in CB-StreamIdentTypeList of  
20 InterfaceCapabilities.

#### 21 **46.2.5.3.2 IEEE802-VlanTag**

22 The IEEE802-VlanTag group provides the Customer VLAN Tag (C-TAG of Clause 9) that applies to the  
23 network side of the user/network boundary.

24 NOTE—On the user side, the VLAN tag is in DataFrameSpecification.IEEE802-VlanTag (including untagged if that  
25 field is not provided).

26 This group uses the specifications from DataFrameSpecification.IEEE802-VlanTag (46.2.3.4.2).

27 If the user provides a VLAN ID in the IEEE802-VlanTag of DataFrameSpecification, the Stream's data  
28 frames are assumed to be limited to the active topology for that VLAN ID. Therefore, if the network uses a  
29 different VLAN ID in this configuration value, the network shall ensure that the replacement VLAN ID is  
30 limited to the equivalent active topology.

31 This configuration value is not provided unless VlanTagCapable of InterfaceCapabilities is true.

#### 32 **46.2.5.3.3 IPv4-tuple**

33 The IPv4-tuple group provides the IPv4 identification that applies to the network side of the user/network  
34 boundary.

35 This group uses the specifications from DataFrameSpecification.IPv4-tuple (46.2.3.4.3).

36 This configuration value is not provided unless IEEE Std 802.1CB is supported and a value for IP Stream  
37 identification is provided in CB-StreamIdentTypeList of InterfaceCapabilities.

#### 1 46.2.5.3.4 IPv6-tuple

2 The IPv6-tuple group provides the IPv6 identification that applies to the network side of the user/network  
3 boundary.

4 This group uses the specifications from DataFrameSpecification.IPv6-tuple (46.2.3.4.4).

5 This configuration value is not provided unless IEEE Std 802.1CB is supported and a value for IP Stream  
6 identification is provided in CB-StreamIdenTypeList of InterfaceCapabilities.

#### 7 46.2.5.3.5 TimeAwareOffset

8 If the TSpecTimeAware group is present in the TrafficSpecification group (46.2.3.5) of the Talker, this  
9 configuration value shall be provided by the network to the Talker.

10 If the TSpecTimeAware group is not present in the TrafficSpecification group (46.2.3.5) of the Talker, this  
11 configuration value shall not be provided by the network.

12 This configuration value shall not be provided to Listeners as it is not applicable.

13 TimeAwareOffset specifies the offset that the Talker shall use for transmit. The network returns a value  
14 between EarliestTransmitOffset and LatestTransmitOffset of the Talker's TrafficSpecification. The value is  
15 expressed as nanoseconds after the start of the Talker's Interval. The data type is uint32.

#### 16 46.2.5.4 FailedInterfaces

17 When a failure occurs in network configuration (i.e., nonzero FailureCode in StatusInfo group),  
18 FailedInterfaces provides a list of one or more physical interfaces (distinct points of attachment) in the failed  
19 end station or Bridge. Each identifier is sufficient to locate the interfaces in the physical topology.

20 The FailedInterfaces group is optional.

21 FailedInterfaces consists of a sequence of zero or more entries, each entry using the InterfaceID group  
22 specified in 46.2.3.3.

#### 23 46.2.6 Protocol operations

24 The TSN user/network configuration makes use of protocol operations to request specific actions and to  
25 receive notifications. The following operations are supported:

- 26 — **Remote Procedure Calls (RPC):** this protocol operation allows requesting an action for the  
27 complete YANG data model.
- 28 — **Actions:** this protocol operation allows requesting an action on a specific part of the YANG data  
29 model.
- 30 — **Notifications:** this protocol operation provides information, e.g., it allows the CNC to inform the  
31 CUC that computing the configuration has finished.

#### 32 46.2.7 Remote Procedure Calls

33 The TSN user/network configuration provides the following RPCs:

- 34 — ComputeStreams (46.2.7.1)
- 35 — ComputePlannedAndModifiedStreams (46.2.7.2)
- 36 — ComputeAllStreams (46.2.7.3)
- 37 — RequestDomainId (46.2.7.4)
- 38 — RequestFreeStreamId (46.2.7.5)

### 1 **46.2.7.1 ComputeStreams**

2 This RPC starts the computation of path and resource allocation for one or more Streams. The Streams that  
3 are to be included in the computation are specified by providing their associated DomainID (46.2.2.1),  
4 CucID (46.2.2.2), and StreamID (46.2.3.1). This RPC can be applied to compute new Streams as well as  
5 recompute already configured Streams.

6 The RPC returns information that indicates only if the Stream computation has been started successfully or  
7 not. It does not return information on whether the Stream configuration itself has been successful or not,  
8 because computation and configuration can take an arbitrary amount of time. The notifications  
9 ComputeStreamsCompleted (46.2.9.1) and ConfigureStreamsCompleted (46.2.9.2) are available to the CNC  
10 to return information on success or failure of the Stream computation and configuration, after the actions  
11 have finished.

### 12 **46.2.7.2 ComputePlannedAndModifiedStreams**

13 This RPC starts the computation of path and resource allocation for Streams that have not been configured  
14 or that have been configured and have been modified since configuration. The Streams that are to be  
15 included in the computation are specified by providing their associated DomainID (46.2.2.1) and CucID  
16 (46.2.2.2). The object StreamStatus (46.2.3.8) is used to determine if a Stream is included in the computation  
17 initiated by this RPC.

18 The RPC returns information that indicates only if the Stream computation has been started successfully or  
19 not. It does not return information on whether the Stream configuration itself has been successful or not,  
20 because computation and configuration can take an arbitrary amount of time. The notifications  
21 ComputeStreamsCompleted (46.2.9.1) and ConfigureStreamsCompleted (46.2.9.2) are available to the CNC  
22 to return information on success or failure of the Stream computation and configuration, after the actions  
23 have finished.

### 24 **46.2.7.3 ComputeAllStreams**

25 This RPC starts the computation of path and resource allocation for all Streams in a Configuration Domain  
26 and that are belonging to a specified CUC. The Streams that are to be included in the computation are  
27 specified by providing their associated DomainID (46.2.2.1) and CucID (46.2.2.2).

28 The RPC returns information that indicates only if the Stream computation has been started successfully or  
29 not. It does not return information on whether the Stream configuration itself has been successful or not,  
30 because computation and configuration can take an arbitrary amount of time. The notifications  
31 ComputeStreamsCompleted (46.2.9.1) and ConfigureStreamsCompleted (46.2.9.2) are available to the CNC  
32 to return information on success or failure of the Stream computation and configuration, after the actions  
33 have finished.

### 34 **46.2.7.4 RequestDomainId**

35 This RPC allows a CUC to request the DomainID (46.2.2.1) of the Configuration Domain that the CUC  
36 belongs to from the CNC. If a CUC already knows the Configuration Domain it belongs to, this RPC can be  
37 used to verify that the information the CUC has is correct.

### 38 **46.2.7.5 RequestFreeStreamId**

39 This RPC allows a CUC to request a free StreamID (46.2.3.1) from a CNC. Requesting a free StreamID  
40 allows a CUC to provide an unused, i.e., unique, StreamID for a Stream when requesting that Stream from  
41 the CNC.

## 1 **46.2.8 Actions**

2 The TSN user/network configuration provides the following actions:

- 3 — RemoveStreams (46.2.8.1)

### 4 **46.2.8.1 RemoveStreams**

5 This action starts the removal of one or more Streams. Each Stream that is to be removed is specified by  
6 providing its associated StreamID (46.2.3.1). This action returns information that indicates only if the  
7 Stream removal has been started successfully or not. It does not return information on whether the Stream  
8 removal itself has been successful or not, because execution can take an arbitrary amount of time. When a  
9 Stream is successfully removed, the StreamID associated with that Stream can be used as a free StreamID by  
10 the RPC RequestFreeStreamId (46.2.7.5) again.

11 The notification RemoveStreamsCompleted (46.2.9.3) is available to the CNC to return information on  
12 success or failure of the Stream removal.

## 13 **46.2.9 Notifications**

14 The TSN user/network configuration provides the following notifications:

- 15 — ComputeStreamsCompleted (46.2.9.1)  
16 — ConfigureStreamsCompleted (46.2.9.2)  
17 — RemoveStreamsCompleted (46.2.9.3)

### 18 **46.2.9.1 ComputeStreamsCompleted**

19 This notification is used by the CNC to inform a CUC that has requested the computation of one or more  
20 Streams, that the computation for these Streams has finished. If the computation of these Streams impacts  
21 other Streams that are already configured in the network, it can also be used to notify the CUCs that  
22 originally requested the impacted Streams about the modification.

23 NOTE—ComputeStreamsCompleted returns only information on the computation of Streams. This does not provide any  
24 information on whether the configuration of these Streams has been performed successfully or not.

25 It returns a list of Domains, identified by their DomainIDs (46.2.2.1), CUCs in that domain, identified by  
26 their CucIDs (46.2.2.2) and Streams associated with a CUC, identified by their StreamIDs (46.2.3.1). For  
27 each Stream it also returns either 0, if the Stream computation was successful, or a FailureCode (46.2.5.1.3),  
28 if it was not.

### 29 **46.2.9.2 ConfigureStreamsCompleted**

30 This notification is used by the CNC to inform a CUC that has requested the computation of one or more  
31 Streams, that the computation and configuration for these Streams has finished. If the computation or  
32 configuration of these Streams impacts other Streams that are already configured in the network, it can also  
33 be used to notify the CUCs that originally requested the impacted Streams about the modification.

34 It returns a list of Domains, identified by their DomainIDs (46.2.2.1), CUCs in that domain, identified by  
35 their CucIDs (46.2.2.2) and Streams associated with a CUC, identified by their StreamIDs (46.2.3.1). For  
36 each Stream it also returns either 0, if the Stream computation and configuration was successful, or a  
37 FailureCode (46.2.5.1.3), if it was not.

### 1 46.2.9.3 RemoveStreamsCompleted

2 This notification is used by the CNC to inform a CUC that has requested the removal of one or more  
3 Streams, that the removal of these Streams has finished. It returns a list of Domains, identified by their  
4 DomainIDs (46.2.2.1), CUCs in that domain, identified by their CucIDs (46.2.2.2) and Streams associated  
5 with a CUC, identified by their StreamIDs (46.2.3.1). For each Stream it also returns either 0, if the Stream  
6 removal was successful, or 1, if it was not.

### 7 46.3 YANG for TSN user/network configuration

8 In order to support the use of YANG-based protocols for the fully centralized model (46.1.3.3), 48.6.3, and  
9 48.6.23 specify YANG modules.

10 The YANG module of 48.6.3 provides YANG text for each group of elements in 46.2. Each element is  
11 specified using a YANG `leaf`. Each group is specified as a YANG `typedef` or `grouping`. The YANG  
12 module for user/network configuration (48.6.23) imports the YANG module of 48.6.3 and uses the  
13 `typedef` and `grouping` nodes in order to specify the schema tree used for communication between CUC  
14 and CNC.

15 YANG identifiers use a naming convention of hyphens between lowercase names (e.g., “mac-address”).  
16 Identifiers for elements and groups in 46.2 use a naming convention of camel case (e.g., “MacAddress”).  
17 The specifications for an identifier in 48.6.3 and 48.6.23 apply to the corresponding identifier in 46.2  
18 regardless of differences in naming convention (e.g., requirements for “MacAddress” in 46.2 apply to “mac-  
19 address” in 48.6.3).

20 In the YANG module definitions of 48.6.3 and 48.6.23, if any discrepancy between the “description” text  
21 and the corresponding specifications in 46.2 occurs, the specifications in 46.2 take precedence.

22

## 1 47. Asynchronous Traffic Shaping (ATS) in end stations

### 2 47.1 Talker transmission behavior

3 The operation of ATS traffic classes in Bridges is specified as a combination of per-stream classification and  
4 metering for ATS (8.6.5.2.2) and the ATS transmission selection algorithm (8.6.8.5). In order for end station  
5 originated data streams to make use of ATS traffic classes in Bridges, it is required that Talkers emit data  
6 streams in a compliant manner, and that the parameters of ATS scheduler state machines and ATS scheduler  
7 groups in Bridges are consistently set.

#### 8 47.1.1 ATS traffic class model in Talkers

9 End stations that are Talkers have to emit streams consistent with the operation of the ATS scheduler state  
10 machines in Bridges (8.6.11). This subclause specifies a model of ATS traffic classes that satisfies this  
11 purpose. End stations shall exhibit the transmission behavior of this model at the egress ports.

12 In this model, Talker ports are composed by ATS scheduler instances, which assign eligibility times to the  
13 frames of all emitted streams at the egress port, followed by a queue per traffic class, for which the ATS  
14 transmission selection algorithm is executed. The relationship between ATS scheduler instances and streams  
15 is one-to-one, and each scheduler state machine is associated with a dedicated scheduler group. This  
16 effectively eliminates the association of multiple streams to an ATS scheduler instance, as well as the  
17 coupling of multiple ATS scheduler instances by ATS scheduler groups.

#### 18 47.1.2 Simplified ProcessFrame(frame) procedure

19 Due to the one-to-one relationship between streams and ATS scheduler instances, as well as ATS scheduler  
20 instances and scheduler groups, the ProcessFrame(frame) procedure of ATS scheduler state machines, as  
21 specified in 8.6.11.3, can be simplified. The simplified procedure is described by the following pseudo-code.

```
22 ProcessFrame(frame) {  
    lengthRecoveryDuration    = length(frame) /  
                               CommittedInformationRate;  
    emptyToFullDuration       = CommittedBurstSize /  
                               CommittedInformationRate;  
    schedulerEligibilityTime   = BucketEmptyTime +  
                               lengthRecoveryDuration;  
    bucketFullTime            = BucketEmptyTime +  
                               emptyToFullDuration;  
    eligibilityTime            = max(arrivalTime(frame),  
                                   schedulerEligibilityTime);  
  
    BucketEmptyTime           = (eligibilityTime < bucketFullTime) ?  
                               schedulerEligibilityTime :  
                               schedulerEligibilityTime + eligibilityTime - bucketFullTime;  
    AssignAndProceed(frame, eligibilityTime);  
}
```

#### 39 47.1.3 System clock functions and processing delays

40 This model has a single implementation specific local system clock function, which is used as:

- 41 a) ATS scheduler clock (8.6.11.1) for all ATS scheduler instances and
- 42 b) Transmission selection clock (8.6.8.5) of all ATS traffic classes.

43 The processing delay from the ATS scheduler instances to the transmission selection is zero in this model  
44 (8.6.11.3.2):

$$0 = \text{ProcessingDelayMin} = \text{ProcessingDelayMax}$$

## 1 47.2 Scheduler parameter consistency

2 The ATS scheduler parameters CommittedBurstSize (8.6.11.3.5) and CommittedInformationRate  
3 (8.6.11.3.6) of Talker streams have to be consistently set to the respective parameters in the Bridge  
4 component connected to the Talker. In the Bridge component, a single ATS scheduler instance can be  
5 associated with multiple streams of this Talker.

6 For  $n$  streams associated with a single ATS scheduler instance in Bridge component, Equation (47-1) and  
7 Equation (47-2) can be used for scheduler parameter consistency.

$$8 \quad \text{CBS}_{\text{Bridge}} \geq \sum_{i=1}^n \text{CBS}_i \quad (47-1)$$

$$9 \quad \text{CIR}_{\text{Bridge}} \geq \left( \frac{1 + 10^{-6} \text{ClkDev}_{\text{Talker}}}{1 - 10^{-6} \text{ClkDev}_{\text{Bridge}}} \right) \sum_{i=1}^n \text{CIR}_i \quad (47-2)$$

10 where

- 11  $\text{CIR}_{\text{Bridge}}$  is the CommittedInformationRate parameter of the scheduler instance in the Bridge
- 12  $\text{CIR}_i$  is the CommittedInformationRate parameter of the  $i$ th stream in the Talker
- 13  $\text{CBS}_{\text{Bridge}}$  is the CommittedBurstSize parameter of the scheduler instance in the Bridge
- 14  $\text{CBS}_i$  is the CommittedBurstSize parameter of the  $i$ th stream in the Talker
- 15  $\text{ClkDev}_{\text{Bridge}}$  is the maximum deviation of the associated ATS scheduler clock (8.6.11.1) in the Bridge  
16 from its nominal frequency, in ppm
- 17  $\text{ClkDev}_{\text{Talker}}$  is the maximum deviation of the transmission selection clock (8.6.8.5 and 47.1.3) in the  
18 Talker from its nominal frequency, in ppm

19

20

## 1 48. YANG Data Models

2 This clause specifies YANG data models that provide control and status monitoring of systems and system  
3 components that implement functionality specified in this standard. These data models are based on the set  
4 of managed objects and their functionality specified in Clause 12.

5 This clause:

- 6 a) Introduces the YANG framework that governs the naming and hierarchy of configuration and  
7 operational data structures in the data models, and the modeling of network interfaces (48.1)
- 8 b) Describes each of the data models and its relationship to the operational processes and managed  
9 objects specified in the other clauses of this standard, and provides a UML representation of each  
10 data model (48.2)
- 11 c) Describes the structure of the data models, each of which comprises or makes use of one or more  
12 YANG modules (48.3)
- 13 d) Reviews security considerations applicable to each of the data models, with specific reference to  
14 data nodes in the YANG modules that compose the model (48.4)
- 15 e) Includes a schema tree for each of the YANG modules (48.5)
- 16 f) Includes each of the YANG modules (48.6)

17 NOTE 1—The MIB modules specified in Clause 17 were also derived from Clause 12. Consequently, the capabilities  
18 and structure of the YANG data models align closely with the MIBs. However the YANG data model has not been  
19 derived from the MIB, and there has been no attempt to include data or modeling constructs that might appear in the  
20 MIB but not in the information model.

21 NOTE 2—OMG UML 2.5 [B60] conventions together with C++ language constructs are used in this clause as a  
22 representation to convey model structure and relationships.

23 The YANG data models specified in this clause include the following:

- 24 — A VLAN Bridge components data model (48.2.1) that allows control and status monitoring of one or  
25 more C-VLAN or S-VLAN Bridge components (8.2) that compose all or part of a system's  
26 functionality, and the Bridge Port interfaces that support those components.
- 27 — A Two-Port MAC Relay data model (48.2.2) that both subsets and augments the VLAN Bridge  
28 components model to model a VLAN-unaware TPMR (3.292)
- 29 — A Customer VLAN Bridge model (48.2.3) that comprises a single VLAN Bridge component from  
30 the VLAN Bridge components model.
- 31 — A Provider Bridges model that uses one or multiple components from the VLAN Bridge  
32 components model to compose an S-VLAN component Provider Bridge or a Provider Edge Bridge.
- 33 — Connectivity Fault Management (CFM) models (48.2.3) for use with the VLAN Bridge components  
34 and related models in systems that provide CFM functionality.
- 35 — A Stream filters and stream gates model (48.2.6) that augments the VLAN Bridge components  
36 model.
- 37 — An Asynchronous Traffic Shaping (ATS) model that augments the VLAN Bridge components  
38 model and the Stream filters and stream gates model.

### 39 48.1 YANG Framework

40 This clause has been developed according to the YANG guidelines published in IETF RFC 6087 [B38] as  
41 applicable to IEEE standards.

42 The YANG framework applies hierarchy in the following areas:

- 43 1) The uniform resource name (URN), as specified in IEEE Std 802d–2017. The structure of the  
44 URN is such that ieee is the root (i.e., name-space identifier), followed by the standard, then the  
45 working group developing the standard.

- 1        2) The YANG objects form a hierarchy of configuration and operational data structures that define
- 2        the YANG model. These hierarchical relationships are described in 48.3.
- 3 The general YANG framework hierarchy is illustrated in Figure 48-1.

**Figure 48-1—General YANG hierarchy**

- 4 The YANG hierarchical structure that incorporates the IEEE 802.1Q YANG models supported by this
- 5 standard is represented in Figure 48-2.

**Figure 48-2—YANG root hierarchy with IEEE 802.1Q YANG modules**

#### 48.1.1 Interface Management (IETF RFC 8343) Model

Network interfaces are central to the management of protocols. Thus, it is important to establish a common data model for how interfaces are identified, configured, and monitored. The IETF Interface Management model (IETF RFC 8343) defines a generic YANG data model for the management of network interfaces. The Interface Management YANG model is augmented by the IEEE 802.1Q YANG models, and specifically the Bridge Port. A UML representation of the Interface Management model is illustrated in Figure 48-3.<sup>50</sup>

1

**Figure 48-3— Interface YANG model**

<sup>50</sup> The representation of the Interface YANG model is derived from IETF RFC 8343.

## 1 48.2 IEEE 802.1Q YANG models

2 The YANG data models are based on the management model outline in Clause 12. UML representations of  
3 the models are provided in the following subclauses.

### 4 48.2.1 VLAN Bridge components model

5 A network system can include one or more VLAN Bridge components.

6 Each VLAN Bridge component (5.4–5.6) comprises a single VLAN-aware MAC Relay Entity and its  
7 associated functionality (8.2, Figure 48-4), and is supported by a number of Bridge Ports (3.30,  
8 Figure 48-5). Each Bridge Port is associated with a single MAC Relay Entity, presents a single interface (a  
9 service access point) to that MAC Relay Entity, and comprises the interface stack that supports that service  
10 access point (6.1, 7.4 of IEEE Std 802.1AC-2016). In the 802.1Q YANG models, that interface is  
11 represented by the Interface Management (IETF RFC 8343) model augmented as shown in Figure 48-5.

12 Each MAC Relay Entity has a *bridge-type* attribute (e.g., *customer-vlan-bridge*), and the manageable  
13 attributes for the component can reflect that type: TPMR components (48.2.2), for example, are VLAN  
14 unaware.

15 A Bridge Port and the attributes associated with a media access method specific MAC entity (e.g., as  
16 specified by IEEE Std 802.3) supporting that Bridge Port can both be represented by augmentations of the  
17 same IETF\_RFC\_8343 Interface and identified by the same Interface index (*if-index*). In other cases  
18 *higher-layer-if* and *lower-layer-if* attributes define the interface stacking relationships within the Bridge  
19 Port. For example, an Aggregator (as defined by IEEE Std 802.1AX) Interface could be a Bridge Port. The  
20 *lower-layer-if* attributes associated with the Aggregator would point to the Aggregation Ports.

21 Each Bridge Port is uniquely identified, amongst those Bridge Ports supporting a given VLAN Bridge  
22 component, by a Port Number (*port-number*). A port number has no mandatory relationship to an Interface  
23 index (*if-index*).

1

Figure 48-4—VLAN Bridge components model (MAC Relay Entities)

1

Figure 48-5—Bridge Port model

## 48.2.2 Two-Port MAC Relay (TPMR) model

A TPMR (5.15, 5.16) comprises a single VLAN-unaware MAC Bridge component supported by only two TPMR Ports (Clause 8, 8.5.2). The TPMR's VLAN-unaware MAC Relay Entity is modeled (Figure 48-6) as a subset of a VLAN Bridge component's MAC Relay Entity (Figure 48-4). This subset does not include the bridge-vlan, bridge-mst, and filtering-database nodes.

Figure 48-6—TPMR model (MAC Relay Entity)

<sup>1</sup> The TPMR model extends the VLAN Bridge components' Bridge Port model as illustrated in Figure 48-7.

<sup>2</sup>

**Figure 48-7—TPMR Port model**

### **1 48.2.3 Customer VLAN Bridge model**

2 A Customer VLAN Bridge (5.5) comprises a single C-VLAN Bridge component (Clause 8). The C-VLAN  
3 Bridge component's MAC Relay Entity and its Bridge Ports are modeled by the VLAN Bridge components  
4 model (48.2.1), with a single bridge component node with a type-of-bridge of customer-vlan-bridge (48.6.4)  
5 [a ComponentType of cVlanComponent in 12.3].

## 1 48.2.4 Provider Bridge model

2 A Provider Bridge (5.10, Clause 16) can be an S-VLAN Bridge with a single S-VLAN component or a  
3 Provider Edge Bridge with an S-VLAN component and multiple C-VLAN components. A Provider Bridge's  
4 MAC Relay Entities and its Bridge Ports (S-VLAN and C-VLAN Interfaces) are modeled (Figure 48-8,  
5 Figure 48-9, Figure 48-10) by extending the VLAN Bridge components model (48.2.1).

6

Figure 48-8—Provider Bridge model (MAC Relay Entities)

1

Figure 48-9—Provider Edge Bridge C-VLAN Interface model

1

Figure 48-10—Provider Edge Bridge S-VLAN Interface model

## 1 48.2.5 CFM Model

2 The CFM UML data model is composed of the following set of major objects:

- 3 — The **Maintenance Domain** object is associated with a device (e.g., Bridge). It contains information  
4 used to identify the maintenance domain used to bind/contain Maintenance Association objects.
- 5 — The **Maintenance Association** objects are contained within a Maintenance Domain object. They  
6 contain maintenance point information related to the service instance being monitored.
- 7 — The **Maintenance Group** objects provide a convenient binding of a Maintenance Association object  
8 with a Maintenance Domain object.
- 9 — The **Maintenance association Endpoint** (MEP) object is associated with an Interface (e.g., Bridge  
10 Port) and a Maintenance Association Group object. It contains all information to manage a CFM  
11 entity, associated with a specific DoSAP of a service instance, which can generate and receive CFM  
12 PDUs and track any responses.
- 13 — The **Maintenance domain Intermediate Point** (MIP) object is associated with an Interface (e.g.,  
14 Bridge Port) and a service (e.g., VID) to allow the explicit creation of an MHF.
- 15 — The **CFM Stack** object is associated with a device (e.g., Bridge). It contains information about  
16 maintenance points on a particular device Interface (e.g., Bridge Port or Aggregation Port).
- 17 — The **Default MD Level** object is associated with a device (e.g., Bridge) component. It contains  
18 MHF information needed for the creation of these functions on the services (e.g., VIDs) that are not  
19 attached to any Maintenance Association.

20 The **Configuration Error List** is associated with a device (e.g., Bridge). It contains configuration error  
21 information that is identifiable on a per-Interface (e.g., Bridge Port) and per-service (e.g., VID) basis.

22 The UML model representing the relationship between relevant Bridge objects to CFM objects is illustrated  
23 in Figure 48-11.

24 The CFM objects (e.g., cfm-stack, configuration-error-list, default-md-level, maintenance-domain)  
25 reference the device (i.e., Bridge and/or Bridge Component) to which they belong. This reference allows  
26 CFM objects to be associated with other types of devices (e.g., non-Bridges, end stations) where  
27 appropriate.

28 The Maintenance Group is modeled as a list that contains a convenient reference to a Maintenance  
29 Association object and its corresponding Maintenance Domain object. The identification of this collection  
30 of objects allows other CFM objects to more easily attach to a maintenance group and, in turn, simplifies  
31 configuration and operation retrieval procedures supported by the data model.

1

Figure 48-11—Bridge to CFM YANG model

As illustrated in Figure 48-12, MEP objects reference an Interface and are associated with a Maintenance Group. The interface relationship allows a MEP to be associated with a Bridge Port, as specified by this standard. This model also allows MEPs to be associated with other Interface types (for other devices).

Figure 48-12—CFM MEP model relationships

The MEP object has relationships with other MEP-related objects. As illustrated in Figure 48-13, the CFM continuity check protocol suite-specific data needed to initiate protocol-specific sessions or maintain protocol-specific state information are grouped together. In addition, the MEP object will also reference the MEP CCM database and Stats objects.

#### 1 48.2.5.1 CFM model support of CFM Operations

2 The CFM model also supports the initiation of Continuity Check, Loopback, and Linktrace protocol  
3 sessions. The general structure of the CFM session action data model is illustrated in Figure 48-14.

4

Figure 48-13—CFM MEP model

5

Figure 48-14—CFM operations structure

## 48.2.6 Stream filters and stream gates model

The stream filters and stream gates model augments the Bridge component model (48.3.1) by nodes that represent the following managed objects:

- a) Stream Filter Instance Table (12.31.2)
- b) Stream Gate Instance Table (12.31.3)

The UML representation of the stream filters and stream gates model is illustrated in Figure 48-15.

Figure 48-15—Stream filters and stream gates model

## 48.2.7 Asynchronous Traffic Shaping (ATS) model

The ATS model augments the Bridge component model (48.3.1) and the stream filters and stream gates model (48.3.6) by nodes that represent to following managed objects:

- The Scheduler Instance Table (12.31.5)
- The Scheduler Group Instance Table (12.31.6)
- The Scheduler Port Parameter Table (12.31.7)
- The Scheduler Timing Characteristics Table (12.31.8)
- A Stream Filter specification type representing an ATS scheduler instance identifier (12.31.2.5)

The UML representation of the ATS model is illustrated in Figure 48-16.

Figure 48-16—Asynchronous Traffic Shaping model

## 48.2.8 Congestion Isolation (CI) model

The CI model augments the Bridge components model (48.2.1) and the Interface Management model for Bridge ports (48.3.1) by nodes that represent the following managed objects:

- CI entity managed object (12.33.1)
- CI Peer Table (12.33.2)
- CI Stream Table (12.33.3)
- CIP entity managed object (12.33.4)

The UML representation of the CI model is illustrated in Figure 48-17.

Figure 48-17—Congestion Isolation model

## 1 48.2.9 Scheduled Traffic model

2 The Scheduled Traffic model augments the Bridge Port model (48.2.1) with nodes that represent the  
3 managed objects contained in the following table:

4 a) Gate Parameter Table (12.29.1)

5 The Scheduled Traffic model is illustrated in Figure 48-18.

6 There is one gate-parameter-table per Port of a Bridge component. Each object of the table represents  
7 parameters that support the enhancements for scheduled traffic (8.6.8.4) as detailed in Table 12-32. The  
8 admin-control-list and gate-control-list are sequences of gate-control-entry as specified in 12.29.1.2. Each  
9 gate-control-entry consists of an operation name followed by a set of parameters associated with that  
10 operation as defined in Table 8-7. The basic operation for Scheduled Traffic is SetGateStates. Additionally,  
11 if Frame Preemption is supported, two additional operations can be performed Set-And-Hold-MAC and  
12 Set-And-Release-MAC.

13

Figure 48-18—Scheduled Traffic model

## 48.2.10 Frame Preemption model

The Frame Preemption model augments the Bridge Port model (48.2.1) with nodes that represent the managed objects contained in the following table:

a) Frame Preemption Parameter Table (12.30.1)

The Frame Preemption model is illustrated in Figure 48-19.

There is one Frame Preemption Parameter Table per Port of a Bridge component or end station. Each object of the table represents parameters that support frame preemption (6.7.2) as detailed in Table 12-33.

8

Figure 48-19—Frame Preemption model

## 48.2.11 Per-Stream Filtering and Policing model

The Per-Stream Filtering and Policing (PSFP) model augments the Bridge components model (48.2.1) and the Stream filters and stream gates model (48.2.6) with nodes that represent the managed objects contained in the following tables:

- The Stream Parameter Table (12.31.1)
- The Stream Filter Instance Table (12.31.2)
- The Stream Gate Instance Table (12.31.3)
- The Flow Meter Instance Table (12.31.4)

The PSFP model is illustrated in Figure 48-20.

There is one stream-filter-instance-table per Bridge component. Each object of the table contains a set of parameters that defines a single Stream Filter (8.6.5.3), as detailed in Table 12-35. The table rows form an ordered list of filter instances, the order being determined by the StreamFilterInstance parameter.

There is one stream-gate-instance-table per Bridge component. Each object of the table contains a set of parameters that defines a single Stream Gate Instance (8.6.5.4), as detailed in Table 12-36.

There is one flow-meter-instance-table per Bridge component. Each object of the table contains a set of parameters that defines a single Flow Meter Instance (8.6.5.5), as detailed in Table 12-37.

1

Figure 48-20—PSFP model

## 1 48.2.12 CNC-configuration model

2 The CNC-configuration model allows communication between a CUC and a CNC and can be implemented  
3 in an end station or Bridge.

4 The CNC-configuration model consists of three high-level groups, Talker (46.2.3), Listener (46.2.4), and  
5 Status (46.2.5) and is modeled as illustrated in Figure 48-21 and Figure 48-22.

Figure 48-21—CNC-configuration model A

Figure 48-22—CNC-configuration model B

1 **48.2.13 Credit-based shaper algorithm model**

- 2 The credit-based shaper algorithm model augments the Bridge Port model (48.2.1) with nodes that represent
- 3 the managed objects of the credit-based shaper algorithm in Table 12-4.
- 4 The credit-based shaper algorithm model is illustrated in Figure 48-23.

**Figure 48-23—Credit-based shaper algorithm model**

## 1 48.2.14 Rapid Spanning Tree Protocol (RSTP) model

2 The RSTP model augments the VLAN Bridge component model (48.2.1, Figure 48-4) and the Interface  
3 management model for Bridge Ports (48.2.1, Figure 48-5) with nodes common to both RSTP and MSTP.  
4 These nodes control the configuration of the CST (and the CIST, when augmented by the Multiple Spanning  
5 Trees model, 48.2.15) and report on protocol operation. The RSTP model is illustrated in Figure 48-24.

| component (name)   |                         |                 |
|--------------------|-------------------------|-----------------|
| string             | name;                   | // r-w          |
| ...                |                         |                 |
| rstp // (13.4)     |                         |                 |
| enum               | force-protocol-version; | // (13.7.2) r-w |
| bridge-id          | bridge-id;              |                 |
| { uint64           | bridge-id;              | // (13.26.2) r  |
| id-priority        | bridge-priority;        | // (14.2) r-w   |
| uint16             | system-id-extension;    | // (13.26.2) r  |
| ieee:macaddress    | bridge-address; };      | // (8.13.8) r   |
| bridge-id          | root-id                 |                 |
| { uint64           | bridge-id;              | // (13.4) r     |
| id-priority        | bridge-priority;        | // (14.2) r     |
| uint16             | system-id-extension;    | // (13.26) r    |
| ieee:macaddress    | bridge-address; };      | // (8.13.8) r   |
| uint32             | root-path-cost;         | // (13.4) r     |
| union              | root-port;              | // (13.4) r     |
| uint8              | max-age;                | // (13.15) r    |
| uint8              | hello-time;             | // (13.25) r    |
| uint8              | forward-delay;          | // (13.25) r    |
| uint8              | bridge-max-age;         | // (13.25) rw   |
| uint8              | bridge-forward-delay;   | // (13.25) rw   |
| uint8              | tx-hold-count;          | // (13.25) rw   |
| yang:date-and-time | last-topology-change;   | // (13.25) r    |

| bridge-port     |                                |                |
|-----------------|--------------------------------|----------------|
| leafref         | bridge-name;                   | // r-w         |
| leafref         | component-name;                | // r-w         |
| ...             |                                |                |
| rstp // (13.4)  |                                |                |
| bool            | admin-bridge-port-enabled;     | // (8.4) rw    |
| port-state      | port-state;                    | // (8.4) r     |
| port-role       | port-role;                     | // (13.4) r    |
| bool            | restricted-role;               | // (13.20) rw  |
| bool            | restricted-tcn;                | // (13.20) rw  |
| port-id         | port-id                        |                |
| { uint16        | port-id;                       | // (13.26) r   |
| id-priority     | port-priority;                 | // (14.2) rw   |
| id-port-number  | port-number; };                | // (12.3) r    |
| uint32          | fix-port-path-cost;            | // (13.10) r-w |
| uint32          | port-path-cost;                | // (13.4) r-w  |
| uint8           | designated-protocol-version;   | // (14.2) r    |
| bridge-id       | root-id                        |                |

☐ Objects added or augmented by this model

Figure 48-24—RSTP model

## 48.2.15 Multiple Spanning Tree Protocol (MSTP) model

The Multiple Spanning Tree Protocol model augments the bridge-mst container of the VLAN Bridge components model (48.2.1) and the RSTP model (48.2.14) with nodes for MSTP. These nodes control the configuration of the CIST and MSTIs and the assignment of VLANs and VIDs to MSTIs (8.9) within MST Regions. They also report on MSTP protocol operation. The Multiple Spanning Tree Protocol model is illustrated in Figure 48-25.

Figure 48-25—MSTP model

## 1 48.3 Structure of the YANG models

2 The YANG models specified by this standard use the YANG modules summarized in Table 48-1.<sup>51</sup>

3 In the YANG module definitions, if any discrepancy between the DESCRIPTION text and the  
4 corresponding definition in any other part of this standard occur, the definitions outside this clause  
5 (Clause 48) take precedence.

6

**Table 48-1—Summary of the YANG modules**

| Module                                    | References          | Managed functionality    | Initial YANG specification Notes                                                                                                                                |
|-------------------------------------------|---------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|

<sup>51</sup> An amendment's designation is often used to refer to functionality in an IEEE standard after the amendment has been incorporated in a revision of the standard, even if the functionality has been revised. The amendment that added each YANG module is identified to help locate the relevant provisions of this standard.

**Table 48-1—Summary of the YANG modules (*continued*)**

| Module                                    | References       | Managed functionality                    | Initial YANG specification Notes                                                                                        |
|-------------------------------------------|------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| ieee802-dot1q-ats                         | 48.5.13, 48.6.13 | 8.6                                      | IEEE Std 802.1Qcr<br>ATS extensions to ieee802-dot1q-stream-filters-gates and ieee802-dot1q-bridge modules.             |

The relationship between the models listed in 48.2 and the YANG modules listed in Table 48-1 is described in 48.3.1 through 48.3.15.

### 48.3.1 VLAN Bridge components model

This model provides basic bridging capabilities and allows for augmentation by specific YANG models (e.g., Two-Port MAC Relay model, Customer VLAN Bridge model, Provider Bridge model).

A system implementing the VLAN Bridge components model implements the YANG modules listed in Table 48-2.

### 48.3.2 Two-Port MAC Relay model

A system implementing the TPMR YANG model (48.3.2) implements the YANG modules listed in Table 48-3.

### 48.3.3 Customer VLAN Bridge model

A system implementing the Customer VLAN Bridge model (48.3.3) implements the YANG modules listed in Table 48-4.

### 48.3.4 Provider Bridge model

A system implementing the Provider Bridge model (48.3.4) implements the YANG modules listed in Table 48-5.

**Table 48-2—VLAN Bridge component model YANG modules**

| YANG module          |
|----------------------|
| ieee802-types        |
| ieee802-dot1q-types  |
| ieee802-dot1q-bridge |

**Table 48-3—Two-Port MAC Relay (TPMR) model YANG modules**

| YANG module          |

| ieee802-types        |
| ieee802-dot1q-types  |
| ieee802-dot1q-bridge |
| ieee802-dot1q-pb     |

**48.3.5 CFM model**

A system implementing the CFM models (48.3.5) implements the YANG modules listed in Table 48-6.

**Table 48-6—CFM model YANG modules**

| YANG module              |
|--------------------------|
| ieee802-types            |
| ieee802-dot1q-types      |
| ieee802-dot1q-cfm-types  |
| ieee802-dot1q-bridge     |
| ieee802-dot1q-cfm        |
| ieee802-dot1q-cfm-bridge |
| ieee802-dot1q-cfm-alarm  |

**48.3.6 Stream filters and stream gates model**

The Stream filters and stream gates model (48.3.6) provides basic stream filter (8.6.5.3) and stream gate (8.6.5.4) capabilities and allows for augmentation by specific YANG models (e.g., the ATS model). A system implementing the stream filters and stream gates model implements the YANG modules as described in Table 48-7.

**Table 48-7—Stream filters and stream gates model YANG modules**

| YANG module                               |
|-------------------------------------------|
| ieee802-types                             |
| ieee802-dot1q-types                       |
| ieee802-dot1q-bridge                      |
| ieee802-dot1q-stream-filters-gates        |
| ieee802-dot1q-stream-filters-gates-bridge |

### 1 48.3.7 Asynchronous Traffic Shaping (ATS) model

2 A system implementing the ATS model (48.3.7) implements the YANG modules as described in  
3 Table 48-8.

**Table 48-8—ATS model YANG modules**

| YANG module                        |
|------------------------------------|
| ieee802-types                      |
| ieee802-dot1q-types                |
| ieee802-dot1q-bridge               |
| ieee802-dot1q-stream-filters-gates |
| ieee802-dot1q-ats                  |
| ieee802-dot1q-ats-bridge           |

### 4 48.3.8 Congestion Isolation (CI) model

5 A system implementing the CI model (48.3.8) implements the YANG modules in Table 48-6.

**Table 48-9—YANG module dependencies for the CI model**

| YANG Module                               |
|-------------------------------------------|
| ieee802-types                             |
| ieee802-dot1q-types                       |
| ieee802-dot1q-bridge                      |

| ieee802-dot1q-congestion-isolation        |
| ieee802-dot1q-congestion-isolation-bridge |

### 6 48.3.9 Scheduled Traffic model

7 A Bridge implementing the Scheduled Traffic model (48.2.9) implements the YANG modules in  
8 Table 48-10.

**Table 48-10—Scheduled Traffic model YANG modules**

| YANG module                |
|----------------------------|
| ieee802-types              |
| ieee802-dot1q-types        |
| ieee802-dot1q-bridge       |
| ieee802-dot1q-sched        |
| ieee802-dot1q-sched-bridge |

**1 48.3.10 Frame Preemption model**

2 A Bridge implementing the Frame Preemption model (48.2.10) implements the YANG modules in  
3 Table 48-11.

**Table 48-11—Frame Preemption model YANG modules**

| YANG module                     |
|---------------------------------|
| ieee802-dot1q-types             |
| ieee802-dot1q-bridge            |
| ieee802-dot1q-preemption        |
| ieee802-dot1q-preemption-bridge |

**4 48.3.11 Per-Stream Filtering and Policing model**

5 A Bridge implementing the Per-Stream Filtering and Policing model (48.2.11) implements the YANG  
6 modules in Table 48-12.

**Table 48-12—Per-Stream Filtering and Policing model YANG modules**

| YANG module                               |
|-------------------------------------------|
| ieee802-types                             |
| ieee802-dot1q-types                       |
| ieee802-dot1q-bridge                      |
| ieee802-dot1q-stream-filters-gates        |
| ieee802-dot1q-stream-filters-gates-bridge |
| ieee802-dot1q-psfp                        |
| ieee802-dot1q-psfp-bridge                 |

### 1 48.3.12 User/Network Interface model

2 A station implementing the CNC-configuration model (48.2.12) implements the YANG modules in  
3 Table 48-13.

**Table 48-13—CNC-configuration model YANG modules**

| YANG module              |
|--------------------------|
| ieee802-dot1q-tsn-types  |
| ieee802-dot1q-cnc-config |

### 4 48.3.13 Credit-based shaper algorithm model

5 A bridge implementing the credit-based shaper algorithm model (48.2.13) implements the YANG modules  
6 in Table 48-14.

**Table 48-14—Credit-based shaper algorithm model YANG modules**

| YANG Module               |
|---------------------------|
| ieee802-types             |
| ieee802-dot1q-types       |
| ieee-802-dot1q-tsn-types  |
| ieee802-dot1q-bridge      |
| ieee802-dot1q-cbsa        |
| ieee802-dot1q-cbsa-bridge |

### 7 48.3.14 RSTP model

8 A bridge implementing the RSTP model (48.2.14) implements the YANG modules in Table 48-15.

**Table 48-15—RSTP model YANG modules**

| YANG module               |
|---------------------------|
| ieee802-types             |
| ieee802-dot1q-types       |
| ieee802-dot1q-bridge      |
| ieee802-dot1q-rstp        |
| ieee802-dot1q-rstp-bridge |

**1 48.3.15 MSTP model**

**2** A bridge implementing the MSTP model (48.2.15) implements the YANG modules in Table 48-16.

**Table 48-16—MSTP model YANG modules**

| YANG module               |
|---------------------------|
| ieee802-types             |
| ieee802-dot1q-types       |
| ieee802-dot1q-bridge      |
| ieee802-dot1q-rstp        |
| ieee802-dot1q-rstp-bridge |
| ieee802-dot1q-mstp        |
| ieee802-dot1q-mstp-bridge |

3

## 1 48.4 Security considerations

2 The YANG modules defined in this clause are designed to be accessed via a network configuration protocol,  
3 e.g., NETCONF protocol (IETF RFC 6241 [B39]). In the case of NETCONF, the lowest NETCONF layer is  
4 the secure transport layer and the mandatory to implement secure transport is SSH (IETF RFC 6242 [B40]).  
5 The NETCONF access control model (IETF RFC 6536 [B41]) provides the means to restrict access for  
6 particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and  
7 content.

8 It is the responsibility of a system's implementor and administrator to ensure that the protocol entities in the  
9 system that support NETCONF, and any other remote configuration protocols that make use of these YANG  
10 modules, are properly configured to allow access only to those principals (users) that have legitimate rights  
11 to read or write data nodes. This standard does not specify how the credentials of those users are to be stored  
12 or validated.

13 There are a number of management objects defined in the YANG modules specified in this standard that are  
14 configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be considered sensitive  
15 or vulnerable in some network environments. A network configuration protocol, such as NETCONF, can  
16 support protocol operations that can edit or delete YANG module configuration data (e.g., edit-config,  
17 delete-config, copy-config). If this is done in a non-secure environment without proper protection, then  
18 negative effects on the network operation are possible.

### 19 48.4.1 Security considerations of the VLAN Bridge components model

20 The following objects in the ieee802-dot1q-bridge YANG module can be manipulated to interfere with the  
21 operation of VLANs and priority classes. This could, for example, be used to force a reinitialization of state  
22 machines, thus causing network instability, or to change the forwarding and filtering policies. Another  
23 possibility would be for an attacker to override established policy on Port priorities, thus giving a user (or an  
24 attacker) unauthorized preferential treatment.

25 interfaces/interface/bridge-port  
26 interfaces/interface/bridge-port/priority-regeneration  
27 interfaces/interface/bridge-port/transmission-selection-table  
28 bridges/bridge/component/traffic-class-enabled  
29 bridges/bridge/component/bridge-vlan/protocol-group-database  
30 interfaces/interface/bridge-port/traffic-class  
31 interfaces/interface/bridge-port/protocol-group-vid-set

- 32 a) The configurable object bridges/bridge/component/filtering-database/aging-time controls how fast  
33 dynamically learned forwarding information is aged out. Setting this object to a large value may  
34 simplify FDB overflow attacks. Setting this object to too small a value may compromise the  
35 throughput of the network by causing excessive flooding.
- 36 b) The configurable object bridges/bridge/component/filtering-database/filtering-entries/entry-type  
37 provides a filtering mechanism controlling which Ports frames originating from a specific source  
38 may be forwarded to. Write access to this table can be used to turn provisioned filtering off or to add  
39 filters to prevent rightful use of the network.

40 Some of the readable data in this YANG module may be considered sensitive or vulnerable in some network  
41 environments. It is thus important to control all types of access (e.g., including NETCONF get, get-config  
42 operations) to these objects and possibly to even encrypt the values of these objects when sending them over  
43 the network. These tables and objects and their sensitivity/vulnerability are described as follows:

- 44 — The object bridges/bridge/component/capabilities could be used by an attacker to determine which  
45 attacks might be useful to attempt against a given device.

1 — The readable objects defined in the `ieee802-dot1q-bridge` module provide information about the  
2 topology of a bridged network and the attached active stations. The addresses listed in the  
3 `bridges/bridge/component/filtering-database/filtering-entries` usually reveal information about the  
4 manufacturer of the MAC hardware, which can be useful information for mounting other specific  
5 attacks. In some networks, information about attached active stations can be considered personal  
6 identifying information about the user of the station. Unauthorized use of these objects can be  
7 considered a privacy threat.

#### 8 **48.4.2 Security considerations of the Two-Port MAC Relay model**

9 The following objects in the `ieee802-dot1q-tpmr` YANG module could be manipulated to interfere with the  
10 operation of MAC status propagation on a TPMR port and, for example, be used to cause network  
11 instability:

12 `interfaces/interface/bridge-port/mac-status-propagation/link-notify`  
13 `interfaces/interface/bridge-port/mac-status-propagation/link-notify-wait`  
14 `interfaces/interface/bridge-port/mac-status-propagation/link-notify-retry`  
15 `interfaces/interface/bridge-port/mac-status-propagation/mac-notify`  
16 `interfaces/interface/bridge-port/mac-status-propagation/mac-notify-time`  
17 `interfaces/interface/bridge-port/mac-status-propagation/mac-recover-time`

#### 18 **48.4.3 Security considerations of the Customer VLAN Bridge model**

19 The Customer VLAN Bridge YANG model is based on, and has the same security considerations as, the  
20 VLAN Bridge components model. See 48.4.1.

#### 21 **48.4.4 Security considerations of the Provider Bridge model**

22 The following objects in the `ieee802-dot1q-pb` YANG module can be manipulated to interfere with the  
23 operation of VLANs. This could, for example, be used to force a reinitialization of state machines, thus  
24 causing network instability, or to change the forwarding and filtering policies.

25 `interfaces/interface/bridge-port`  
26 `interfaces/interface/bridge-port/cvid-registration`  
27 `interfaces/interface/bridge-port/service-priority-regeneration`

#### 28 **48.4.5 Security considerations of the CFM model**

29 The following objects in the `ieee802-dot1q-cfm` YANG module could be manipulated to interfere with the  
30 operation of a CFM port. This could, for example, be used to force a reinitialization of CFM state machines,  
31 thus causing network instability, or to change the management policies.

32 `cfm/maintenance-domain`  
33 `cfm/maintenance-group`

34 See 48.4.1 for related `ieee802-dot1q-bridge` YANG model security considerations.

#### 35 **48.4.6 Security considerations of the Stream filters and stream gates model**

36 The following objects in the `ieee802-dot1q-stream-filters-gates` YANG module could be manipulated to  
37 interfere with the operation of stream filtering and gating. This could, for example, be used to force a  
38 reinitialization of PSFP or ATS state machines, thus causing network instability.

39 `bridges/bridge/component/stream-filters`

1 bridges/bridge/component/stream-gates

2 See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

### 3 **48.4.7 Security considerations of the Asynchronous Traffic Shaping model**

4 The following objects in the ieee802-dot1q-ats YANG module could be manipulated to interfere with the  
5 operation of stream filtering. This could, for example, be used to force a reinitialization of ATS state  
6 machines, thus causing network instability.

7 bridges/bridge/component/stream-filters

8 interfaces/interface/bridge-port/ats-port-parameters

9 bridges/bridge/component/schedulers

10 bridges/bridge/component/scheduler-groups

11 See 48.4.1 and 48.4.6 for related ieee802-dot1q-bridge and ieee802-dot1q-stream-filters-gates YANG model  
12 security considerations.

### 13 **48.4.8 Security considerations of the Congestion Isolation model**

14 The following objects in the ieee802-dot1q-congestion-isolation YANG module could be manipulated to  
15 interfere with the operation of MAC status propagation on a TPMR port and, for example, be used to cause  
16 network instability:

17 bridges/bridge/component/ci-master-enable

18 bridges/bridge/component/ci-peers/ci-peer-table

19 bridges/bridge/component/ci-streams

20 bridges/bridge/component/stream-gates/stream-gate-instance-table

21 bridges/bridge/component/stream-filters/stream-filter-instance-table

22 bridges/bridge/component/queue-map

23 bridges/bridge/component/min-header-octets

24 bridges/bridge/component/min-cim-tx

### 25 **48.4.9 Security considerations of the Scheduled Traffic model**

26 The following objects in the ieee802-dot1q-sched YANG module could be manipulated to interfere with the  
27 operation of egress gating. This could, for example, be used to force a reinitialization of Scheduled Traffic  
28 state machines, thus causing network instability.

29 interfaces/interface/bridge-port/gate-parameter-table

30 See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

### 31 **48.4.10 Security considerations of the Frame Preemption model**

32 The following objects in the ieee802-dot1q-preemption YANG module could be manipulated to interfere  
33 with the operation of preemption. This could, for example, be used to force a reinitialization of the Frame  
34 Preemption status table, thus causing network instability.

35 interfaces/interface/bridge-port/frame-preemption-parameters

36 See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

#### 1 **48.4.11 Security considerations of the Per-Stream Filtering and Policing model**

2 The following objects in the ieee802-dot1q-psfp YANG module could be manipulated to interfere with the  
3 operation of stream filtering and gating. This could, for example, be used to force a reinitialization of PSFP  
4 state machines, thus causing network instability.

5 bridges/bridge/component/stream-filters

6 bridges/bridge/component/stream-gates

7 bridges/bridge/component/flow-meters

8 See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

#### 9 **48.4.12 Security considerations of the CNC-configuration model**

10 The ieee802-dot1q-cnc-config YANG module is structured in a way that allows access to specific parts of  
11 the YANG tree to be restricted, e.g., by using standard mechanisms as described in IETF RFC 8341 [B48].

12 The following objects in the ieee802-dot1q-cnc-config YANG module could be manipulated to interfere  
13 with the operation of streams in a configuration domain and, for example, be used to cause network  
14 instability:

15 cnc-config/domain/cuc/stream

16 cnc-config/domain/cuc/remove\_streams

#### 17 **48.4.13 Security considerations of the credit-based shaper algorithm model**

18 The following objects in the ieee802-dot1q-cbsa YANG module could be manipulated to interfere with the  
19 operation of the credit-based shaper algorithm. This could, for example, be used to force a reinitialization of  
20 credit-based shaper algorithm state, thus causing network instability.

21 interfaces/interface/bridge-port/cbsa/cbsa-parameter-table

#### 22 **48.4.14 Security considerations of the RSTP model**

23 All writeable nodes in the ieee802-dot1q-rstp YANG module could be manipulated to interfere with basic  
24 networking connectivity.

25 See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

#### 26 **48.4.15 Security considerations of the Multiple Spanning Trees model**

27 All writeable nodes in the ieee802-dot1q-mstp YANG module could be manipulated to interfere with basic  
28 networking connectivity.

29 See 48.4.1 for related ieee802-dot1q-bridge YANG model security considerations.

30

## 1 48.5 YANG schema tree definitions

2 A simplified graphical representation of the data model is used in this document. The meaning of the  
3 symbols in these diagrams is as follows:

- 4 — Brackets “[” and “]” enclose list keys.
- 5 — Abbreviations before data node names: “rw” means configuration (read-write), and “ro” means state  
6 data (read-only).
- 7 — Symbols after data node names: “?” means an optional node, “!” means a presence container, and  
8 “\*” denotes a list and leaf-list.
- 9 — Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (“:”).
- 10 — Ellipsis (“...”) stands for contents of subtrees that are not shown.

### 11 48.5.1 Schema for the ieee802-types YANG module

12 This YANG module does not have a YANG schema tree.

### 13 48.5.2 Schema for the ieee802-dot1q-types YANG module

14 This YANG module does not have a YANG schema tree.

### 15 48.5.3 Schema for the ieee802-dot1q-tsn-types YANG module

16 This YANG module does not have a YANG schema tree.

### 17 48.5.4 Schema for the ieee802-dot1q-bridge YANG module

```

```

```
1  description
2  "The source of a chassis identifier.";
3  reference
4  "IEEE Std 802
5  IETF RFC 2737
6  IETF RFC 2863";
7  }
8  typedef chassis-id-type {
9  type string {
10     length "1..255";
11  }
12  description
13     "The format of a chassis identifier string. Objects of this type are
14     always used with an associated chassis-id-subtype object, which
15     identifies the format of the particular chassis-id object
16     instance.
17
18     If the associated chassis-id-subtype object has a value of
19     chassis-component, then the octet string identifies a particular
20     instance of the entPhysicalAlias object (defined in IETF RFC 2737) for
21     a chassis component (i.e., an entPhysicalClass value of chassis(3)).
22
23     If the associated chassis-id-subtype object has a value of
24     interface-alias, then the octet string identifies a particular
25     instance of the ifAlias object (defined in IETF RFC 2863) for an
26     interface on the containing chassis. If the particular ifAlias object
27     does not contain any values, another chassis identifier type should be
28     used.
29
30     If the associated chassis-id-subtype object has a value of
31     port-component, then the octet string identifies a particular instance
32     of the entPhysicalAlias object (defined in IETF RFC 2737) for a port
33     or backplane component within the containing chassis.
34
35     If the associated chassis-id-subtype object has a value of
36     mac-address, then this string identifies a particular unicast source
37     address (encoded in network byte order and IEEE 802.3 bit
38     significance), of a port on the containing chassis as defined in
39     IEEE Std 802.
40
41     If the associated chassis-id-subtype object has a value of
42     network-address, then this string identifies a particular network
43     address, encoded in network byte order, associated with one or more
44     ports on the containing chassis. The first octet contains the IANA
45     Address Family Numbers enumeration value for the specific address
46     type, and octets 2 through N contain the network address value in
47     network byte order.
48
49     If the associated chassis-id-subtype object has a value of
50     interface-name, then the octet string identifies a particular instance
51     of the ifName object (defined in IETF RFC 2863) for an interface on
52     the containing chassis. If the particular ifName object does not
53     contain any values, another chassis identifier type should be used.
54
55     If the associated chassis-id-subtype object has a value of local,
56     then this string identifies a locally assigned Chassis ID.";

62    status "deprecated";
63    description
64      "This typedef is deprecated. Use stream-id-type-upper instead.
65
66      This typedef specifies a Stream ID, a unique identifier of the
67      Stream's configuration, used by protocols in the network to
68      associate the user's Stream with TSN resources.
69
70      The Stream ID is a string that represents two fields:
71
```

1       MAC Address:

2

3       A 48-bit IEEE 802 MAC address associated with the Talker sourcing

4       the Stream to the bridged network. The entire range of MAC

5       addresses are acceptable.

6

7       NOTE 1: The MAC address component of the StreamID can, but does not

8       necessarily, have the same value as the source\_address parameter

9       of any frame in the actual data Stream. For example, the Stream ID

10       can be assigned by a TSN CUC (see 46.1.3.3 of IEEE Std

11       802.1Q-2022), using a pool of MAC addresses that the TSN CUC

12       maintains.

13

14       NOTE 2: If the MAC addresses used to construct Stream IDs are not

15       unique within the network, duplicate Stream IDs can be generated,

16       with unpredictable results.

17

18       Unique ID:

19

20       A 16-bit unique ID that is used to distinguish between multiple

21       Streams within the station identified by MAC Address.

22

23       The string specifies eight octets, with each octet represented as

24       two hexadecimal characters. The first six octets specify the MAC

25       Address, using the canonical format of IEEE Std 802, with a dash

26       separating each octet. The last two octets specify the Unique ID,

27       with the high-order octet, a dash, and then the low-order octet.

28       The MAC Address and Unique ID are separated by colon.

29

30       stream-id-type is intended for use by other modules as the type

31       for a key to a list of Stream configurations (using group-talker

32       and group-listener) and a list of Stream status (using

33       group-status-stream and group-status-talker-listener).";

32 "mac-address is the unique individual MAC address (IEEE Std 802) of  
33 the interface in the station (end station or Bridge). This MAC  
34 address uniquely identifies the station within the local  
35 network.  
36  
37 mac-address shall be included in an instance of a container  
38 using group-interface-id.  
39  
40 NOTE: This MAC address can be discovered in the physical topology  
41 using protocols such as IEEE Std 802.1AB (LLDP). LLDP supports  
42 MAC address as a subtype for the stations Chassis ID and Port  
43 ID. If the station does not use MAC address for its LLDP IDs,  
44 remote management can be used to associate this mac-address to  
45 the values provided in the LLDP IDs.  
46  
47 The string uses the hexadecimal representation specified in IEEE  
48 Std 802 (i.e. canonical format).";

51 type string;  
52 description  
53 "interface-name is the name of the interface that is assigned  
54 locally by the station (end station or Bridge).  
55  
56 interface-name may be included in an instance of a container  
57 using group-interface-id.  
58  
59 IEEE Std 802 recommends that each distinct point of attachment  
60 to an IEEE 802 network have its own EUI MAC address. If the  
61 identified station follows this IEEE 802 recommendation, the  
62 mac-address leaf uniquely identifies the interface as well as  
63 the station, and interface-name is not needed.  
64  
65 If the mac-address applies to more than one interface (distinct  
66 point of attachment) within the station, interface-name provides  
67 a locally assigned name that can help to identify the interface.  
68  
69 When YANG is used for management of the station, interface-name  
70 is the interface name that serves as the key for the stations  
71 interface list (RFC7223).  
72

```

1     NOTE 1: The TSN CNC is typically located in a different physical
2     product than the station identified by this group-interface-id.
3     Since the interface-name is assigned locally by the identified
4     station, it is possible that the stations product will change
5     interface-name in a manner that the TSN CNC cannot detect. For
6     example, RFC7223 mentions that the YANG interface name can
7     change when a physical attachment point is inserted or removed.
8
9     NOTE 2: This interface name can be discovered in the physical
10    topology using protocols such as IEEE Std 802.1AB (LLDP). LLDP
11    supports interface name as a subtype for its Port ID. If the
12    station does not use interface name for its LLDP Port ID, remote
13    management can be used to associate this interface-name to the
14    values provided in the LLDP Port ID.";

63     reference
64         "46.2.3.6 of IEEE Std 802.1Q-2022";
65     leaf num-seamless-trees {
66         type uint8;
67         default "1";
68         description
69             "num-seamless-trees specifies the number of trees that the
70             network will configure to deliver seamless redundancy for the
71             Stream.
72 
```

1       The value zero is interpreted as one (i.e. no seamless  
2       redundancy).  
3  
4       This requirement is provided from the Talker only. Listeners  
5       shall set this leaf to one.  
6  
7       From each Talker to a single Listener, the network configures a  
8       path that relays Stream data through Bridges. If the Talker has  
9       more than one Listener, the network configures a tree of  
10      multiple paths.  
11  
12      num-seamless-trees specifies the number of maximally disjoint  
13      trees that the network shall configure from the Talker to all  
14      Listeners. Each tree is disjoint from other trees, in that the  
15      network evaluates the physical topology to avoid sharing the  
16      same Bridge and links in each trees paths. This computation of  
17      disjoint trees is maximal, in that shared Bridges and links are  
18      avoided to the maximum extent allowed by the physical topology.  
19      For example, if a single link exists from a Bridge to a  
20      Listener, and num-seamless-trees is 3, then all 3 trees will  
21      share that link to the Listener.  
22  
23      When num-seamless-trees is greater than one, the transfer of the  
24      Streams data frames shall use a seamless redundancy standard,  
25      such as IEEE Std 802.1CB. When a link shared by multiple trees  
26      diverges to multiple disjoint links, the seamless redundancy  
27      standard replicates (i.e. forwards a distinct copy of each data  
28      frame to the disjoint trees). When disjoint trees converge to a  
29      single link, the seamless redundancy standard eliminates the  
30      duplicate copies of each data frame. Assuming that other sources  
31      of frame loss are mitigated (e.g. congestion), failure of a link  
32      or Bridge in one disjoint tree does not result in frame loss as  
33      long as at least one remaining disjoint tree is operational.  
34  
35      If the Talker sets this leaf to one, the network may make use of  
36      redundancy standards that are not seamless (i.e. failure of link  
37      results in lost frames), such as MSTP and IS-IS.  
38  
39      If the Talker sets this leaf to greater than one, and seamless  
40      redundancy is not possible in the current network (no disjoint  
41      paths, or no seamless redundancy standard in Bridges),  
42      group-status-stream.status-info.failure-code is non-zero  
43      (46.2.4.1 of IEEE Std 802.1Q-2022).  
44  
45      If group-user-to-network-requirements is not provided by the  
46      Talker or Listener, the network shall use the default value of  
47      one for this leaf."  
48      reference  
49      "46.2.3.6.1 of IEEE Std 802.1Q-2022";  
50    }  
51    leaf max-latency {  
52      type uint32;  
53      default "0";  
54      description  
55        "Maximum latency from Talker to Listener(s) for a single frame  
56        of the Stream.  
57  
58        max-latency is specified as an integer number of nanoseconds.  
59  
60        Latency shall use the definition of 3.102, with additional  
61        context as follows: The Known reference point in the frame is  
62        the message timestamp point specified in IEEE Std 802.1AS for  
63        various media (i.e. start of the frame). The first point is in  
64        the Talker, at the reference plane marking the boundary between  
65        the network media and PHY (see IEEE Std 802.1AS). The second  
66        point is in the Listener, at the reference plane marking the  
67        boundary between the network media and PHY.  
68  
69        When this requirement is specified by the Talker, it must be  
70        satisfied for all Listeners.  
71  
72        When this requirement is specified by the Listener, it must be

1 satisfied for this Listener only.

2

3 If group-user-to-network-requirements is not provided by the

4 Talker or Listener, the network shall use the default value of

5 zero for this leaf.

6

7 The special value of zero represents usage of the initial value

8 of group-status-talker-listener.accumulated-latency as the

9 maximum latency requirement. This effectively locks-down the

10 initial latency that the network calculates after successful

11 configuration of the Stream, such that any subsequent increase

12 in latency beyond that value causes the Stream to fail.

13

14 The assumption for when the first point occurs in the Talker

15 depends on the presence of the time-aware container in the

16 Talkers traffic-specification.

17

18 When time-aware is not present:

19

20 The Talker is assumed to transmit at an arbitrary time (not

21 scheduled).

22

23 When time-aware is present:

24

25 The first point is assumed to occur at the start of each

26 traffic-specification.interval, as if the Talkers offsets

27 (earliest-transmit-offset and latest-transmit-offset) are both

28 zero. The Talkers offsets are not typically zero, but use of the

29 start of interval for purposes of max-latency allows the

30 Listener(s) to schedule their application independently from the

31 Talkers offset configuration.

32

33 The Listener determines max-latency based on its scheduling of a

34 read function in the application. Nevertheless, the time from

35 frame reception (i.e. second point) to execution of the read

36 function is in the user scope, and therefore not included in

37 max-latency.

38

39 max-latency can be set to a value greater than the Talkers

40 interval, in order to specify a longer latency requirement. For

41 example, if the Talkers interval is 500 microsec, and

42 max-latency is 700 microsec, the Listener receives the frame no

43 later than 200 microsec into the interval that follows the

44 Talkers interval.";

5      (how/when transmitted) - Talkers requirements from the network -
6      TSN capabilities of the Talkers interface(s)
7
8      In the fully centralized model of TSN configuration, this grouping
9      originates from the CUC, and is delivered to the CNC.";
10   reference
11     "46.2.3 of IEEE Std 802.1Q-2022";
12   container stream-rank {
13     description
14       "Rank of this Stream's configuration relative to other Streams
15       in the network. This rank is used to determine success/failure
16       of Stream resource configuration, and it is unrelated to the
17       Streams data.";
18     reference
19       "46.2.3.2 of IEEE Std 802.1Q-2022";
20     leaf rank {
21       type uint8;
22       description
23         "The Rank is used by the network to decide which Streams can
24         and cannot exist when TSN resources reach their limit. If a
25         Bridges Port becomes oversubscribed (e.g. network
26         reconfiguration, IEEE 802.11 bandwidth reduction), the Rank is
27         used to help determine which Streams can be dropped (i.e.
28         removed from Bridge configuration).
29
30         The only valid values for Rank shall be zero and one. The
31         configuration of a Stream with Rank zero is more important
32         than the configuration of a Stream with Rank one. The Rank
33         value of zero is intended for emergency traffic, and the Rank
34         value of one is intended for non-emergency traffic.
35
36         NOTE: It is expected that higher layer applications and
37         protocols can use the Rank to indicate the relative importance
38         of Streams based on user preferences. Those user preferences
39         are expressed by means beyond the scope of this standard. When
40         multiple applications exist in a network (e.g. audio/video
41         along with industrial control), it can be challenging for the
42         varied applications and vendors to agree on multiple Rank
43         values. To mitigate such challenges, this Rank uses a simple
44         concept of emergency (zero) and non-emergency (one) that can
45         be applied over all applications. For example, in a network
46         that carries audio Streams for fire safety announcements, all
47         applications are likely to agree that those Streams use Rank
48         of zero.";

3     min-elements 1;
4     description
5         "data-frame-specification specifies the frame that carries the
6         Talkers Stream data. The network uses the specification to
7         identify this Streams frames as TSN, in order to apply the
8         required TSN configuration.
9
10        The specification is based on the users knowledge of the frame,
11        without any network specifics. In other words, this specifies
12        the frame that the Talker would use in the absence of TSN.
13
14        The specification is provided as a list of fields that the user
15        knows. The list is ordered from start of frame to end of header.
16        For example, if the Talker uses a VLAN-tagged Ethernet frame
17        (not IP), the list consists of ieee802-mac-addresses followed by
18        ieee802-vlan-tag. For example, if the Talker uses a UDP/IPv4
19        packet without knowledge of the Ethernet header, the list
20        consists of ipv4-tuple.
21
22        This list is optional, and its absence indicates that Stream
23        transformation is performed in the Talker and Listeners of this
24        Stream (46.2.2 of IEEE Std 802.1Q-2022).";

71             "This interval specifies the period of time in which the
72             traffic specification cannot be exceeded. The traffic
```

specification is specified by max-frames-per-interval and max-frame-size.

The interval is a rational number of seconds, defined by an integer numerator and an integer denominator.

If the time-aware container is not present, the interval specifies a sliding window of time. The Talkers transmission is not synchronized to a time on the network, and therefore the traffic specification cannot be exceeded during any interval in time.

If the time-aware container is present, the interval specifies a window of time that is aligned with the time epoch that is synchronized on the network. For example, if IEEE Std 802.1AS-2011 is used with the PTP timescale, the first interval begins at 1 January 00:00:00 TAI. If CurrentTime represents the current time, then the start of the next interval (StartOfNextInterval) is: StartOfNextInterval = N \* interval where N is the smallest integer for which the relation StartOfNextInterval >= CurrentTime would be TRUE.";

```

```

1      is specified as an unsigned integer number of nanoseconds.
2
3      The maximum difference means sooner or later than the ideal
4      (e.g. transmit +/- 500 nanoseconds relative to IEEE 802.1AS
5      time results in jitter of 500).
6
7      The ideal synchronized network time refers to time at the
8      source (e.g. IEEE 802.1AS grandmaster). The jitter does not
9      include inaccuracies as time is propagated from the time
10     source to the Talker, because those inaccuracies are assumed
11     to be known by the network, and time synchronization is a
12     network technology. The jitter leaf is intended to specify
13     inaccuracies in the Talkers implementation. For example, if
14     the Talkers IEEE 802.1AS time is +/- 812 nanoseconds
15     relative to the grandmaster, and the Talker schedules using
16     a 100 microsecond timer tick driven by IEEE 802.1AS time,
17     Jitter is 50000 (not 50812).
18
19     The Talkers transmit offsets include
20     earliest-transmit-offset, latest-transmit-offset, and the
21     time-aware-offset returned to the Talker in
22     group-status-talker-listener.interface-configuration.";

18         description
19         "accumulated-latency provides the worst-case maximum latency
20         that a single frame of the Stream can encounter along its
21         current path(s).
22
23         When provided to a Listener, accumulated-latency is the
24         worst-case maximum latency for that Listener only.
25
26         When provided to a Talker, accumulated-latency is the worst-case
27         maximum latency for all Listeners (worst path).
28
29         accumulated-latency is specified as an integer number of
30         nanoseconds.
31
32         accumulated-latency uses the same definition for latency as
33         user-to-network-requirements.max-latency.
34
35         For successful status-info, the network returns a value less
36         than or equal to user-to-network-requirements.max-latency.
37
38         If the time-aware container is present in the
39         traffic-specification of the Talker, the value is expressed as
40         nanoseconds after the start of the Talkers
41         traffic-specification.interval.
42
43         If the time-aware container is not present in the
44         traffic-specification of the Talker, the value is expressed as
45         nanoseconds after the Talkers transmit of any frame in the
46         Stream, at any arbitrary time.
47
48         If user-to-network-requirements.num-seamless-trees is one,
49         accumulated-latency shall provide the worst-case maximum latency
50         for the current path from Talker to each Listener. If the path
51         is changed (e.g. by a spanning tree protocol),
52         accumulated-latency changes accordingly.
53
54         If user-to-network-requirements.num-seamless-trees is greater
55         than one, accumulated-latency shall provide the worst-case
56         maximum latency for all paths configured from the Talker to each
57         Listener.";

67                 originating this LTM.
68
69                 The low-order six octets contain a 48-bit IEEE MAC
70                 address unique to the system in which the MEP Linktrace
71                 Initiator or Linktrace Responder resides. The high-order
72                 two octets contain a value sufficient to uniquely

```

```
1         identify the MEP Linktrace Initiator or Linktrace
2         Responder within that system.
3
4         For most Bridges, the address of any MAC attached to the
5         Bridge will suffice for the low-order six octets, and 0
6         for the high-order octets. In some situations, e.g., if
7         multiple virtual Bridges utilizing emulated LANs are
8         implemented in a single physical system, the high-order
9         two octets can be used to differentiate among the
10        transmitting entities.
11
12        The value returned is undefined if the
13        transmit-linktrace input action was not accepted.";

35    // cfm-stack
36    list default-md-level {
37        key "bridge-id component-id service-selector primary-service-id";
38        description
39            "For each bridge component, the Default MD Level Managed Object
40            controls MHF creation for VIDs that are not attached to a
41            specific Maintenance Association Managed Object, and Sender ID
42            TLV transmission by those MHFs.
43
44            For each Bridge Port, and for each VLAN ID whose data can pass
45            through that Bridge Port, an entry in this table is used by the
46            algorithm in subclause 22.2.3 only if there is no entry in the
47            Maintenance Association table defining an MA for the same VLAN
48            ID and MD Level as this table's entry, and on which MA an Up MEP
49            is defined. If there exists such an MA, that MA's objects are
50            used by the algorithm in subclause 22.2.3 in place of this table
51            entry objects.
52
53            The agent maintains the value of md-status to indicate whether
54            this entry is overridden by an MA. When first initialized, the
55            agent creates this table automatically with entries for all VLAN
56            IDs, with the default values specified for each object. After
57            this initialization, the writable objects in this table need to
58            be persistent upon reboot or restart of a device.";

## 49. Congestion Isolation

Congestion Isolation (CI) mitigates head-of-line blocking caused by the frequent use of PFC in lossless networks and reduces frame loss in lossy networks that are not using PFC. CI identifies the flows that are most likely causing congestion, isolates them to a separate lower priority traffic class and signals to the upstream peer to do the same. CI effectively moves the congesting flows out of the way, temporarily delaying the delivery of congesting frames, while the higher layer congestion control feedback loop has time to take effect.

This clause introduces the concepts and protocols essential to congestion isolation as follows:

- a) The objectives for congestion isolation (49.1).
- b) Principles of congestion isolation (49.2).
- c) Congestion Isolation Aware Forwarding Process (49.3).
- d) Congestion Isolation Protocol (49.4).
- e) Topology Recognition (49.5).

In current data center networks, traffic can be a mix of various multi-tenant TCP and UDP flows across both the physical underlay and virtual overlay network. Intermittent congestion within the network can occur from an unfortunate mix of flows across the network. For example, a small number of long duration ‘elephant’ flows can align in such a way to create queuing delays for the larger number of short, but critical, ‘mice’ flows. In this case, the ‘elephant’ flows would be considered congesting flows to the ‘mice’ flows. Any flow can become a congesting flow when it contributes to congestion in the network.

Queuing delays deter the end-to-end congestion control loop, and in a lossless environment, cannot prevent Priority-based Flow Control (PFC) from being invoked (see Clause 36). When buffers fill and eventual flow-control kicks in (for lossless networks), non-congesting flows can be blocked by the backlog of frames from congesting flows. If PFC is not being used, frame loss for non-congesting flows can result in long retransmission timeouts, significantly penalizing such flows, which are often used for application control and synchronization.

Figure 49-1—Congestion Isolation example operation

1 Figure 49-1 shows an example operation of CI. In the figure, all of the relay systems are layer-3 routers and  
2 are congestion isolation aware systems. The example shows a network of layer-3 routers, but congestion  
3 isolation also applies to Bridged Networks. Each system is showing two queues on each port; a monitored  
4 queue and a congesting queue. Server-to-server traffic is flowing from left to right across a data center  
5 network. When congestion is detected CI attempts to identify the congesting flows (49.2.1). For each  
6 identified congesting flow (e.g. the red flow in Figure 49-1), the congestion isolation aware system takes  
7 local actions to isolate the congesting flow, sends a Congestion Isolation Message (CIM) upstream if the  
8 congesting queue is congested, and sends Explicit Congestion Notification (ECN) downstream.

9 The local actions taken by a congestion isolation aware system deprioritize frames from the congesting flow  
10 and place them in a dedicated congesting flow queue (49.2.3). An entry is made in the IEEE Std 802.1CB  
11 Stream identity table of the local system so that subsequent frames from the congesting flow can be  
12 identified and deprioritized (49.2.2).

13 When a flow is isolated the deprioritized frames are queued in the congesting flow queue. When that queue  
14 becomes congested (49.2.1) and the upstream peer is congestion isolation aware, the CI functionality signals  
15 to the immediate upstream peer using a CIM (49.2.5).

16 The CIM contains flow description information necessary for the upstream peer to identify the same  
17 congesting flow. The upstream peer creates a Stream identity table entry using the contents of the CIM  
18 (49.2.2). The table entry is used to isolate the same flow by identifying subsequent frames and deprioritizing  
19 those frames to the congested flow queue.

20 The IP packets in frames of the congesting flows are marked with higher layer congestion signals such as  
21 those defined by the IETF RFC 3168 for Explicit Congestion Notification (ECN). Since CI is performed  
22 within the network it is essential that end-to-end higher layer congestion control is combined with CI so the  
23 sending sources will reduce their rate of transmission in response to the congestion signals. ECN operates by  
24 marking packets where they encounter queuing delay as they travel towards the destination. At the IP  
25 destination, feedback is signaled to the source system, so it takes time for the signals to propagate and  
26 ultimately impact the transmission rate of the source system.

27 The frames in the congesting flow queue are serviced at a lower priority than other non-congesting queues,  
28 so if congestion persists, the congesting flow queue may fill. When the congesting flow queue fills, the  
29 ingress port feeding that queue can issue PFC for the lower priority queue to avoid frame loss (49.2.4). In  
30 this case, PFC only acts on the lower priority congesting flow queues and other well-behaved flows continue  
31 through the network via non-congesting priority queues.

## 32 **49.1 Congestion isolation objectives**

33 The operation, procedures, and protocols of congestion isolation are designed to meet the following  
34 objectives by category:

### 35 **Functionality**

- 36 a) With high probability, identify the flows that are causing congestion.
- 37 b) Avoid head-of-line blocking of non-congesting flows locally by quickly adjusting the traffic class of  
38 congesting flows.
- 39 c) Avoid head-of-line blocking of non-congesting flows upstream by signaling to upstream peers the  
40 information needed to isolate the same congesting flows.
- 41 d) Reduce the frequency of invoking PFC in a lossless environment.

### 42 **Compatibility**

- 43 e) Work in legacy environments by automatically detecting legacy peers and disabling CIM signaling.
- 44 f) Work in existing lossless environments using PFC without requiring additional traffic classes.

- 1 g) Work in conjunction with higher layer end-to-end congestion control protocols (e.g. Explicit
- 2 Congestion Notification (ECN), Remote Direct Memory Access (RDMA) over Converged Ethernet
- 3 (RoCE), Data Center Quantized Congestion Notification (DCQCN [B69])).
- 4 h) Work in both layer-2 and layer-3 networks.
- 5 i) Coexist with existing traffic scheduling paradigms on other traffic classes.

#### 6 Performance

- 7 j) Reduce average flow completion time across the data center network.
- 8 k) Reduce the amount of time frames are paused when PFC is enabled.
- 9 l) Reduce overall frame loss when PFC is not enabled.
- 10 m) Reduce head-of-line blocking of victim flows at upstream peers from PFC.
- 11 n) Reduce overall congestion control signaling.
- 12 o) Increase link utilization.

#### 13 Scale

- 14 p) Work in arbitrary data center network topologies with a mix of link speeds.
- 15 q) Limit messaging overhead by restricting message propagation to hop-by-hop.
- 16 r) Reduce Stream identity table requirements by only requiring the registration of congesting flows and
- 17 providing facilities to rapidly remove flows that are no longer congesting.

#### 18 Implementation complexity

- 19 s) Limit the impact of existing traffic selection algorithms.
- 20 t) Achieve the benefits of congestion isolation without additional buffer requirements.
- 21 u) Support implementations of existing traffic classes.
- 22 v) Leverage existing standard functionality for congesting flow identification and stream identification.

#### 23 Manageability

- 24 w) Only require a small set of configuration parameters that are consistent across multiple Bridge
- 25 deployments.
- 26 x) Limit the ability to configure an inoperable environment.
- 27 y) Provide auto discovery of peer capabilities using existing LLDP messages and without creating
- 28 additional hello and auto-configuration protocols.

## 29 49.2 Principles of congestion isolation

30 This clause introduces the principles of congestion isolation. Items a) through f) describe the life of a  
31 congesting flow from identification through isolation to returning the flow to non-congesting status. Item g)  
32 describes a mechanism for determining a device's level in the data center topology that can be used to ensure  
33 compatibility and proper operation of existing protocols. Item h) compares and contrasts congestion  
34 isolation with Congestion Notification (see Clause 30).

35 The following items describe the principles of congestion isolation:

- 36 a) Congesting flow identification (49.2.1).
- 37 b) IEEE Std 802.1CB stream identification (49.2.2).
- 38 c) Flow priority modification (49.2.3).
- 39 d) Priority-based Flow Control interaction (49.2.4)
- 40 e) Congestion isolation signaling (49.2.5).
- 41 f) Congesting to non-congesting status change (49.2.6).
- 42 g) System topology and port orientation (49.2.7).
- 43 h) Comparison to Congestion Notification (49.2.8).

### 1 49.2.1 Congesting flow identification

2 An essential step in the process of CI is identifying congesting flows by an Active Queue Management  
3 (AQM) scheme that supports Explicit Congestion Notification (ECN) specified in IETF RFC 3168. There  
4 are many potential methods of identifying congesting flows and interoperable implementations can exist  
5 using different approaches. The CIP Congestion Detection function (49.3.1) of the Congestion Isolation  
6 Aware Forwarding Process (49.3) is responsible for implementing the AQM. This standard defines the CP  
7 algorithm (30.2.1) for detecting Congestion Controlled Flows (CCFs) in congestion aware Bridges. This  
8 approach may be used to detect congesting flows in a CI aware system. A number of other possible  
9 approaches, including those that support the end-to-end ECN congestion control, are discussed in IETF  
10 RFC 7567 [B45].

11 Many modern data centers utilize encapsulated overlay networks, such as those described in  
12 IETF RFC 8014 [B46]. An overlay network can carry multiple encapsulated flows within a single  
13 encapsulation flow. The congesting and non-congesting flows identified by CI are the outer encapsulation  
14 flow as seen by the underlay network. The inner encapsulated flows might not be visible to the bridges and  
15 routers within the data center network, and are therefore not separated into congesting and non-congesting  
16 flows.

### 17 49.2.2 IEEE Std 802.1CB stream identification

18 Subsequent frames of congesting flows are identified by matching in the IEEE Std 802.1CB Stream identity  
19 table. Congesting flow entries are added to and removed from the Stream identity table as `tsnStreamIdEntry`  
20 objects using the managed object interface specified in Clause 9 of IEEE Std 802.1CB-2017. The  
21 `tsnStreamIdIdentificationType` for these objects is IP stream identification. The contents for an IP stream  
22 `tsnStreamIdEntry` come from the received frame that has been identified as causing congestion or from the  
23 parameters in the CIM PDU (49.4.3.4) from a peer. Flows matching in the Stream identity table will provide  
24 a `stream_handle` for congesting flows to the EISS. The `stream_handle` for congesting flows is used as the  
25 `tsnStreamIdHandle` entity of the `tsnStreamIdEntry` object.

26 Congestion isolation uses `stream_handles` to identify frames of congesting and non-congesting flows. This  
27 use prohibits `stream_handles` from being used by other functionality requiring `stream_handles` on a port  
28 where congestion isolation operates.

### 29 49.2.3 Flow priority modification

30 CI uses the facilities of per-stream classification and metering (8.6.5.2) to modify the priority of congesting  
31 flow frames. The `stream_handle`, available as part of the `connection_identifier`, is provided by the Stream  
32 identification function and accompanies frames of congesting flows as they pass through a relay. This  
33 `stream_handle` is used to select a stream filter instance and stream gate instance that will modify the priority  
34 of the frame for congesting flows. A single stream filter instance from the stream filter instance table  
35 (8.6.5.2.3), with a wildcard match on the `stream_handle`, is used to select a stream gate instance that contains  
36 the new internal priority value (IPV). Configuration of the stream filter instance table and stream gate  
37 instance table is described in 8.6.5.

38 The process of modifying the priority of subsequent frames of a congesting flow brings with it the risk of  
39 misordering. There may be a period of time where frames for the same flow exist in multiple queues at the  
40 same time. Strict priority transmission selection can ensure ordering is maintained for congesting flows  
41 because the monitored queue is higher priority than the congesting queue. However, other transmission  
42 selection algorithms may be desired. Congestion isolation implementations need to ensure that misordering  
43 (6.5.3) remains negligible. Annex W discusses possible approaches for ensuring ordering.

### 44 49.2.4 Priority-based Flow Control interaction

45 Priority-based Flow Control (PFC) (Clause 36) is used in data centers to create lossless traffic classes in the  
46 data center network. PFC allows link flow control to be performed on a per-priority basis. For PFC to  
47 operate properly, it is imperative that the downstream system can determine the priority of the frame when it

egresses the upstream peer. The Priority Code Point (PCP—see 6.9.3) field of a VLAN tag encodes a frame's priority. Since an upstream congestion isolation aware system modifies the priority of congesting frames, it must also modify the PCP so the downstream system can assert PFC, if needed, on the correct priority. Therefore all frames must be VLAN tagged when operating CI with PFC in a lossless environment. Additional design considerations for the interaction of PFC and CI are discussed in W.2.

#### 49.2.5 Congestion isolation signaling

Once a flow has been isolated and subsequent frames are forwarded through the congesting queue and the congesting queue becomes congested, it is useful to inform the upstream peer of this event by signaling a Congestion Isolation Message (CIM). Upon receiving a CIM, the upstream peer can isolate the same flow by creating an entry in the IEEE Std 802.1CB Stream identity table. The benefit of isolating a flow upon the directive of a peer is that the congesting flow can be moved out of the way of other non-congesting flows and the potential for head-of-line blocking can be reduced.

The CIM contains parameters and a portion of the received frame so the upstream peer can identify the congesting flow and create an entry in its Stream identity table. The parameters and portion of the received frame included in the CIM must be the same as those of the frame sent by the upstream peer in order for that peer to identify the same flow. Features such as the VID translation table (6.9) can change the frame's parameters from what was sent by the upstream peer and should not be used with CI.

The CIM is addressed to the upstream peer. The system generating the CIM must locate CIM format information and the address parameters of the upstream peer by indexing into the CI Peer Table (49.3.6) using the reception port as the index. The CI Peer Table is built using information provided by LLDP and the Congestion Isolation TLV (D.2.15).

By default, a CIM contains the first 64 bytes of the congesting frame's `mac_service_data_unit`. Systems encapsulating and decapsulating flows for overlay networks may request the peer to include up to 512 octets of the received frame in the CIM. This allows the systems to access and identify encapsulated flows within the congesting flow encapsulation.

#### 49.2.6 Congesting to non-congesting status change

Flows that are no longer causing congestion may be removed from the Stream identity table. Many methods of determining that a flow is no longer causing congestion are possible, but at a minimum, all flows in the Stream identity table for the port can be removed when the congesting queue for that port becomes empty. Waiting until the congesting queue is empty can cause congesting flows to remain in the congesting state longer than necessary, but it allows an implementation to easily abide by the frame misordering requirements of (6.5.3). Other approaches can react quickly and independently of other congesting flows, but may bring the risk of misordering. Implementations need to ensure that misordering is negligible. An example approach for avoiding misordering when returning a flow to non-congesting status can be seen in Annex W.

Frames from congesting flows received downstream from the root of congestion may be safely returned to the non-congesting traffic class. These frames are easily identified downstream because they are received on the congesting traffic class, but do not have a matching entry in the Stream identity table and will therefore not have a `stream_handle` parameter when passed through relay. These frames are isolated to the congesting queue by an upstream peer and the traffic class, as well as the associated Priority Code Point (PCP—see 6.9.3) or other indicators used to select a traffic class, such as the Differentiated Services Code Point (DSCP—see IETF RFC 2474) are modified upstream to indicate they are part of a congesting flow. Downstream from the congestion, however, these frames can be safely forwarded through the monitored queue. A second stream filter instance is used to return these frames to the monitored queue and update the PCP or other indicators used to select a traffic class. This stream filter is defined to match on the absence of

1 a stream\_handle and the priority for the congesting queue. The end-to-end ECN congestion markings remain  
2 unchanged and the congestion indications in the higher layer protocols will be noted at the source of the flow  
3 once the feedback is propagated.

4 NOTE—As noted in 6.8.1, modification to a frame's PCP or other indicators used to select a traffic class, will require the  
5 FCS to be regenerated. Options for regenerating the FCS are discussed in Annex O.

## 6 49.2.7 System topology and port orientation

7 Figure 49-1 shows an example of a popular data center topology. Other topologies are possible, but they all  
8 can be described as having devices positioned at levels within the topology. The topology levels are  
9 distinguished by considering the number of link hops from any interior system to non-relay end stations or  
10 servers at the edge of the network. By this definition, end stations and servers are at level 0. The immediate  
11 attached device would be at level 1 and further interior only systems could be at level 2 or higher depending  
12 on the connectivity of the topology.

13 A port's orientation is distinguished by considering the level in the topology a port is facing. A port facing a  
14 lower level has an orientation of a downlink, while a port facing a higher level has an orientation of an  
15 uplink. A port facing a system at the same level has an orientation of a crosslink.

16 Congestion isolation benefits from knowing a system's level in the topology. Recognizing the level is  
17 automated by the use of the LLDP Topology Recognition TLV (D.2.16) and the procedures defined in  
18 49.5.3. During the process of isolating a congesting flow, the frame's priority may be changed from its  
19 original value. The corresponding Priority Code Point (PCP—see 6.9.3) or Differentiated Services Code  
20 Point (DSCP—see IETF RFC 2474) received at the destination may be different than the value provided by  
21 the original sender. To avoid complications with unexpected PCP or DSCP values, the Bridge or router at  
22 level 1 in the topology may change the PCP or DSCP back to the original value for the monitored queue.

23 In addition to avoiding complications with changed PCP or DSCP values, knowing a system's level in the  
24 topology can assist in identifying the type of congestion experienced and consequentially a strategy for  
25 mitigating it. Ports of Bridges or routers at level 1 in the topology are connected to non-relay end stations or  
26 servers. Congestion on these ports can often be attributed to incast traffic patterns. Congestion on links of  
27 systems that are at level 2 or higher in the topology may be experiencing in-network congestion. It has been  
28 shown that load balancing techniques, which may alleviate in-network congestion, are counter productive at  
29 addressing incast congestion [B61].

30 Lossless networks enabled by PFC have been shown, in certain circumstances, to have circular buffer  
31 dependencies that can cause deadlocks when traffic is re-routed due to link failures [B5]. Again, knowing  
32 the position in the topology assists in knowing when traffic has been re-routed and can be used to break  
33 circular buffer dependent deadlocks [B4].

## 34 49.2.8 Comparison to Congestion Notification

35 Congestion Isolation and Congestion Notification (Clause 30) share common aspects but are distinctly  
36 different. Both generate congestion messages and send them upstream, but CN directs the message across  
37 the Bridged Network to the source station, while CI directs the message to the immediate peer. CI is  
38 intended to operate in layer 3 and layer 2 networks with higher layer end-to-end congestion control  
39 supported by the end stations to regulate the rate of traffic injection into the network. CN is designed to  
40 operate across a large layer 2 domain where reaction points in end-station network adapters regulate traffic  
41 injection. CI isolates congesting flows by reclassifying their traffic class. CN does not modify the traffic  
42 class of frames.

## 49.3 The Congestion Isolation Aware Forwarding Process

This clause specifies the architecture of the Congestion Isolation Point (CIP) in the Forwarding Process of a congestion isolation aware Bridge. In this architecture, a router is as a higher layer entity that relays frames using layer-3 information but uses the forwarding process of the underlying congestion isolation aware Bridge to deliver frames to peers and end stations.

The models of operation in this clause provide a basis for specifying the externally observable behavior of CI, and are not intended to place additional constraints on implementations; these can adopt any internal model of operation compatible with the externally observable behavior specified. Conformance of equipment to this standard is purely in respect of observable protocol.

Figure 8-12 illustrates the Bridge Forwarding Process at its highest conceptual level. Figure 8-16 shows the specific filtering and assignment functions of the flow classification and metering elements in the Forwarding Process of a congestion isolation aware Bridge. Figure 49-2 focuses on the operation of a single Bridge Port and the relationship of new elements to the queuing and classification functions. Five new elements and two new managed tables are specified for a CI aware Bridge as follows:

- a) CIP Congestion Detection (49.3.1).
- b) CIP transmission gates (49.3.2).
- c) CIM Demultiplexer (49.3.3).
- d) Congesting flow identification (49.3.4).
- e) CIM Multiplexer (49.3.5).
- f) CI Peer Table (49.3.6).
- g) CI Stream Table (49.3.7).

Figure 49-2—Congestion Isolation reference diagram

### 1 49.3.1 CIP Congestion Detection

2 CIP Congestion Detection identifies frames of a congesting flow, inserts frames passed by the Queuing  
3 Frames entity (8.6.6) into the appropriate queue or discards them and can generate a CIM based on the  
4 contents of the frame. CIP Congestion Detection is also responsible for creating entries in the Stream  
5 identity table and the CI Stream Table (49.3.7) for newly identified congesting flows. As described in 49.2.1,  
6 frames of a congesting flow are identified by a suitable AQM implemented by CIP Congestion Detection,  
7 such as the algorithm specified by a CP in 30.2.1.

8 Frames given to CIP Congestion Detection by the Queuing Frames entity (8.6.6) in an  
9 EM\_UNITDATA.request (49.4.2.2) may be identified by the AQM as being part of a congesting flow. CIP  
10 Congestion Detection creates a new entry in the Stream identity table and the CI Stream Table for congesting  
11 flows received on a monitored queue. A CIM may be generated from the parameters obtained with the  
12 received frame and values from the CI Peer Table entry for the source port of the received frame. The CIM is  
13 delivered to the upstream peer via the CIM Multiplexer.

14 On each EM\_UNITDATA.request, CIP Congestion Detection and its associated AQM indicate to the CIP  
15 procedures (49.4) whether a monitored or congesting queue is empty, congested, or not congested. The  
16 AQM or other means can be used to provide the queue status.

### 17 49.3.2 CIP transmission gates

18 CIP transmission gates control whether or not a queued frame can be selected for transmission by the  
19 transmission selection algorithm. The purpose of controlling a queue's availability to traffic selection is to  
20 allow the CI implementation a means to preserve order of congesting flow frames. The need to preserve  
21 order is dependent upon the transmission selection algorithm configured for the congesting and monitored  
22 queues. When the transmission selection algorithm is strict priority, the state of the transmission gate is  
23 permanently *open*. When the transmission selection algorithm is anything other than strict priority the  
24 implementation is responsible for ensuring order. An example approach is discussed in Annex W.

### 25 49.3.3 CIM Demultiplexer

26 The CIM Demultiplexer identifies CIMs received from the LAN and uses the content of the CIM PDU  
27 (49.4.3.4) to create an entry in the IEEE Std 802.1CB Stream identity table. A CIM PDU may be  
28 encapsulated by three different CIM encapsulations; layer-2, IPv4, or IPv6. Implementations supporting  
29 IPv4 and IPv6 encapsulations must be able to identify and validate IPv4 and/or IPv6 packets in the CIM  
30 Demultiplexer. The rules for validating received CIMs are specified in 49.4.3.5.

### 31 49.3.4 Congesting flow identification

32 Frames received from the LAN belonging to congesting flows are identified by the Stream identification  
33 function of IEEE Std 802.1CB. The Stream identification function provides a *stream\_handle* subparameter  
34 in the *connection\_identifier* parameter of an EM\_UNITDATA.indication for frames of congesting flows and  
35 does not provide a *stream\_handle* for frames of non-congesting flows. The presence or non-presence of the  
36 *stream\_handle* is used to match a stream filter instance in the per-stream classification and metering function  
37 to modify the frame's priority (8.6.5.2.3).

### 38 49.3.5 CIM Multiplexer

39 The CIM Multiplexer inserts CIMs generated by the CIP Congestion Detection element among frames  
40 received from the LAN. Layer-2 encapsulated CIMs (49.4.3.1) are delivered to the upstream peer through  
41 the Bridge relay. Layer-3 encapsulated CIMs (49.4.3.2 and 49.4.3.3) are routed to the upstream peer by a  
42 higher-layer routing function that is beyond the scope of this standard.

### 1 49.3.6 CI Peer Table

2 The CI Peer Table (12.33.2) contains entries for each participating immediate peer and provides the  
3 information needed to generate a CIM for transmission to the peer. The entries are indexed by port number.  
4 An entry contains the format type of the CIM needed to reach the peer as well as the addressing information  
5 needed to generate the message. This includes the MAC address to use as the destination address and  
6 optionally an IPv4 or IPv6 address. The entry provides the UDP port number to use when the CIM  
7 encapsulation is a layer-3. An entry also contains the number of bytes of the received congesting flow frame  
8 to encapsulate in the CIM PDU itself. The contents of the entry are obtained from the LLDP Congestion  
9 Isolation TLV (D.2.15) received from participating peers.

### 10 49.3.7 CI Stream Table

11 The CI Stream Table (12.33.3) contains entries for each congesting flow and has a 1:1 mapping to entries in  
12 the IEEE Std 802.1CB Stream identity table. The entries are indexed by the stream\_handle provided as a  
13 subparameter of the connection\_identifier in EM\_UNITDATA.request (49.4.2.2) invocations at the EISS.  
14 Each entry contains controlling variables (49.4.1.5) that allow an implementation to manage a congesting  
15 flow. This includes a means of identifying the congesting queue used to isolate the congesting flow. It also  
16 maintains a count of the CIMs sent on behalf of the congesting flow as well as an indication of why the entry  
17 was created or updated.

## 18 49.4 Congestion Isolation Protocol

19 Congestion isolation aware systems control forwarding elements, participate in congestion isolation  
20 protocols, and act upon the LLDP Congestion Isolation TLV as specified in this clause. This includes:

- 21 a) Variables controlling operation (49.4.1).
- 22 b) CIP procedures (49.4.2).
- 23 c) Encoding of the CIM PDU and CIM encapsulations (49.4.3).
- 24 d) LLDP Congestion Isolation TLV (49.4.4).

### 25 49.4.1 Variables controlling operation

26 The congestion isolation variables control the operation of the CI entity and the CIP entity.

#### 27 49.4.1.1 CI entity variables

28 Every congestion isolation aware system has a set of CI entity variables to control the overall operation of  
29 CI. These variables are included in the CI entity managed object (12.33.1). These include the following:

- 30 a) ciMasterEnable (49.4.1.1.1).
- 31 b) ciCIMTransmitPriority (49.4.1.1.2).
- 32 c) ciMaxFlowLife (49.4.1.1.3).

##### 33 49.4.1.1.1 ciMasterEnable

34 A boolean value specifying whether CI is enabled in this system. If ciMasterEnable is FALSE all congestion  
35 isolation activity is disabled; CIMs and LLDP Congestion Isolation TLVs are not generated and are ignored  
36 on receipt. If ciMasterEnable is TRUE the other managed objects and variables specified in the clause  
37 control the operation of CI.

##### 38 49.4.1.1.2 ciCIMTransmitPriority

39 An integer specifying the priority value to be used when transmitting CIMs from the system. The default  
40 is 6.

### 1 **49.4.1.1.3 ciMaxFlowLife**

2 An unsigned integer specifying the maximum number of centiseconds that a congesting flow entry, created  
3 by the receipt of a CIM, can remain in the CI Stream Table beyond the time indicated by the per-port  
4 per-queue variable cipNonCongestedTime (49.4.1.4.2). The default value is 100.

### 5 **49.4.1.2 CIP entity variables**

6 The following variables control the operation of a CIP:

- 7 a) cipMacAddress (49.4.1.2.1)
- 8 b) cipIPv4Address (49.4.1.2.2)
- 9 c) cipIPv6Address (49.4.1.2.3)
- 10 d) cipCIMUDPPort (49.4.1.2.4)
- 11 e) cipQueueMap[] (49.4.1.2.5)
- 12 f) cipMinHeaderOctets (49.4.1.2.6)

#### 13 **49.4.1.2.1 cipMacAddress**

14 The MAC address, belonging to the system transmitting the CIM (49.4.3), used as the source\_address of  
15 CIMs sent from the CIP.

#### 16 **49.4.1.2.2 cipIPv4Address**

17 The IPv4 address, belonging to the system transmitting the IPv4 layer-3 CIM (49.4.3.2), used as the IPv4  
18 source address in the IPv4 header (IETF RFC 791) of IPv4 layer-3 CIMs sent from the CIP. The  
19 cipIPv4Address is included in the LLDP Congestion Isolation TLV (D.2.15) to allow peers to properly  
20 generate IPv4 layer-3 CIMs that can be received by the system.

#### 21 **49.4.1.2.3 cipIPv6Address**

22 The IPv6 address, belonging to the system transmitting the IPv6 layer-3 CIM (49.4.3.3), used as the IPv6  
23 source address in the IPv6 header (IETF RFC 8200) of IPv6 layer-3 CIMs sent from the CIP. The  
24 cipIPv6Address is included in the LLDP Congestion Isolation TLV (D.2.15) to allow peers to properly  
25 generate IPv6 layer-3 CIMs that can be received by the system.

#### 26 **49.4.1.2.4 cipCIMUDPPort**

27 The destination UDP port number in the UDP header (IETF RFC 768) of IPv4 and IPv6 layer-3 CIMs sent  
28 by peers. The value is also used as the UDP source port number in layer-3 CIMs sent to peers. The UDP port  
29 number must be selected from the range of dynamic port numbers, between 49152 and 65535, as specified in  
30 IETF RFC 6335. The port number must be currently available for use by the implementation. For example,  
31 an implementation may use UDP port 58622, if it is not currently being used by any other application in the  
32 system.

#### 33 **49.4.1.2.5 cipQueueMap[]**

34 An array of integers, one entry for each traffic class, 0 through 7, specifying a value that can be translated to  
35 the numeric value of the traffic class to be used as either the congesting traffic class or the monitored traffic  
36 class for the traffic class specified by the index. The integers range in value from –8 to 8. A value of 0 in the  
37 table specifies that the traffic class is not participating in congestion isolation. A positive number specifies a  
38 traffic class for a monitored queue that is one less than the value (e.g., a value of 5 represents traffic class 4).  
39 A negative number specifies a traffic class for a congesting queue that is one less than the absolute value  
40 (e.g., a value of –4 represents traffic class 3).

41 NOTE—Configuration of the cipQueueMap[] is flexible, allowing the arrangement of multiple monitored and  
42 congesting queue sets.

1 Frames from flows that the AQM determines are causing congestion and are currently transferring through  
2 the monitored traffic class specified by the index into this table may have their priority remapped to the  
3 translated traffic class specified by the entry in the `cipQueueMap[]`. Frames from flows that have an entry in  
4 the Stream identity table have a `stream_handle` that specifies a stream filter to remap the priority to the IPV.  
5 Frames that are transferring through a congesting traffic class and do not have a `stream_handle` match on the  
6 null-handle stream filter entry to have their priority remapped to the monitored traffic class specified in the  
7 IPV.

8 The `cipQueueMap[]` is included in the LLDP Congestion Isolation TLV (D.2.15) to inform peers of the  
9 system's configuration. Mismatched configurations can be detected by comparing the queue map received in  
10 the TLV with configured `cipQueueMap[]`.

#### 11 **49.4.1.2.6 cipMinHeaderOctets**

12 The minimum number of octets that the CIP is to return in the Encapsulated MSDU field of each CIM  
13 generated. The default value is 48. The `cipMinHeaderOctets` is included in the LLDP Congestion Isolation  
14 TLV (D.2.15) to inform peers of the required minimum. The `cipMinHeaderOctets` value from peers is stored  
15 in the CI Peer Table (49.3.6) and used to generate CIMs to be transmitted to the peer.

#### 16 **49.4.1.2.7 cipMaxCIM**

17 The maximum number of times a CIM PDU will be sent for a congesting flow. The default value is 3. A  
18 larger value provides more resilience to lost CIMs, but generates more traffic on the network.

#### 19 **49.4.1.3 CIP entity per-port variables**

20 For each port in a congestion isolation aware system there is the following set of variables:

- 21 a) `ciRxPort` (49.4.1.3.1)
- 22 b) `ciAddDel` (49.4.1.3.2)

##### 23 **49.4.1.3.1 ciRxPort**

24 A local variable holding the reception port number for a congesting flow. The CI Stream Table (12.33.3) is  
25 indexed by this local variable during the construction of a CIM. The value may be loaded during an  
26 `EM_UNITDATA.request` or when entries are being removed from the CI Stream Table and IEEE Std  
27 802.1CB Stream identity table.

##### 28 **49.4.1.3.2 ciAddDel**

29 A local variable holding an enumeration `{add, delete}` that provides an indication of the reason to build and  
30 send a CIM. The Add/Del field of the CIM PDU informs the peer that a congesting flow is either being  
31 added or deleted. The `ciAddDel` variable is used by the common `buildAndSendCim()` procedure (49.4.2.5)  
32 to parameterize and properly set the Add/Del field.

#### 33 **49.4.1.4 CIP entity per-port per-traffic class variables**

34 For each port and monitored or congesting queue in a congestion isolation aware system there is the  
35 following set of variables:

- 36 a) `cipGateControl` (49.4.1.4.1)
- 37 b) `cipNonCongestedTime` (49.4.1.4.2)
- 38 c) `cipCongesting` (49.4.1.4.3)

#### 1 **49.4.1.4.1 cipGateControl**

2 Determines the state of the transmission gate for a monitored or congesting queue. There is an instance of  
3 `cipGateControl` for each queue that is participating in congestion isolation. The transmission gate allows  
4 implementations to maintain frame order when isolating a congesting flow. The value of the `cipGateControl`  
5 variable is either *open* or *closed*. It is directly tied to the state of the transmission gate of the monitored  
6 queues and the congesting queue. When the transmission selection algorithm is strict priority, the  
7 `cipGateControl` shall be *open* for all queues. Other transmission selection algorithms may require that order  
8 is maintained by controlling the values of `cipGateControl`. An example implementation approach for a  
9 traffic selection algorithm other than strict priority is described in Annex W.

#### 10 **49.4.1.4.2 cipNonCongestedTime**

11 The time (`SysUpTime`, IETF RFC 3418) at which the queue last transitioned from congested to  
12 non-congested. This timestamp is used by the background `periodicTableCleanup()` procedure (49.4.2.10) to  
13 remove stale CI Stream Table entries that were created because of the receipt of a CIM and still remain in the  
14 table for a period longer than the `ciMaxFlowLife` (49.4.1.1.3).

#### 15 **49.4.1.4.3 cipCongesting**

16 A boolean value that is set during the processing of a frame by the `EM_UNITDATA.request` (49.4.2.2)  
17 procedure. The value is set true when the AQM indicates that the monitored queue is no longer congested or  
18 the congesting queue is empty. The variable is initialized to false.

#### 19 **49.4.1.5 CIP entity per-stream variables**

20 For each `tsnStreamIdEntry` object created in the IEEE Std 802.1CB Stream identity table there is a  
21 corresponding entry in the CI Stream Table (12.33.3). The entry contains per-stream variables that identify  
22 the congesting queue for a congesting flow, count the number of CIMs that have been transmitted for the  
23 congesting flow, and register the reasons for creating or updating the `tsnStreamIdEntry` object. Each entry  
24 contains the following variables:

- 25 a) `ciStreamIdHandle` (49.4.1.5.1)
- 26 b) `ciCIMCount` (49.4.1.5.2)
- 27 c) `ciCreateTime` (49.4.1.5.3)
- 28 d) `ciStreamCreateMask` (49.4.1.5.4)
- 29 e) `ciQueueKey` (49.4.1.5.5)
- 30 f) `ciDestination_address` (49.4.1.5.6)
- 31 g) `ciSource_address` (49.4.1.5.7)
- 32 h) `ciVlan_identifier` (49.4.1.5.8)
- 33 i) `ciMsdu` (49.4.1.5.9)

#### 34 **49.4.1.5.1 ciStreamIdHandle**

35 The `stream_handle` value used to create the `tsnStreamIdEntry` object in the IEEE Std 802.1CB Stream  
36 identity table. This variable provides the 1:1 mapping of the CI Stream Table entry with the  
37 `tsnStreamIdEntry` object.

#### 38 **49.4.1.5.2 ciCIMCount**

39 An integer containing a count of the number of CIMs sent for the congesting flow. The count is reset when a  
40 frame from a congesting flow is received on a monitored queue.

### 1 **49.4.1.5.3 ciCreateTime**

2 The time (SysUpTime, IETF RFC 3418) at which the CI Stream Table entry was created.

### 3 **49.4.1.5.4 ciStreamCreateMask**

4 A 2-bit mask indicating the reason for creating or updating the CI Stream Table entry. The LSB indicates  
5 that the entry was created or updated because the AQM determined that a forwarded frame is part of a  
6 congesting flow. The MSB indicates that the entry was created or updated because of the receipt of a CIM.  
7 The ciStreamCreateMask allows an implementation to take different actions when de-isolating a congesting  
8 flow.

### 9 **49.4.1.5.5 ciQueueKey**

10 An integer that represents the unique queue identity of a congesting queue at an egress port that a congesting  
11 flow is traversing. The key is calculated by the product of the congesting traffic class number plus one and  
12 the port number. The key is used to help find all congesting flows using the same queue so the  
13 flushCongestingFlows() procedure (49.4.2.9) can efficiently remove them.

### 14 **49.4.1.5.6 ciDestination\_address**

15 A MAC address obtained from the destination\_address parameter of an EM\_UNITDATA.indication for a  
16 congesting flow or from the destination\_address field of a received CIM PDU.

### 17 **49.4.1.5.7 ciSource\_address**

18 A MAC address obtained from the source\_address parameter of an EM\_UNITDATA.indication for a  
19 congesting flow or from the source\_address field of a received CIM PDU.

### 20 **49.4.1.5.8 ciVlan\_identifier**

21 A VLAN Identifier obtained from the vlan\_identifier parameter of an EM\_UNITDATA.indication for a  
22 congesting flow or from the vlan\_identifier field of a received CIM PDU.

### 23 **49.4.1.5.9 ciMsdu**

24 An octet string containing an MSDU obtained from the mac\_service\_data\_unit parameter of an  
25 EM\_UNITDATA.indication for a congesting flow or from the Encapsulated MSDU field of a received CIM  
26 PDU.

## 27 **49.4.2 CIP procedures**

28 Congestion isolation is implemented through the procedures of a CIP. These include the following:

- 29 a) ciInitialize() (49.4.2.1)
- 30 b) EM\_UNITDATA.request (parameters) (49.4.2.2)
- 31 c) condTransmitCimAddPdu() (49.4.2.3)
- 32 d) transmitCimDelPdu() (49.4.2.4)
- 33 e) buildAndSendCim() (49.4.2.5)
- 34 f) processCimPdu() (49.4.2.6)
- 35 g) addCongestingFlow() (49.4.2.7)
- 36 h) delCongestingFlow() (49.4.2.8)
- 37 i) flushCongestingFlows() (49.4.2.9)
- 38 j) periodicTableCleanup() (49.4.2.10)

#### 1 49.4.2.1 ciInitialize()

2 Initializes CI support (8.6.5.2.3) for per-stream classification and metering (8.6.5.2) including the creation of  
3 stream filter instances and stream gate instances needed for CI operation. At initialization time the procedure  
4 performs the following:

- 5 a) For each entry in the ciQueueMap[] table do the following:
  - 6 1) If the value of the entry in ciQueueMap[] is 0, do nothing and move on to the next entry.
  - 7 2) If the value of the entry in ciQueueMap[] is positive, the index specifies a monitored queue and  
8 the value can be translated to a congesting queue. Create a stream gate and stream filter as  
9 follows:
    - 10 i) Allocate a new StreamGateInstance.
    - 11 ii) Set the StreamGateEnable attribute to TRUE.
    - 12 iii) Set the StreamGateAdminGateStates to open.
    - 13 iv) Set the StreamGateAdminIPV to the value of the entry minus one.
    - 14 v) Allocate a new StreamFilterInstance.
    - 15 vi) Set the StreamHandleSpec to the wildcard.
    - 16 vii) Set the PrioritySpec to the index of the entry.
    - 17 viii) Set the StreamGateInstanceID to the StreamGateInstance.
  - 18 3) If the value of the entry in ciQueueMap[] is negative, the index specifies a congesting queue  
19 and the value can be translated to a monitored queue. Create a stream gate and stream filter as  
20 follows:
    - 21 i) Allocate a new StreamGateInstance.
    - 22 ii) Set the StreamGateEnable attribute to TRUE.
    - 23 iii) Set the StreamGateAdminGateStates to open.
    - 24 iv) Set the StreamGateAdminIPV to the absolute value of the entry minus one.
    - 25 v) Allocate a new StreamFilterInstance.
    - 26 vi) Set the StreamHandleSpec to none.
    - 27 vii) Set the PrioritySpec to the index of the entry.
    - 28 viii) Set the StreamGateInstanceID to the StreamGateInstance.
  - 29 4) Set cipCongesting for the queue to false.

#### 30 49.4.2.2 EM\_UNITDATA.request (parameters)

31 A CIP offers an instance of the EISS (6.8) to the Queuing frames function (8.6.6). When called upon to  
32 enqueue a frame the priority parameter specifies the target queue that represents the received priority of the  
33 frame. The CIP determines if the target queue is a congesting queue or a monitored queue by indexing into  
34 the cipQueueMap[] table using the priority parameter.

35 If the cipQueueMap[priority] value is 0 then the target queue is not participating in congestion isolation and  
36 the frame can be enqueued on the target queue with no further processing.

37 If the cipQueueMap[priority] value is positive then the target queue is a monitored queue. The value from  
38 the cipQueueMap[] table determines the congesting queue that will be used for isolating congesting flows  
39 from the monitored queue. The congesting queue for this monitored queue is one less than the value of  
40 cipQueueMap[priority]

41 If the cipQueueMap[priority] value is negative then the target queue is a congesting queue. The value from  
42 the cipQueueMap[] table determines the monitored queue that will be used for de-isolating congesting flows  
43 from the congesting queue. The monitored queue for this congesting queue is one less than the absolute  
44 value of cipQueueMap[priority].

45 The CIP determines if the frame belongs to a flow that has been causing congestion by first checking for the  
46 presence of a stream\_handle parameter. Frames with the stream\_handle parameter are known to be from  
47 congesting flows. If the frame does not have a stream\_handle and the target queue is a monitored queue, the

1 CIP interacts with the AQM to determine if the frame is part of a flow that is creating congestion in the  
2 monitored queue. Newly identified congesting flows will cause entries to be created in the Stream identity  
3 table. If the frame does not have a stream\_handle and the target queue is a congesting queue, the CIP remaps  
4 the priority to the monitored queue by using the translated value from the cipQueueMap[] table.

5 Frames that have a stream\_handle parameter or have been determined by the AQM (see 49.2.1) to be  
6 creating congestion may cause a CIM to be transmitted. The conditions by which a CIM is transmitted are  
7 described in condTransmitCimAddPdu().

8 The CIP uses the same AQM for both the congesting and monitored queues to ensure consistent end-to-end  
9 congestion control for frames from a common flow that traverse both queues.

10 For each frame that is presented for queuing, the CIP performs the following:

- 11 a) Determine if the target queue is a monitored queue, a congesting queue or not participating in CI by  
12 indexing into the cipQueueMap[] table using the priority parameter and translating the contents as  
13 described above.
- 14 b) If the target queue is a monitored queue and the stream\_handle is not present, then determine if the  
15 AQM indicates the frame is from a flow causing congestion in the monitored queue.
  - 16 1) If the monitored queue is congested:
    - 17 i) Set the LSB and clear the MSB of the ciStreamCreateMask to indicate an entry is being  
18 created because congestion has been detected locally by the AQM.
    - 19 ii) Call addCongestingFlow() to create an entry in the IEEE Std 802.1CB Stream  
20 identification function and the CI Stream Table and initialize the ciCIMCount variable to  
21 0.
    - 22 iii) Call condTransmitCimAddPdu() to conditionally generate and transmit a CIM to the peer.
    - 23 iv) Modify the frame's PCP to indicate the priority of the congesting queue.
    - 24 v) Enqueue the frame on the congesting queue.
    - 25 vi) Set cipCongesting true.
  - 26 2) If the monitored queue is not congested, enqueue the frame on the monitored queue.
- 27 c) If the target queue is a monitored or a congesting queue and the stream\_handle is present, the frame  
28 is from a congesting flow. Determine from the AQM if the congesting queue is empty, congested, or  
29 not congested.
  - 30 1) If the congesting queue is empty, call flushCongestingFlows() to remove all flows from the  
31 IEEE Std 802.1CB Stream identification function and the CI Stream Table for the target queue.
  - 32 2) If the congesting queue is congested:
    - 33 i) Load the ciCIMCount variable with the value from the CI Stream Table.
    - 34 ii) Call condTransmitCimAddPdu() to conditionally generate and transmit a CIM to the peer.
  - 35 3) If the congesting queue is not congested, then optionally:
    - 36 i) Call delCongestingFlow() to remove the flow from the IEEE Std 802.1CB Stream  
37 identification function and the CI Stream Table.
    - 38 ii) Ensure the cipGateControl variable for the monitored and congesting queues are properly  
39 set to ensure ordering requirements for the transmission selection algorithm in use.
    - 40 iii) Modify the frame's PCP to indicate the priority of the monitored queue.
    - 41 iv) Enqueue the frame on the monitored queue.
  - 42 4) If the target queue is a monitored queue, reset the ciCIMCount variable in the CI Stream Table.
- 43 d) If the target queue is a congesting queue and the stream\_handle is not present, the frame is from a  
44 flow that may be congesting upstream, but is not congesting locally. The frame priority can be  
45 remapped back to the monitored queue.
  - 46 i) The PCP is modified to indicate the priority of the monitored queue.
  - 47 ii) The frame is enqueued on the monitored queue.

- 1 e) Check if the congesting queue is empty and call `flushCongestingFlows()` to remove all flows from  
2 the IEEE Std 802.1CB Stream identification function and the CI Stream Table for the congesting  
3 queue.

#### 4 **49.4.2.3 condTransmitCimAddPdu()**

5 This is called by the CIP to conditionally generate and transmit a CIM instructing the peer to add a  
6 congesting flow. A CIM will be generated and transmitted if fewer than `ciMaxCIM` messages have been  
7 sent since the `ciCIMCount` was last reset and the AQM has determined that the congesting queue is  
8 congested. The `ciCIMCount` variable is loaded prior to invoking `condTransmitCimAddPdu()`.

9 NOTE—Implementations may have additional conditions to restrict or allow the creation of CIMs for adding congesting  
10 flows without risking interoperability.

11 The procedure performs the following:

- 12 a) If the `ciCIMCount` is less than `ciMaxCIM` and the AQM indicates the congesting queue is  
13 congested then do the following:  
14 1) Set `ciAddDel` to *add*  
15 2) Call `buildAndSendCim()`

#### 16 **49.4.2.4 transmitCimDelPdu()**

17 This is called by the CIP to generate and transmit a CIM instructing the peer that a congesting flow is being  
18 removed from the IEEE Std 802.1CB Stream identity table and the CI Stream Table.

19 The procedure performs the following:

- 20 a) Set `ciAddDel` to *delete*  
21 b) Call `buildAndSendCim()`

#### 22 **49.4.2.5 buildAndSendCim()**

23 This is a common procedure shared by `condTransmitCimAddPdu()` and `transmitCimDelPdu()` to construct  
24 and send the CIM. To properly generate the CIM, the CI Peer Table must be searched to retrieve the type of  
25 CIM and the address information of the peer that will receive the CIM. There are three formats for a CIM;  
26 layer-2, IPv4, and IPv6. All of the formats encapsulate a common CIM PDU. The CIM is constructed in the  
27 space provided by the parameters of the `EM_UNITDATA.indication`. The local variables holding the  
28 parameters from an `EM_UNITDATA.request` are expected to be loaded before the procedure is invoked,  
29 whether those parameters came from an actual `EM_UNITDATA.request` or were loaded from the CI Stream  
30 Table. The local `ciAddDel` variable determines the contents of the Add/Del field of the CIM PDU. The local  
31 `ciRxPort` determines the source port of the congesting flow that is represented in the CIM.

32 The procedure performs the following:

- 33 a) Search the CI Peer Table (12.33.2) using `ciRxPort` as an index to obtain the `ciCIMType`,  
34 `ciPeerMacAddress`, and `ciPeerCIMEncapLen` for the peer. If the `ciCIMType` is `ipv4` then obtain the  
35 `ciPeerIPv4Address` and `ciPeerUDPPort` from the entry. If the `ciCIMType` is `ipv6` then obtain the  
36 `ciPeerIPv6Address` and `ciPeerUDPPort` from the entry. If the entry is not found the procedure does  
37 nothing; no further processing takes place and no CIM will be generated or transmitted.  
38 b) Fill the Version (49.4.3.4.1) field of the CIM PDU with 0.  
39 c) If `ciAddDel` is *add* then set the Add/Del bit to 1 otherwise set the Add/Del bit to 0.  
40 d) Set the `destination_address` (49.4.3.4.4) of the CIM PDU to the value of the `destination_address`.  
41 e) Set the `source_address` (49.4.3.4.5) of the CIM PDU to the value of the `source_address`.  
42 f) Set the `vlan_identifier` (49.4.3.4.6) of the CIM PDU to the value of the `vlan_identifier`.

- 1 g) Fill the Encapsulated MSDU (49.4.3.4.8) field with the first octets of the `mac_service_data_unit`.  
2 The Encapsulated MSDU field should be filled with the lesser of `ciPeerCIMEncapLen` or the length  
3 of the `mac_service_data_unit`.
- 4 h) Set the Encapsulated MSDU length (49.4.3.4.7) to the number of octets filled into the Encapsulated  
5 MSDU field.
- 6 i) The format of the CIM constructed in the `mac_service_data_unit` of the `EM_UNITDATA.indication`  
7 depends upon the `ciCIMType` variable as follows:
- 8 1) If the `ciCIMType` is l2:
- 9 i) Insert the CIM PDU EtherType (Table 49-1) encapsulation at the beginning of the  
10 `mac_service_data_unit` of the `EM_UNITDATA.indication`.
- 11 ii) Fill the Version (49.4.3.1.1) field of the layer 2 CIM encapsulation with 0.
- 12 iii) Fill the Subtype (49.4.3.1.2) field of the layer 2 CIM encapsulation with 0.
- 13 2) If the `ciCIMType` is ipv4:
- 14 i) Insert the IPv4 EtherType (Figure 49-4) encapsulation at the beginning of the  
15 `mac_service_data_unit` of the `EM_UNITDATA.indication`.
- 16 ii) Use the `ciPeerIPv4Address` as the destination IPv4 address, the `cipIPv4Address` as the  
17 source IPv4 address, and the value 17 as the IP protocol field to construct and insert an  
18 IETF RFC 791 compliant IPv4 header after the IPv4 EtherType in the  
19 `mac_service_data_unit` of the `EM_UNITDATA.indication`.
- 20 iii) Use the `ciPeerUDPPort` as the UDP destination port number and the `cipCIMUDPPort` as  
21 the source port number to construct and insert an IETF RFC 768 compliant UDP header  
22 after the IPv4 header in the `mac_service_data_unit` of the `EM_UNITDATA.indication`.
- 23 3) If the `ciCIMType` is ipv6:
- 24 i) Insert the IPv6 EtherType (Figure 49-5) encapsulation at the beginning of the  
25 `mac_service_data_unit` of the `EM_UNITDATA.indication`.
- 26 ii) Use the `ciPeerIPv6Address` as the destination IPv6 address, the `cipIPv6Address` as the  
27 source IPv6 address, and the value 17 as the next header field to construct and insert an  
28 IETF RFC 8200 compliant IPv6 header after the IPv6 EtherType in the  
29 `mac_service_data_unit` of the `EM_UNITDATA.indication`.
- 30 iii) Use the `ciPeerUDPPort` as the UDP destination port number and the `cipCIMUDPPort` as  
31 the source port number to construct and insert an IETF RFC 768 compliant UDP header  
32 after the IPv6 header in the `mac_service_data_unit` of the `EM_UNITDATA.indication`.
- 33 j) Use the `ciPeerMacAddress` as the `destination_address` of the `EM_UNITDATA.indication` for the  
34 CIM.
- 35 k) Use the `cipMacAddress` (49.4.1.2.1) as the `source_address` of the `EM_UNITDATA.indication` for  
36 the CIM.
- 37 l) Set the priority parameter of the `EM_UNITDATA.indication` for the CIM to the value of the  
38 `ciCIMTransmitPriority` (49.4.1.1.2) variable.
- 39 m) Pass the CIM as an `EM_UNITDATA.indication` to the CIM Multiplexer (49.3.5) for transmission to  
40 the peer.

#### 1 49.4.2.6 processCimPdu()

2 The CIM Demultiplexer (49.3.3) receives CIMs from peers and invokes processCimPdu() to process the  
3 CIM and either create entries in the IEEE Std 802.1CB Stream identification function and CI Stream Table  
4 or remove entries from the tables. The procedure performs the following actions upon receipt of a CIM:

- 5 a) The CIM is validated according to 49.4.3.5 and is discarded if invalid.
- 6 b) If the Add/Del bit is set do the following:
  - 7 1) Clear the LSB and set the MSB of the ciStreamCreateMask to indicate an entry is being created  
8 because of a received CIM.
  - 9 2) Extract the parameters and the Encapsulated MSDU from the CIM PDU and call  
10 addCongestingFlow().
- 11 c) If the Add/Del bit is clear then do the following:
  - 12 1) Search the CI Stream Table for an entry that matches the destination\_address, source\_address,  
13 vlan\_identifier, and Encapsulated MSDU fields of the CIM.
  - 14 2) If no entry is found, then processing is done.
  - 15 3) If the MSB of the ciStreamCreateMask is set, then clear it. Otherwise processing is done.
  - 16 4) If the LSB of the ciStreamCreateMask is set, then update the CI Stream Table entry with the  
17 updated ciStreamCreateMask and processing is done.
  - 18 5) If the LSB of the ciStreamCreateMask is clear then call delCongestingFlow().

#### 19 49.4.2.7 addCongestingFlow()

20 Registers a flow with the IEEE Std 802.1CB Stream identification function as described in 49.2.2. A  
21 tsnStreamIdEntry is created by using initialized variables and the contents of the mac\_service\_data\_unit that  
22 is obtained from the received frame or the encapsulated header of a received CIM. The set of managed  
23 objects that make up the tsnStreamIdEntry are created as follows:

- 24 a) Set the tsnStreamIdHandle object to newly allocated and unique stream\_handle.
- 25 b) Set the tsnStreamIdOutFacInputPortList include the list of all ports in the system.
- 26 c) Set the tsnStreamIdOutFacOutputPortList, tsnStreamIdInFacInputPortList, and  
27 tsnStreamIdInFacOutputPortList to null.
- 28 d) Set the tsnStreamIdIdentificationType to IP stream identification as specified in IEEE Std 802.1CB.
- 29 e) Set the tsnStreamIdParameters for an IP stream identification type as follows:
  - 30 1) Set the tsnCpeIpIdDestMac to the destination\_address of the received frame or parameter from  
31 the CIM.
  - 32 2) Set the tsnCpeIpIdTagged to the value **all** as specified in IEEE Std 802.1CB.
  - 33 3) Set the tsnCpeIpIdVlan to the vlan\_identifier of the received frame or parameter from the CIM.
  - 34 4) Set the tsnCpeIpIdIpSource to the IPv4 (IETF RFC 791) or IPv6 (IETF RFC 8200) source  
35 address parameter that is contained within the mac\_service\_data\_unit.
  - 36 5) Set the tsnCpeIpIdIpDestination to the IPv4 (IETF RFC 791) or IPv6 (IETF RFC 8200)  
37 destination address parameter that is contained within the mac\_service\_data\_unit.
  - 38 6) Set the tsnCpeIpIdDscp to a value of 64 decimal to ignore the DSCP (IETF RFC 2474) code  
39 point when matching received frames.
  - 40 7) Set the tsnCpeIpIdNextProtocol to UDP (IETF RFC 768) if the mac\_service\_data\_unit  
41 contains a UDP packet, TCP (IETF RFC 793) if it contains a TCP packet, or SCTP (IETF RFC  
42 4960) if it contains an SCTP packet. If the mac\_service\_data\_unit contains another  
43 non-supported IP protocol by the implementation then set the tsnCpeIpIdNextProtocol to none  
44 and the tsnCpeIpIdSourcePort and tsnCpeIpIdDestinationPort will be ignored.
  - 45 8) Set the tsnCpeIpIdSourcePort to the UDP, TCP, or SCTP source port number from the  
46 mac\_service\_data\_unit. Set the tsnCpeIpIdSourcePort to 0 if the tsnCpeIpIdNextProtocol field  
47 is none.

- 1        9) Set the `tsnCpeIpIdDestinationPort` to the UDP, TCP, or SCTP destination port number from the  
2        `mac_service_data_unit`. Set the `tsnCpeIpIdDestinationPort` to 0 if the `tsnCpeIpIdNextProtocol`  
3        field is none.
- 4    f) Write the `tsnStreamIdEntry` to the IEEE Std 802.1CB Stream identity table using the specified  
5        management operations.
- 6    g) Create a new entry in the CI Stream Table:
  - 7        1) Set the entry `ciStreamHandleId` index to the `stream_handle`.
  - 8        2) Set the entry `ciCIMCount` to 0.
  - 9        3) Set the entry `ciStreamCreateMask` to the variable `ciStreamCreateMask`.
  - 10       4) Set the entry `ciQueueKey` to the product of the congesting queue plus one and the port number  
11       that the queue is supporting.
  - 12       5) Set the entry `ciDestination_address` to the `destination_address`.
  - 13       6) Set the entry `ciSource_address` to the `source_address`.
  - 14       7) Set the entry `ciVlan_identifier` to the `vlan_identifier`.
  - 15       8) Fill the entry `ciMsdu` with the first octets of the `mac_service_data_unit`. The number of octets  
16       to fill the `ciMsdu` attribute with is determined by the lesser of `ciPeerCIMEncapLen` or the  
17       length of the `mac_service_data_unit`.
  - 18       9) Set the entry `ciCreateTime` to `sysUpTime` as specified by IETF RFC 3418.

#### 19 **49.4.2.8 delCongestingFlow()**

20 Removes entries from the IEEE Std 802.1CB Stream identification function and the CI Stream Table as  
21 discussed in 49.2.6. The procedure performs the following:

- 22    a) Load the `destination_address`, `source_address`, `vlan_identifier`, and `mac_service_data_unit`  
23       parameters from the entry `ciDestination_address`, `ciSource_address`, `ciVlan_identifier`, and `ciMsdu`,  
24       respectively.
- 25    b) Call `transmitCimDelPdu()` to inform the peer that a congesting flow is no longer congesting.
- 26    c) Set the `tsnStreamIdHandle` object to the `stream_handle` parameter of the frame triggering the  
27       deletion.
- 28    d) Remove the `tsnStreamIdEntry` associated with the `tsnStreamIdHandle` in the IEEE Std 802.1CB  
29       Stream identification function.
- 30    e) Remove the CI Stream Table entry.
- 31    f) if `cipCongesting` is true, set `cipCongesting` false and set `cipNonCongestedTime` to `sysUpTime`.

#### 32 **49.4.2.9 flushCongestingFlows()**

33 Removes all entries from the IEEE Std 802.1CB Stream identification function that were not created  
34 because of the receipt of a CIM and are associated with the current congesting queue at the egress port as  
35 discussed in 49.2.6. The procedure performs the following:

- 36    a) Calculate the `ciQueueKey` by taking the product of the congesting traffic class plus one and the  
37       egress port number.
- 38    b) For each entry in the CI Stream Table with the same `ciQueueKey` and the MSB of the `ciCreateMask`  
39       in the entry is not set:
  - 40        1) Load the `destination_address`, `source_address`, `vlan_identifier`, and `mac_service_data_unit`  
41        parameters from the entry `ciDestination_address`, `ciSource_address`, `ciVlan_identifier`, and  
42        `ciMsdu`, respectively.
  - 43        2) Call `transmitCimDelPdu()` to inform the peer that a congesting flow is no longer congesting.
  - 44        3) Set the `tsnStreamIdHandle` object to the `ciStreamIdHandle`.
  - 45        4) Remove the `tsnStreamIdEntry` associated with the `tsnStreamIdHandle` in the IEEE Std 802.1CB  
46        Stream identification function.
  - 47        5) Remove the CI Stream Table entry.

- 1 c) if `cipCongesting` is true, set `cipCongesting` false and set `cipNonCongestedTime` to `sysUpTime`.

#### 2 49.4.2.10 `periodicTableCleanup()`

3 A background procedure that calculates the number of centiseconds between the creation time of a CI  
4 Stream Table entry (49.4.1.5.3) and the `cipNonCongestedTime` (49.4.1.4.2), and removes any entries with  
5 only the MSB of the `ciStreamCreateMask` (49.4.1.5.4) set that have a calculated value greater than  
6 `ciMaxFlowLife` (49.4.1.1.3). The procedure should be invoked at least once every `ciMaxFlowLife` time  
7 intervals. The procedure performs the following:

- 8 a) For each entry in the CI Stream Table with the MSB set and the LSB clear in the  
9 `ciStreamCreateMask`:
- 10 1) Calculate the difference between the `cipNonCongestedTime` for the queue specified by the  
11 `ciQueueKey` and the entry `ciCreateTime`.
  - 12 2) If the difference is greater than `ciMaxFlowLife`:
    - 13 i) Load the `destination_address`, `source_address`, `vlan_identifier`, and `mac_service_data_unit`  
14 parameters from the entry `ciDestination_address`, `ciSource_address`, `ciVlan_identifier`, and  
15 `ciMsdu`, respectively.
    - 16 ii) Call `transmitCimDelPdu()` to inform the peer that a congesting flow is no longer  
17 congesting.
    - 18 iii) Set the `tsnStreamIdHandle` object to the `ciStreamIdHandle`.
    - 19 iv) Remove the `tsnStreamIdEntry` associated with the `tsnStreamIdHandle` in the IEEE Std  
20 802.1CB Stream identification function.
    - 21 v) Remove the CI Stream Table entry.

#### 22 49.4.3 Encoding of the CIM PDU

23 This clause specifies the method of encoding Congestion Isolation Message (CIM) PDUs. There are three  
24 ways of encapsulating CIM PDUs; a layer-2 CIM PDU encapsulation that can be delivered to peers via the  
25 Bridge relay and IPv4 and IPv6 layer-3 CIM PDU encapsulations that can be delivered to peers via a higher  
26 layer entity above Bridge relay such as a router. All CIMs contain an integral number of octets.

27 The octets in a Congestion Isolation Message PDU are numbered starting from 1 and increasing in the order  
28 they are put into the MSDU that accompanies a request to or indication from the instance of the MAC  
29 Internal Sublayer Service (ISS or EISS) used by a congestion isolation entity. The bits in an octet are  
30 numbered from 1 to 8 in order of increasing bit significance, where 1 is the LSB in the octet.

31 Where octets and bits within a Congestion Isolation Message PDU are represented using a diagram, octets  
32 shown higher on the page than subsequent octets and octets shown to the left of subsequent octets at the  
33 same height on the page are lower numbered; bits shown to the left of other bits within the same octet are  
34 higher numbered.

35 Where two or more consecutive octets are represented as hexadecimal values, lower numbered octet(s) are  
36 shown to the left and each octet following the first is preceded by a hyphen, for example,  
37 01-80-C2-00-00-00. When consecutive octets are used to encode a binary number, the lower octet number  
38 has the more significant value. When consecutive bits within an octet are used to encode a binary number,  
39 the higher bit number has the most significant value. When bits within consecutive octets are used to encode  
40 a binary number, the lower octet number composes the more significant bits of the number. A flag is  
41 encoded as a single bit, and is set (TRUE) if the bit takes the value 1, and clear (FALSE) otherwise. The  
42 remaining bits within the octet can be used to encode other protocol fields.

### 49.4.3.1 Layer-2 CIM PDU encapsulation

The means for identifying layer-2 encapsulated CIM PDUs consists of two octets containing the EtherType value shown (in hexadecimal notation) in Table 49-1.

**Table 49-1—Congestion Isolation Message EtherType**

| Name                                           | Value |
|------------------------------------------------|-------|
| IEEE 802.1Q Congestion Isolation Message (CIM) | 89-A2 |

The layer-2 CIM PDU encapsulation is shown in Figure 49-3.

**Figure 49-3—Layer-2 CIM Encapsulation**

#### 49.4.3.1.1 Version

This field, 4 bits in length, shall be transmitted with the value 0 in this standard. If two Version fields are interpreted as unsigned binary numbers, the greater identifies the more recently defined Version. The Version field occupies the most significant bits of the first octet of the layer-2 CIM encapsulation.

#### 49.4.3.1.2 Subtype

This field, 4 bits in length, shall be transmitted with the value 0 to indicate an encapsulated CIM PDU. The Subtype field occupies the least significant 4 bits of the first octet of the layer-2 CIM encapsulation.

### 49.4.3.2 IPv4 layer-3 CIM PDU encapsulation

The means of identifying IPv4 layer-3 encapsulated CIM PDUs consist of 2 octets containing the EtherType value for IPv4 packets (08-00) as well as the associated IPv4 header decoding for a UDP datagram carrying the CIM PDU. The encoding of an IPv4 header is defined in IETF RFC 791. IP options are not included in the IPv4 layer-3 encapsulated CIM PDU. The IP protocol field in the IPv4 header consists of 1 octet and identifies the UDP datagram with the value 17. The encoding of a UDP header is defined in IETF RFC 768. The destination port field of the UDP header consists of 2 octets and identifies the encapsulated CIM PDU with the value from the ciPeerUDPPort field of the CI Peer Table (12.33.2) for the row associated with the port of the receiving upstream peer. The source port field of the UDP header is the value of the cipCIMUDPPort variable. The IPv4 encapsulation is shown in Figure 49-4.

**Figure 49-4—IPv4 layer-3 CIM Encapsulation**

### 49.4.3.3 IPv6 layer-3 CIM PDU encapsulation

The means of identifying IPv6 layer-3 encapsulated CIM PDUs consist of 2 octets containing the EtherType value for IPv6 packets (86-DD) as well as the associated IPv6 header decoding for a UDP datagram carrying the CIM PDU. The encoding of an IPv6 header is defined in IETF RFC 8200. IPv6 Extension Headers are not used in the IPv6 layer-3 encapsulated CIM PDU. The next header field in the IPv6 headers indicates the upper layer protocol field and consists of 1 octet identifying the UDP datagram with the value 17. The encoding of a UDP header is defined in RFC 768. The destination port field of the UDP header consists of 2 octets and identifies the encapsulated CIM PDU with the value from the ciPeerUDPPort field of the CI Peer Table (12.33.2) for the row associated with the port of the receiving upstream peer. The source port field of the UDP header is the value of the cipCIMUDPPort variable. The IPv6 encapsulation is shown in Figure 49-5.

Figure 49-5—IPv6 layer-3 CIM Encapsulation

### 49.4.3.4 Congestion Isolation Message PDU format

The format of a Congestion Isolation Message (CIM) PDU is illustrated in Figure 49-6.

Figure 49-6—CIM PDU

#### 49.4.3.4.1 Version

This field, 4 bits in length, shall be transmitted with the value 0 in this standard. If two Version fields are interpreted as unsigned binary numbers, the greater identifies the more recently defined Version. The Version field occupies the most significant bits of the first octet of the CIM PDU.

#### 49.4.3.4.2 Reserved

This field, 3 bits in length, shall be transmitted as 0 and ignored on receipt.

#### 49.4.3.4.3 Add/Del

This field, 1 bit in length, instructs the peer to add a congesting flow entry to the IEEE Std 802.1CB Stream identity table and the CI Stream Table, or to remove an entry. When the bit is set, the peer is instructed to add, and when the bit is clear, the peer is instructed to delete. The Add/Del bit occupies the least significant bit of the first octet of the CIM PDU.

#### 49.4.3.4.4 destination\_address

This field, 6 octets in length, contains the destination MAC address of the frame triggering the transmission of this CIM.

#### 1 **49.4.3.4.5 source\_address**

2 This field, 6 octets in length, contains the source MAC address of the frame triggering the transmission of  
3 this CIM.

#### 4 **49.4.3.4.6 vlan\_identifier**

5 This field, 12 bits in length, contains the VLAN Identifier for the frame triggering the transmission of this  
6 CIM.

#### 7 **49.4.3.4.7 Encapsulated MSDU length**

8 This field, 2 octets in length, contains the number of octets returned in the Encapsulated MSDU field. The  
9 minimum value is 48. The maximum value is 512.

#### 10 **49.4.3.4.8 Encapsulated MSDU**

11 This field, a maximum of 512 octets in length, contains the initial octets of the mac\_service\_data\_unit of the  
12 frame that triggered the transmission of this CIM.

#### 13 **49.4.3.5 CIM Validation**

14 A CIM PDU received by a CIM Demultiplexer (49.3.3) shall be considered invalid and be discarded if:

- 15 a) There are fewer than 48 octets in the mac\_service\_data\_unit or greater than 512.
- 16 b) The Encapsulated MSDU length is less than 48 or greater than 512.

17 The following condition shall not cause a received CIM PDU to be considered invalid:

- 18 a) There are nonzero bits in the Version (49.4.3.4.1) field.

#### 19 **49.4.4 LLDP Congestion Isolation TLV**

20 The Congestion Isolation TLV (D.2.15) is used to advertise support for Congestion Isolation to peers on the  
21 network. It informs the peers of the configuration of local monitored queues and the congesting queue in  
22 order to detect potential misconfiguration. It also advertises the desired length of the encapsulated headers  
23 sent in a CIM. The source address of a received LLDPDU is used to populate the CI Peer Table (49.3.6) in  
24 order to properly form a CIM.

#### 25 **49.4.4.1 LLDP Congestion Isolation TLV procedures**

26 When the congestion isolation aware LLDP agent detects a change in the set of TLVs advertised by a peer it  
27 will invoke the relevant LLDP TLV procedures to add or delete entries in the CI Peer Table (12.33.2). The  
28 congestion isolation TLV procedures include:

- 29 a) addCiPeer() (49.4.4.1.1)
- 30 b) delCiPeer() (49.4.4.1.2)

#### 1 49.4.4.1.1 addCiPeer()

2 This creates or updates a CI Peer Table entry. The entry is indexed by the port number of the received  
3 LLDPDU. The procedure performs the following:

- 4 a) Set the table index to the port of the received LLDPDU.
- 5 b) Set the ciPeerMacAddress to the MAC Address field (D.2.15.5) of the Congestion Isolation TLV.
- 6 c) If the Address Family field (D.2.15.7) of the Congestion Isolation TLV is 1, set the  
7 ciPeerIPv4Address to the IP Address field (D.2.15.8) of the Congestion Isolation TLV.
- 8 d) If the Address Family field (D.2.15.7) of the Congestion Isolation TLV is 2, set the  
9 ciPeerIPv6Address to the IP Address field (D.2.15.8) of the Congestion Isolation TLV.
- 10 e) Set the ciPeerUDPPort to the UDP Port Number field (D.2.15.6) of the Congestion Isolation TLV.
- 11 f) Set the ciPeerCIMEncapLen to the CIM Encap Length field (D.2.15.4) of the Congestion Isolation  
12 TLV.
- 13 g) Write the CI Peer Table entry into the CI Peer Table at the table index.

#### 14 49.4.4.1.2 delCiPeer()

15 This deletes a CI Peer Table entry. The entry is indexed by the port number of the received LLDPDU that  
16 indicates a congestion isolation peer is no longer present or enabled. The procedure performs the following:

- 17 a) Set the table index to the port where the missing or disabled CI peer is detected.
- 18 b) Delete the CI Peer Table entry at the table index.

### 19 49.5 Topology Recognition

20 Bridges, routers, and end stations in the data center network can determine their level and port orientation  
21 within the topology through the use of the LLDP Topology Recognition TLV (D.2.16) and the manipulation  
22 of associated managed objects. The level in the topology is relative to non-relay end stations or servers at the  
23 edge of the network. Non-relay end stations or servers are at level 0. Bridges or routers attached to non-relay  
24 end stations or servers are at level 1 or higher. Virtualization environments, including those that support an  
25 edge relay defined by this standard (Clause 40), are end stations that contain a relay and appear at level 1 or  
26 higher in the topology. The virtual stations within the virtualization environment appear at level 0.

27 The systems can determine their level in the topology and the receiving port's orientation by examining the  
28 current state of the Topology Recognition (TR) variables and manipulating them based on the received  
29 values in the LLDP Topology Recognition TLV. This clause specifies how to determine a system's level and  
30 a port's orientation within the topology. It includes:

- 31 a) TR theory of operation (49.5.1)
- 32 b) TR variables controlling operation (49.5.2)
- 33 c) TR procedures (49.5.3)

#### 34 49.5.1 TR theory of operation

35 The TR functionality is supported by a set of procedures and controlling variables that map to attributes of  
36 the LLDP Topology Recognition TLV. Changes to the controlling variables will update the associated  
37 objects in the IEEE 802.1/LLDP extension MIB (D.5) and the trSet() procedure defined in this clause will  
38 cause the transmission of an LLDPDU to occur by invoking the somethingChangedLocal() procedure  
39 defined in IEEE Std 802.1AB. When attributes of a received LLDP Topology Recognition TLV change, the  
40 somethingChangedRemote() procedure in IEEE Std 802.1AB is invoked and control is passed to the  
41 trUpdate() procedure to process the changes. The TR procedures that act upon the changes ensure that the  
42 values of the controlling variables converge to a set of consistent values that represent the topology level and  
43 port orientation of all participating devices in the network.

1 The LLDP Topology Recognition TLV contains three attributes that enable the recognition process; the  
2 device type, the currently known topology level, and the currently known port orientation. The device type  
3 includes non-relay end stations or servers, Bridges, and routers. The topology level attribute contains the  
4 level number (0 through 254) or the value of unknown (255). The port orientation indicates whether the port  
5 is facing an *uplink*, *downlink*, *crosslink*, or whether the orientation is *unknown*. The trDeviceType variable  
6 holds the device type of a system and is a known factory setting of the device. The initial value of the level  
7 is held in the trLevel variable and the initial value of the port orientation is held in the trPortOrientation  
8 variable. These values are known by non-relay end stations or servers because they are at the edge of the  
9 network and are always at level 0 with a port orientation of *uplink*. Bridges and routers initially do not know  
10 their level or port orientation, but will recognize them when they receive LLDP Topology Recognition TLVs  
11 from peers that have non-relay end stations or servers attached. There is a single trLevel variable for the  
12 system, but each port contains a trPortOrientation. As TLVs are exchanged and changes are processed by the  
13 procedures, the contents of trLevel and trPortOrientation are updated to converge upon the representation of  
14 the stable state of the active topology.

## 15 49.5.2 TR variables controlling operation

16 The TR variables controlling operation hold the contents of attributes sent in the LLDP Topology  
17 Recognition TLV and can be updated by the TR procedures. The TR variables include:

- 18 a) trDeviceType (49.5.2.1)
- 19 b) trLevel (49.5.2.2)
- 20 c) trPortOrientation (49.5.2.3)

### 21 49.5.2.1 trDeviceType

22 The trDeviceType is a read-only variable that contains the contents of the Device Type field of the LLDP  
23 Topology Recognition TLV. The possible values of the trDeviceType are assigned as a factory setting and  
24 are specified in Table D-14.

### 25 49.5.2.2 trLevel

26 A single octet integer holding the currently known level of the system in the topology. Non-relay end  
27 stations or servers shall set this variable to 0. Other systems shall initialize this variable to 255 indicating  
28 unknown and can set the variable to values between 1 and 254 as determined by the TR procedures (49.5.3).  
29 The content of the trLevel variable is used for the Topology Level field of the LLDP Topology Recognition  
30 TLV.

### 31 49.5.2.3 trPortOrientation

32 Each port in a participating system has a trPortOrientation variable that holds the contents of the currently  
33 known Port Orientation of the LLDP Topology Recognition TLV. The possible values of the  
34 trPortOrientation variable are specified in Table D-15. Non-relay end stations or servers shall set the  
35 trPortOrientation variable to *uplink*. Other systems shall initialize this variable to *unknown* and will update  
36 the variable to either *uplink*, *downlink*, or *crosslink* as determined by the TR procedures (49.5.3).

## 37 49.5.3 TR procedures

38 The TR procedures process changes and cause the transmission of LLDP Topology Recognition TLVs. The  
39 procedures modify the TR variables and implement the algorithm that allows topology level and port  
40 orientation recognition to converge upon a stable set of variables in the topology. The procedures include:

- 41 a) trInit() (49.5.3.1)
- 42 b) trSet() (49.5.3.2)
- 43 c) trUpdate() (49.5.3.3)

### 1 49.5.3.1 trInit()

2 The trInit() procedure initializes the controlling variables to a known state after system initialization or a  
3 restart of the TR functionality. The procedure performs the following:

- 4 a) If trDeviceType is 0, specifying a non-relay end station or server then:
  - 5 1) Set trLevel to 0.
  - 6 2) Set trPortOrientation to *uplink*.
- 7 b) If trDeviceType is not 0:
  - 8 1) Set trLevel to 255, specifying *unknown*.
  - 9 2) Set trPortOrientation to 255, specifying *unknown*.
- 10 c) Call trSet() to cause the transmission of an LLDPDU to peers.

### 11 49.5.3.2 trSet()

12 This calls the somethingChangedLocal() procedure defined in IEEE Std 802.1AB, which causes the  
13 transmission of an LLDPDU. The trLevel and trPortOrientation variables map to objects in the IEEE  
14 802.1/LLDP extension MIB (D.5). A change to the single system wide trLevel variable causes the  
15 transmission of an LLDPDU on each participating port. A change to the per-port trPortOrientation variable  
16 causes the transmission of an LLDPDU on the associated port.

### 17 49.5.3.3 trUpdate()

18 The trUpdate() procedure is invoked when the somethingChangedRemote() procedure, defined in IEEE Std  
19 802.1AB, determines that fields of a received LLDP Topology Recognition TLV have changed. The  
20 procedure is responsible for updating the local TR variables and calling trSet() according to the following  
21 algorithm:

- 22 a) If trDeviceType is 0, the receiving system is a non-relay end station or server and no action is  
23 required. The procedure exits.
- 24 b) If trDeviceType is not 0, the following steps are taken depending upon the current state of trLevel  
25 and trPortOrientation for the receiving port:
  - 26 1) If the received Topology Level is *unknown*, the peer is not providing additional information and  
27 no further action is required and the procedure exits.
  - 28 2) If the received Topology Level is known with a value of L, where L is the current value of  
29 trLevel:
    - 30 i) If trPortOrientation is *crosslink*, no further action is required and the procedure exits.
    - 31 ii) Set trPortOrientation of the receiving port to *crosslink*.
  - 32 3) If the received Topology Level is known with a value of L + 1, where L is the current value of  
33 trLevel:
    - 34 i) If trPortOrientation is *uplink*, no further action is required and the procedure exits.
    - 35 ii) Set trPortOrientation of the receiving port to *uplink*.
  - 36 4) If the received Topology Level is known with a value of L – 1, where L is the current value of  
37 trLevel:
    - 38 i) If trPortOrientation is *downlink*, no further action is required and the procedure exits.
    - 39 ii) Set trPortOrientation of the receiving port to *downlink*.
  - 40 5) If the received Topology Level is known and is less than trLevel – 1 or trLevel is *unknown*:
    - 41 i) Set trLevel to the received Topology Level plus one.
    - 42 ii) Set trPortOrientation of the receiving port to *downlink*.
    - 43 iii) Set trPortOrientation of all other ports to *unknown*.
  - 44 6) Call trSet().

45

## 50. PBBN Auto Attach

When a C-VLAN or S-VLAN aware system is connected to a Provider Backbone Bridged Network (PBBN), the Backbone Edge Bridge's (BEB's) mapping of the Backbone Service Instance Identifiers (I-SIDs) to the C-VLAN or S-VLAN Identifiers (C-VIDs or S-VIDs) used by the system needs to be configured. This clause specifies an Auto Attach Protocol (AAP) that runs over the Link Layer Discovery Protocol (LLDP, IEEE Std 802.1AB) and allows Auto Attach capable devices (AADs) and BEBs (AABs) to automate this configuration. Clause 12 (Bridge Management) and Clause 17 (Management Information Base) specify supporting management functionality, and Annex D specifies LLDP TLVs and TLV management for PBBN Auto Attach.

### 50.1 Overview

In order to automate the attachment of Auto Attach Devices (AADs) to an Auto Attach BEB (AAB), the Auto Attach Protocol (AAP) is used. The AAP, which runs over LLDP, avoids manual configuration by mapping C-VIDs or S-VIDs to I-SIDs to establish a C-VLAN or S-VLAN to BSI mapping at the AAB. The AAP is only supported over a point-to-point single peer-to-peer topology.

Figure 50-1 depicts the Auto Attach architectural framework model that allows an AAD to communicate VLAN to BSI mapping requests for attachment over a PBBN.

Figure 50-1—PBBN Auto Attach model

The conceptual example in Figure 50-1 depicts the process where an AAD end station or Bridge uses AAP running over LLDP to communicate the need to connect a C-VLAN to the appropriate BSI via the AAB. LLDP agents exchange IEEE 802.1 Organizationally Specific TLVs (D.2.17, D.2.18) to automate VID to I-SID assignment and registration.

An AAD is an end station, C-VLAN Bridge, S-VLAN Bridge, or MAC Bridge that advertises desired C-VID or S-VID to I-SID assignments using the PBBN Auto Attach System TLV (D.2.17) and PBBN Auto Attach Assignment TLV (D.2.18).

An AAB is a BEB along with C-VLAN components that manages and maintains C-VID or S-VID to I-SID assignments used to attach AADs. An AAB uses Auto Attach System and Auto Attach Assignment TLVs to activate C-VID or S-VID to I-SID assignments advertised by the Auto Attach Assignment TLVs.

The AAP operates between an AAB and an AAD port. The AAP controls the exchange of Auto Attach TLVs, and configuration of VLAN and BSI mappings between the participating systems.

1 The AAP invokes LLDP when there is a change to an Auto Attach TLV by invoking the  
2 SomethingChangedLocal() procedure, specified by IEEE Std 802.1AB, causing transmission to a peer AAS.  
3 Likewise, an AAS is invoked by LLDP when there is an update to an Auto Attach TLV triggering the  
4 SomethingChangedRemote() procedure, specified by IEEE Std 802.1AB.

5 Figure 50-2 depicts the Auto Attach functions that invoke the base LLDP transmission and reception of  
6 LLDPDUs. The LLDP state machines are defined in Clause 9 of IEEE Std 802.1AB-2016.

**Figure 50-2—PBBN Auto Attach functions diagram**

## 7 50.2 Service interfaces

8 An AAB provides two types of service interface, one for S-tagged service and another for C-tagged service.  
9 Which of these interfaces is selected is determined by the AAD system type requesting attachment. If the  
10 AAD system type is S-VLAN aware AAD, then the AAB provides an S-tagged service interface and all  
11 mappings within the assignment TLV are for S-VID to I-SID. For all other AAD types, a C-tagged service  
12 interface is provided and all mappings within the assignment TLV are for C-VID to I-SID.

### 13 50.2.1 S-tagged service interface

14 The S-tagged service interface maps a service instance from a Provider Bridged Network (PBN), identified  
15 by an S-VID, to a backbone service instance on the PBBN, identified by an I-SID. The S-tagged service  
16 interface performs a one-to-one mapping of S-VIDs to I-SIDs. Frames that are mapped to the I-SID are  
17 carried over the PBBN while frames that are not mapped to an I-SID are not carried over the PBBN.

18 An S-tagged service interface is provided by an AAB over a Customer Network Port provided by the AAB's  
19 I-component. The S-tagged interface does not carry the S-TAG over the PBBN. The DEI and PCP bits are  
20 regenerated on ingress and are then carried in the I-DEI and I-PCP bits in the I-TAG across the PBBN. On  
21 egress to an S-tagged interface, the S-TAG can be deduced from the I-TAG received from the PBBN (the  
22 I-SID is mapped to an S-VID, the I-DEI and I-PCP bits are regenerated and then carried in the DEI and PCP  
23 bits).

## 1 50.2.2 C-tagged service interface

2 The C-tagged service interface maps a service instance from a Customer Bridged Network (CBN), identified  
3 by a C-VID, to a backbone service instance on the PBBN, identified by an I-SID. The C-tagged service  
4 interface performs a one-to-one mapping of C-VIDs to I-SIDs. Frames that are mapped to the I-SID are  
5 carried over the PBBN while frames that are not mapped to an I-SID are not carried over the PBBN.

6 A C-tagged service interface is provided by an AAB over a Customer Edge Port (CEP) as illustrated by  
7 Figure 50-3. The C-tagged interface does not carry the C-TAG over the PBBN. The DEI and PCP bits are  
8 regenerated on ingress and are then carried in the I-DEI and I-PCP bits in the I-TAG across the PBBN. On  
9 egress to a C-tagged interface, the C-TAG can be deduced from the I-TAG received from the PBBN (the  
10 I-SID is mapped to a C-VID, the I-DEI and I-PCP bits are regenerated and carried in the DEI and PCP bits).

11 Each of the C-VLAN components used to provide CEP service at the edge of an AAB is composed of a  
12 single CEP and a single Provider Edge Port (PEP) for each service instance that can be provided through that  
13 CEP. Each PEP is connected within the AAB, as specified in 6.14, to a distinct CNP on the I-component.  
14 Each C-VLAN component implements RSTP, with the enhancements to support CEPs, as specified in 13.41.

15 NOTE 1—The restriction that each CBN C-VLAN map to a single backbone service instance on the PBBN allows the  
16 CBN equipment receiving frames to correctly identify the service instance used to deliver that frame and prevents the  
17 configuration of the I-component to create a multi-point service from point-to-point service instances, which could result  
18 in the creation of data loops. The backbone provider can offer a multi-point service through appropriate configuration of  
19 the B-VLAN component.

20 Figure 50-3 illustrates a CBN attached to a PBBN using a C-tagged service interface. The customer network  
21 uses C-VLAN aware end stations or Bridges connecting to the PBBN. The PBBN in turn is composed of  
22 AABs or BEBs interfacing to the customer Provider Bridges and BCBs used to forward frames between the  
23 AABs or BEBs.

Figure 50-3—PBBN Auto Attach for customer networks

1 Customer VLAN unaware Bridges and MAC relay end station equipment can connect to Customer Network  
2 Ports (CNPs) using an unprotected port-based service interface (25.3).

3 Service attachment requests from VLAN unaware (untagged) AADs send an assignment TLV with one  
4 VID/I-SID assignment to the AAB. The port-based service interface on the AAB uses the specified VID to  
5 update port VLAN membership used by the CNP to map the VID to an I-component.

6 A Port-based service interface allows a single mapping instance of an untagged service to an I-SID.

7 NOTE 2—An AAB includes both BEB and Provider Edge Bridge components. In particular, an AAB supports a  
8 C-tagged service interface (15.4) for attachment to a CBN by including a C-VLAN component with PEPs that connect to  
9 the CNPs of an I-component.

## 10 50.3 State machine overview

11 The AAP is specified by the external behavior indicated by the AAD state machine in 50.6 and the AAB  
12 state machine in 50.7. These AAP state machines operate over LLDP on a point-to-point single peer-to-peer  
13 topology. Each port enabled for PBBN Auto Attach runs an independent copy of the AAP.

14 When Auto Attach is enabled on a port, the AAP begins to write and read information to the local system  
15 LLDP database. The initial process for an AAS is to write system information into the local LLDP database.  
16 Information written into the LLDP database is transmitted on the port within the PBBN Auto Attach System  
17 TLV in the next LLDPDU interval. Once an AAS has learned its neighbors and formed an association with a  
18 neighboring AAS, the AAD can update the local LLDP database with assignment mappings that are  
19 transmitted on the port within the PBBN Auto Attach Assignment TLV. The AAB receives the assignment  
20 mappings advertised by the AAD in the remote LLDP database. When the AAB receives new VID/I-SID  
21 assignments from the AAD it determines if it can activate them. The AAB then updates its local database  
22 with the VID/I-SID pairs from the AAD and indicates the status as pending, active, or rejected-with reasons.  
23 For rejected assignments the AAB supplies some further information on the cause for the rejection.

24 The AAP state machine diagrams (50.6, 50.7) specify state transitions based on changes to the local  
25 structures aaRemSysTlv and aaRemAsgnsTlv. These structures are updated whenever the LLDP routine  
26 SomethingChangedRemote() calls the Auto Attach LLDP call back procedure (50.5.16). The structure  
27 aaRemSysTlv reflects the current PBBN Auto Attach System TLV within the remote LLDP database,  
28 however transformed to machine local byte and bit order. The structure aaRemAsgnsTlv reflects the current  
29 PBBN Auto Attach Assignment TLV within the remote LLDP database, however transformed to machine  
30 local byte and bit order. If no remote database is present, or if either Auto Attach TLV is absent in the remote  
31 database, then aaRemSysTlv and(or) aaRemAsgnsTlv is set to NULL.

32 When a system TLV (D.2.17) is received, the AAS enters the VALIDATE\_REMOTE\_ASSOCIATION state  
33 to determine whether an association can be formed with the AAS neighbor.

34 The following actions are performed by the state machine to validate an association:

- 35 — For an AAS verify this port has a point-to-point single peer-to-peer topology on this port by
- 36 verifying there is only a single remote LLDP database
- 37 — For an AAS verify there is only a single system TLV in the remote database
- 38 — For an AAD verify the assoc state of the remote system is READY-TO-ASSOC
- 39 — For an AAD verify the remote system type is AAB
- 40 — For an AAD verify the AAB tagging matches the AAD
- 41 — For an AAB verify the remote system type is AAD
- 42 — For an AAB verify the AAD tagging is supported and indicated in the AAB system TLV

1 If there is an error validating the remote system, such as a system type mismatch,  
2 VALIDATE\_REMOTE\_ASSOCIATION continues to check any received system TLVs until an error free  
3 configuration is detected.

4 Once the system TLV validation has completed, the AAD verifies if it already has an active association on a  
5 different port. If no other association is active, then the AAD activates the association on this port and begins  
6 sending assignment TLVs. If the AAD finds it already has an active association on a different port it holds  
7 this association in standby and does not issue an assignment TLV for this port. If the AAD active association  
8 is disabled or fails, the AAD state machine resets the port and restarts the association process on that port.  
9 On restart the AAD breaks all assignments on the reset port, withdraws all Auto Attach TLVs,  
10 resynchronizes with the peer AAB state machine, and starts the association process over. If the AAD has any  
11 associations in standby, the first to recognize the active association has broken becomes active and issues an  
12 assignment TLV.

13 The AAB can only accept assignment TLVs from an AAD with a valid system TLV. The AAB only allows a  
14 single active association for each AAD. If the AAB finds an AAD attempting to activate a port with an  
15 invalid system TLV or if the AAD attempts to activate more than one association, the AAB resets its port  
16 invalidating the association and forcing a restart of the peer AAD state machine. On restart the AAB breaks  
17 all assignments on the reset port, withdraws all Auto Attach TLVs, resynchronizes with the peer AAD state  
18 machine, and starts the association process over.

19 An AAD is responsible for initiating one or more VID/I-SID assignment binding requests and sending them  
20 to the AAB in the assignment TLV. The AAD uses aaAdminPortVidIsidAsgns[] (50.4.3.2) to determine the  
21 requested assignments. Bindings are individually processed by the AAB to determine whether the specified  
22 VID can be bound to the I-SID. If the binding is allowed, the AAB creates the VLAN and BSI as indicated  
23 by the AAD assignment TLV. Once all assignments are updated, the assignment TLV is updated by the AAB  
24 and sent to the AAD with the status of all assignment requests. The AAD updates all VID/I-SID assignments  
25 and reflects the current status back to the AAB in its assignment TLV.

### 26 **50.3.1 System inactivity**

27 If the remote LLDP database for an AAS is deleted, Auto Attach TLVs are deleted from the database, or  
28 Auto Attach System TLVs are not received, then all operating VID to I-SID assignments are deactivated and  
29 the AAP restarts.

### 30 **50.3.2 Multiple AAD systems**

31 The Auto Attach function is intended to operate in a point-to-point single peer-to-peer topology. Multiple  
32 AADs are not permitted to form an association on a single AAB port. Only one AAD system is permitted to  
33 form an association per port interface of an AAB.

### 34 **50.3.3 AAD assignment requests**

35 Assignment mapping requests are communicated from the AAD to the AAB using the PBBN Auto Attach  
36 Assignment TLV (D.2.18). These service assignment requests are a combination of the VID/I-SID mapping  
37 and assignment status.

38 Assignment mappings are established when two criteria are met:

- 39 a) An AAB is discovered by an AAD and has a valid remote association determined by the  
40 ValidateRemoteAssociation state machine procedures (50.6).
- 41 b) The Auto Attach variable aaAdminPortVidIsidAsgns[] for this port is configured with one or more  
42 VID/I-SID assignments using the management interface (12.34.4).

### 1 50.3.4 AAB assignment request processing

2 Each VLAN that is associated with a VID/I-SID assignment mapping is configured on the AAD by setting  
3 the VID/I-SID mapping in the PBBN Auto Attach assignment table (12.34.4). The port associated with the  
4 link connecting the AAD to the AAB is a member of the VLAN(s) in the VID/I-SID assignment list received  
5 and accepted by the AAB. This allows traffic on these VLANs to pass into the BSI.

6 All initial VID/I-SID assignment mapping requests are sent by the AAD with an assignment status of  
7 pending until the AAB completes processing the request. The AAD updates and reflects the assignment  
8 status changes for each VID/I-SID according to the last assignment status received from the AAB.

9 Each VID/I-SID assignment request received by the AAB is processed individually and is either accepted or  
10 rejected. Assignment requests are processed for interfaces on which the port is in operation, LLDP is  
11 enabled, Auto Attach TLV processing is enabled, and AAS valid association has occurred.

12 If an assignment is accepted the following happens:

- 13 — Each VLAN that is associated with an accepted VID/I-SID assignment is instantiated on the AAB if  
14 it does not already exist, in order that proper data packet encapsulation and decapsulation is  
15 supported.

16 There are two conditions associated with the interface assignment mapping and binding process:

- 17 a) If the I-SID already exists on the AAB, due to a previous configuration from any type of interface  
18 binding method, then the AAB configures the associated interface to the pre-existing I-SID.
- 19 b) If the I-SID does not exist on the AAB already, then it is responsible for creating the BSI with the  
20 associated I-SID.

21 Port tagging and port VLAN membership updates are performed by the AAD based on assignment  
22 acceptance.

23 If an assignment is rejected, a response with a reason is returned to the AAD based on the following:

- 24 — Generic (undefined rejection error)
- 25 — Auto Attach resources unavailable
- 26 — Invalid VLAN ID
- 27 — VLAN resources unavailable
- 28 — Invalid I-SID
- 29 — I-SID resources unavailable
- 30 — Application interaction (VLAN, PBB) issue
- 31 — Assignment not allowed

32 Rejected assignments are returned to the originating AAD with a rejected status and indicate why the  
33 rejection occurred using status as defined in D.2.18.6. An AAD continues to request a rejected assignment  
34 until the assignment is administratively removed.

### 35 50.3.5 Assignment updates

36 All active VID/I-SID assignments on the AAB are updated using the current assignment TLV information  
37 from the AAD.

38 When a new assignment TLV is received at the AAB containing additional mapping requests, removing  
39 existing mapping requests, or changing existing mapping requests, the AAB state machine processes the  
40 new requests by adding, deleting, or updating the assignments that were changed in the new assignment  
41 TLV.

1 If one or more VID/I-SID assignments are not present in any subsequent assignment TLVs from the AAD,  
2 the AAB removes the mapping of those missing assignments from the active list and releases the binding.

### 3 **50.4 State machine variables**

4 The Auto Attach state machines use both port local (50.4.3) and system wide variables (50.4.2). Updating a  
5 system wide variable requires assuring consistency since multiple instances of the state machines (one per  
6 port) can access the system wide variables.

7 The Auto Attach state machines use some complex structures (50.4.1). These structures are copied and  
8 compared within the state machines in the same manner as strings. Copies result in a new structure of the  
9 same length and content duplicated in a new variable. Compares test equal when two structures are exactly  
10 the same size and content, otherwise they are not equal.

11 Arrays are indexed with their first element starting at zero.

12 When manipulating structures the state machine diagrams use dot notation to illustrate access to objects  
13 within a structure. The syntax for accessing the objects within a structure used in the state machines is:

14 `<structure instance>.<object name>`

15 At times the state machine diagrams need to exclude a field from a structure that is being compared as a  
16 string. This is expressed by prefixing the object name with “except”:

17 `<structure instance>.<except><object name>`

### 18 **50.4.1 Structure type definitions**

19 Type definitions are used to define some of the state machine variables. They are represented by C style  
20 typedefs. Though C structures can not be manipulated and compared as though they are strings the state  
21 machine both copies and compares these structures to simplify the state machine description.

#### 22 **50.4.1.1 Assignment TLV type definition**

23 The type *ASGNSstring* models the PBBN Auto Attach Assignment TLV (D.2.18). It contains elements for  
24 all the fields defined for the assignment TLV, however transformed into machine local byte and bit order.

25 Part of the *ASGNSstring* type is an array of triples, *ASGNStriple*, identifying the assignment  
26 status/VID/I-SID. This array is variable in size and so instances of *ASGNSstring* can vary in size.

```
27 typedef struct {
28     Unsigned          status : 4;
29     Unsigned          vid : 12;
30     Unsigned          isid : 24;
31 } ASGNStriple;
32 typedef struct {
33     Unsigned Char      numAsgns;
34     ASGNStriple        asgnsArray[];
35 } ASGNSstring;
```

#### 36 **50.4.1.2 Discovered association table object**

37 This object is the structure used by an AAS state machine for each object of the discovered remote attach  
38 port table (50.4.2.2).

```
39 typedef struct {
40     Unsigned          locPortId;
41     PORTNETIDstring   remPortNetId;
42 } DISCport;
```

### 1 50.4.1.3 System TLV type definition

2 The type *SYSstring* models the PBBN Auto Attach System TLV (D.2.17). It contains elements for all of the  
3 fields defined for the system TLV, however transformed into machine local byte and bit order.

```
4 typedef struct {
5     Unsigned          sysMAC : 48;
6     Unsigned16        reserved;
7     Unsigned32        portId;
8 } PORTNETIDstring;
9 typedef struct {
10    Unsigned char      state;
11    Unsigned          sysType : 4;
12    Unsigned          portTagging : 4;
13    Unsigned char      reserved;
14    PORTNETIDstring    portNetId;
15 } SYSstring;
```

### 16 50.4.1.4 VID to I-SID assignment table object

17 This object is the 2-tuples *VIDISIDpair* containing a single VID to I-SID assignment. This type is used by  
18 the state machine for typing arrays of the assignment requests.

```
19 typedef struct {
20     Unsigned          vid : 12;
21     Unsigned          isid : 24;
22 } VIDISIDpair;
```

## 23 50.4.2 Per AAS variables

### 24 50.4.2.1 aaAdminSystemEnable

25 When FALSE this Boolean variable causes all AAP state machines on all ports to immediately enter the  
26 INIT state. When set to TRUE this variable allows the AAP state machines to progress. The variable  
27 aaAdminSystemEnable is set by the management system object aaSystemEnable (12.34.1).

### 28 50.4.2.2 aaOperDiscAssocTable[]

29 This table lists all of the currently associated ports discovered on remote AASs. It is an array of type  
30 DISCport (50.4.1.2). When accessing or updating this table the state machine's implementation takes care of  
31 any required interlocking for sharing this table.

### 32 50.4.2.3 aaOperAadActiveAssocIndex

33 This variable provides an index into the aaOperDiscAssocTable[] for the active association on this AAD. If  
34 no association is active, then aaOperAadActiveAssocIndex is set to NO\_ACTIVE\_ASSOC. When updating  
35 or accessing this variable the state machine's implementation takes care of any required interlocking for  
36 sharing this variable.

### 37 50.4.2.4 aaSystemMAC

38 A MAC address selected to uniquely identify this AAS over the administrative domain. This variable is set  
39 by the system to an appropriate value (such as the LLDP ChassisID) at system startup. If the system is a  
40 DRNI the single aaSystemMAC refers to both devices in the DRNI pair.

### 41 50.4.2.5 aaSystemType

42 The system type can take the values (1)AAB, (2)CVLAN\_AWARE\_AAD, (3)VLAN\_UNAWARE\_AAD,  
43 or (4)SVLAN\_AWARE\_AAD. This variable is set by the system to an appropriate value at system startup.

#### 1 **50.4.2.6 aaSystemResetTime**

2 A variable used to initialize the aaResetTimer during a state machine reset. The time in seconds can range  
3 from 1 to 1200 seconds.

#### 4 **50.4.2.7 BEGIN**

5 A Boolean variable controlled by the system initialization process. A value of TRUE causes all state  
6 machines to continuously execute their initial state. A value of FALSE allows all state machines to perform  
7 transitions out of their initial state.

### 8 **50.4.3 Per port variables**

#### 9 **50.4.3.1 aaAdminPortEnable**

10 When FALSE this Boolean variable causes the AAP state machine on this port to immediately enter the  
11 INIT state. A value of TRUE allows the AAP state machine on the port to progress. The aaAdminPortEnable  
12 is set by the management port table object aaPortEnable (12.34.2).

#### 13 **50.4.3.2 aaAdminVidIsidAsgns[]**

14 The administratively assigned VID/I-SID pairs desired by an AAD on this port. The array is loaded by  
15 management with the assignments table entries (12.34.4) for this port. This array is only used by the AAD  
16 state machine.

17 This variable is an array of 2-tuples each containing a VID to I-SID assignment of type VIDISIDpair  
18 (50.4.1.4). The state machine can compare or copy the entire array to an array of the same type with an  
19 assignment, compare equal, or compare not equal operator. To be equal the two arrays must be of the same  
20 size and contain the same elements in each 2-tuple.

21 The variables aaAdminVidIsidAsgns[n].vid and aaAdminVidIsidAsgns[n].isid of each 2-tuple within  
22 aaAdminVidIsidAsgns[] is exposed at the management interface. Each row of the management database  
23 assignment table represents an index into aaAdminVidIsidAsgns[]. So, for instance, the first row refers to  
24 aaAdminVidIsidAsgns[0] and value of the first VID/ISID pair is set to the objects of the first row of the  
25 Auto Attach assignment table entry for this port.

#### 26 **50.4.3.3 aaAsgnsTlvEnable**

27 Enables and disables transmission of the PBBN Auto Attach Assignment TLV on this port. This variable is  
28 the LLDP MIB object lldpXdot1AaConfigAsgnsTxEnable (D.5.6) or LLDP YANG object  
29 tlvs-tx-org-aa-system-enable.aaAssign (D.6.6.7).

30 PBBN Auto Attach assignment TLV transmission is controlled by the Auto Attach state machines. When  
31 aaAsgnsTlvEnable is FALSE, LLDP does not include the Auto Attach Assignment TLV in its transmissions.  
32 When the aaAsgnsTlvEnable is TRUE, LLDP includes the Auto Attach Assignment TLV in its  
33 transmissions.

#### 34 **50.4.3.4 aaCurVidIsidAsgns[]**

35 An array of 2-tuples each containing a VID to I-SID assignment of type VIDISIDpair (50.4.1.4), containing  
36 the VID/I-SID assignments currently advertised by an AAD in LLDP assignment TLVs.

#### 37 **50.4.3.5 aaCurRemAsgnsTlv**

38 A structure of type ASGNSstring (50.4.1.1) containing the state machine's current assignment TLV.

#### 1 **50.4.3.6 aaLocAsgnsTlv**

2 A structure of type ASGNSstring (50.4.1.1) containing the current LLDP local database assignment TLV  
3 (D.2.18) in machine local byte and bit format. This structure is transferred to the LLDP local database object  
4 lldpV2Xdot1LocAaAsgnsTlvString in network byte and bit order by the procedure aaSetAsgnsTlv()  
5 (50.5.14).

#### 6 **50.4.3.7 aaLocSysTlv**

7 A structure of type SYSstring (50.4.1.3) containing the current LLDP local database PBBN Auto Attach  
8 System TLV (D.2.17) in machine local byte and bit format. This structure is transferred to the LLDP local  
9 database object lldpV2Xdot1LocAaSysTlvString in network byte and bit order by the procedure  
10 aaSetSysTlv() (50.5.15).

#### 11 **50.4.3.8 aaOperLocAsgnsTlv**

12 A structure of type ASGNSstring (50.4.1.1) containing the state machine's operational assignment TLV.

#### 13 **50.4.3.9 aaOperLocSysTlv**

14 A structure of type SYSstring (50.4.1.3) containing the state machine's operational PBBN Auto Attach  
15 System TLV.

#### 16 **50.4.3.10 aaOperRemAsgnsTlv**

17 A structure of type ASGNSstring (50.4.1.1) containing the state machine's operational assignment TLV.

#### 18 **50.4.3.11 aaOperRemSysTlv**

19 A structure of type SYSstring (50.4.1.3) containing the state machine's operational PBBN Auto Attach  
20 System TLV.

#### 21 **50.4.3.12 aaPendingCompleted**

22 An AAB boolean used to indicate when a pending operation has completed. When TRUE a pending  
23 operation has completed. The conditions setting this boolean to TRUE are implementation dependent. The  
24 AAB state machine uses this boolean to process the completion of operations that are delayed pending  
25 completion of requests to management or control functions.

#### 26 **50.4.3.13 aaPortId**

27 Set by the system at startup to the if-ref for this port.

#### 28 **50.4.3.14 aaPortTagging**

29 Set by the system to the tagging options currently configured on the port. This variable can take the values  
30 specified for the PBBN Auto Attach System TLV tagging field listed in Table D-18.

#### 31 **50.4.3.15 aaRemAsgnsTlv**

32 A structure of type ASGNSstring (50.4.1.1) containing the current LLDP remote database assignment TLV  
33 (D.2.18) derived from lldpV2Xdot1RemAaAsgnsTlvString (D.5.6). If no remote entry exists or if more than  
34 a single remote entry exists then aaRemSysTlv == NULL.

#### 35 **50.4.3.16 aaRemSysTlv**

36 A structure of type SYSstring (50.4.1.3) containing the current LLDP remote database PBBN Auto Attach  
37 System TLV (D.2.17) derived from lldpV2Xdot1RemAaSysTlvString (D.5.6) for this port. If no remote  
38 entry exists or if more than a single remote entry exists then aaRemSysTlv == NULL.

1 **50.4.3.17 aaResetTimer**

2 The Auto Attach state machines use a timer to allow the AAB and AAD to return to synchronization after a  
3 reset condition. This timer operates as a countdown timer (i.e., it expires when its value reaches zero). The  
4 aaTimer:

- 5 a) Has a resolution of one second.
- 6 b) Is started by loading an initial integer value,  $n$ , where  $0 < n \leq 1200$ .
- 7 c) Is decremented by one per timer tick, as long as  $n > 0$ ; the interval between timer ticks is the same as  
8 the timer resolution.
- 9 d) Represents the remaining time in the period.

10 **50.4.3.18 aaStatsAssocAttached**

11 A statistic counter providing the number of times an association attached.

12 **50.4.3.19 aaStatsAssocFailed**

13 A statistic counter providing the number of times an association failed.

14 **50.4.3.20 aaStatsAssocReset**

15 A statistic counter providing the number of times an association was reset.

16 **50.4.3.21 aaStatsAssocStandby**

17 A statistic counter providing the number of times an association was a standby.

18 **50.4.3.22 aaStatsVidIsidAsgnsAccepted**

19 A statistic counter providing the number of VID/ISID assignments accepted by the AAB.

20 **50.4.3.23 aaStatsVidIsidAsgnsRejected**

21 A statistic counter providing the number of VID/ISID assignments rejected by the AAB.

22 **50.4.3.24 aaStatsVidIsidAsgnsRequested**

23 A statistic counter providing the number of VID/ISID assignments requested by the AAD.

24 **50.4.3.25 aaStatsVidIsidAsgnsWithdrawn**

25 A statistic counter providing the number of VID/ISID assignment requests withdrawn by the AAD.

26 **50.4.3.26 aaSysTlvEnable**

27 This variable enables and disables transmission of PBBN Auto Attach System TLVs on this port. This  
28 variable is the LLDP MIB object `lldpXdot1AaConfigSysTxEnable` (D.5.6) or LLDP YANG object  
29 `tlvs-tx-org-aa-system-enable.aaSystem` (D.6.6.7).

30 PBBN Auto Attach System TLV transmission is controlled by the Auto Attach state machine. When  
31 `aaSysTlvEnable` is FALSE, LLDP does not include the Auto Attach System TLV in its transmissions. When  
32 the `aaSysTlvEnable` is TRUE, LLDP includes the Auto Attach System TLV in its transmissions.

33 **50.4.3.27 aaTopologyError**

34 A boolean indicating a topology error. If the port is attached to a point-to-point single peer-to-peer network  
35 then `aaTopologyError` is set to FALSE, otherwise `aaTopologyError` is set to TRUE. When this variable is set  
36 to TRUE, the state machines immediately exit their current state and enter the INIT state.

## 1 50.5 State machine functions

2 The state machine functions described here are expressed in both words and pseudo-code fragments. Code  
3 fragments use C style syntax; however, when implementation specific operations are required that extend  
4 outside the scope of this standard, a word description is inserted in the pseudo-code and italicized. These  
5 functions are intended to describe the external behavior requirements of the AAP, however are not intended  
6 to be an implementation of the protocol.

7 Many of these functions operate on SYSstring and ASGNSstring structures. The functions operating on  
8 these structures directly modify the structure instance within the state machine. Some of these functions also  
9 provide return codes containing the status of the operations performed.

### 10 50.5.1 aaBuildSysTlv( SYSstring tlv )

11 This function loads the argument tlv with the current parameters for this port. The following values are set in  
12 tlv. The function returns with the modified tlv.

```
13 tlv->state = NOT_READY;
14 tlv->sysType = aaSystemType;
15 tlv->portTagging = aaPortTagging;
16 tlv->reserved = 0;
17 tlv->portNetId.sysMAC = aaSystemMAC;
18 tlv->portNetId.reserved = 0;
19 tlv->portNetId.portId = aaPortId;
```

20 No errors are reported by this routine, however in an implementation there can be internal errors found.

### 21 50.5.2 aaBuildAsgnsTlv( ASGNSstring tlv, VIDISIDpair vidIsidArray[], ASGNSstring 22 operTlv )

23 This function loads tlv with the current parameters for this port, with the assignment requests contained in  
24 vidIsidArray[], and with the current operational status from operTlv. Any new assignment status is set to  
25 PENDING. In an AAD the operTlv is an internal copy of the current Auto Attach LLDP remote assignment  
26 TLV from the AAB.

27 The function begins by determining the number of elements in the argument vidIsidArray[]. This number is  
28 designated here by *n*. The function then initializes the header variables of the tlv argument as follows:

```
29 tlv->numAsngs = n;
```

30 Next the function loads the asgnsArray with the VID/ISID pairs requested by the AAD. For each element of  
31 the vidIsidArray[] designated by *i* aaBuildAsgnsTlv() sets:

```
32 if ( n > 0 ) {
33     for ( i=0; i < n; i++ ) {
34         tlv->asgnsArray[i].status = PENDING;
35         tlv->asgnsArray[i].vid = vidIsidArray[i].vid;
36         tlv->asgnsArray[i].isid = vidIsidArray[i].isid;
37     };
38 };
```

39 Next the function loads the asgnsArray with current status for each old VID/ISID pair using the operTlv.

```
40 for ( i=0; i < n; i++ ) {
41     for ( j=0; j < operTlv->numAsngs; j++ ) {
42         if (tlv->asgnsArray[i].vid == operTlv->asgnsArray[j].vid &&
43             tlv->asgnsArray[i].isid == operTlv->asgnsArray[j].isid ) {
44             tlv->asgnsArray[i].status = operTlv->asgnsArray[j].status;
45             break;
46         };
47     };
48 };
```

49 No errors are reported by this routine, though in an implementation there can be internal system errors.

### 1 50.5.3 aaConfigAabAsgn( unsigned vid, unsigned isid )

2 This function configures the AAB port as a Customer Edge Port (CEP) or a Customer Network Port (CNP),  
3 depending on the type of AAD requesting attachment. If the attachment is to an S-VLAN aware AAD then a  
4 CNP is provided and the requested S-VLAN is activated and coupled to the requested backbone service  
5 instance (BSI, 50.2). If the attachment is to any other AAD type, a CEP is provided and the requested  
6 C-VLAN is activated and coupled to the requested BSI. The function uses the state machine variables  
7 aaPortId and aaOperRemSysTlv to identify the AAB port where the VLAN attaches to the AAB and to  
8 determine the tagging type to use to interface to the AAD. The settings required to configure the AAB are  
9 implementation dependent.

10 To perform the configuration the AAB needs to configure:

- 11 a) The Customer Edge Port, Provider Edge Port, and filtering database are configured in the C-VLAN  
12 component providing customer service on this AAB port identified by the aaPortId state machine  
13 variable and with tagging parameters specified in the aaOperRemSysTlv for this port (50.2).
- 14 b) The Customer Network Port, Provider Instance Port, and filtering database are configured in the  
15 I-component.
- 16 c) The Customer Backbone Port and filtering database are configured in the B-component.
- 17 d) If the desired BSI identified by the I-SID is not already coupled to the AAB, the AAB advertises the  
18 I-SID to the network using either Shortest Path Bridging (SPB) or requests to a central management  
19 plane (PBB) to form an attachment to the desired BSI.
- 20 e) The function returns ACCEPT if the configuration is complete or PENDING if the configuration is  
21 in progress. Once the pending action is complete the system sets the state machine variable  
22 aaPendingCompleted = TRUE.

### 23 50.5.4 aaDisableAabVidIsidAsgns( ASGNSstring tlvNew, ASGNSstring tlvOld )

24 This function determines which VID to I-SID assignments to disable on this port. The function compares the  
25 list of VID to I-SID assignments in tlvOld to those in tlvNew and disables all the assignments found in  
26 tlvOld with status ACCEPT but either missing in tlvNew or REJECTED in tlvNew. A pseudo-code sketch  
27 of aaDisableAabVidIsidAsgns() is as follows:

```
28 if ( tlvOld == NULL || tlvOld->numAsgns == 0 ) return; // no running assignments
29 for ( i=0; i < tlvOld->numAsgns; i++ ) {
30     match = FALSE;
31     if ( tlvNew != NULL && tlvNew->numAsgns != 0 )
32         for ( j=0; j < tlvNew->numAsgns; j++ ) {
33             if ( tlvOld->asgnsArray[i].vid == tlvNew->asgnsArray[j].vid
34                 && tlvOld->asgnsArray[i].isid==tlvNew->asgnsArray[j].isid )
35                 { match = TRUE; k = j; };
36         }; // for each j
37     if ( match == FALSE ) { // tlvOld vid/isid not in tlvNew
38         if ( tlvOld->asgnsArray[i].status == ACCEPT ) {
39             disable tlvOld->asgnsArray[i];
40         };
41         /* the disable operation indicates removing all operating state */
42         /* within the AAB for this VID to I-SID mapping */
43     };
44     if ( match == TRUE // tlvOld vid/isid ACCEPT but tlvNew vid/isid REJECT
45         && tlvOld->asgnsArray[i].status == ACCEPT
46         && tlvOld->asgnsArray[i].status != tlvNew->asgnsArray[k].status )
47         disable tlvOld->asgnsArray[i];
48         /* the disable operation indicates removing all operating */
49         /* state within the AAB for this VID to I-SID mapping */
50 }; // for each i
```

51 In the pseudo-code the italicized “*disable tlvOld->asgnsArray[i]*” indicates execution of an implementation  
52 dependent operation to disable the VID to I-SID mapping.

### 1 50.5.5 aaDisableLldpAaTlvTx()

2 This function disables LLDP transmission of the Auto Attach TLVs. Pseudo-code for  
3 aaDisableLldpAaTlvTx() is as follows:

```
4 if ( aaSysTlvEnable == ENABLED ||  
5     aaAsgnsTlvEnable == ENABLED ) {  
6     aaAsgnsTlvEnable = DISABLED;  
7     aaSysTlvEnable = DISABLED;  
8     SomethingChangedLocal();  
9 }
```

### 10 50.5.6 aaDisableVidIsidAsgns()

11 This function disables all active VID to I-SID assignments on this port. All AAS internal state required to  
12 activate the VID to I-SID assignment on this port is deleted.

### 13 50.5.7 aaDiscAssocAabTblCheck( unsigned port, SYSstring tlv )

14 A function used to search aaOperDiscAssocTable[] for an entry where the Auto Attach System MAC  
15 address contained within an aaOperDiscAssocTable.remPortNetId object matches the Auto Attach System  
16 MAC address contained within tlv.portNetId or for an existing entry for this AAB port. The function returns  
17 ASSOC\_ATTACHED if no match was found or if the AAD is already discovered on this AAB port. The  
18 function returns ASSOC\_INVALID if the AAD is already discovered on a different AAB port or this is a  
19 new AAD identified on the AAB port.

20 A pseudo-code sketch of the function is as follows:

```
21 for ( each i an index to aaOperDiscAssocTable[] ) {  
22     if ( aaOperDiscAssocTable[i].remPortNetId == tlv->portNetId &&  
23         aaOperDiscAssocTable[i].locPortId == port ) return ASSOC_ATTACHED;  
24     if ( aaOperDiscAssocTable[i].remPortNetId.sysMAC  
25         == tlv->portNetId.sysMAC ) return ASSOC_INVALID;  
26     if ( aaOperDiscAssocTable[i].locPortId == port ) return ASSOC_INVALID;  
27 } //for each i  
28 return ASSOC_ATTACHED;
```

29 Within the pseudo-code, the italicized text for operator “*each i an index to aaOperDiscAssocTable[]*”  
30 replaces the normal C code for loop conditions because the structure of the table aaOperDiscAssocTable is  
31 implementation dependent. The for loop within the pseudo-code executes for each member of the  
32 aaOperDiscAssocTable, regardless of the table implementation.

### 1 50.5.8 aaDiscAssocAadTblCheck( unsigned port, SYSstring tlv )

2 An AAD can only have a single active association. It is assumed that the aaOperDiscAssocTable[] has  
3 already inserted a discovery entry for this port. The aaOperDiscAssocTable[] entry for the active association  
4 is indexed by the variable aaOperAadActiveAssocIndex. The function returns ASSOC\_ATTACHED if there  
5 is no other active association or if the current active association is this local port with this remote port.  
6 Otherwise the function returns ASSOC\_STANDBY.

```
7 if ( aaOperAadActiveAssocIndex == NO_ACTIVE_ASSOC ) {
8     for ( each i an index of aaOperDiscAssocTable[] ) {
9         if ( aaOperDiscAssocTable[i].locPortId == port &&
10             aaOperDiscAssocTable[i].remPortNetId == tlv->portNetId ) {
11             aaOperAadActiveAssocIndex = i; return ASSOC_ATTACHED;
12         };
13     };
14 } else {
15     i= aaOperAadActiveAssocIndex;
16     if ( aaOperDiscAssocTable[i].locPortId == port &&
17         aaOperDiscAssocTable[i].remPortNetId == tlv->portNetId )
18         return ASSOC_ATTACHED;
19 }
20 return ASSOC_STANDBY;
```

21 Within the pseudo-code, the italicized text for operator “*each i an index of aaOperDiscAssocTable[]*”  
22 replaces the normal C code for loop conditions because the structure of the table aaOperDiscAssocTable is  
23 implementation dependent. The for loop within the pseudo-code executes for each member of the  
24 aaOperDiscAssocTable, regardless of the table implementation.

### 25 50.5.9 aaDiscAssocTblDelete( unsigned port )

26 This function deletes an entry in aaOperDiscAssocTable[]. The function deletes the table entry *i* matching  
27 the condition aaOperDiscAssocTable[i].locPortId == port.

### 28 50.5.10 aaDiscAssocTblInsert( unsigned port, SYSstring tlv )

29 This function inserts a new entry in aaOperDiscAssocTable[]. The function builds a DISCport entry and  
30 inserts it into a new table entry *i*. It is assumed the table is already checked to assure a duplicate entry is not  
31 present. The entry is as follows:

```
32 aaOperDiscAssocTable[i].locPortId = port;
33 aaOperDiscAssocTable[i].remPortNetId = tlv->portNetID;
```

### 34 50.5.11 aaEnableAabVidIsidAsgns( ASGNSstring tlv )

35 This function determines which VID to I-SID assignments to activate. The function is responsible for  
36 determining if each pending VID to I-SID pair contained in the tlv argument can be activated. In addition,  
37 this function builds all state required by the AAB to activate a VID to I-SID assignment.

1 The function modifies the status associated with each VID to I-SID pair to reflect the action taken on the  
2 pair. The codes that can be returned are listed in Table D-20. A pseudo-code sketch is as follows:

```
3 if ( tlv == NULL || tlv->numAsgns == 0 ) return;
4 for ( i=0; i < tlv->numAsgns; i++ ) {
5     if ( tlv->asgnsArray[i].status == PENDING ) {
6         if ( the VID to I-SID assignment is acceptable to the AAB ) {
7             st=aaConfigAabAsgn(tlv->asgnsArray[i].vid,
8                               tlv->asgnsArray[i].isid);
9             /* The aaConfigAabAsgn() builds all operating state */
10            /* within the AAB for this VID to I-SID mapping */
11            tlv->asgnsArray[i].status = st;
12        } else tlv->asgnsArray[i].status = REJECT; //including reason
13    };
14 }; //for each i
```

15 In this pseudo-code the condition “*the VID to I-SID assignment is acceptable to the AAB*” is a catch-all for  
16 any internal checks the AAB performs to allow the assignment before attempting configuration.

#### 17 50.5.12 aaEnableAadVidIsidAsgns( ASGNSstring tlv )

18 This function enables VID to I-SID assignments. It sets all of the AAD internal state required to enable or  
19 disable each VID to I-SID pair. Each pair marked with tlv->asgnsArray[i].status == ACCEPT is enabled,  
20 otherwise the pair is disabled. The operations required to enable or disable the identified VLAN are system  
21 dependent and so not explicitly described in the pseudo-code. Instead the italicized *enable* and *disable*  
22 operations are used to indicate the implementation dependent operations.

```
23 if ( tlv == NULL || tlv->numAsgns == 0 ) return; // no assigns received
24 for ( i=0; i < tlv->numAsgns; i++ ) {
25     if ( tlv->asgnsArray[i].status == ACTIVE )
26         enable the VLAN identified by tlv.asgnsArray[i].vid
27     else disable the VLAN identified by tlv.asgnsArray[i].vid;
28 };
```

#### 29 50.5.13 aaPortClearStats()

30 This function clears all the statistic counters for this port.

#### 31 50.5.14 aaSetAsgnsTlv( ASGNSstring tlv )

32 The function is used to place a state machine internal structure of type ASGNSstring into the LLDP  
33 database. The ASGNSstring referenced by tlv is transformed from the local machine byte and bit order to  
34 the assignment TLV byte and bit order as it is moved into the LLDP database for this port.

35 The function aaSetAsgnsTlv() locks out LLDP from building an LLDPDU during the update. Once the TLV  
36 is transfered and LLDP unlocked, the routine sets aaAsgnsTlvEnable = ENABLED then calls  
37 SomethingChangedLocal() and returns.

#### 38 50.5.15 aaSetSysTlv( SYSstring tlv )

39 The aaSetSysTlv() function is used to place a state machine internal structure of type SYSstring into the  
40 LLDP database. The object referenced by tlv is transformed from the local machine byte and bit order to the  
41 PBBN Auto Attach System TLV byte and bit order as it is moved into the LLDP database for this port.

42 The function aaSetSysTlv() locks out LLDP from building an LLDPDU during the update. Once the TLV is  
43 transfered and LLDP unlocked, the routine sets aaSysTlvEnable = ENABLED then calls  
44 SomethingChangedLocal() and returns.

#### 1 **50.5.16 aaSomethingChangedRemote()**

2 This procedure is called by the LLDP routine SomethingChangedRemote() (IEEE Std 802.1AB-2016  
3 clause 9.2.7.9) when something changes in the remote LLDP database. The procedure performs the  
4 following operations:

- 5 — The remote LLDP database entries are checked to determine if multiple remote databases are  
6 present on this port. If multiple databases are present, then the port is not connected to a  
7 point-to-point single peer-to-peer topology and so the procedure sets aaTopologyError = TRUE,  
8 aaRemSysTlv = NULL, aaRemAsgnsTlv = NULL. Otherwise the routine sets aaTopologyError =  
9 FALSE.
- 10 — If aaTopologyError == FALSE, then the procedure updates the aaRemSysTlv as follows:  
11 If a PBBN Auto Attach System TLV is not present in the remote database or if multiple Auto Attach  
12 System TLVs are present, then aaRemSysTlv = NULL, otherwise the contents of the Auto Attach  
13 System TLV are transformed from the big-endian format used for network transmission into the  
14 local machine format and placed in aaRemSysTlv.
- 15 — If aaTopologyError == FALSE, then the procedure updates the aaRemAsgnsTlv as follows:  
16 If a PBBN Auto Attach Assignment TLV is not present in the remote database or if multiple copies  
17 are present, then aaRemAsgnsTlv = NULL, otherwise the contents of the PBBN Auto Attach  
18 Assignment TLV are transferred from the big-endian format used for network transmission into the  
19 local machine format and placed in aaRemAsgnsTlv.

#### 20 **50.5.17 aaSomethingChangeRemoteInit()**

21 This procedure used to initialize the LLDP callback routine aaSomethingChangedRemote(). The function  
22 registers aaSomethingChangedRemote() with LLDP for call back by the LLDP routine  
23 SomethingChangedRemote() and initializes aaTopologyError = FALSE, then calls  
24 aaSomethingChangedRemote() to initialize the variables aaTopologyError, aaRemSysTlv, and  
25 aaRemAsgnsTlv.

## 1 50.5.18 aaUpdateReqDelVidIsidStats( ASGNSstring tlvNew, ASGNSstring tlvOld )

2 This routine is used to update the requested and withdrawn VID to I-SID assignment statistics for both the  
3 AAB and AAD. The VID to I-SID assignment status indicated in tlvOld is compared with the VID to I-SID  
4 status in tlvNew. Only VID to I-SID assignments that are different in tlvOld and tlvNew are considered in  
5 the counts. A pseudo-code sketch of aaUpdateReqDelVidIsidStats() is as follows:

```

6 if ( tlvOld == NULL && tlvNew == NULL ) return;
7 if ( tlvOld != NULL && tlvOld->numAsgns != 0 )
8     if ( tlvNew == NULL || tlvNew->numAsgns == 0 ) {
9         aaStatsVidIsidAsgnsWithdrawn += tlvOld->numAsgns;
10        return;
11    };
12 if ( tlvNew != NULL && tlvNew->numAsgns != 0 )
13     if ( tlvOld == NULL || tlvOld->numAsgns == 0 ) {
14         aaStatsVidIsidAsgnsRequested += tlvNew->numAsgns;
15        return;
16    };
17 if ( tlvOld != NULL && tlvOld->numAsgns != 0
18 && tlvNew != NULL && tlvNew->numAsgns != 0 ) {
19     for ( i=0; i < tlvNew->numAsgns; i++ ) {
20         flag = FALSE;
21         for ( j=0; j < tlvOld->numAsgns; j++ ) {
22             if ( tlvNew->asgnsArray[i].vid == tlvOld->asgnsArray[j].vid
23                 && tlvNew->asgnsArray[i].isid == tlvOld->asgnsArray[j].isid )
24                 flag = TRUE;
25         }; // for each j
26         if ( flag == FALSE ) aaStatsVidIsidAsgnsRequested++;
27     }; // for each i
28     for ( i=0; i < tlvOld->numAsgns; i++ ) {
29         flag = FALSE;
30         for ( j=0; j < tlvNew->numAsgns; j++ ) {
31             if ( tlvNew->asgnsArray[i].vid == tlvOld->asgnsArray[j].vid
32                 && tlvNew->asgnsArray[i].isid == tlvOld->asgnsArray[j].isid )
33                 flag = TRUE;
34         }; // for each j
35         if ( flag == FALSE ) aaStatsVidIsidAsgnsWithdrawn++;
36     }; // for each i
37 };

```

### 1 50.5.19 aaUpdateAcptRejVidIsidStats( ASGNSstring tlvNew, ASGNSstring tlvOld )

2 This routine is used to update the accepted and rejected VID to I-SID assignment statistics for both the AAB  
3 and AAD. The VID to I-SID assignment status indicated in tlvOld is compared with the VID to I-SID status  
4 in tlvNew. Only VID to I-SID assignments that are different in tlvOld and tlvNew are considered in the  
5 counts. A pseudo-code sketch of aaUpdateAcptRejVidIsidStats() is as follows:

```
6 if ( tlvNew == NULL || tlvNew->numAsgns == 0 ) return;
7 if ( tlvOld == NULL || tlvOld->numAsgns == 0 ) {
8     for ( i=0; i < tlvNew->numAsgns; i++ ) {
9         if ( tlvNew->asgnsArray[i].status == ACCEPTED )
10             aaStatsVidIsidAsgnsAccepted++
11         else if ( tlvNew->asgnsArray[i].status != PENDING )
12             aaStatsVidIsidAsgnsRejected++;
13     };
14 } else
15     for ( i=0; i < tlvNew->numAsgns; i++ ) {
16         flag = FALSE;
17         for ( j=0; j < tlvOld->numAsgns; j++ ) {
18             if ( tlvNew->asgnsArray[i].vid == tlvOld->asgnsArray[j].vid
19                 && tlvNew->asgnsArray[i].isid == tlvOld->asgnsArray[j].isid
20                 && tlvNew->asgnsArray[i].status ==
21                     tlvOld->asgnsArray[j].status )
22                 flag = TRUE;
23         }; // for each j
24         if ( flag == FALSE ) {
25             if ( tlvNew->asgnsArray[i].status == ACCEPTED )
26                 aaStatsVidIsidAsgnsAccepted++
27             else if ( tlvNew->asgnsArray[i].status != PENDING )
28                 aaStatsVidIsidAsgnsRejected++;
29         };
30 }; //for each i
```

### 31 50.5.20 SomethingChangedLocal()

32 This is an LLDP routine that is called when the Auto Attach state machines make updates to the local LLDP  
33 database entries. The routine is defined in the IEEE Std 802.1AB state machines.

## 50.6 AAD state machine

In an implementation that supports auto attachment, the Auto Attach Device (AAD) state machine implements the functions specified by Figure 50-4. The state machine requires the AAD to form a valid association with one AAB. Therefore, all VID/I-SID requests from an AAD are received on one AAB port supporting an independent VID space.

Figure 50-4—PBBN Auto Attach Device (AAD) state machine

## 1 50.7 AAB state machine

2 In an implementation that supports auto attachment, the Auto Attach BEB (AAB) state machine implements  
3 the functions specified by Figure 50-5. The state machine requires the AAB to provide a VLAN service  
4 specified by the AAD and requires the AAB to have an independent VID space for each port, therefore only  
5 one AAD is supported per AAB port.

Figure 50-5—PBBN Auto Attach BEB (AAB) state machine

## 1 Annex A

2 (normative)

### 3 PICS proforma—Bridge implementations<sup>55</sup>

#### 4 A.1 Introduction

5 The supplier of a protocol implementation that is claimed to conform to this standard shall complete the  
6 following Protocol Implementation Conformance Statement (PICS) proforma.

7 A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of  
8 which capabilities and options of the protocol have been implemented. The PICS can have a number of uses,  
9 including use:

- 10 a) By the protocol implementer, as a checklist to reduce the risk of failure to conform to the standard  
11 through oversight.
- 12 b) By the supplier and acquirer—or potential acquirer—of the implementation, as a detailed indication  
13 of the capabilities of the implementation, stated relative to the common basis for understanding  
14 provided by the standard PICS proforma.
- 15 c) By the user—or potential user—of the implementation, as a basis for initially checking the  
16 possibility of interworking with another implementation (note that, while interworking can never be  
17 guaranteed, failure to interwork can often be predicted from incompatible PICSs).
- 18 d) By a protocol tester, as the basis for selecting appropriate tests against which to assess the claim for  
19 conformance of the implementation.

#### 20 A.2 Abbreviations and special symbols

##### 21 A.2.1 Status symbols

|    |            |                                                                                             |
|----|------------|---------------------------------------------------------------------------------------------|
| 22 | M          | mandatory                                                                                   |
| 23 | O          | optional                                                                                    |
| 24 | <i>O.n</i> | optional, but support of at least one of the group of options labeled by the same numeral n |
| 25 |            | is required                                                                                 |
| 26 | X          | prohibited                                                                                  |
| 27 | <u>A.n</u> | <a href="#">completion of PICS Table A.n is required if the Item is supported</a>           |
| 28 | pred:      | conditional-item symbol, including predicate identification: see A.3.4                      |
| 29 | ¬          | logical negation, applied to a conditional item's predicate                                 |

## **1 A.3 Instructions for completing the PICS proforma**

### **2 A.3.1 General structure of the PICS proforma**

3 The first part of the PICS proforma, implementation identification and protocol summary, is to be completed  
4 as indicated with the information necessary to identify fully both the supplier and the implementation.

5 The main part of the PICS proforma is a fixed-format questionnaire, divided into several subclauses, each  
6 containing a number of individual items. Answers to the questionnaire items are to be provided in the  
7 rightmost column, either by simply marking an answer to indicate a restricted choice (usually Yes or No) or  
8 by entering a value or a set or range of values. (Note that there are some items where two or more choices  
9 from a set of possible answers can apply; all relevant choices are to be marked.)

10 Each item is identified by an item reference in the first column. The second column contains the question to  
11 be answered; the third column records the status of the item—whether support is mandatory, optional, or  
12 conditional: see also A.3.4. The fourth column contains the reference or references to the material that  
13 specifies the item in the main body of this standard, and the fifth column provides the space for the answers.

14 A supplier may also provide (or be required to provide) further information, categorized as either Additional  
15 Information or Exception Information. When present, each kind of further information is to be provided in a  
16 further subclause of items labeled  $A_i$  or  $X_i$ , respectively, for cross-referencing purposes, where  $i$  is any  
17 unambiguous identification for the item (e.g., simply a numeral). There are no other restrictions on its format  
18 and presentation.

19 A completed PICS proforma, including any Additional Information and Exception Information, is the  
20 Protocol Implementation Conformation Statement for the implementation in question.

21 NOTE—Where an implementation is capable of being configured in more than one way, a single PICS may be able to  
22 describe all such configurations. However, the supplier has the choice of providing more than one PICS, each covering  
23 some subset of the implementation's configuration capabilities, in case that makes for easier and clearer presentation of  
24 the information.

### **25 A.3.2 Additional information**

26 Items of Additional Information allow a supplier to provide further information intended to assist the  
27 interpretation of the PICS. It is not intended or expected that a large quantity will be supplied, and a PICS  
28 can be considered complete without any such information. Examples might be an outline of the ways in  
29 which a (single) implementation can be set up to operate in a variety of environments and configurations, or  
30 information about aspects of the implementation that are outside the scope of this standard but that have a  
31 bearing on the answers to some items.

32 References to items of Additional Information may be entered next to any answer in the questionnaire and  
33 may be included in items of Exception Information.

### **34 A.3.3 Exception information**

35 It may occasionally happen that a supplier will wish to answer an item with mandatory status (after any  
36 conditions have been applied) in a way that conflicts with the indicated requirement. No preprinted answer  
37 will be found in the Support column for this item. Instead, the supplier shall write the missing answer into  
38 the Support column, together with an  $X_i$  reference to an item of Exception Information, and shall provide the  
39 appropriate rationale in the Exception item itself.

40 An implementation for which an Exception item is required in this way does not conform to this standard.

41 NOTE—A possible reason for the situation described previously is that a defect in this standard has been reported, a  
42 correction for which is expected to change the requirement not met by the implementation.

## 1 A.3.4 Conditional status

### 2 A.3.4.1 Conditional items

3 The PICS proforma contains a number of conditional items. These are items for which both the applicability  
4 of the item itself, and its status if it does apply—mandatory or optional—are dependent on whether certain  
5 other items are supported.

6 Where a group of items is subject to the same condition for applicability, a separate preliminary question  
7 about the condition appears at the head of the group, with an instruction to skip to a later point in the  
8 questionnaire if the “Not Applicable” answer is selected. Otherwise, individual conditional items are  
9 indicated by a conditional symbol in the Status column.

10 A conditional symbol is of the form “**pred:** S” where **pred** is a predicate as described in A.3.4.2 below, and  
11 S is a status symbol, M or O.

12 If the value of the predicate is true (see A.3.4.2), the conditional item is applicable, and its status is indicated  
13 by the status symbol following the predicate: The answer column is to be marked in the usual way. If the  
14 value of the predicate is false, the “Not Applicable” (N/A) answer is to be marked.

### 15 A.3.4.2 Predicates

16 A predicate is one of the following:

- 17 a) An item-reference for an item in the PICS proforma: The value of the predicate is true if the item is  
18 marked as supported and is false otherwise.
- 19 b) A predicate-name, for a predicate defined as a boolean expression constructed by combining item-  
20 references using the boolean operator OR: The value of the predicate is true if one or more of the  
21 items is marked as supported.
- 22 c) The logical negation symbol “¬” prefixed to an item-reference or predicate-name: The value of the  
23 predicate is true if the value of the predicate formed by omitting the “¬” symbol is false, and vice  
24 versa.

25 Each item whose reference is used in a predicate or predicate definition, or in a preliminary question for  
26 grouped conditional items, is indicated by an asterisk in the Item column.

## 1 A.4 PICS proforma for IEEE Std 802.1Q—~~Bridge implementations~~

### A.4.1 Implementation identification

|                                                                                                                                                                                                                                                                                                                                                |  |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

## 1 PICS Issues and Changes (Work In Progress)

2 Collected actions outstanding, issues, and changes from current work in progress.

- 3 1. Q-2022 has a PICS (Annex A) for Bridge implementations and a separate PICS (Annex B) for End  
4 station implementations. Since we are mainly concerned with peer-to-peer (“peer” = “equal”)  
5 protocols it is not surprising that much of the material in Annex B is a simple duplication of Annex  
6 A. This makes for impressive bulk in the standard, but is a burden for maintenance. Further the  
7 largest single contributor to the PICS is CFM, which does not follow that division but introduces an  
8 item ‘BRG’ which is used as a qualifier on a large proportion of the items. The imputed meaning of  
9 ‘BRG’ is ‘you think that this is a bridge’, but that attribute is not defined precisely in the standard.  
10 This proposal move all the PICS material into a single Annex A. I suggest that we pursue the  
11 conversation started a while ago with editorial staff and relocate the Bibliography to Annex B, so it  
12 does not get moved by every amendment that adds an Annex.
- 13 2. Many of the items in the Q-2022 PICS are auto-numbered following a prefix string. This makes  
14 creating the items easy. However it means that deleting or inserting any item(s) will result in the  
15 relabelling of all subsequent items, which makes tracking items from draft to draft difficult. I have  
16 attempted to generate a recognizable unique identifier for each item.
- 17 3. References in questions and reference column  
18 It is not necessary to include references in each PICS question where they are (as they should be) in  
19 the References column. Further it is not the job of the PICS to provide a table of contents for each  
20 item, where a referenced clause (major or minor) contains the supporting information, e.g.  
21 references to Tables within that clause, the PICS should not be bulked up by replicating that  
22 information. This is particularly egregious where the additional references in the PICS are a subset  
23 of what has to be consulted.
- 24 4. Multiple questions where one would be sufficient.  
25 Not only would one question suffice, but in a number of cases the questions had different expression  
26 of scope (what is being considered) so were not consistent.
- 27 5. Unnecessary use of/complication of conditional status conditions  
28 No need to indicate that a status item is conditional if the PICS Table is only applicable if the  
29 condition is true, or the condition is detailed in the Feature description.
- 30 6. Requirement that each Bridge Port be connected directly to an IEEE 802 LAN.  
31 Issue. This is historic, dating from early 802.1D. At the time the aim was to avoid conformance  
32 claims from historic forwarding devices, connected to other links (such as T.1) possibly using  
33 proprietary packet formats. Since then the position has changed to accepting all interfaces that  
34 support the ISS. Note in particular recent liaison with the BBF and the decision to correct the YANG  
35 module to allow all interfaces ‘derived-from-or-self’ from an 802.3/Ethernet interface. There is a  
36 decision to be made, with options: a) are all interfaces that claim to derived from Ethernet (or from  
37 any other 802 LAN interfaces) permitted; b) are any requirements as to the identification of publicly  
38 available specifications to be specified (the risks of random nonsense do not appear to have  
39 diminished with time).
- 40 7. Q-2022 PICS A.7 RLY-1 required discard of MAC frames in error citing 6.3 and 8.5, but these make  
41 no such statement and support of the ISS by MACs would not pass up errored frames. Believed to be  
42 historic from early 802.1D. Deleted.
- 43 8. Port Type capabilities  
44 The Q-2022 PICS provided fill in entries for the various Provider Bridge Port Types (apparently by  
45 number). That only works for fixed configurations, where there is a very brief way of identifying  
46 specific ports. It does not work for systems with variable configurations, hot swappable cards of

- 1 different capabilities etc. Replaced by a simple requirement to identify an item of Supplementary  
2 Information.
- 3 9. VLAN-CMP
- 4 Reference is to top level statement as per 5.4 d).
- 5 5.4 a) and b) are covered by MAC (A.7.3) and IF (A.7), but a) is not worded correctly as it does not  
6 include 6.14, 6.15. 5.4 c) needs to be replaced by a protocol identification statement, reference Std  
7 802.
- 8 10. BridgeID
- 9 Previously incorrectly described as including Port Identifier. Split into Bridge Identifier and Port  
10 Identifier questions.
- 11 11. MMRP addresses
- 12 Table 10-1 specifies the “Customer and Provider Bridge MMRP address” but <5.18.1> specifies use  
13 of the “Individual LAN Scope group address, Nearest Bridge group address” for end station use.  
14 The desire in the latter specification might well be to avoid flooding of end station generated MMRP  
15 frames when the edge bridge does not support MMRP. This could be consider a distinct case from  
16 tunneling of MMRP frames through intermediate bridges in the core of the network where those  
17 bridges do not support MMRP, but strategically placed bridges do provide that support. A solution to  
18 the interoperability issue raised that does not unnecessarily flood frames and does not require  
19 additional logic to distinguish end station links from internal links (which may not work properly on  
20 shared media in any case) would be for the end stations to also receive MMRPDUs addressed to the  
21 “Customer and Provider Bridge MMRP address”, and for the bridges to also receive MMRPDUs  
22 addressed to the “Individual LAN Scope group address”. This issue should be addressed in the main  
23 text, which properly done should allow a slight simplification of the PICS text. Also check the main  
24 text to make sure it allows ..?
- 25 12. MAP Context for MMRP in VLAN Bridges
- 26 5.4.1.3 (VLAN Bridge options) incorrectly states that MMRP is to operate in the Base Spanning  
27 Tree Context for VLAN Bridges. That disagrees with what is in Clause 10, and is only true for  
28 VLAN-unaware MAC Bridges. Even in an SST VLAN Bridge, MMRP has to operate in a VLAN  
29 Context because otherwise registration for Group MAC Addresses only relevant to a particular  
30 VLAN could propagate beyond the extent of that VLAN.
- 31 13. MAP Context Identifiers
- 32 In 10.12.1.1 “Use of MAP Contexts by MMRP” we have the statement “The MAP Context  
33 Identifier used to identify a VLAN Context shall be equal to the VID used to identify the  
34 corresponding VLAN.” This is just tub thumping since “shall” should really be “is”, there being no  
35 possibility within the specification of an implementer or administrator using any other value. In  
36 12.32.4 “MRP External Control” we have the very reasonable “For the MSRP application, although  
37 35.2.4.5 implies that a single MAP Context exists, the specifications of 35.1.3.1 ensure that every  
38 distinct value of vlan\_identifier propagates along the corresponding VLAN context (10.3.1).  
39 Therefore, for the purposes of indexing this managed object, MSRP uses the vlan\_identifier as the  
40 MAP Context identifier.” According the aforementioned “shall” will be removed, and there is no  
41 need for a corresponding PICS item.
- 42 14. Same address for Customer Bridge and Provider Bridge MMRP.
- 43 Use of the same address for both C-VLAN and S-VLAN Bridges inhibits customer address  
44 propagation across a PBN that uses MMRP internally for its own purposes (?). Without attempting  
45 to change this, the PICS question has been moved to the C-VLAN Bridge component and S-VLAN  
46 Bridge component PICS so those two cases can be considered separately.
- 47 15. Propagation of MMRP information on “all Ports”.

It is sufficient to specify that propagation of the information is supported for all supported Contexts, thus accommodating the possibility that some ports on some types of bridges, or indeed on some types of end station (e.g. dual attached edge devices) will not support a context that propagates information between its two down-links (it never forwards information between those links).

16. Encoding of MMRP Attributes

The 2022 PICS only checked for the encoding of FirstValues. Changed to cover the complete encoding of Attributes.

17. MMRP propagation of Group service requirements.

10.10.2 is potentially misleading in that it says propagation occurs through all port of the bridge, whereas in a VLAN bridge propagation only occurs in the appropriate MAP Context (i.e. that are forwarding for that VLAN) unless ‘propagation’ is understood in a particular sophisticated way. The current description of MMRP is inconsistent in its reference to MAP Contexts (see, e.g., 10.11 which does take them into account). The registration is definitely per VID, see the paragraph preceding item w) in <8.8>.

18. MVRP support is mandatory for all types of VLAN Bridge, but addressing is not specified for Provider Bridges

See item o) in <5.4> and <Table 10-1>. Current resolution is to remove PICS item for VLAN Bridge components in general, and create a C-VLAN Bridge component item with the specified addressing. If this is the agreed way forward, <5.4> conformance needs to be changed.

19. Transmission of MVRP Attribute 0 was shown as dependent on support of a New-Only participant.

There appears to be no support for this in the main text.

20. Vague reference to Registration Fixed (New propagated)

The 2022 PICS (item MVRP17) referenced 11.2.6 for “Does MVRP ignore New messages in MVRPDUs for VLANs not Registration Fixed (New propagated) when configured for New propagated”, 11.2.6 references item d) in 12.7.7.3.3 which says nothing specific on the subject but is an output from a supposed management operation and simply says “Port Map— a set of control indicators as appropriate for the entry (that may include a Connection Identifier), as specified in 8.8.1 through 8.8.5” which does not help. Item b) 1) i) in <8.8.2> is “Registration Fixed (New ignored) which is much clearer and should be a direct reference. It is unclear from the 8.8.2 text whether that agrees the optionality of the New-Only Participant as stated in 11.2.6, but in any case the negative in MVRP17 is better replaced by the direct reference to “Registration Fixed (New ignored)”, which if it exists is to be followed whether or not the New-Only Participant is implemented, thus simplifying the condition for this PICS Item. That’s it for the PICS, but I have yet to dig into whether the 11.2.6 needs to be simplified by aligning it with the 8.8.2 text. However perhaps the PICS entry should be entirely replaced by one that references 8.8.2. A further complication lies in what is meant by supported “Is an MVRP New-Only Participant supported”. Does that mean that the MVRP participant on the port can be configured just to send New messages (i.e. be a New-Only Participant”) or will it include the necessary behavior to work with a peer Port (connected to the same point-to-point LAN) that is itself a New-Only Participant.

Above now believed fixed (apart from directionality of new Participant?)

21. CNP always connected directly to an 802 LAN?

5.10 of Q-2022 says “Each Port configured as a ... CNP shall be capable of attaching the S-VLAN component of the Provider Bridge directly to an IEEE 802 LAN”. But that is not what CNPs do in Provider Edge Bridges: they connect to an Internal ‘LAN’ which connects to a C-VLAN component PEP.

22. Auto Attach Device functionality features in the Clause 5 Conformance multiple times (for C-VLAN Bridge, S-VLAN-Bridge, MAC Bridge) with identical; text in these cases. It is then referenced in Q-2022 PCS A.5 AAD without qualification as to device type - thus making the

repetition in Clause 5 irrelevant. Remove the all encompassing item from the PICS as part of sorting out A.5 ‘Major features’ and just used a single Table for an AAD claim. Apart from removing redundancy this change allows other systems to be built with a component providing the AAD functionality for the system as a whole.

23. Unwanted Inheritance

The reuse of the specifications of common components without necessarily much thought has lead to a number of cases of unwanted (and unexpected) mandatory or optional provisions in some of the children. Are, for example, all of the derivatives of the basic VLAN Bridge component (including I-components and DCB variants) expected to implement all the requirements of 5.4: implementing RSSTP, specifying Filtering Database Sizes, implementing MVRP). In some cases these requirements have been overruled in text, but that may have led to inconsistency and conflict rather than clarity. In other cases optional features have been adopted wholesale without thought as to their utility. This issue has been addressed by ‘promoting’ the capability to a level where it is more clearly useful, e.g. by moving RSTP up to the C-VLAN or S-VLAN component level. It is possible that some of the capabilities need to be promoted further, e.g., to the C-VLAN Bridge level. It is also possible that promotion is necessary but that more than one higher level needs to have the address capability.

24. CFM and particular systems, components, and capabilities

In the Conformance clause CFM is introduced as a VLAN Bridge component option [5.4.1 c)] referencing 5.4.1.4 “Connectivity Fault Management (CFM) (optional)”. 5.4.1.4 is definitely VLAN component specific, as it leads items with reference to a VLAN Bridge component and includes VID specific mandatory items. 5.4.5 “Shortest Path Bridging (SPB) operation (optional)” references [h)] CFM modifications for SPBM an option, though it does not spell out the necessity for implementing the basic CFM capabilities to use that option (obvious?) and does not clarify that these modifications are necessary (as would appear to be the case from 20.2.2, 20.3, 20.3.1, 20.11.1, 20.17.1, 20.28.1, 20.31.1, and possibly elsewhere). 5.6.2 has further modifications for PBB-TE. 5.7.1 has a CFM related item for an I-component PIP. 5.8.1 has a CFM related item for a CBP. 5.8.2 has a CFM related item for TESIs. 5.13.1 has a CFM item for a VLAN-unaware MAC Bridge which references 5.4.1.4 despite there being no VIDs in a MAC Bridge. 5.19 covers CFM for VLAN-unaware end stations, duplicating many of the requirements for the VLAN Bridge component except those for MIPs. 5.15 “TPMR component conformance” requires a MIP on each Bridge Port, but does not actually include the text ‘CFM’ so is easy to miss.

25. Derivative components “may implement any of the options specified for a ... component”.

Apparently whether it makes sense or not, and without the detailed examination of any new feature introduced for the based reference component or whether the standard describes some generalized way of proceeding as being inappropriate in a given case.

26. CFM Port Status TLV transmission.

21.5.4 ‘Port Status TLV’ prohibits the transmission of a Port Status TLV when the MEP does not have an unambiguous Port Status, e.g. when it is configured in a position where frames with many VIDs might pass through the MEP and whether data would pass through depends on the VID. The text in 21.5.4 refers explicitly to “not associated with a single value for the Port State and VID member set” and gives a multiple spanning tree example. The inclusion of “VID member set” in this prohibition is unnecessary—the reference to Port State not having a single value is sufficient, and the multiple spanning tree is just an example. The PICS entry has been simplified for the first point, and a separate PICS entry for the example has been removed (as the remaining entry points to the 21.5.4 text).

27. Q-2022 CFM PICS item Bridge or otherwise too specific

In the Q-2022 PICS a number of PICS items were made specific to the operation of a Bridge or (in at least one case) specific to transmitter or receive behavior, whereas the main normative text does not

included such a restriction. PICS changed to reflect the general case where the requirement applies equally to end stations (such as a Router using CFM to monitor connectivity to a neighbour).

28. Cross-reference format for hard to find items

It is really hard to pick out the correct ‘b)’ or other LetteredList item in source files that contain many many such lists (like the Conformance clause). While not a complete solution, the following cross-reference format (derived from one originally developed by Norm Finn) helps by providing both the enclosing clause heading (5.4.1.4, for example) as well as the letter list identification. I have named the cross-reference format ‘Hn item)’ and the Format definition is ‘<\$paranumonly[H1,H2,H3,H4,H5,H6]>\ <\$paranum>’. It produces, for example, ‘5.4.1.4 g)’ with a non-breaking en space between the heading number (the nearest prior one of the H1 though H6 listed) and the lettered list item. Using it provides confirmation that the correct list item has been selected, and serves as a guide to navigating up or down the lists if it is not.

29. T-component mandates too many MIPs

T-component conformance (5.17) is inherited from TPMR-component conformance (5.15) which requires a MIP on both ports. This is surely unwanted on a BEB T-component, at least on the inner facing side.

30. Creation of MEP on every Port

Q-2022 PICS included a separate item for this, although it is apparently completely covered by the requirement to support creation of eight Down MEPs on each Port as per Q-2022 PICS CFM-19.

31. Q-2022 PICS CFM PDU validation items repeated

One item specified validating all types, with references for all cases, and separate items were also present for each type with (in sum) mostly the same references. Cut down the first of these to the general validation in 20.51.3 and 20.51.4 and left the type specific references to those type cases.

32. Single feature split over multiple items, with references in common

Consolidated into a single question, avoided cross-references between groups of PICS Tables where possible.

33. CFM support in VLAN-unaware MAC Bridges

This is discussed in 22.1.7, however it is not clear to me how that discussion affects the conformance requirements for the creation of Maintenance Domains (at eight MD Levels, with multiple Maintenance Domains at each MD Level?). I suspect that this is much simplified, as is the number of MPs to be supported. The relevant conformance probably needs to be split out at the top-level.

34. Shortest Path Bridging PICS seems light

The SPB PICS seems rather light on detail. However, as Editor, suggesting further detail is beyond the scope of what I believe I can accomplish.

35. ECMP dependency on SPB

The only substantive main text explaining the use of ECMP (and hence of the F-TAG) is in Clause 44 which deals with SPB. However it appears (to the Editor) that the use of the F-TAG is assumed, in Clause 12, some MIB definitions, and particularly in CFM and in conformance clause material apparently related to PBB-TE and not just SPB, that the use F-TAG is assumed to be more general. This appears to be another instance where the management specification wishes to take a different view of what has been standardized and assume its extension or variation. This would take some work to clean up, if anyone is willing to make the effort (the current state is unsatisfactory, but as usual once vague functionality has been added to the spec there is probably little enthusiasm for further work. There is one reference (in main text) to ECMP functionality being covered in Clause 13, which is not correct).

- 1 36. Including an IETF RFC in the References column is not accurate (and thus not helpful) when the  
2 normative text of this standard (for a specific PICS item) is calling out a particular of the RFC.  
3 References should be to the text of this standard, unless a full defined set of the referenced document  
4 is intended (there are probably few cases for which this is true). RFC references removed from the  
5 PCR PICS.
- 6 37. The characteristics which define a TPMR (as opposed to a TPMR component) were split over  
7 multiple questions, this is unnecessary and perhaps gives the illusion that they are not essential to  
8 recognizing a TPMR, but merely possible aspects of behavior. They have been combined.
- 9 38. The 802.1Q-2022 TPMR PICS in A.27 goes into some detail as to the forwarding, filtering, and  
10 traffic selection capabilities of a TPMR whereas the standard's normative text (outside Clause 5)  
11 simply refers to VLAN-unaware Bridge behavior. This is inconsistent, and the PICS should not be  
12 taking an approach to conformance not supported by main normative text. A simple reference to  
13 common Bridge component capabilities in Table A.5.3 is all that is required.
- 14 39. PICS Feature entries should be questions (throughout this Table), worded briefly and not duplicating  
15 additional information in the referenced text, see also Issue/Change 2.
- 16 40. No need to repeat top level Clause number for individual line items for features.
- 17 41. The 802.1Q-2022 A.31 PICS Table for SRP (which is the base for the present A.16.2) makes no  
18 reference to MVRP which is required, in addition to MSRP, for SRP. There is also no reference to  
19 Clause 5. There needs to be at least one of the latter, with a possible line item (through still top-level)  
20 breakdown.
- 21 42. At least one 802.1Q-2022 SRP PICS Item replicates information basic to MRP and has been  
22 removed (the MRP PICS Table will be completed for SRP).
- 23 43. 802.1Q-2022 SRP-3 specifies that registration information is to be propagated in accordance with  
24 the Base Spanning Tree Context. This is wrong as it is clear that VLANs are to be used to support  
25 alternate active topologies, and MSRP is not constrained to a single Spanning Tree. 802.1Q-2022  
26 SRP-1 discusses exchange of MSRPDUs, but its list of references goes into fine detail of encoding,  
27 which is actually covered by other PICS Items (so remove the references in the MSRPDU exchange  
28 item). SRP-4 discusses forwarding, filtering, or discard of MRPDUs in general which is already  
29 covered in the MRP Table (so omit). Also removed SRP-20 as it stated transmission of MRPDUs on  
30 all Ports, which will not happen if MMRP pruning is being used. Note that SRP-20 referenced 35.2  
31 which does not contain such a simple requirement. SRP-31 and SRP-32 are misleading as they have  
32 expanded the italicized variable names, inserting space between normal text words, so they appear  
33 to be a general description of functionality, rather than the specific controls described in normative  
34 text.
- 35 44. ProtocolVersion handling for received MSRPDUs is important and normative, but is referenced by a  
36 NOTE (necessarily not normative) in 35.2.2.3, and the NOTE uses "must" instead of "shall"  
37 (although neither is strictly required since the referenced 10.8.3.5 includes the normative language).  
38 The choice is between removing the must, so the normative burden is entirely taken by 10.8.3.5, or  
39 making the NOTE main text and changing "must" to shall. The former has been implemented.
- 40 45. While 802.1Q-2022 SRP-8 through SRP-11 cover details of SRP Attribute encoding (Attribute  
41 Types, Length Values, pacing, First Values) their coverage, which is taken from basic MRP is not  
42 complete. Missing, for example, is the use of ThreePackedEvents. Changed to simplify by  
43 substituting one item for encoding covering these four items. Further noted that the 802.1Q-2022  
44 PICS References pick at 35.2.2 in considerable detail, down to the 5th heading level (35.2.2.8.7, for  
45 example) but this detail is in fact incomplete. For example latency update failure is mentioned in  
46 35.2.2.8.6 and 35.2.2.8.7 but SRP-13 just has the latter, whereas the former is in SRP-12. Latency  
47 update failure is also mentioned in a number of 35.2.2.10 clauses, but not all are present. It may  
48 have been the intent to record in the PICS every time failure is mentioned, but that is necessarily  
49 incomplete given the repetition in the normative text. Simplified this and following multiple

- 1 references to a reference to 35.2.2. It is worse to give the reader that the detailed reference is all that  
2 has to be checked when other detailed sections touch on the same subject. The reader is better served  
3 by a pdf search if it is desired to present (almost) all times failure is mentioned. Noted that this just  
4 one example of editing practice not keeping up with the technology transition from printed paper to  
5 electronically read documents. Further it is not necessary to supply forward references, e.g. to  
6 coding Tales, when these are given in the referenced text.
- 7 46. Talker pruning is described in more of 35.2.4.3 than just the 35.2.4.3.2 referenced in the  
8 802.1Q-2022 PICS.
- 9 47. The normative text describes mapping MLME services. While these do use MAD primitives, the  
10 PICS feature should follow the normative text, not restate it in different terms as was done in  
11 802.1Q-2022 A.31 SRPMDDOT11-3.
- 12 48. The wording of 802.1Q-2022 PICS item SRPMDMOCA-1 does not match the normative text as it  
13 uses “support ... to” rather than “append ... to”, and the reference to C.2.1.2 misses the important  
14 “append” normative text which is in C.2.1.1. Changed to use “append” and changed the reference to  
15 C.2.1 to cover the use as well as the structure of the Information Element.
- 16 49. The 802.1Q-2022 PICS for scheduled traffic calls out CQF specifically. However there is no  
17 difference between the items’ status for SCHED (scheduled traffic) and for CQF, there being an OR  
18 between the conditions. Further, scheduled traffic conformance is a requirement for CQF. There is  
19 therefore no need for a CQF reference in these PICS items, and notably they contain no reference to  
20 Annex T (which describes how to use 1Q mechanisms to provide CQF). The mention of CQF has  
21 therefore been removed. This removal is separate from the issue of CQF being described in an  
22 Informative Annex, and thus not a proper target for a conformance statement.
- 23 50. The status condition for the option to implement the MIB was dependent on the condition ‘MIB’.  
24 That is not useful, since that condition is independent of the particular MIB module implemented, so  
25 can be expected to be set if any MIB module is implemented (a provision requiring the  
26 implementation of all MIB modules if any are implemented is unrealistic, and at odds with the  
27 present option). The option to implement the MIB is therefore only relevant if the feature is  
28 implemented and can therefore be simply replaced with ‘O’. The references included a reference to  
29 5.4.1 ad) which does not mention the MIB at all. The references included a reference to CQF which  
30 is redundant since CQF needs the whole of scheduled traffic support, so a single reference to that is  
31 would be what was needed.
- 32 51. A number of PICS Items use the cliché “Does the implementation support” which appears to  
33 introduce some wiggle room (the implementation supports it, but it may not be used for performance  
34 or other reasons) while the normative text has a simple “shall”. These instances changed to simple  
35 question of the form ‘Is this done’.
- 36 52. The referenced normative text uses a “should” rather than a “shall”, so the status of this item has  
37 been changed from “M” to “O”.
- 38 53. The 802.1Q-2022 PICS Item SRP-21 and SRP-22 call for the number of Talker and Listener  
39 registration values supported per Port. However the normative text makes no such per Port  
40 requirement, nor does it say that the number of values for Talkers is independent of that for  
41 Listeners. The constraints in a real implementation may be quite different and depend on a number  
42 of factors. Substituted a placeholder for an item of Supplementary information, and combined the  
43 two items, so the completed PICS can provide relevant information.
- 44 54. PICS item was not a simple reference to normative text, but rather an elaboration of the  
45 consequences or constraints of the normative text. If it is desired that the referenced normative text  
46 in a particular clause be more explicit or explain consequences then a change should be made to that  
47 text. It is not the purpose of the PICS to rewrite normative text.
- 48 55. 802.1Q-2022 PICS Item had incorrect reference for this feature.

- 1 56. SRP could support MAC Address pruning (per port) even if MMRP is not implemented, but  
2 clarifying this point is really an issue for normative text, not for the PICS.
- 3 57. The 802.1Q-2022 PICS item for ATS' references specifically called out item d) and e) in 8.6.6. This  
4 is either unnecessary or obscure as these items do not mentions ATS. They refer to IPV use, and here  
5 is non-normative text (a Note) elsewhere describing limited IPV use by ATS. These specific list  
6 items removed, but 8.6.6 retained (possibly elsewhere). If the specific ATS use for ATS needs to be  
7 called out perhaps the main text needs to state that normatively in a way that is clear. Of course 8.6.6  
8 does refer to ATS as well as to other transmission selection mechanisms. It is not the function of the  
9 PICS to provided normative information not clear in main text. Note items that are specifically  
10 referenced by following line items do not need to be duplicated in this lead item, and have been  
11 removed.
- 12 58. Surprisingly the initial item in the 802.1Qdj-2024 PICS did not reference Clause 46.
- 13 59. As per the rules for the PICS completion, the appropriate way to enter additional information is by  
14 way of a Supplementary item, adding S.n (or just "n" where "S." is already present and "n" is chosen  
15 by the person completing the PICS. The "n" then refers to an additional item which can be as brief or  
16 as extensive as needed. This avoid the need to guess how much space needs to be provided on the  
17 PICS form.
- 18 60. The 802.1Qdj-2024 PICS did not align with its own 5.29 conformance clause requirements, but is  
19 written as if 12.32 specified the managed object definition and encodings. However naturally those  
20 precise definitions (the way they work) is the province of the particular management protocol. There  
21 are in fact two questions to be answered in 5.29 a). First, which management protocol(s) are supported  
22 [5.29 a) 1)], and second, which specifications for managed object definitins and supported for the (each)  
23 management protocol. 12.32 is more careful and describes "attributes" that are managed by the  
24 procool, thus avoiding any suggestion that it is defining encoding. The following items in the  
25 present PICS Table have been changed to align with that approach. Note that 5.29 does not currently  
26 align with 12.32 in this respect.
- 27 61. This item does not appear in 5.29, which is the conformance clause for the CNC station. It should be  
28 added to 5.29 or removed from the PICS.
- 29 62. The 802.1Qdj-2024 PICS also had a separate PICS Item for "the conditional requirements" but  
30 these requirements were nothing more than this item and the two following, so that additional item  
31 has been removed. Note also that these items are not simply O(ptional) as per the Qdj PICS but  
32 mandatory if SRP is supported (see 5.29 d).
- 33 63. The 802.1Q-2022 PICS for Congestion Notification items appear in apparently random order, not  
34 aligned with the relevant conformance clause (5.4.3), while items are missing for some, e.g. for  
35 5.4.3 c). While the latter may appear in the management collection, that's a lot of digging around in the spirit of  
36 having to go through every feature ever developed for 802.1Q to claim conformance for a reasobnable limited  
37 subset. The items have been reordered, and an item is present for at least each conformamce clause item. If it is  
38 decided to reshuffle Clause 5 items, then the PICS items can be reordered as they are now uniquely named  
39 independent of order. To increase alignment with congestion clause items cover 802.1Q-2022 CN-5 as part of  
40 supporting the defense modes by adding CN-5 references to the defense mode items.
- 41 64. 5.4.3 i) references (as an option) the possibility of creating up to 7 CPs on a port. The limit is set by  
42 the number of possible priorities (reserving one of the 8 total for non-CCF traffic, likely best effort).  
43 The 802.1Q-2022 PICS splits this into two items: CN-7 deals with the bare possibility of there being  
44 more than one CP on some port; CN-8 is curious in that it asks the question about more than 7 on a  
45 port with status mandatory and then has a No [] where one would expect Yes[.]. Neither of these is  
46 useful to the recipient of the PICS, would would like to no how many CPs can be supported on a  
47 port and is not much concerned with the simple impossibility of there being more than 7. Asking  
48 questions requiring a simple Number does not work well in the increasingly complex systems that

- 1 may be the subject of the PICS, so the conformamnce clause items have been folded into one PICS  
2 item with a request for Supplementary information for the non-trivial one per port all ports the same  
3 case, allowing useful information to be provided.,
- 4 65. Removed 31.1.1 from References, as it is only a passing introductory mention for this item. If  
5 necessary main text should back reference 31.1.1 from the 32.2.1 detail.
- 6 66. The 802.1Q-2022 PICS has an item for all four possible defense modes for a bridge, and then  
7 (separately in Annex B) items for two modes mandatory for an end station with an end station option  
8 for the other two. The present item deals with the two modes that a mandatory for both bridges and  
9 end station, with a single item for the other two to match the probable intent of 5.21 m) [see below]  
10 although the use of cptInterior Ready in an end station is not clear. There is an error in Q-2022 as 5.21 e)  
11 mandates end station support for cptDisabled and cptInterior while 5.21 m) makes end station support for  
12 cptInterior and cptInteriorReady optional (though apparently requiring implementation of both if the option is  
13 implemented), and neither mentions cptEdge. Further the Q-2022 B-11 end station PICS has cptDisabled and  
14 cptInterior mandatory [CN-8], cptInterior and cptInteriorReady optional [CN-10], and a separate option for  
15 cptEdge [CN-11]. CN-11 uses “on any CNPV” while the others are supported “on each CNPV”, and it is not  
16 clear why cptEdge capability should vary by CNPV. A NOTE in 32.1.1 says that cptEdge is optional in an end  
17 station, there is no corresponding statement for cptInteriorReady.
- 18 67. 32.4.9 cncpDoesEdge describes a variable that tells whether cptEdge is implemented on a given port for a given  
19 priority in an end station, but says that the variable is not a managed object and it is not accessible by  
20 management, but it does affect the operation of the CND defense state machine (!).

## 1 A.5 MAC Bridge conformance

2 Tables A.5.1 through A.5.5 comprise PICS items for the following:<sup>56</sup>

- 3 — A VLAN-unaware MAC Bridge (A.5.1) and a MAC Bridge component (A.5.2).
- 4 — Functionality common to VLAN-unaware MAC Bridge and VLAN Bridge components (A.5.3,
- 5 A.5.3.1—A.5.3.4).
- 6 — Support of each Bridge Port's interface stack by an instance of the MAC Internal Sublayer Service
- 7 (ISS) provided by a Media Access Control (MAC) method or by an internal LAN, with the optional
- 8 use of MACsec and Link Aggregation as specified by the standards for those capabilities (A.5.4).
- 9 — Support of the ISS by specific media access control methods (A.5.5).

10 Complete A.5.1, and all Tables identified in the References column for Mandatory items or selected  
11 Options, for a claim of conformance for an implementation of a VLAN-unaware MAC Bridge.

12 This introductory text and tables for which the answer to the lead item (first row) is No or N/A (not  
13 applicable) can be omitted from the completed PICS. If a table is referenced by an applicable mandatory  
14 item in another completed table, the only conformant answer to the lead item is Yes, and the table and  
15 referenced tables for all mandatory items and selected options are to be completed.

### 16 A.5.1 MAC Bridge conformance

| Item         | Feature                                                                                                                                          | Status | References  | Support         |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------|--------|-------------|-----------------|
| M-BRIDGE     | Can the system be configured as a VLAN-unaware MAC Bridge, comprising a single MAC Bridge component, with each Bridge Port supported by the ISS? |        | 5.14, A.5.2 | Yes [ ] N/A [ ] |
| M-BRIDGE-MAC | Can each Bridge Port be configured to attach directly to an IEEE 802 LAN? <a href="#">Action 6</a>                                               | M      | 5.14        | Yes [ ]         |

### 17 A.5.2 MAC Bridge component conformance

| Item        | Feature                                                                                                                                                                                                                  | Status | References                                  | Support         |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|---------------------------------------------|-----------------|
| M-CMP       | Does the component provide VLAN-unaware relay and filtering of frames, maintaining and supporting management of the necessary information?                                                                               | M      | 5.13, 8.1, 8.5, 8.6, 8.7, 8.8, A.5.3, A.5.4 | Yes [ ] N/A [ ] |
| M-RSVD-ADDR | Are the Reserved Addresses in Table 8-1 permanently configured in the FDB?                                                                                                                                               | M      | Table 8-1                                   | Yes [ ]         |
| M-RSTP      | Does the component support RSTP operation, encoding and decoding BPDUs as specified?                                                                                                                                     | M      | Clause 13                                   | Yes [ ]         |
| M-RSTP-ADDR | Does the component's Spanning Tree Protocol Entity use the Bridge Group Address to transmit and receive BPDUs?                                                                                                           | M      | 8.13.5.1, Table 8-1                         | Yes [ ]         |
| M-MMRP      | Does the component support Extended Filtering Services with MMRP operating in the Base Spanning Tree Context, transmitting and receiving MRPDUs addressed to the Customer Bridge MMRP address. <a href="#">Action 11</a> | O      | 6.16.5, Table 10-1, A.8.1                   | Yes [ ] No [ ]  |

<sup>56</sup> These tables with those in A.6 cover the functionality introduced in 1.3.1.

## <sup>1</sup> A.5.3 Bridge component conformance

| Item   | Feature                                                                                             | Status | References                                                          | Support         |
|--------|-----------------------------------------------------------------------------------------------------|--------|---------------------------------------------------------------------|-----------------|
| BRIDGE | Is the functionality common to VLAN-unaware and VLAN-aware Bridge components provided? <sup>a</sup> |        | Clause 8, A.5.3.1, A.5.3.2, A.5.3.3, A.5.3.4, A.5.3.5, A.5.4, A.7.1 | Yes [ ] N/A [ ] |

<sup>a</sup> If Yes complete this table and referenced tables for all selected items (Yes answers).

### <sup>2</sup> A.5.3.1 Bridge component conformance—addressing

| Item        | Feature                                                                                                                                                                                                                                | Status                | References                         | Support |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|------------------------------------|---------|
| ADDR        | Does the component conform to this standard's requirements for addressing?                                                                                                                                                             | M                     | 8.13                               | Yes [ ] |
| BRG-ADDR    | Is an EUI-48 universally administered MAC Address assigned as the component's Bridge Address?                                                                                                                                          | M                     | 8.13.8                             | Yes [ ] |
| PORT-ADDR   | Does each Bridge Port have a distinct individual MAC address?                                                                                                                                                                          | M                     | 8.13.2                             | Yes [ ] |
| PORT-IFADDR | Is the individual MAC Address of each Bridge Port supported by an interface stack using one or more LAN interfaces, the individual MAC Address of one of those interfaces?                                                             | M                     | 8.13.2                             | Yes [ ] |
| HLE-SA      | Is the Source MAC Address of frames transmitted by a Higher Layer Entity using a Bridge Port that Port's individual address?                                                                                                           | M                     | 8.5, 8.13.2                        | Yes [ ] |
| HLE-RX      | Are frames, received by or relayed to a Bridge Port, with a Destination MAC Address that is the Port's individual address or a Group Address used by a Higher Layer Entity attached to the Port submitted to that Higher Layer Entity? | M                     | 8.5, 8.13, 8.13.2, 8.13.9, 8.13.10 | Yes [ ] |
| HLE-TX      | Are frames transmitted by a Higher Layer Entity using a Bridge Port submitted to both the interface stack supporting that Port and to the MAC Relay Entity's Forwarding Process as if received by the interface stack?                 | –TPMR: M <sup>a</sup> | 8.5, 8.5.1, 8.13, 8.13.9, 8.13.10  | Yes [ ] |

<sup>a</sup> Any condition not defined takes the value False, so this item does not apply if the Bridge component is not a TPMR component.

### <sup>1</sup> A.5.3.2 Bridge component conformance—forwarding

| Item      | Feature                                                                                                                                                                                                                         | Status | References                              | Support                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|-----------------------------------------|---------------------------|
| FWD       | Are correctly received user data frames relayed subject to the conditions imposed by the Forwarding Process, with forwarding decisions and data using EISS parameters not in the ISS iff VLAN-aware functionality is provided?? | M      | 8.4, 8.6, 8.8, Tables 8-10, 8-11, 8-12. | Yes [ ]                   |
| FWD-DATA  | Are user data frames the only type of frame relayed?                                                                                                                                                                            | M      | 8.5                                     | Yes [ ]                   |
| FWD-ORDER | Is the order of relayed user data frames preserved as required?                                                                                                                                                                 | M      | 8.6.6                                   | Yes [ ]                   |
| FWD-DELAY | Is a maximum Bridge transit delay enforced for relayed frames?                                                                                                                                                                  | M      | 8.6.7                                   | Yes [ ]                   |
| FWD-STATE | Are queued user data frames discarded if their selected transmission port is no longer forwarding for those frames.                                                                                                             | M      | 8.6.7                                   | Yes [ ]                   |
| FWD-FCS   | Is the undetected frame error rate of forwarded frames no greater than supported by the original FCS?                                                                                                                           | M      | 6.5.7, 6.8.1                            | Yes [ ]                   |
| TC-NUM    | How many traffic classes are supported for each Bridge Port?                                                                                                                                                                    | M      | 8.6.6                                   | _____                     |
| TC-MAP    | Is the recommended mapping of priority to traffic classes supported for each Port?                                                                                                                                              | O      | 8.6.6, Table 8-5                        | Yes [ ] No [ ]<br>N/A [ ] |
| TC-MGMT   | Can the traffic class tables be managed?                                                                                                                                                                                        | O      | 8.6.6, Table 8-5                        | Yes [ ] No [ ]<br>N/A [ ] |
| TX-DFLT   | Is the default (strict priority) algorithm for selecting frames for transmission supported?                                                                                                                                     | M      | 8.6.8, Table 8-6, 8.6.8.1               | Yes [ ]                   |
| TX-ALG    | Are additional algorithms for selecting frames for transmission supported?                                                                                                                                                      | O      | 8.6.8, Table 8-6, A.5.3.3               | Yes [ ] No [ ]            |

### <sup>2</sup> A.5.3.3 Bridge component conformance—transmission selection

| Item    | Feature                                                                                      | Status             | References                        | Support        |
|---------|----------------------------------------------------------------------------------------------|--------------------|-----------------------------------|----------------|
| TX      | Is the default (strict priority) algorithm for selecting frames for transmission supported?  | M                  | 8.6.8, Table 8-6, 8.6.8.1         | Yes [ ]        |
| TX-CBSA | Is credit-based shaper algorithm transmission selection supported?                           | VLAN-CMP:O<br>Why? | 8.6.8, Table 8-6, 8.6.8.2         | Yes [ ] No [ ] |
| TX-ETS  | Is ETS transmission selection supported?                                                     | O                  | 8.6.8, Table 8-6, 8.6.8.3, A!!    | Yes [ ] No [ ] |
| TX-SCHD | Does each Port support transmission gates and the associated state machines and management ? | O                  | 8.6.8, Table 8-6, 8.6.8.4, A.16.5 | Yes [ ] No [ ] |
| TX-ATS  | Is ATS transmission selection supported?                                                     | O                  | 8.6.8, Table 8-6, 8.6.8.5, A.16.6 | Yes [ ] No [ ] |
| TX-OTHR | Are other algorithms for selecting frames for transmission supported?                        | O                  | 8.6.8, Table 8-6                  | Yes [ ] No [ ] |

#### 1 A.5.3.4 Bridge component conformance—learning and filtering

| Item        | Feature                                                                                                                                                                                                                                                           | Status                                    | References                  | Support                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|-----------------------------|---------------------------|
| LRN         | Are Dynamic Filtering Entries created and updated by correctly received user data frames iff they have an individual source address and an applicable <i>learning</i> variable value is TRUE?                                                                     | –TPMR:M<br>TPMR:X                         | 8.4, 8.7,<br>8.8.3          | Yes [ ]                   |
| AGE         | Are Dynamic Filtering Entries created by the Learning Process aged out if not updated?                                                                                                                                                                            | M                                         | 8.8, 8.8.3                  | Yes [ ]                   |
| AGE-DFLT    | Can the default Ageing Time be configured?                                                                                                                                                                                                                        | O                                         | 8.8.3,<br>Table 8-9         | Yes [ ] No [ ]            |
| AGE-RNG     | Can the Ageing Time be configured to any value in the range specified?                                                                                                                                                                                            | O                                         | 8.8.3,<br>Table 8-9         | Yes [ ] No [ ]            |
| RSVD-ADDR   | Can Reserved Address entries in the Permanent Database and Filtering Database be removed or modified?                                                                                                                                                             | X                                         | 8.13.4                      | No [ ]                    |
| SFLTR       | Can Permanent Database and Filtering Database Static Filtering Entries be created, modified, and deleted by management subject to the specified restrictions?                                                                                                     | M-CMP:O<br>VLAN-CMP:M<br>MMRP:M<br>TPMR:X | 8.8.1                       | Yes [ ] No [ ]            |
| SFLTR-INIT  | Is the Filtering Database initialized with the entries in the Permanent Database?                                                                                                                                                                                 | SFLTR:M                                   | 8.8.1                       | Yes [ ]                   |
| SFLTR-IG    | Can Static Filtering Entries be created for both Individual and Group Addresses?                                                                                                                                                                                  | SFLTR:M                                   | 8.8.1                       | Yes [ ]                   |
| SFLTR-BCAST | Can Static Filtering Entries be created for the broadcast MAC Address?                                                                                                                                                                                            | SFLTR:M                                   | 8.8.1                       | Yes [ ]                   |
| SFLTR-MAP   | Can each Static Filtering Entry specify a forwarding Port Map?                                                                                                                                                                                                    | SFLTR:M                                   | 8.8.1                       | Yes [ ]                   |
| SFLTR-DYN-G | Can each Static Filtering Entry's per Port control element s represents a group address, or All Group Addresses, or All Unregistered Group Addresses, and specify unconditional forwarding, unconditional filtering, or the use of dynamic filtering information? | SFLTR:M                                   | 8.8.1                       | Yes [ ]                   |
| SFLTR-DYN-I | Can an individual address Static Filtering Entry specify use of dynamic filtering information?                                                                                                                                                                    | SFLTR:O<br>MMRP:M                         | 8.8.1                       | Yes [ ] No [ ]<br>N/A [ ] |
| MMRP        | Is the Multiple MAC Registration Protocol (MMRP) implemented in support of Extended Filtering Services?                                                                                                                                                           | SFLTR:O                                   | 6.16,<br>6.16.7.1,<br>A.8.1 |                           |
| MRP-ADDRS   | Are MAC frames with MRP Application destination addresses forwarded or filtered as specified?                                                                                                                                                                     | M                                         | 5.4.1.3,<br>8.13.6          | Yes [ ]                   |
| FDB-SIZE    | State the Filtering Database Size.                                                                                                                                                                                                                                | M                                         | 8.8                         | ____ entries              |
| PDB-SIZE    | State the Permanent Database Size.                                                                                                                                                                                                                                | M                                         | 8.8                         | ____ entries              |

### <sup>1</sup> A.5.3.5 Bridge component conformance—performance

| Item     |                                                                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## A.5.5 Media access control methods

| Item            | Feature                                                                                                                       | Status      | References       | Support                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------|-------------|------------------|---------------------------|
|                 | Which media access control methods are implemented?                                                                           |             | 5.4              |                           |
| MAC-802.3       | Ethernet, IEEE Std 802.3                                                                                                      | O.1         | 802.1AC          | Yes [ ] No [ ]            |
| MAC-802.3-MIN   | Is the minimum tagged frame length that can be transmitted on IEEE 802.3 Ports less than 68 (but 64 or more) octets?          | MAC-802.3:O | 802.1AC          | Yes [ ] No [ ]<br>N/A [ ] |
| MAC-802.11-PORT | IEEE 802.11 LAN Portal, IEEE Std 802.11                                                                                       | O.1         | G.4.1, 802.1AC   | Yes [ ] No [ ]            |
| MAC-PMPN-N      | PMPN multiple port, IEEE Std 802.1AC                                                                                          | O.1         | G.4.1, 802.1AC   | Yes [ ] No [ ]            |
| MAC-PMPN-1      | PMPN single port, IEEE Std 802.1AC                                                                                            | O.1         | G.4.1, 802.1AC   | Yes [ ] No [ ]            |
| MAC-PTP         | Do all the system's MSAPs support the ISS adminPointToPointMAC and operPointToPointMAC parameters?                            | M           | IEEE Std 802.1AC | Yes [ ]                   |
| MAC-DPRI        | Do received frames use the Default Priority where specified for the MAC?                                                      | M           | IEEE Std 802.1AC | Yes [ ]                   |
| MAC-DPRI-M      | Can the Default Priority be set in the range 0-7?                                                                             | O           | IEEE Std 802.1AC | Yes [ ] No [ ]            |
| MAC-PICS        | Has a PICS been completed for each of the media access control methods implemented as required by the relevant MAC standards? | MAC:M       |                  | Yes [ ]                   |

## 1 A.6 Customer VLAN Bridge conformance

2 Tables A.6.1 through A.6.4 comprise PICS items for the following:<sup>57</sup>

- 3 — A C-VLAN Bridge (A.6.1) and a C-VLAN Bridge component (A.6.2).
- 4 — Functionality common to all VLAN Bridge components (A.6.3) in addition to that common to both
- 5 VLAN Bridge and VLAN-unaware MAC Bridge components (A.5.3).
- 6 — Support of the VLAN-aware component's MAC Relay Entity by the EISS provided by each Bridge
- 7 Port (A.6.4).

8 Complete A.6.1, and all Tables identified in the Reference column for Mandatory items or selected Options,  
9 for a claim of conformance for an implementation of a C-VLAN Bridge. Table A.6.2 can be completed  
10 independently of A.6.1 to claim conformance for a C-VLAN component (identified by Supplementary  
11 information, and possibly referenced by another PICS Table) that is part of a system but not directly part of  
12 a C-VLAN Bridge.

13 This introductory text and tables for which the the lead item (first row) is No or N/A (not applicable) can be  
14 omitted. If a table is referenced by an applicable item in another completed table, the only conformant  
15 answer to the lead item is Yes, and the table and referenced tables for all mandatory items and selected  
16 options are to be completed.

### 17 A.6.1 C-VLAN Bridge conformance

| Item         | Feature                                                                                             | Status | References | Support        |
|--------------|-----------------------------------------------------------------------------------------------------|--------|------------|----------------|
| C-BRIDGE     | Can the system be configured as a C-VLAN Bridge, operating as a single conformant C-VLAN component? |        | 5.9, A.6.2 | Yes [ ] No [ ] |
| C-BRIDGE-MAC | Can each Bridge Port be configured to attach directly to an IEEE 802 LAN? <a href="#">Issue 6</a>   | M      | 5.9        | Yes [ ]        |

<sup>57</sup>These tables with those in A.5 cover the functionality introduced in 1.3.1.

## 1 A.6.2 C-VLAN component conformance

| Item        | Feature                                                                                                                                                                                                                                                        | Status | References                                    | Support                         |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|-----------------------------------------------|---------------------------------|
| C-CMP       | Does the component provide C-VLAN Bridge component functionality?                                                                                                                                                                                              |        | 5.9, A.6.3                                    | Yes [ ] N/A [ ]                 |
| C-EISS      | Does each Bridge Port support the component's MAC Relay Entity with the EISS using C-TAGs?                                                                                                                                                                     | M      | 5.4 b), 6.8, 6.9, 9.5, A.6.4                  | Yes [ ]                         |
| C-RSVD-ADDR | Are the Reserved Addresses in Table 8-1 permanently configured in the FDB?                                                                                                                                                                                     | M      | Table 8-1                                     | Yes [ ]                         |
| C-RSTP      | Does the component support RSTP operation, encoding and decoding BPDUs as specified? <a href="#">Action 23</a>                                                                                                                                                 | M      | 5.4 g), Clause 13                             | Yes [ ]                         |
| C-RSTP-ADDR | Does the component's Spanning Tree Protocol Entity use the Bridge Group Address to transmit and receive BPDUs?                                                                                                                                                 | M      | 8.13.5.1, Table 8-1                           | Yes [ ]                         |
| C-MST       | Does the component support MST operation, not constraining frames to a single spanning tree? <a href="#">Action 23</a>                                                                                                                                         | O      | 5.4.1 a), 5.4.1.1, Clause 13                  | Yes [ ] No [ ]                  |
| C-MVRP      | Does the component support automatic configuration and management of VLAN topology using MVRP with MAP Contexts for the Base Spanning Tree (CIST) and each supported MST, with MRPDUs addressed to the Customer Bridge MVRP address. <a href="#">Action 18</a> | M      | 5.4 o), 6.16.5, Table 10-1, Clause 11, A.8.2  | Yes [ ]<br>S <sup>a</sup> _____ |
| C-MMRP      | Does the component support Extended Filtering Services with MMRP operating in a specified number of VLAN Contexts, with MRPDUs addressed to the Customer Bridge MMRP address. <a href="#">Action 11</a> <a href="#">Action 12</a>                              | O      | 5.4.1 g), 6.16.5, Table 10-1, Clause 10 A.8.1 | Yes [ ]<br>S <sup>a</sup> _____ |

<sup>a</sup> If Yes, provided Supplementary information for the VLAN Contexts supported.

## 2 A.6.3 VLAN Bridge component conformance

| Item     | Feature                                                                                                                                                                                              | Status | References                             | Support         |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|----------------------------------------|-----------------|
| VLAN-CMP | Does the component relay and filter frames, maintaining and supporting management of the necessary information, as described in 8.1 and specified in 8.5, 8.6, 8.7, and 8.8? <a href="#">Issue 9</a> |        | 5.4 d), 8.1, 8.5, 8.6, 8.7, 8.8, A.5.3 | Yes [ ] N/A [ ] |
| VLAN-IMP | Provide the following implementation parameters:                                                                                                                                                     | M      | 5.4, 8.8                               |                 |
|          | Maximum number of VIDs supported                                                                                                                                                                     |        | _____ VIDs                             |                 |
|          | Range of supported VID values                                                                                                                                                                        |        | 0 through _____                        |                 |
|          | Maximum number of FIDs supported                                                                                                                                                                     |        | _____ FIDs                             |                 |
|          | Maximum number of VIDs that can be allocated to each FID                                                                                                                                             |        | _____ VIDs                             |                 |

2

## 1 A.7 RST and MSTP conformance

2 Tables A.7.1 through A.7.3 comprise PICS items for the following:<sup>58</sup>

- 3 — The Rapid Spanning Tree Algorithm and Protocol (RSTP) (A.7.1).
- 4 — The Multiple Spanning Tree Algorithm and Protocol (MSTP) (A.7.2).
- 5 — The Bridge Protocol Data Unit (BPDU) encoding used by MSTP and RSTP (A.7.3)

6 Complete tables referenced by Mandatory items or selected Options in other tables completed for claims of  
7 system or component conformance.

8 This introductory text and tables for which the answer to the lead item (first row) is No or N/A (not  
9 applicable) can be omitted from the completed PICS. If a table is referenced by an applicable Mandatory  
10 item or selected Option in another completed table, the only conformant answer to the lead item is Yes, and  
11 the table and referenced tables for all mandatory items and selected options are to be completed.

### 12 A.7.1 Rapid Spanning Tree Protocol (RSTP)

| Item          | Feature                                                                                                                                                            | Status | References                               | Support         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|------------------------------------------|-----------------|
| RSTP-SMCHS    | Is a per Bridge component Port Role Selection and the per Port state machines and associated parameters and timers implemented as specified for the CIST for RSTP? |        | 13.5.2, 13.24                            | Yes [ ] N/A [ ] |
| RSTP-IDS      | Does each Bridge have a unique identifier based on the Bridge Address, and a unique identifier for each Port?                                                      | M      | 13.2                                     | Yes [ ]         |
| RSTP-TOPOD    | Are the default values of Bridge Identifier Priority, Port Path Costs, and Port Identifier Priorities as recommended?                                              | O      | 13.18                                    | Yes [ ] No [ ]  |
| RSTP-TOPOM    | Can the Bridge Identifier Priority, Port Path Costs, and Port Identifier Priorities be set to any of the values in the ranges specified?                           | O      | 13.1, 13.4.1, 13.18, 13.25, 13.26, 13.27 | Yes [ ] No [ ]  |
| RSTP-PPCA     | Are Port Path Costs changed automatically by default if port speeds change?                                                                                        | X      | 13.18                                    | No [ ]          |
| RSTP-EDGED    | Are the default values of AdminEdge (False) and AutoEdge (True) as recommended?                                                                                    | O      | 13.27.1, 13.27.18                        | Yes [ ] No [ ]  |
| RSTP-EDGEM    | Can the values of AdminEdge and AutoEdge be set for each Port?                                                                                                     | O      | 13.27.1, 13.27.18                        | Yes [ ] No [ ]  |
| RSTP-TIMED    | Are the default values of Migrate Time, Bridge Hello Time, Bridge Max Age, Bridge Forward Delay, and Transmit Hold Count as recommended?                           | O      | 13.25                                    | Yes [ ] No [ ]  |
| RSTP-TIMEM    | Can Bridge Max Age, Bridge Forward Delay, Transmit Hold Count be set to any value in the permitted range?                                                          | O      | 13.25, 13.30, Table 13-5                 | Yes [ ] N/A [ ] |
| RSTP-TIMES    | Are the relationships between Bridge Hello Time, Bridge Max Age, and Bridge Forward Delay enforced?                                                                | M      | 13.25                                    | Yes [ ] N/A [ ] |
| RSTP-HOLDS    | Is the txCount variable for a Port set to zero if the Port's Transmit Hold Count is modified?                                                                      | M      | 13.26                                    | Yes [ ]         |
| RSTP-FPV-INIT | Is the Spanning Tree Protocol Entity reinitialized if the Force Protocol Version parameter is modified?                                                            | M      | 13.26                                    | Yes [ ]         |

<sup>58</sup> These tables with those in A.8 cover the functionality introduced in 1.3.2.

## A.7.1 Rapid Spanning Tree Protocol (RSTP) (continued)

| Item         | Feature                                                                                                                                                         | Status | References          | Support        |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|---------------------|----------------|
| RSTP-TOPOI   | Are spanning tree priority vectors and Port Role assignments recomputed if the Bridge Identifier Priority, Port Identifier Priority, or Port Path Costs change? | M      | 13.26               | Yes [ ]        |
| RSTP-TXRX    | Are BPDUs transmitted and received on all MAC_Operational Ports with Administrative Bridge Port State enabled except during an in-service upgrade?              | M      | 13.4, 13.22         | Yes [ ]        |
| RSTP-ACTIVEP | Are all MAC_Operational Ports with Administrative Bridge Port State enabled included in the computation of for Forwarding and Learning Port States?             | M      | 13.9, 8.4, 8.6, 8.7 | Yes [ ]        |
| RSTP-MCHK    | Can each port's Port Protocol Migration state machine's mcheck variable be set by management?                                                                   | O      | 13.27.38            | Yes [ ] No [ ] |
| RSTP-DELAYS  | Are the values for maximum RSTP processing delay and maximum BPDU transmission delay ever exceeded?                                                             | X      | 24.3, Table 24-1    | No [ ]         |
| RSTP-TRSFR   | Are learned MAC addresses transferred from a retiring Root Port to a new Root Port?                                                                             | O      | 13.19               | Yes [ ] No [ ] |

## A.7.2 Multiple Spanning Tree Protocol (MSTP)

| Item             | Feature                                                                                                                                                                                                                  | Status | References               | Support         |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------------------|-----------------|
| MSTP-STATE-MCHNS | Are the per Bridge component per Port Role Selection and the per Port state machines and the associated parameters and timers implemented for the CIST and a stated maximum number of MSTIs as specified for MSTP?       | M      | 5.4.1, 8.8.8, 13.24      | Yes [ ] N/A [ ] |
| MSTP-FIDS        | Is at least one FID for the CIST, plus at least one FID associated with each MSTI, supported?                                                                                                                            | M      | 5.4, 5.4.1, 8.8.8, 8.9.3 | Yes [ ]         |
| MSTP-MCID        | Is the MST Configuration Identifier (MCID) parameter for the Bridge component configuration maintained?                                                                                                                  | M      | 5.4, 8.9.2               | Yes [ ]         |
| MSTP-MCID-IN     | Is the Spanning Tree Protocol Entity reinitialized if the MCID is modified?                                                                                                                                              | M      | 13.26                    | Yes [ ]         |
| MSTP-ACTIVEP     | Are all Ports that are MAC_Operational with an enabled Administrative Bridge Port State included in the computation of Port States for use by the Forwarding and Learning for frames associated with each spanning tree? | M      | 13.9, 8.4, 8.6, 8.7      | Yes [ ]         |
| MSTP-16          | Transfer learned MAC addresses from a retiring Root Port to a new Root Port for a given spanning tree                                                                                                                    | O      | 13.16                    | Yes [ ] No [ ]  |
| MSTP-MXHOPS      | Is the default values of Max Hops as recommended?                                                                                                                                                                        | O      | 13.18                    | Yes [ ] No [ ]  |
| MSTP-MXHOPM      | Can the value of Max Hops be set to any value in the permitted range?                                                                                                                                                    | O      | 13.25, Table 13-5        | Yes [ ]         |
| MSTP-TRSFR       | Are MAC addresses learned using a FID transferred from the retiring Root Port of the associated tree to the tree's new Root Port?                                                                                        | O      | 13.19                    | Yes [ ] No [ ]  |

2

### A.7.3 BPDU encoding

| Item   | Feature                                                                                                                                                                                                                         | Status | References | Support         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|------------|-----------------|
| BPDU-1 | Do all BPDUs contain an integral number of octets?                                                                                                                                                                              | M      | Clause 14  | Yes [ ]         |
| BPDU-2 | Are all the following BPDU parameter types encoded as specified?<br><br>Protocol Identifiers<br>Protocol Version Identifiers<br>BPDU Types<br>Flags<br>Bridge Identifiers<br>Root Path Cost<br>Port Identifiers<br>Timer Values | M      | Clause 14  | Yes [ ]         |
| BPDU-3 | Do Configuration BPDUs have the format, parameters, and parameter values specified?                                                                                                                                             | M      | Clause 14  | Yes [ ]         |
| BPDU-4 | Do Topology Change Notification BPDUs have the format, parameters, and parameter values specified?                                                                                                                              | M      | Clause 14  | Yes [ ]         |
| BPDU-5 | Do transmitted RST BPDUs have the format, parameters, and parameter values specified?                                                                                                                                           | M      | Clause 14  | Yes [ ]         |
| BPDU-6 | Are received BPDUs validated as and only as specified?                                                                                                                                                                          | M      | Clause 14  | Yes [ ]         |
| BPDU-7 | Does the implementation process BPDUs of prior and possible later protocol versions as specified?                                                                                                                               | M      | Clause 14  | Yes [ ]         |
| BPDU-8 | Do transmitted MST BPDUs have the format, parameters, and parameter values specified?                                                                                                                                           | M      | 14.1       | Yes [ ] N/A [ ] |

## 1 A.8 MMRP, MVRP, and MRP conformance

2 Tables A.8.1 through A.8.3 comprise PICS items for the following:<sup>59</sup>

- 3 — The Multiple MAC Registration Protocol (MMRP) (A.8.1).
- 4 — The Multiple VLAN Registration Protocol (MVRP) (A.8.2).
- 5 — The Multiple Registration Protocol (MRP) used by MMRP and MVRP (A.8.3).

6 Complete tables referenced by Mandatory items or selected Options in other tables completed for claims of  
7 system or component conformance.

8 This introductory text and tables for which the answer to the lead item (first row) is No or N/A (not  
9 applicable) can be omitted from the completed PICS. If a table is referenced by an applicable Mandatory  
10 item or selected Option in another completed table, the only conformant answer to the lead item is Yes, and  
11 the table and referenced tables for all mandatory items and selected options are to be completed.

### 12 A.8.1 Multiple MAC Registration Protocol (MMRP)

| Item         | Feature                                                                                                                                                          | Status | References                        | Support                   |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|-----------------------------------|---------------------------|
| MMRP         | Is MRPDU exchange and MAP propagation of MMRP information for all applicable Contexts supported?<br><a href="#">Changed 15</a>                                   | M      | 10.8, 10.12, A.8.3                | Yes [ ] N/A [ ]           |
| MMRP-ETYPE   | Is the specified MMRP EtherType used to identify MRPDUs conveying MMRP information?                                                                              | M      | 10.12.1.4, Table 10-2             | Yes [ ]                   |
| MMRP-VERSION | Does the ProtocolVersion used for the implementation of MMRP take the hexadecimal value 0x00?                                                                    | M      | 10.12.1.5, 10.8.3.5               | Yes [ ]                   |
| MMRP-ATTR    | Are the MMRP Attribute Type values as specified?<br><a href="#">Changed 15</a>                                                                                   | M      | 10.12.1.6                         | Yes [ ]                   |
| MMRP-ENCODE  | Are MMRP Attributes encoded as specified? <a href="#">Changed 16</a>                                                                                             | M      | 10.12.1.7 - 10.12.1.10            | Yes [ ]                   |
| MMRP-FULLP   | Can each Bridge Port be an MMRP Full Participant?                                                                                                                | O.1    | 5.4.1.3                           | Yes [ ] No [ ]            |
| MMRP-FP2P    | Can each Bridge Port operate as an MMRP Full Participant point-to-point subset?                                                                                  | O.1    | 5.4.1.3                           | Yes [ ] No [ ]            |
| MMRP-REG     | Is MMRP registration controlled by Static Filtering Entries as specified? <a href="#">Action 20</a>                                                              | M      | 8.8.1, 10.12.2.3,                 | Yes [ ]                   |
| MMRP-RSTCTM  | Can the Restricted_MAC_Address_Registration control be managed?                                                                                                  | O      | 10.12.2                           | Yes [ ] No [ ]            |
| MMRP-RSTCTD  | If the Restricted_MAC_Address_Registration control cannot be managed, is it FALSE for all Ports?                                                                 | M      | 10.12.2                           | Yes [ ] N/A [ ]           |
| MMRP-RNUM    | Can the implementation support registrations of any possible Group membership or individual MAC address up to a stated maximum number? <a href="#">Changed 4</a> | M      | 10.10.2 <a href="#">Action 17</a> | Yes [ ] S___ <sup>a</sup> |

<sup>a</sup> If Yes, provided Supplementary information for the number supported.

<sup>59</sup>These tables with those in A.7 cover the functionality introduced in 1.3.2.

## 1 A.8.2 Multiple VLAN Registration Protocol (MVRP)

| Item          | Feature                                                                                                                                    | Status | References                                   | Support         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|--------|----------------------------------------------|-----------------|
| MVRP          | Does the implementation support MRPDUs exchange and MAP propagation of MVRP information using the Spanning Tree Context for each VID?      | M      | 5.4.2, 10.8, 10.3.1, 11.2, 11.2.3.1.2, A.8.3 | Yes [ ] N/A [ ] |
| MVRP -VTR     | If a VID translation table is in use, are VIDs in MRPDUs translated as specified?                                                          | M      | 11.2.4                                       | Yes [ ]         |
| MVRP -ETYPE   | Is the specified MVRP EtherType used to identify MRPDUs conveying MVRP information?                                                        | M      | 11.2.3.1.4, Table 10-2                       | Yes [ ]         |
| MVRP -VERSION | Does the ProtocolVersion used for the implementation of MVRP take the hexadecimal value 0x00?                                              | M      | 11.2.3.1.5                                   | Yes [ ]         |
| MVRP -ATTR    | Are the MVRP Attribute Type values as specified?                                                                                           | M      | 11.2.3.1.6                                   | Yes [ ]         |
| MVRP -ENCODE  | Are MMRP Attributes encoded as specified? <b>Changed 16</b>                                                                                | M      | 11.2.3.1.7                                   | Yes [ ]         |
| MVRP -VALS    | Are all MVRP attribute values in the possible range supported? <b>Changed 4</b>                                                            | M      | 11.2.7                                       | Yes [ ]         |
| MVRP -FP      | Can each Bridge Port operate as an MVRP Full Participant?                                                                                  | O.1    | 5.4.2                                        |                 |
| MVRP -FP2P    | Can each Bridge Port operate as an MVRP Full Participant point-to-point subset?                                                            | O.1    | 5.4.2                                        |                 |
| MVRP -NEWP    | Can each Bridge Port be configured to operate as an MVRP New-Only Participant?                                                             | O      | 11.2.6                                       | Yes [ ] No [ ]  |
| MVRP -REG     | Can MVRP registration and propagation of registrations and New messages be controlled for each VID and Port as specified? <b>Action 20</b> | M      | 8.8.2, 11.2.6,                               | Yes [ ]         |
| MVRP -TXA0    | Is the MVRP Attribute value 0 transmitted as specified? <b>Changed 19</b>                                                                  | M      | 11.2.3.1.7                                   | Yes [ ]         |
| MVRP -RXA0    | Is a received MVRP Attribute value 0 interpreted as indicating the PVID for the transmitting Port?                                         | M      | 11.2.3.1.7                                   | Yes [ ]         |

1

### A.8.3 Multiple Registration Protocol (MRP)

| Item      | Feature                                                                                                                                                                    | Status | References                         | Support         |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|------------------------------------|-----------------|
| MRP       | Is each implemented MRP application supported as specified?                                                                                                                | M      | Clause 10                          | Yes [ ] N/A [ ] |
| -MRP ADDR | Are frames addressed to MRP Application addresses forwarded, filtered , or discarded as specified?                                                                         | M      | 10.5, 8.13.3                       | Yes [ ]         |
| MRP -FP   | Does each Full Participant operate the complete Applicant, Registrar, LeaveAll, and PeriodicTransmission state machines?                                                   | M      | 10.6, 10.7                         | Yes [ ] N/A [ ] |
| MRP -FP2P | Does each Full Participant point-to-point subset operate the point-to-point subset of the Applicant, and the Registrar, LeaveAll, and PeriodicTransmission state machines? | M      | 10.6, 10.7, Table 10-3             | Yes [ ] N/A [ ] |
| MRP -NWOP | Does each New-Only Participant operate the identified subsets of the Applicant and Registrar state machines, transmitting and receiving only New messages?                 | M      | 10.6, 10.7, Table 10-3, Table 10-4 | Yes [ ] N/A [ ] |
| MRP -AOP  | Does each Applicant-Only Participant operate the complete Applicant state machines?                                                                                        | M      | 10.6, 10.7                         | Yes [ ] N/A [ ] |
| MRP -SP   | Does each Simple-Applicant Participant operate the point-to-point subset of Applicant state machine?                                                                       | M      | 10.6, 10.7                         | Yes [ ] N/A [ ] |

## 1 A.9 Provider Bridge conformance

2 Tables A.9.1 through A.9.4 comprise PICS items for the following:<sup>60</sup>

- 3 — An S-VLAN Bridge (A.9.1) and a S-VLAN Bridge component (A.9.2).
- 4 — A Provider Edge Bridge (A.9.3).
- 5 — Remote Customer Service Interface (RCSI) system capability (A.9.4).

6 Complete A.9.1, and all Tables identified in its References column for Mandatory items or selected Options,  
7 for a claim of conformance for an implementation of a S-VLAN Bridge. Table A.9.2 can be completed  
8 independently of A.9.1 to claim conformance for a S-VLAN component that is part of a system but not the  
9 principal component of a S-VLAN Bridge.

10 This introductory text and tables for which the answer to the lead item (first row) is No or N/A (not  
11 applicable) can be omitted from the completed PICS. If a table is referenced by an applicable Mandatory  
12 item or selected Option in another completed table, the only conformant answer to the lead item is Yes, and  
13 the table and referenced tables for all mandatory items and selected options are to be completed.

### 14 A.9.1 S-VLAN Bridge conformance

| Item         | Feature                                                                                             | Status | References               | Support        |
|--------------|-----------------------------------------------------------------------------------------------------|--------|--------------------------|----------------|
| S-BRIDGE     | Can the system be configured as a S-VLAN Bridge, operating as a single conformant S-VLAN component? |        | 5.10.1, Clause 15, A.9.2 | Yes [ ] No [ ] |
| S-BRIDGE-MAC | Can each Bridge Port be configured to attach directly to an IEEE 802 LAN? <a href="#">Action 21</a> | M      | 5.10                     | Yes [ ]        |

### 15 A.9.2 S-VLAN component conformance

| Item        | Feature                                                                                                                                                                                 | Status | References                                     | Support                                |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|------------------------------------------------|----------------------------------------|
| S-CMP       | Does the component <sup>a</sup> provide S-VLAN component functionality?                                                                                                                 |        | 5.6, A.6.3                                     | Yes [ ] N/A [ ]                        |
| S-EISS      | Does each Bridge Port support the MAC Relay Entity with the EISS using S-TAGs?                                                                                                          | M      | 5.6 b), 6.8, 6.9, 9.5, A.6.4                   | Yes [ ]                                |
| S-RSVD-ADDR | Are the Reserved Addresses in Table 8-2 permanently configured in the FDB?                                                                                                              | M      | Table 8-2                                      | Yes [ ]                                |
| S-RSTP      | Does the component support RSTP operation, encoding and decoding BPDUs as specified?                                                                                                    | M      | 5.4 g), A.7.1, A.7.3                           | Yes [ ]                                |
| S-RSTP-ADDR | Is the Provider Bridge Group Address used to transmit and receive BPDUs?                                                                                                                | M      | 8.13.5.1, Table 8-2                            | Yes [ ]                                |
| S-MMRP      | Does MMRP support Extended Filtering Services with a specified number of VLAN, using the Customer and Provider Bridge MMRP address. <a href="#">Action 11</a> <a href="#">Action 12</a> | O      | 5.4.1 g), 6.16.7, Table 10-1, 10.12.1.1, A.8.1 | Yes [ ] No [ ]<br>S <sup>b</sup> _____ |
| S-MVRP      | Is MVRP configuration of VLAN topology supported with MAP Contexts for the CIST and each MST and the Provider Bridge MVRP address. <a href="#">Action 18</a>                            | M      | 5.4 o), 5.6 e), 6.16.5, Table 10-1, A.8.2      | Yes [ ]<br>S <sup>a</sup> _____        |

<sup>a</sup> If the system comprises multiple S-VLAN components for which the responses to this Table or referenced Tables would differ, complete Tables for each providing Supplementary identifying information.

<sup>60</sup>These tables with items in A.6 cover the functionality introduced in 1.3.3.

<sup>b</sup> If Yes, provided Supplementary information for the Contexts supported.

### <sup>1</sup> A.9.3 Provider Edge Bridge (PEB) conformance

| Item     | Feature                                                                                                                                                  | Status     | References                            | Support         |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|------------|---------------------------------------|-----------------|
| PEB      | Can the system be configured as the Provider Edge Bridge, with a primary S-VLAN component capable of supporting one or more C-VLAN components?           |            | 5.10.2, A.9.2, A.6.2                  | Yes [ ] N/A [ ] |
| CEP      | Does each C-VLAN component support a single Customer Edge Port?                                                                                          | M          | 5.10.2                                | Yes [ ]         |
| CEP-PEP  | Does each C-VLAN component use a distinct PEP for each customer service instance to connect to the primary S-VLAN component?                             | M          | 5.10.2<br>S <sub>—</sub> <sup>a</sup> | Yes [ ]         |
| CEP-RSTP | Can each C-VLAN component implement RSTP with the enhancements to support CEPs?                                                                          | M          | 5.10.2, 13.41, A.7.1, A.7.3           | Yes [ ]         |
| PNP      | Can one or more primary S-VLAN component Bridge Ports be configured as Provider Network Ports, attached directly to an IEEE 802 LAN?                     | O          | 5.10 a)                               | Yes [ ] No [ ]  |
| RCSI     | Can the PEB be configured with one or more Remote Customer Access Ports (RCAPs), each supporting one or more Remote Customer Service Interfaces (RCSIs)? | O          | 5.10.2, 15.6, A.9.4                   | Yes [ ] No [ ]  |
| PEB-CFM  | Does the Provider Edge Bridge support CFM?                                                                                                               | O          | Clauses 18-22                         | Yes [ ] N/A [ ] |
| CEP-MEP  | Does the Provider Edge Bridge support creation of a Down MEP on each Customer Edge Port (CEP)?                                                           | PEB-CFM: M | 22.6.1                                | Yes [ ] N/A [ ] |

<sup>a</sup> Provide Supplementary information for the number of customer service instances supported.

### <sup>2</sup> A.9.4 Remote Customer Service Interface (RCSI) conformance

| Item     | Feature                                                                                      | Status     | References | Support         |
|----------|----------------------------------------------------------------------------------------------|------------|------------|-----------------|
| RCAP     | Is each configured Remote Customer Access Port supported by a Port-mapping S-VLAN component? |            | 15.6       | Yes N/A [ ]     |
| RCAP-PNP | Does each Port-mapping component have a PNP attached to the PEB's primary S-VLAN component?  | M          | 15.6       | Yes [ ]         |
| RCAP-PIF | Are Port-based RCSIs supported??                                                             | O.1        | 15.6       | Yes [ ] No [ ]  |
| RCAP-CIF | Are C-tagged RCSIs supported?                                                                | O.1        | 15.6       | Yes [ ] No [ ]  |
| CEP-MEP  | Does the Provider Edge Bridge support creation of a Down MEP on each RCAP?                   | PEB-CFM: M | 22.6.4     | Yes [ ] N/A [ ] |

## 1 A.10 Connectivity Fault Management (CFM) conformance

2 Tables A.10.1 through A.10.12 comprise PICS items for CFM functionality.<sup>61</sup>

3 Table A.10.1 identifies, by reference to Tables A.10.2 through A.10.12, CFM functionality for:

- 4 — A VLAN-unaware MAC Bridge component.
- 5 — The VLAN Bridge component of a C-VLAN or S-VLAN Bridge.
- 6 — The Primary S-VLAN component (relaying between Provider Network Ports and Customer
- 7 Network Ports) and the C-VLAN components (relaying between Provider Edge Ports and Customer
- 8 Edge Ports) of a Provider Edge Bridge.
- 9 — A Port-mapping S-VLAN component (relaying between a Remote Customer Service Interfaces
- 10 and/or Provider Access Ports and a Remote Customer Access Port) of a Provider Edge Bridge.
- 11 — Backbone Edge Bridge components.
- 12 — A TPMR.
- 13 — A VLAN-aware end station.

14 Complete Table A.10.1 for each mandatory or optional claim of CFM conformance for the systems, system  
15 components, or capability item identified by its ‘Features’ entry, marking Support as ‘N/A’ (Not Applicable)  
16 for items not implemented, and ‘No’ (where permitted) if implemented without support for CFM. If all items  
17 are ‘No’ or ‘N/A’ this section (A.10) can be omitted from the completed PICS, as can any Table not  
18 referenced or for which all items are ‘N/A’. Separate copies of the Tables referenced by Table A.10.1 are to  
19 be completed if the CFM capabilities for individual configurable items in the system differ, and those items  
20 identified by Supplementary information. This introductory text and any of the Tables A.10.2 through  
21 A.10.12 that are not referenced can be omitted.

### 22 A.10.1 CFM—System and component support

| Item     | Feature                                                                                                                                          | Status        | References                                        | Support                   |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------------------------------------------|---------------------------|
| CFM-BRG  | Does the MAC Bridge, C-VLAN Bridge, S-VLAN Bridge, or the Primary S-VLAN of the Provider Edge Bridge (PEB) support CFM. <a href="#">Issue 33</a> | O             | 5.4.1 c), A.10.2, A.10.3, A.10.4, A.10.7, A.10.10 | Yes [ ] No [ ]<br>N/A [ ] |
| CFM-PEBC | Do the C-VLAN components of the PEB support CFM? <a href="#">Issue 24</a>                                                                        | O             | 5.10.2, 15.4, A.10.5                              | Yes [ ] No [ ]<br>N/A [ ] |
| CFM-RCSI | Does each PEB or BEB Port-mapping component supporting RCSI support CFM?                                                                         | O             | 5.10.2, 15.6, A.10.5                              | Yes [ ] No [ ]<br>N/A [ ] |
| CFM-BEB  | Does the BEB support CFM?                                                                                                                        | O,<br>PBBTE:M | A.10.11                                           | Yes [ ] No [ ]<br>N/A [ ] |
| CFM-TPMR | Does the TPMR support an MA not associated with any VLAN, with a MIP on each Bridge Port.                                                        | M             | 5.15 g), A.10.7, A.10.8, A.10.10                  | Yes [ ] N/A [ ]           |
| CFM-ES   | Does the VLAN-aware end station or end station functionality of the system support CFM?                                                          | O             | 5.19, A.10.2, A.10.3, A.10.9, A.10.10             | Yes [ ] No [ ]<br>N/A [ ] |

<sup>61</sup>These Tables cover the CFM functionality introduced in 1.3.4, with additions to support 1.3.5, 1.3.6, 1.3.8, and 1.3.10.

1

## A.10.2 CFM—Maintenance Domains and Maintenance Associations

| Item        | Feature                                                                                                                                   | Status <sup>a</sup> | References          | Support         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|---------------------|---------------------|-----------------|
| CFM-MD      | Can the system (Bridge or end station) create Maintenance Domains at eight MD Levels, with multiple Maintenance Domains at each MD Level? | M                   | 5.4.1.4 a), 5.19 a) | Yes [ ] N/A [ ] |
| CFM-MA      | Can Maintenance Associations (MAs) be created for each VID supported by the system at each MD Level?                                      | M                   | 5.4.1.4 b), 5.19 b) | Yes [ ]         |
| CFM-MMA     | Is the creation of MAs that are associated with more than one VID supported?                                                              | O                   | 5.4.1.4 o), 5.19 k) | Yes [ ] No [ ]  |
| CFM-SPBM-MA | Are SPBM VID MAs supported?                                                                                                               | SPBM:<br>O          | 27.18, Clause 20    | Yes [ ] No [ ]  |
| CFM-GRPMA   | Are SPBM group MAs supported?                                                                                                             | SPBM:<br>O          | 27.18, Clause 20    | Yes [ ] No [ ]  |
| CFM-PMA     | Are SPBM path MAs supported?                                                                                                              | SPBM:<br>O          | 27.18, Clause 20    | Yes [ ] No [ ]  |
| CFM-ECMPMA  | Are ECMP path MAs supported?                                                                                                              | FF:O                | 44.2.5, Clause 20   | Yes [ ] No [ ]  |

<sup>a</sup> If referenced by A.10.1, N/A otherwise.

## A.10.3 CFM—Down MEPs

| Item     | Feature                                                                                                                            | Status <sup>a</sup> | References                               | Support                   |
|----------|------------------------------------------------------------------------------------------------------------------------------------|---------------------|------------------------------------------|---------------------------|
| MEP      | Can each Port support creation of eight Down MEPs for each VID, with each MEP at a different MD Level?<br><a href="#">Issue 30</a> | M                   | 5.4.1.4 e), 5.19 c), 22.3 A.10.6, A.10.8 | Yes [ ] N/A [ ]           |
| MEP0     | Can each Port support creation of eight Down MEPs associated with no VID, each at a different MD Level?                            | M                   | 5.4.1.4 f), 5.19 k)                      | Yes [ ]                   |
| MEP-MIPL | Can MEPs be created at MD Levels equal to or higher than those of MIPs on other VIDs on the Port?                                  | O                   | 5.4.1.4 l), 22.3                         | Yes [ ] No [ ]<br>N/A [ ] |
| MEP-ADDR | Does the Down MEP(s) MAC Address assignment differ from that for any Down MEP on other Ports?                                      | M                   | 19.4                                     | Yes [ ] N/A [ ]           |

<sup>a</sup> If referenced by A.10.1, N/A otherwise.

3

## A.10.4 CFM—Up MEPs

| Item | Feature                                                                                                                         | Status <sup>a</sup> | References                          | Support         |
|------|---------------------------------------------------------------------------------------------------------------------------------|---------------------|-------------------------------------|-----------------|
| MEP  | Can the Port support creation of eight Up MEPs for each VID, with each MEP at a different MD Level?<br><a href="#">Issue 30</a> |                     | 5.4.1.4 e), 5.19 c), A.10.6, A.10.8 | Yes [ ] N/A [ ] |
| MEP0 | Can the Port support creation of eight Up MEPs associated with no VID, each at a different MD Level?                            | M                   | 5.4.1.4 f), 5.19 d)                 | Yes [ ]         |

<sup>a</sup> If referenced by A.10.1, N/A otherwise.

5

## A.10.5 CFM—PEB Customer Edge and Access Port Down MEPs

| Item    | Feature                                                                         | Status <sup>a</sup> | References             | Support         |
|---------|---------------------------------------------------------------------------------|---------------------|------------------------|-----------------|
| MEP-CEP | Does each CEP support creation of a Down MEP for an MA associated with no VID?  | M                   | 22.6.1, A.10.6, A.10.8 | Yes [ ] N/A [ ] |
| MEP-CEP | Does each RCAP support creation of a Down MEP for an MA associated with no VID? | M                   | 22.6.4, A.10.6, A.10.8 | Yes [ ] N/A [ ] |

<sup>a</sup> If referenced by A.10.1, N/A otherwise.

## A.10.6 CFM—Common (Up and Down) MEP functionality

| Item           | Feature                                                                                                                                                                                             | Status <sup>a</sup> | References                           | Support         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|--------------------------------------|-----------------|
| MEP-SM         | Are the state machines and procedure supporting MEP operation implemented as specified?                                                                                                             | M                   | 5.4.1.4 i), 5.19 g), 19.2, Clause 20 | Yes [ ] N/A [ ] |
| MEP-LTF        | Is the LTFwhile timer implemented?                                                                                                                                                                  | M                   | 20.5, 20.5.1                         | Yes [ ] N/A [ ] |
| MEP-TIMERS     | Are the per-MEP timers CCIwhile, errorCCMwhile, xconCCMwhile, LBIwhile, and FNGwhile implemented?                                                                                                   | M                   | 20.5, 20.5.2–20.5.6                  | Yes [ ] N/A [ ] |
| MEP-RMEPT      | Is the per-MEP per-remote MEP timer rMEPwhile implemented?                                                                                                                                          | M                   | 20.5, 20.5.10                        | Yes [ ] N/A [ ] |
| MEP-DFCT       | Does a MEP set rMEPCCMdefect no sooner than $(3.25 \times \text{CCMtime}(\text{CCMinterval}))$ and no longer than $(3.25 \times \text{CCMtime}(\text{CCMinterval}))$ after receipt of the last CCM? | M                   | 20.5.10                              | Yes [ ] N/A [ ] |
| MEP-CCMITX     | Does the system transmit a nonzero value for the CCM Interval in CCMs?                                                                                                                              | M                   | 20.8.1, 20.11.1 g)                   | Yes [ ] N/A [ ] |
| MEP-MEP-CCM-DB | Does each MEP maintain a MEP CCM Database?                                                                                                                                                          | M                   | 5.4.1.4 g), 5.19 e), 19.2.2 h)       | Yes [ ] N/A [ ] |
| MEP-MIP-CCM-DB | Does each MEP maintain a MIP CCM Database? <a href="#">Action 27</a>                                                                                                                                | O                   | 5.4.1.4 m), 5.19 e), 19.2.2 h)       | Yes [ ] N/A [ ] |
| MEP-PST        | Can a MEP not associated with a single value for the Port State transmit a Port Status TLV? <a href="#">Action 26</a>                                                                               | X                   | 21.5.4                               | No [ ] N/A [ ]  |

<sup>a</sup> If referenced by A.10.3, A.10.4, or A.10.5. N/A otherwise.

## A.10.10 CFM PDU format transmission and validation

| Item        | Feature                                                                                                                                  | Status <sup>a</sup> | References                                          | Support         |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|---------------------|-----------------------------------------------------|-----------------|
| CFM-FMT     | Are all transmitted CFM PDUs formatted as specified, with an integral number of octets?                                                  | M                   | 5.4.1.4 j), 5.19 h), Clause 21, 21.1                | Yes [ ] N/A [ ] |
| CFM-HDR     | Are fixed header fields transmitted as specified?                                                                                        | M                   | 20.51.2                                             | Yes [ ]         |
| CFM-RB      | Are all reserved bits and fields transmitted as 0?                                                                                       | M                   | 20.51.2, 21.6.6                                     | Yes [ ]         |
| CFM-RC      | Are code points in any field that are reserved, by this standard or by ITU-T G.8013/Y.1731, transmitted?                                 | X                   | 20.51.2                                             | No [ ]          |
| CMF-ADD     | Are any additional fields in any TLV defined by this standard transmitted?                                                               | X                   | 20.51.2                                             | No [ ]          |
| CFM-ORG     | Can Organization-Specific TLVs be transmitted?                                                                                           | O                   | 20.51.2, 21.5.2                                     | Yes [ ] No [ ]  |
| CFM-VI      | Does any Organization-Specific TLV used violate any requirement of this standard?                                                        | X                   | 21.5.2                                              | No [ ]          |
| CFM-IND     | Is the information transmitted in an Organization-Specific TLV independent from information in a TLV received from any other port?       | M                   | 21.5.2                                              | Yes [ ]         |
| CFM-LRG     | Do transmitted Organization-Specific TLV(s) provide a means for sending messages that are larger than would fit within a single CFM PDU? | X                   | 21.5.2                                              | No [ ]          |
| CFM-MGTADDR | Does the Management Address Domain field in the Sender ID TLV(s) transmitted (if any) conform to section 8.19 of ITU-T X.690 (2002)?     | M                   | 21.5.3.5                                            | Yes [ ]         |
| CFM-VLDT    | Are all CFM PDUs validated as specified?<br><a href="#">Action 31</a>                                                                    | M                   | 20.51.3, 20.51.4<br>20.28.1, 20.33.1                | Yes [ ]         |
| CFM-VERS    | Is the version used to process CFM PDUs as specified without prohibited validation criteria?                                             | M                   | 20.17.1, 20.17.2,<br>20.28.1, 20.33.1,<br>20.51.4.2 | Yes [ ]         |
| CFM-FTLV    | Is First TLV Offset field in transmitted CFM PDUs as specified for each OpCode?                                                          | M                   | 21.4.5                                              | Yes [ ]         |
| CCM-MAID    | Is the Maintenance Association Identifier (MAID) transmitted in a CCM exactly 48 octets?                                                 | M                   | 21.6.5                                              | Yes [ ]         |
| CCM-SEQ     | Do transmitted CCMs contain either 0 or successive integers in the Sequence Number field?                                                | M                   | 20.1, 20.11.1 i)                                    | Yes [ ] No [ ]  |
| CCM-SEQI    | Do transmitted CCMs contain successive integer values in the Sequence Number field?                                                      | O                   | 20.1, 20.11.1 i)                                    | Yes [ ] No [ ]  |
| CCM-OPT     | Are the optional TLVs included in every CCM?                                                                                             | O                   | 21.6.7                                              | Yes [ ] No [ ]  |
| CCM-ORG     | Are Organization-Specific TLVs in CCMs?                                                                                                  | O                   | 21.6.7                                              | Yes [ ] No [ ]  |
| CCM-SZ      | Are all transmitted CCMs less than 128 octets?                                                                                           | M                   | 21.6                                                | Yes [ ]         |
| CCM-CHK     | Is every received CCM validated?                                                                                                         | M                   | 20.17.1, 20.17.2                                    | Yes [ ] No [ ]  |
| CCM-ORDR    | Does receive behavior differ if the CCM or LBR TLV order, other than the End TLV, is altered?                                            | X                   | 21.6.7, 21.9.6                                      | No [ ]          |
| CCM-P       | Can all valid CCMs of 128 octets or less be received and processed?                                                                      | M                   | 21.6                                                | Yes [ ]         |
| CCM-LCHK    | Are received CCMs exceeding 128 octets discarded?                                                                                        | O                   | 21.6                                                | Yes [ ] No [ ]  |

### A.10.10 CFM PDU format transmission and validation (*continued*)

| Item         | Feature                                                                                                | Status <sup>a</sup> | References                | Support        |
|--------------|--------------------------------------------------------------------------------------------------------|---------------------|---------------------------|----------------|
| CCM-SEQT     | Are received CCMs' Sequence Numbers tracked in the MEP CCM Database, and out-of-sequence CCMs counted? | O                   | 20.1, 20.17.1 e), f), g)  | Yes [ ] No [ ] |
| LBM-SNDR     | Is the Sender ID TLV included in every LBM?                                                            | O                   | 21.5.3, 21.7.4            | Yes [ ] No [ ] |
| LBM-MGT-ADDR | Is the Management Address included in the LBM Sender ID TLV?                                           | O                   | 21.5.3                    | Yes [ ] No [ ] |
| LBM-ORG      | Are Organization-Specific TLVs included in LBMs?                                                       | O                   | 21.7.4                    | Yes [ ] No [ ] |
| LBM-TXD      | Can transmitted LBMs include the Data TLV?                                                             | O                   | 21.5.6                    | Yes [ ] No [ ] |
| LBR-RXD      | Is Data TLV content interpreted except when receiving an LBR? <a href="#">Action 27</a>                | X                   | 21.5.6                    | No [ ]         |
| LB-MCHK      | Are the mandatory checks and processing applied to each received LBM and LBR?                          | M                   | 20.2.2, 20.28.1, 20.33.1  |                |
| LB-OCHK      | Are the optional checks and processing applied to each received LBM and LBR?                           | O                   | 20.2.2, 20.28.1, 20.33.1  |                |
| LB-CMP       | Are received LBRs bit-by-bit compared with the original LBM?                                           | O                   | 20.2.3, 20.33.1           | Yes [ ] No [ ] |
| LBM-RATE     | Can transmitted LBMs overflow output queues in the absence of other data traffic?                      | X                   | 20.2.1                    | No [ ]         |
| LTM-ID       | Does every transmitted LTM contain an LTM Egress Identifier TLV?                                       | M                   | 21.8.7                    | Yes [ ]        |
| LTR-ID       | Does every transmitted LTR contain an LTR Egress Identifier TLV?                                       | M                   | 21.9.6                    | Yes [ ]        |
| LT-VLDT      | Are all received LTMs, LTRs, LTMs validated?                                                           | M                   | 20.33.1, 20.44.1, 20.47.1 | Yes [ ]        |
| CFM-RXRT     | Can a high CFM PDUs receive rate increase the probability of network forwarding loops?                 | X                   | 20.51.5                   | No [ ]         |

<sup>a</sup> To avoid needless repetition, all questions in this table (A.10.10) are specific to CFM PDUs. If the system does not support CFM conformance, the Table is not applicable and can be omitted from the completed PICS.

## <sup>1</sup> A.10.11 CFM—Backbone Edge Bridge (BEB) functionality

| Item     | Feature                                                                                | Status <sup>a</sup> | References                                        | Support                   |
|----------|----------------------------------------------------------------------------------------|---------------------|---------------------------------------------------|---------------------------|
| CFM-BCMP | Does the B-component of the BEB support CFM.                                           | M                   | 5.4.1 c), A.10.2, A.10.3, A.10.4, A.10.7, A.10.10 | Yes [ ] N/A [ ]           |
| CFM-ICMP | Does each I-component of the BEB support CFM?                                          | O                   | 5.4.1.4, 5.7.1 d), 26.8                           | Yes [ ] No [ ]<br>N/A [ ] |
| CFM-TCMP | Does each T-component of the BEB support CFM?<br><a href="#">Issue 29</a>              | O                   | 5.17, 26.8                                        | Yes [ ] N/A [ ]           |
| CFM-BSI  | Can CFM monitor TESIs using back-to-back Backbone Service Instance Multiplex Entities? | O                   | 5.7.1, 5.8.1                                      | Yes [ ] No [ ]            |
| CFM-TE   | If the BEB supports PBB-TE, does it support CFM?                                       | M                   | 26.8, A.10.12                                     | Yes [ ] N/A [ ]           |

<sup>a</sup> If referenced by A.10.1, N/A otherwise.

| Item             | Feature                                                                                                                                                                                                                                                                          | Status <sup>a</sup> | References                                                       | Support         |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|------------------------------------------------------------------|-----------------|
| TESI-MA          | Can an MA be created per TESI for each MD Level?                                                                                                                                                                                                                                 | M                   | 5.8.2, 26.9                                                      | Yes [ ] N/A [ ] |
| TESI-MEP         | Can an Up MEP be created per TESI on each CBP?                                                                                                                                                                                                                                   | M                   | 5.8.2, 6.19, 26.9.3                                              | Yes [ ]         |
| TESI-MEPS        | Can eight Up MEPs be created per TESI, each at a different MD Level, on each CBP?                                                                                                                                                                                                | O                   | 5.8.2                                                            | Yes [ ] No [ ]  |
| TESI-MIPS        | Can MIPs be created on TESIs?                                                                                                                                                                                                                                                    | O                   | 5.6.2, 5.8.2                                                     | Yes [ ] No [ ]  |
| TESI-LBM-MIP     | Is the PBB-TE MIP TLV included in every LBM targeting a PBB-TE MIP?                                                                                                                                                                                                              | M                   | 20.2, 21.7.5                                                     | Yes [ ]         |
| TESI-LTM-MA      | Is the PBB-TE MIP TLV included in every LTM that is associated with a PBB-TE MA?                                                                                                                                                                                                 | M                   | 20.3, 21.7.5                                                     | Yes [ ]         |
| TESI-LBM-MEP     | Is the PBB-TE MIP TLV included in LBMs that are targeting a PBB-TE MEP?                                                                                                                                                                                                          | X                   | 20.2, 21.7.5                                                     | No [ ]          |
| TESI-LBM-MIP-TLV | Is the PBB-TE MIP TLV the first TLV in an LBM targeting a PBB-TE MIP?                                                                                                                                                                                                            | M                   | 20.2, 21.7.5                                                     | Yes [ ]         |
| TESI-RMAC        | Is the Reverse MAC field included in LBMs/LTMs for Point-to- Multipoint PBB-TE MAs?                                                                                                                                                                                              | M                   | 20.2, 20.3, 21.7.5                                               | Yes [ ]         |
| TESI-MAID-CHK    | Does the PBB-TE MEP check the MAID in received CCMs?                                                                                                                                                                                                                             | O                   | 20.1.3, 20.17.1                                                  | Yes [ ] No [ ]  |
| TESI-MTCH        | Are protection switching mismatch defects detected using the Traffic field bit in CCMs, the per-PBB-TE MEP timers mmCCMwhile, mmLocwhile, and mmFNGwhile, and the MEP Traffic Field Mismatch, MEP Local Mismatch, and MEP Mismatch Fault Notification Generator state machines ? | O                   | 26.12, 20.11.1, 20.16.3, 20.17.1, 21.6.1.4, 20.5.7, 20.24, 20.40 | Yes [ ] No [ ]  |

<sup>a</sup> If referenced by A.10.11 , N/A otherwise.

## 1 A.11 Provider Backbone Bridge conformance

2 Tables A.11.1 through A.11.8 comprise PICS items for the following:<sup>62</sup>

- 3 — A Backbone Core Bridge (BCB, A.11.1) and a Backbone Edge Bridge (BEB, A.11.2).
- 4 — The I- (A.11.3) and T- (A.11.4) BEB components, and their Virtual Instance Ports (VIPs, A.11.5).
- 5 — The B-component (A.11.6) of a BEB.
- 6 — Provider Backbone Traffic Engineering (PBBTE) capabilities common to BCB S-VLAN aware
- 7 component and BEB B-components (A.11.7), and those specific to BEBs (A.11.8).

8 Complete tables as required for claims of system or component conformance. This introductory text and  
9 tables for which the the lead item (first row) is No or N/A (not applicable) can be omitted.<sup>63</sup> If a table is  
10 referenced by an applicable item in another completed table, the only conformant answer to the lead item is  
11 Yes, and the table and referenced tables for all mandatory items and selected options are to be completed.

### 12 A.11.1 Backbone Core Bridge (BCB) conformance

| Item   | Feature                                                       | Status | References                | Support        |
|--------|---------------------------------------------------------------|--------|---------------------------|----------------|
| BCB    | Can the system be configured as a Backbone Core Bridge (BCB)? | O      | 12.15, A.9.1 <sup>a</sup> | Yes [ ] No [ ] |
| BCB-TE | Does the BCB support Traffic Engineering?                     | O      | 5.12.1, <add table>       | Yes [ ] No [ ] |

<sup>a</sup> No functionality beyond that specified for an S-VLAN Bridge is required.

### 13 A.11.2 Backbone Edge Bridge (BEB) conformance

| Item    | Feature                                                                                                           | Status | References               | Support         |
|---------|-------------------------------------------------------------------------------------------------------------------|--------|--------------------------|-----------------|
| BEB     | Can the system be configured as a Backbone Edge Bridge?                                                           | O      | 5.12, Clause 25, A.10.1  | Yes [ ] No [ ]  |
| BEB-PNP | Can one or more Provider Network Ports (PNPs) be configured, each for external connection to a BCB?               | O      | Clause 25, Fig 25-4      | Yes [ ] No [ ]  |
| BEB-PIF | Can the BEB provide Customer Network Port (CNP) Port-based service interfaces, each supported by an I-component?  | O.1    | 25.3, Fig 25-4, Fig 25-5 | Yes [ ] No [ ]  |
| BEB-SIF | Can the BEB provide one or more CNP S-tagged service interfaces, each supported by an I-component?                | O.1    | 25.4, Fig 25-4, Fig 25-5 | Yes [ ] No [ ]  |
| BEB-SMC | Are S-tagged service interfaces for more than one customer supported by separate I-components?                    | M      | 25.4                     | Yes [ ] N/A [ ] |
| BEB-SMB | Are S-tagged service interface with all-to-one bundling supported by separate I-components?                       | M      | 25.4                     | Yes [ ] N/A [ ] |
| BEB-IIF | Can the BEB provide one or more external Customer Bridge Port (CBP) I-tagged service interfaces ?                 | O.1    | 25.5, A.11.6             | Yes [ ] No [ ]  |
| BEB-PIP | Can the BEB provide one or more Provider Instance Port (PIP) I-tagged service interfaces for attachment to a CBP? | O.1    |                          | Yes [ ] No [ ]  |

<sup>62</sup> These tables cover the system functionality introduced in 1.3.5 and 1.3.6.

<sup>63</sup> If the answers to the lead items of A.11.1 and A.11.2 are both no (i.e. the system cannot be configured as a BCB or a BEB, then none of the tables in this section of the PICS (A.11) apply, and it can be omitted entirely.

## A.11.2 Backbone Edge Bridge (BEB) conformance *(continued)*

| Item     | Feature                                                                                      | Status | References    | Support         |
|----------|----------------------------------------------------------------------------------------------|--------|---------------|-----------------|
| BEB-TIF  | Can the BEB be configured to provide one or more transparent service interfaces?             | O.1    | 25.11         | Yes [ ] No [ ]  |
| BEB-TM   | Is each transparent interface supported by a separate T-component?                           | M      | 25.11, A.11.4 | Yes [ ] N/A [ ] |
| BEB-BCMP | If the BEB includes more than one I-component or T-component, does it include a B-component? | M      | 25.4, 25.11   | Yes [ ] N/A [ ] |
| BEB-TE   | Does the BEB support Traffic Engineering?                                                    | O      | 5.12.1        | Yes [ ] No [ ]  |

## <sup>1</sup> A.11.3 BEB I-component conformance

| Item   | Feature                                                                                                                                    | Status | References                     | Support         |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------------------------|-----------------|
| I-CMP  | Is each I-component an S-VLAN component capable of relaying frames between Customer Network Ports (CNPs) and Virtual Instance Port (VIPs)? |        | 5.7, 25.3, A.9.2, A.11.5       | Yes [ ] N/A [ ] |
| I-MS2I | Does the I-component support many-to-one S-VID to I-SID mapping?                                                                           | O      | 5.7.1, 25.2, 25.4, 17.6.2.5.2  | Yes [ ] No [ ]  |
| I-MIRP | Does each I-component support MIRP?                                                                                                        | O      | 5.7.1, Clause 39, 39.1, 39.1.1 | Yes [ ] No [ ]  |
| I-AAB  | Does the I-component support Auto Attach Bridge functionality?                                                                             | O      | A.12.1, A.12.3                 |                 |

## <sup>2</sup> A.11.4 BEB T-component conformance

| Item     | Feature                                                                                                                                                                              | Status | References                  | Support         |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|-----------------------------|-----------------|
| T-CMP    | Is each T-component a TPMR component that relays frames between a Customer Network Port (CNP) and Virtual Instance Port (VIP) supported by a dedicated Provider Instance Port (PIP)? |        | 5.17, 25.11, A.11.5, A.15.2 | Yes [ ] N/A [ ] |
| CBP-EISS | Is the EISS provided by each CBP supported by I-TAG and S-TAG functions?                                                                                                             | M      | 5.8, 6.11, A.6.4            | Yes [ ]         |
| CBP-BSI  | Does each CBP support a manageable Backbone Service Instance table??                                                                                                                 | M      | 6.11                        | Yes [ ]         |

## <sup>3</sup> A.11.5 BEB Virtual Instance Port (VIP) conformance

| Item     | Feature                                                                                   | Status | References       | Support |
|----------|-------------------------------------------------------------------------------------------|--------|------------------|---------|
| VIP-EISS | Does each VIP provide the EISS using a Provider Instance Port (PIP) as specified?         | M      | 6.10, 6.9, A.6.4 | Yes [ ] |
| VIP-ISID | Does each VIP have a manageable VIP-ISID?                                                 | M      | 6.10             | Yes [ ] |
| VIP-BDST | Does each VIP support a Default Backbone Destination paramet, with the specified default? | M      | 6.10             | Yes [ ] |

### A.11.5 BEB Virtual Instance Port (VIP) conformance *(continued)*

| Item     | Feature                                                                                             | Status | References  | Support |
|----------|-----------------------------------------------------------------------------------------------------|--------|-------------|---------|
| VIP-P2P  | Does each VIP support adminPointToPointMAC?                                                         | M      | 6.10        | Yes [ ] |
| VIP-ENCI | Does each VIP support enableConnectionIdentifier?                                                   | M      | 6.10        | Yes [ ] |
| PIP-BMAC | Does each PIP use an individual B-MAC address, the address of the attached CBP, as the PIP address? | M      | 6.10, 25.10 | Yes [ ] |
| PIP-ISS  | Are data indications and requests from and to each PIP processed as specified?                      |        | 6.10        | Yes [ ] |

1

### A.11.6 B-component conformance

| Item      | Feature                                                                                                                                   | Status | References                     | Support         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------------------------|-----------------|
| B-CMP     | Does the configured BEB include a B-component: an S-VLAN component with Customer Backbone Ports (CBPs) and Provider Network Ports (PNPs)? |        | 5.8, A.9.2                     | Yes [ ] N/A [ ] |
| CBP-INT   | Is connectivity between CBPs and PIPs within the system supported as specified?                                                           | M      | 6.14                           | Yes [ ]         |
| CBP-EISS  | Is the EISS provided by each CBP supported by I-TAG and S-TAG functions?                                                                  | M      | 5.8, 6.11, A.6.4               | Yes [ ]         |
| CBP-BSI   | Does each CBP support a manageable Backbone Service Instance(BSI) table, indexed by Backbone-ISID?                                        | M      | 6.11                           | Yes [ ]         |
| -BSI-BVID | Do BSI table entries include a B-VID field?                                                                                               | O      | 6.11                           | Yes [ ] No [ ]  |
| -BSI-LSID | Do BSI table entries include a Local-SID field?                                                                                           | O      | 6.11                           | Yes [ ] No [ ]  |
| -BSI-DFLT | Can each BSI table entry include a Default Backbone Destination field?                                                                    | O      | 6.11                           | Yes [ ] No [ ]  |
| B-MIRP    | Does each B-component support MIRP?                                                                                                       | O      | 5.8.1, Clause 39, 39.1, 39.1.2 | Yes [ ] No [ ]  |

2

### A.11.7 PBB-TE S-VLAN component conformance

| Item    | Feature                                                                                           | Status   | References                   | Support |
|---------|---------------------------------------------------------------------------------------------------|----------|------------------------------|---------|
| TE-VIDS | Can B-VIDs be assigned to the TE-MSTID?                                                           | M        | 5.6.2, 25.10                 | Yes [ ] |
| TE-XLRN | Is learning disabled for B-VIDs assigned to the TE-MSTID?                                         | M        | 5.6.2, 8.4, 8.9              | Yes [ ] |
| TE-UNKN | Are frames with unregistered destination addresses and B-VIDs assigned to the TE-MSTID discarded? | M        | 5.6.2, 8.4, 8.9              | Yes [ ] |
| TE-AGNT | Can all B-VIDs be controlled by an external agent?                                                | O        | 5.6.2                        | Yes [ ] |
| TE-CFM  | Are CFM MIP creation and the CFM extensions for TESIs supported?                                  | O        | 5.6.2, 26.9, A.10.11         | Yes [ ] |
| TE-IPS  | Is 1:1 IPS supported?                                                                             | O        | 5.6.2, 5.6.3, 26.11, 26.11.2 | Yes [ ] |
| TE-IPSM | Is M:1 IPS supported?                                                                             | TE-IPS:O | 5.6.2, 5.6.3, 26.11, 26.11.5 | Yes [ ] |

1

## A.11.8 PBB-TE B-component conformance for PBB-TE

| Item     | Feature                                                                                   | Status | References               | Support |
|----------|-------------------------------------------------------------------------------------------|--------|--------------------------|---------|
| VIP-EISS | Does each VIP provide the EISS using a Provider Instance Port (PIP) as specified?         | M      | 6.10, 6.9, A.6.4, A.10.1 | Yes [ ] |
| VIP-ISID | Does each VIP have a manageable VIP-ISID?                                                 | M      | 6.10                     | Yes [ ] |
| VIP-BDST | Does each VIP support a Default Backbone Destination paramet, with the specified default? | M      | 6.10                     | Yes [ ] |
| VIP-P2P  | Does each VIP support adminPointToPointMAC?                                               | M      | 6.10                     | Yes [ ] |
| VIP-ENCI | Does each VIP support enableConnectionIdentifier?                                         | M      | 6.10                     | Yes [ ] |
| PIP-BMAC | Does each PIP have an individual B-MAC address, for use as the PIP address?               | M      | 6.10                     | Yes [ ] |
| PIP-ISS  | Are data indications and requests from and to each PIP processed as specified?            |        | 6.10                     | Yes [ ] |

2

## 1 A.12 PBBN Auto Attach conformance

2 Tables A.12.1, A.12.2, and A.12.3 comprise PICS items for Auto Attach for Provider Backbone Bridge  
3 Networks (PBBNs).<sup>64</sup> Complete A.12.1 if optional Auto Attach Bridge (AAB) functionality is claimed for a  
4 Backbone Edge Bridge (BEB) I-component (A.11.2). Complete A.12.2 if the optional Auto Attach Device  
5 (AAD) functionality is claimed for an attached device. A.12.3 contains elements common to AABs and  
6 AADs that facilitate their communication, as is to be completed for both. This introductory text and tables  
7 for which the the lead item (first row) is No or N/A (not applicable) can be omitted.<sup>65</sup>

### 8 A.12.1 Auto Attach Bridge (AAB) I-component conformance

| Item | Feature                                         | Status | References                     | Support         |
|------|-------------------------------------------------|--------|--------------------------------|-----------------|
|      | Are S-tagging auto attach interfaces supported? | M      | 5.12.2, 50.2, D.2.17.8, A.12.3 | Yes [ ] N/A [ ] |
|      | Are C-tagging auto attach interfaces supported? | M      | 5.12.2, 50.2, D.2.17.8         | Yes [ ]         |
|      | Is the AAB State Machine supported?             | M      | 5.12.2, 50.7                   | Yes [ ]         |
|      | Is management of PBBN Auto Attach supported?    |        | 5.12.2, 12.34                  | Yes [ ]         |
|      | Is the 802.1Q Management VID TLV supported?     | O      | D.2.6                          | Yes [ ] No [ ]  |

### 9 A.12.2 Auto Attach Device (AAD) conformance

| Item | Feature                                    | Status | References                  | Support         |
|------|--------------------------------------------|--------|-----------------------------|-----------------|
|      | Does the AAD support the AAD State Machine | M      | 5.14.2, 5.9.2, 50.6, A.12.3 | Yes [ ] N/A [ ] |

### 10 A.12.3 Auto Attach (common elements) conformance

| Item    | Feature                                                                                 | Status | References                    | Support         |
|---------|-----------------------------------------------------------------------------------------|--------|-------------------------------|-----------------|
| AA-LLDP | Does the I-component support Link Layer Discovery Protocol (LLDP) transmit and receive? | M      | 5.12.2, 5.14.2                | Yes [ ] N/A [ ] |
| AA-STLV | Does the AAB implementation support the PBBN Auto Attach System TLV?                    | M      | 5.12.2, D.2.17                | Yes [ ] N/A [ ] |
| AA-ATLV | Does the AAD implementation support the PBBN Auto Attach Assignment TLV?                | AAD:M  | 5.12.2, 5.14.2, 5.9.2, D.2.18 | Yes [ ] N/A [ ] |

11

<sup>64</sup> These tables cover the system functionality introduced in 1.3.5 and 1.3.6.

<sup>65</sup> If the answers to the lead items of A.12.1 and A.12.2 are both no (i.e. the system cannot be configured as an AAB or an AAD, then none of the tables in this section of the PICS (A.12) apply, and it can be omitted entirely.

## 1 A.13 Shortest Path Bridging (SPB) conformance

2 Table A.13.1 comprises PICS items for Shortest Path Bridging (SPB).<sup>66</sup> Complete this table if the system  
3 can be configured to provide this functionality. This introductory text and any table for which the the lead  
4 item (first row) is No or N/A (not applicable) can be omitted.

### 5 A.13.1 Shortest Path Bridging (SPB) conformance

| Item     | Feature                                                                                                                   | Status | References                         | Support    |                   |
|----------|---------------------------------------------------------------------------------------------------------------------------|--------|------------------------------------|------------|-------------------|
| SPB      | Can the system be configured to support Shortest Path Bridging (SPB)? <a href="#">Issue 34</a>                            | O      | 5.4.5                              | Yes [ ]    | No [ ]            |
| SPBV     | Is SPB VID mode supported?                                                                                                | O.1    | 5.4.5                              | Yes [ ]    | No [ ]            |
| SPBM     | Is SPBM MAC mode supported?                                                                                               | O.1    | 5.4.5                              | Yes [ ]    | No [ ]            |
| SPB-ISIS | Does the Bridge support IS-IS Link State Protocol with procedures to ensure Loop Prevention?                              | M      | 5.4.5, Clause 28                   | Yes [ ]    |                   |
| SPB-PDUS | Encode, decode, and validate IS-IS Hello PDUs or SPT BPDUs for the Agreement Protocol (AP) and support AP logic in IS-IS? | M      | 5.4.5, Clause 28                   | Yes [ ]    |                   |
| SPB-FIDS | State the maximum number of FIDs supported. Minimum is three for SPB.                                                     | M      | 5.4.5                              | _____ FIDs |                   |
| SPB-ECMP | Does SPBM MAC mode support ECMP? <a href="#">Issue 35</a>                                                                 | SPBM:O | 5.4.5, 5.6.4, Clause 28, Clause 44 | Yes [ ]    | No [ ]<br>N/A [ ] |

6

<sup>66</sup> This table covers the system functionality introduced in 1.3.8.

## 1 A.14 Path Control and Reservation (PCR) conformance

2 Table A.14.1 comprises PICS items for Path Control and Reservation (PCR).<sup>67</sup> Complete this table if the  
3 system can be configured to provide this functionality. This introductory text and any table for which the the  
4 lead item (first row) is No or N/A (not applicable) can be omitted (the Status of other rows depends on that  
5 of the lead item).

### 6 A.14.1 Path Control and Reservation (PCR) conformance

| Item                                                                    | Feature                                                                     | Status | References       | Support |                   |
|-------------------------------------------------------------------------|-----------------------------------------------------------------------------|--------|------------------|---------|-------------------|
| PCR                                                                     | Can the system be configured to support Path Control and Reservation (PCR)? | O      | 5.4.6, Clause 45 | Yes [ ] | No [ ]<br>N/A [ ] |
| PCR-ISIS                                                                | Is the ISIS-PCR protocol supported?                                         | M      | Clause 45        | Yes [ ] |                   |
| Are the following TLVs or sub-TLVs supported? <a href="#">Action 36</a> |                                                                             |        |                  |         |                   |
| PCR-LMTRC                                                               | SPB Link Metric                                                             | M      | 28.12.7          | Yes [ ] |                   |
| PCR-BVIDS                                                               | SPB Base VLAN-Identifiers                                                   | M      | 28.12.4          | Yes [ ] |                   |
| PCR-SPB                                                                 | SPB Instance                                                                | M      | 28.12.5          | Yes [ ] |                   |
| PCR-VADDR                                                               | SPBV MAC address                                                            | M      | 28.12.9          | Yes [ ] |                   |
| PCR-BSID                                                                | SPBM Service Identifier and Unicast Address                                 | BEB:M  | 28.12.10         | Yes [ ] | N/A [ ]           |
| PCR-TOP                                                                 | Topology                                                                    | M      | 45.1.9           | Yes [ ] |                   |
| PCR-HOP                                                                 | Hop                                                                         | M      | 45.1.10          | Yes [ ] |                   |

<sup>67</sup> This table covers the system functionality introduced in 1.3.8.

### A.14.1 Path Control and Reservation (PCR) conformance *(continued)*

| Item       | Feature                                                         | Status | References                   | Support |                   |
|------------|-----------------------------------------------------------------|--------|------------------------------|---------|-------------------|
| ECT-MRTG   | The MRTG ECT Algorithm                                          | O      | 45.1.2, 45.3.4               | Yes [ ] | No [ ]            |
| PCR-LFALTS | Are Loop-Free Alternates for SPBM unicast data flows supported? | SPBM:O | 45.3.1                       | Yes [ ] | No [ ]<br>N/A [ ] |
| PCR-RLXIN  | Is relaxed ingress checking supported?                          | SPBM:O | 8.4, 8.6.1,<br>8.8.3, 45.3.1 | Yes [ ] | No [ ]<br>N/A [ ] |

1

## 1 A.15 TPMR conformance

2 Tables A.15.1 through A.15.3 comprise PICS items for the following:<sup>68</sup>

- 3 — A Two-Port MAC Relay (TPMR, A.15.1) and a TPMR component (A.15.2).
- 4 — MAC Status Propagation (MSP, A.15.3).

5 Complete A.15.1 and all Tables identified in the References column for Mandatory items or selected  
6 Options, for a claim of conformance for an implementation of a TPMR. Complete A.15.2 and its referenced  
7 Tables for an implementation of a TPMR component. Claims of conformance for T-components in a  
8 Backbone Edge Bridge (BEB) are supported by Table A.11.4 which references A.15.2 .

9 Table A.15.3 is mandatory reference of A.15.2, and can also be completed to claim MSP conformance for an  
10 externally attached Bridge Port of a VLAN-unaware MAC Bridge component or a VLAN Bridge  
11 component supporting MSP for attachment to one or a series of TPMRs.

12 This introductory text and tables for which the answer to the lead item (first row) is No or N/A (not  
13 applicable) can be omitted from the completed PICS. If a table is referenced by an applicable mandatory  
14 item in another completed table, the only conformant answer to the lead item is Yes, and the table and  
15 referenced tables for all mandatory items and selected options are to be completed.

### 16 A.15.1 TPMR conformance

| Item      | Feature                                                                                                                                                                                                                    | Status | References   | Support         |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------|-----------------|
| TPMR      | Can the system be configured as a TPMR, comprising a single TPMR component, with exactly two externally accessible Bridge Ports each capable of attaching directly to an IEEE 802 LAN? <b>Action 6 Action 37 Action 37</b> |        | 5.16, A.15.2 | Yes [ ] N/A [ ] |
| TPMR-MGT  | Does the implementation support the management functionality specified in 12.19?                                                                                                                                           | M      | 12.19        | Yes [ ]         |
| TPMR-RMGT | Does the implementation support remote management via at least one of the externally accessible Ports?                                                                                                                     | M      | 5.15, 8.13.7 | Yes [ ]         |

### 17 A.15.2 TPMR component conformance

| Item           | Feature                                                                                                                                                                                                            | Status | References                           | Support         |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------------------------------|-----------------|
| TPMR-CMP       | Does the component provide VLAN-unaware relay and filtering of frames, as specified for a TPMR component?                                                                                                          | M      | 5.15, 8.1, 8.5, 8.6, 8.7, 8.8, A.5.3 | Yes [ ] N/A [ ] |
| TPMR-RSVD-ADDR | Are the Reserved Addresses in Table 8-3 permanently configured in the FDB?                                                                                                                                         | M      | Table 8-3                            | Yes [ ]         |
|                | <b>This row temporarily retained as a reminder that some management capabilities may be applicable to TPMR components in general (which probably means just the BEB T-component, which references this Table).</b> |        |                                      |                 |

<sup>68</sup> These tables cover the functionality introduced in 1.3.10.

### <sup>1</sup> **A.15.3 MAC Status Protocol (MSP)**

| Item     | Feature                                                               | Status | References                 | Support                   |
|----------|-----------------------------------------------------------------------|--------|----------------------------|---------------------------|
| MSP      | Can one or more of the externally accessible Bridge Ports support MSP |        |                            | Yes [ ] No [ ]<br>N/A [ ] |
| MSP-STM  | Is the Status Transmission state machine (STM) supported?             | M      | 23.8                       | Yes [ ]                   |
| MSP-SNM  | Is the Status Notification state machine (SNM) supported?             | M      | 23.9                       | Yes [ ]                   |
| MSP-RX   | Are MSPDUs received and validate MSPDUs as specified?                 | M      | 23.10, 23.16               | Yes [ ]                   |
| MSP-TX   | Are MSPDUs identified address, encoded, and transmitted as specified? | M      | 23.11, 23.13, 23.14, 23.15 | Yes [ ]                   |
| MSP-PRD  | Can MSP performance parameters be read by management?                 | O      | 23.12                      | Yes [ ] No [ ]            |
| MSP-PWR  | Can MSP performance parameters to be modified by management?          | O      | 23.12                      | Yes [ ] No [ ]            |
| MSP-PCT  | Are the specified counts maintained for at least one Port?            | O      | 23.12                      | Yes [ ] No [ ]            |
| MSP-PCTS | Are the specified counts maintained for both Ports?                   | O      | 23.12                      | Yes [ ] No [ ]            |

2

## 1 A.16 Time and loss-sensitive stream transmission

2 Tables A.16.1 through A.16.6 comprise PICS items for the following:<sup>69</sup>

- 3 — Forwarding and queuing for time-sensitive streams (FQTSS, A.16.1).
- 4 — The Stream Reservation Protocol (SRP, A.16.2) and its use of MMRP, MVRP, and MSRP.
- 5 — Designated MSRP Node (DMN) support for SRP on 802.11 (A.16.3) and MoCA (A.16.4)
- 6 — Scheduling traffic using transmission gates (A.16.5).
- 7 — Asynchronous Traffic Shaping (ATS, A.16.6).

8 Complete tables as required for claims of system or component conformance for the support of time and  
9 loss-sensitive stream transmission support. This introductory text and tables for which the the lead item (first  
10 row) is No or N/A (not applicable) can be omitted. If a table is referenced by an applicable item in another  
11 completed table, the only conformant answer to the lead item is Yes, and the table and referenced tables for  
12 all mandatory items and selected options are to be completed.

### 13 A.16.1 Forwarding and queuing for time-sensitive streams (FQTSS)

| Item         | Feature                                                                                                                     | Status | References            | Support                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------|--------|-----------------------|---------------------------|
| FQTSS        | Does the VLAN-aware Bridge component support FQTSS?<br><a href="#">Change 40</a>                                            |        | 5.4.1.5,<br>Clause 34 | Yes [ ] No [ ]<br>N/A [ ] |
| FQTSS-PCMAP  | Are the tables and procedures for mapping priorities to traffic classes supported?                                          | M      | 5.4.1.5, 34.5         | Yes [ ]                   |
| FQTSS-TCMIN  | Are at least two traffic classes supported, one for strict priority and the other an SR class?<br><a href="#">Change 39</a> | M      | 5.4.1.5, 8.6.8.1      | Yes [ ]                   |
| FTQTSS-SRTCS | State the number of SR classes supported, and the default priority regeneration override values for each ST class.          | M      | 5.4.1.5, 6.9.4, 34.6  | Number ____<br>S. ____    |
| FQTSS-CBS    | Can credit-based shaper transmission selection be selected on all Ports for each SR class ?                                 | M      | 5.4.1.5, 8.6.8.2      | Yes [ ]                   |
| FQTSS-DBRGN  | Is the SRP domain boundary port priority regeneration override supported, including the default for SR class “B.”           | M      | 5.4.1.5, 6.9.4        | Yes [ ]                   |

<sup>69</sup> These tables cover the system functionality introduced in 1.3.11, with the exception of frame preemption which is covered in A.5.3.3.

## A.16.2 Stream Reservation Protocol (SRP)

| Item     | Feature                                                                                                                                                                           | Status | References               | Support                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------------------|---------------------------|
| SRP      | Does the VLAN-aware Bridge component support SRP with MSRP and MVRP? <a href="#">Change 41</a> <a href="#">Change 42</a>                                                          |        | Clause 35, A.8.1, A.8.2, | Yes [ ] No [ ]<br>N/A [ ] |
| SRP-MMR  | Is SRP supported by MMRP? <a href="#">Issue 56</a>                                                                                                                                | O      | Clause 35                | Yes [ ] No [ ]            |
| SRP-XP   | Can MSRPDU information be exchanged and propagated for all applicable MAP contexts? <a href="#">Change 43</a>                                                                     | M      | 10.8, 35.1, 35.2         | Yes [ ]                   |
| SRP-DA   | Are MSRPDU transmitted to the Individual LAN Scope group MAC address?                                                                                                             | M      | 35.2.2.1                 | Yes [ ]                   |
| SRP-ET   | Does each MSRPDU use the MSRP EtherType?                                                                                                                                          | M      | 35.2.2.2                 | Yes [ ]                   |
| SRP-TXV  | Is ProtocolVersion 0x01 used in transmitted MSRPDU?                                                                                                                               | M      | 35.2.2.3                 | Yes [ ]                   |
| SRP-RXV  | Are received MSRPDU Protocol Versions processed as specified?                                                                                                                     | M      | 35.2.2.3, 10.8.3.5       | Yes [ ]                   |
| SRP-ATT  | Are MSRP Attributes encoded and decoded as specified? <a href="#">Change 45</a>                                                                                                   | M      | 35.2.2                   | Yes [ ]                   |
| SRP-ALT  | Is Accumulated Latency updated as Talker attributes are propagated, including failure information in the event of insufficient bandwidth or resources ? <a href="#">Change 45</a> | M      | 35.2.2.8, 35.2.2.10      | Yes [ ]                   |
| SRP-TLP  | Is the <i>talkerPruning</i> parameter supported? <a href="#">Change 46</a>                                                                                                        | O      | 35.2.4.3.2               | Yes [ ] No [ ]            |
| SRP-TLPP | Is the <i>talkerPruningPerPort</i> parameter supported?                                                                                                                           | O      | 35.2.4.3.3               | Yes [ ] No [ ]            |
| SRP-TLVP | Is the <i>talkerVLANPruning</i> parameter supported?                                                                                                                              | O      | 35.2.4.3.4               | Yes [ ] No [ ]            |
| SRP-LA   | Are Listener attributes merged and propagated as specified?                                                                                                                       | M      | 35.2.4.4                 | Yes [ ]                   |
| SRP-DYR  | Are Dynamic Reservation Entries updated as specified? <a href="#">Change 51</a>                                                                                                   | M      | 8.8 k), 35.2.4.4.2       | Yes [ ]                   |
| SRP-OIS  | Is operIdleSlope updated as specified?                                                                                                                                            | M      | 35.2.4.4.2,              | Yes [ ]                   |
| SRP-ARV  | Can stream reservations be modified automatically? <a href="#">Change 52</a>                                                                                                      | O      | 35.2.6                   | Yes [ ] No [ ]            |
| SRP-TLR  | State the number of Talker registrations values and Listener registrations values supported? <a href="#">Change 53</a>                                                            | M      | 35.2.7                   | S. ____                   |
| SRP-PVID | Is each Port's SR_PVID always a valid value? <a href="#">Change 53</a>                                                                                                            | M      | 35.2.1.4 i)              | Yes [ ]                   |
| SRP-PVIC | Can the SR_PVID value be changed from the default?                                                                                                                                | O      | 35.2.1.4 i)              | Yes [ ] No [ ]            |
| SRP-ON   | Are both original and new attribute types supported?                                                                                                                              | M      | 35.1                     | Yes [ ]                   |
| SRP-DBD  | Are domain boundaries detected? <a href="#">Change 55</a>                                                                                                                         | M      | 35.1                     | Yes [ ]                   |
| SRP-STR  | Is Stream transformation supported?                                                                                                                                               | O      | 35.2.2.10.5              | Yes [ ] No [ ]            |
| SRP-TLKT | Is protocol version Talker attribute translation supported ?                                                                                                                      | M      | 35.2.4.3.1               | Yes [ ]                   |
| SRP-LSTR | Is protocol version Listener attribute translation supported ?                                                                                                                    | M      | 35.2.4.4.4               | Yes [ ]                   |
| SRP-30   | Is the Domain attribute declared prior to Talker/Listener attributes?                                                                                                             | M      | 35.2.2.9                 | Yes [ ]                   |
| SRP-31   | Is talker pruning per Port supported?                                                                                                                                             | O      | 35.2.4.3.3               | Yes [ ] No [ ]            |
| SRP-32   | Is talker VLAN pruning supported?                                                                                                                                                 | O      | 35.2.4.3.4               | Yes [ ] No [ ]            |

### <sup>1</sup> A.16.3 802.11 Designated MSRP Mode (DMN) conformance

| Item     | Feature                                                                                            | Status | References   | Support                   |
|----------|----------------------------------------------------------------------------------------------------|--------|--------------|---------------------------|
| D11      | Is IEEE 802.11 Access Point (AP) functionality with DMN capability supported on one or more ports? |        | Annex C, C.3 | Yes [ ] No [ ]<br>N/A [ ] |
| D11-S    | Is a single Designated MSRP Node (DMN) supported?                                                  | M      | 35.1.1       | Yes [ ]                   |
| D11-EDCA | Is the EDCA-AC TSPEC supported as specified?                                                       | M      | C.3.3.3      | Yes [ ]                   |
| D11-QAP  | Are the DMN and the BSS QAP function co-located?                                                   | M      | C.3.2        | Yes [ ]                   |
| D11-MLME | Are the MLME services supported as specified?<br>Change 47                                         | M      | C.3.3        | Yes [ ]                   |
| D11-TAG  | Does the IEEE 802.11 interface support VLAN tag encapsulation/de-encapsulation?                    | M      | C.3.3.1      | Yes [ ]                   |
| D11-RSV  | Is the reservation process an atomic operation?                                                    | M      | C.3.1,       | Yes [ ]                   |

### <sup>2</sup> A.16.4 MoCA Designated MSRP Mode (DMN) conformance

| Item      | Feature                                                                                                   | Status | References   | Support                   |
|-----------|-----------------------------------------------------------------------------------------------------------|--------|--------------|---------------------------|
| DMOCA     | Is Multimedia over Coax Alliance (MoCA) functionality with DMN capability supported on one or more ports? |        | Annex C, C.2 | Yes [ ] No [ ]<br>N/A [ ] |
| DMOCA-S   | Is a single Designated MSRP Node (DMN) supported?                                                         | M      | 35.1.1       | Yes [ ]                   |
| DMOCA-DIE | Is the DMN Device Attribute IE appended to the L2ME message? <b>Change 48</b>                             | M      | C.2.1.2      | Yes [ ] N/A [ ]           |
| DMOCA-SEL | Is DMN selection supported?                                                                               | M      | C.2.1.3      | Yes [ ] N/A [ ]           |
| DMOCA-DEC | Are MSRP Attribute Declarations and MAD primitives mapped as specified?                                   | M      | C.2.2        | Yes [ ] N/A [ ]           |

| ATS     | Does the Bridge component support ATS?                   |        | 5.4.1.10,<br>5.13.1.3, 8.6.6 | N/A [ ] |
| ATS-CLM | Is ATS per-stream classification and metering supported? | M      | 8.6.5.2.2                    | Yes [ ] |
| ATS-TX  | Is the ATS transmission selection algorithm supported?   | M      | 8.6.8, 8.6.8.5               | Yes [ ] |
| ATS-SM  | Are the ATS scheduler state machines supported?          | M      | 8.6.11                       | Yes [ ] |
| ATS-MGT | Is management of ATS supported?                          | M      | 12.31                        | Yes [ ] |

## 1 A.17 TSN Centralized Network Configuration (CNC) station

2 Table A.17.1 comprises PICS items for a station supporting centralized time-sensitive network  
3 configuration.<sup>70</sup>

4 Complete the table as required for a claim conformance. This section (A.17) of the PICS can be omitted if  
5 the lead item (first row) would be marked No or N/A (not applicable). If the table is referenced by an  
6 applicable item in another completed table, the only conformant answer to the lead item is Yes, and the table  
7 and referenced tables for all mandatory items and selected options are to be completed.

### 8 A.17.1 TSN Centralized Network Configuration (CNC) station

| Item     | Feature                                                                                                                | Status | References                      | Support                   |
|----------|------------------------------------------------------------------------------------------------------------------------|--------|---------------------------------|---------------------------|
| CNC      | Does the station support TSN Centralized Network Configuration? <a href="#">Change 58</a>                              |        | 5.29, Clause 46, Clause 34      | Yes [ ] No [ ]<br>N/A [ ] |
| CNC-MGTP | Which management protocols are supported (client)? <a href="#">Change 59</a>                                           | M      | 5.29 a)1)                       | S.____                    |
| CNC-MGTO | Which managed objects and encoding specifications are supported? <a href="#">Change 60</a>                             | M      | 5.29 a)2)                       | S.____                    |
| CNC-SRM  | Is management of the attributes required for Stream reservation remote management supported? <a href="#">Change 60</a> | M      | 5.29 b), 12.32                  | Yes [ ]                   |
| CNC-SCHD | Is management of the resources and parameters for scheduled traffic supported? <a href="#">Issue 61</a>                | O      | 12.29                           | Yes [ ] No [ ]            |
| CNC-PRE  | Is management of frame preemption parameters supported? <a href="#">Issue 61</a>                                       | O      | 12.30                           | Yes [ ] No [ ]            |
| CNC-UNC  | Which user/network configuration protocols are supported?                                                              | M      | 5.29 c)), 46.2.2                | S.____                    |
| CNC-MSRP | Is MRP External Control for MSRP supported? <a href="#">Change 62</a>                                                  | SRP:M  | 5.29 d), A.16.2, 46.2, 12.32.4, | Yes [ ] N/A [ ]           |
| CNC-MVRP | Is MRP External Control for MVRP supported?                                                                            | SRP:M  | 5.29 d), A.16.2, 46.2, 12.32.4  | Yes [ ] N/A [ ]           |
| CNC-MMRP | Is MRP External Control for the MMRP supported?                                                                        | SRP:M  | 5.29 d), A.16.2, 46.2, 12.32.4  | Yes [ ] N/A [ ]           |
| CNC-YANG | Are the YANG modules identified in 46.3 supported?                                                                     | O      | 5.29 e), 46.3                   | Yes [ ] No [ ]            |
| CNC-1AS  | Is management for IEEE Std 802.1AS supported? <a href="#">Issue 61</a>                                                 | O      | IEEE Std 802.1AS                | Yes [ ] No [ ]            |
| CNC-1CB  | Is management for IEEE Std 802.1CB supported? <a href="#">Issue 61</a>                                                 | O      | IEEE Std 802.1CB                | Yes [ ] No [ ]            |

<sup>70</sup> Functionality introduced in 1.3.12

## 1 A.18 Congestion notification

2 Table A.18.1 comprises PICS items for a system supporting congestion notification.<sup>71</sup>

3 Complete the table as required for a claim conformance. This section (A.18) of the PICS can be omitted if  
4 the lead item (first row) would be marked No or N/A (not applicable). If the table is referenced by an  
5 applicable item in another completed table, the only conformant answer to the lead item is Yes, and the table  
6 and referenced tables for all mandatory items and selected options are to be completed.

### 7 A.18.1 Congestion notification system conformance

| Item     | Feature                                                                                                                   | Status                     | References                            | Support                            |
|----------|---------------------------------------------------------------------------------------------------------------------------|----------------------------|---------------------------------------|------------------------------------|
| CN       | Does the system support congestion notification?<br><a href="#">Change 63</a>                                             |                            | 5.4.3, 5.21,<br>Clause 30-33          | Yes [ ] No [ ]<br>N/A [ ]          |
| CP       | Can a Congestion Point (CP) be created on one or more<br>Ports? <a href="#">Change 64</a>                                 | VB:M, <sup>a</sup><br>VS:O | 5.4.3 a) i),<br>31.1.1                | Yes [ ] N/A [ ]<br>S. <sub>b</sub> |

|          | Does a system's CP interpret a CN-TAG to any degree<br>beyond simply copying it to the CNM?                               | BRG1<br>AND<br>CN: M       | 33.2.1                                | No [ ] N/A [ ]                     |
|          | Does the CP transmit a 0 in the CNM's Version field?                                                                      | BRG1<br>AND<br>CN: M       | 33.4.1                                | Yes [ ] N/A [ ]                    |

<sup>a</sup> VB = VLAN Bridge component, VS = VLAN-aware End Station.

<sup>b</sup> Include Supplementary information if more than one CP can be supported on all or some ports.

<sup>71</sup> Functionality introduced in 1.3.13.

## 1 Annex C

### 2 (normative)

## 3 Designated MSRP Node (DMN) Implementations

4 This annex describes the DMN implementation on an IEEE 802.11 Network and Coordinated Shared  
5 Networks (CSNs).

### 6 C.1 DMNs on CSNs

7 A CSN is a contention-free, time-division multiplexed-access network, supporting reserved bandwidth  
8 based on priority or flow (QoS). One of the nodes of the CSN acts as the Network Coordinator (NC) node,  
9 granting transmission opportunities to the other nodes of the network. The NC node also acts as the  
10 bandwidth resource manager of the network.

#### 11 C.1.1 CSN characteristics

12 CSNs support two types of transmissions: unicast transmission for node-to-node transmission and multicast/  
13 broadcast transmission for one-node-to-other/all-nodes transmission. Each node-to-node link has its own  
14 bandwidth characteristics that could change over time due to the periodic ranging of the link. The multicast/  
15 broadcast transmission characteristics are the lowest common characteristics of multiple/all the links of the  
16 network.

17 A CSN network is physically a shared network, in that a CSN node has a single physical port connected to  
18 the half-duplex medium, but is also a logically fully-connected one-hop mesh network, in that every node  
19 could transmit to every other node using its own profile over the shared medium.

20 Figure C-1 illustrates a CSN network acting as a backbone interconnecting AV systems.

Figure C-1—CSN backbone

21 Depending on the CSN technology, the Network Coordinator node either may be a fixed node or may be  
22 dynamically selected during normal operation.

## 1 C.1.2 DMN handling on CSN

2 From the bandwidth reservation standpoint a CSN network is modeled as a Bridge as illustrated by  
3 Figure C-2. Each node-to-node link is equivalent to a Bridge's path from an ingress port to an egress port.

**Figure C-2—Bridge's CSN model for bandwidth reservation**

4 A CSN shall provide a single entity called the Designated MSRP Node (DMN) (35.1.1), which  
5 communicates with the MSRP Service to manage the CSN bandwidth resources for the MSRP streams.

6 NOTE 1—The MSRP Service supplies both MSRP Attribute Propagation (MAP) for the CSN and MSRP Attribute  
7 Declaration (MAD) for each MSRP-aware CSN node.

8 NOTE 2—An end station node provides an end station MSRP implementation as outlined in 5.18.3. This MSRP  
9 implementation is logically on the upper layer side of this interface. This standard expects that an MSRP-aware CSN  
10 node will have a single non-CSN interface. If more interfaces are present, they are expected to be connected through a  
11 Bridge function. If this node happens to be the DMN, then this end station MSRP implementation is separate and distinct  
12 from the DMN's MSRP Service.

### 13 C.1.2.1 DMN selection and migration

14 Depending on the CSN technology, the DMN might correspond to a static node or dynamically migrate  
15 between nodes during normal operation. The DMN selection is network specific and described in C.2.1 and  
16 C.3.2.

17 Over time the DMN constructs its database by handling the MSRP Talker and Listener Declarations  
18 generated by the nodes of the CSN. If the DMN migrates, the new DMN broadcasts an MRP LeaveAll  
19 message to all the nodes of the CSN, which will force its neighbors to redeclare their attributes. The MSRP  
20 Participant nodes answer the MRP LeaveAll message by sending an MRP JoinIn message consumed by the  
21 DMN as an MRP Re-Declare! message. These redeclarations permit the new DMN to immediately build its  
22 database.

### 1 C.1.3 MSRPDU handling on a CSN

2 Figure C-3 and Figure C-4 illustrate the flow and handling of MSRPDU messages on a CSN.

Figure C-3—Talker MSRPDU flow

Figure C-4—Listener MSRPDU flow

- 3 a) A MSRP-aware CSN node identifies MSRPDU received on its non-CSN interface (the interface
- 4 either to another network media or to upper layers of the node) by their destination MAC address
- 5 (35.2.2.1) and EtherType (35.2.2.2).
- 6 b) Non-DMN nodes send MSRPDU to the DMN over the CSN.
- 7 c) The DMN delivers MSRPDU, along with information about the originating interface, to the MSRP
- 8 Service.
- 9 d) The DMN translates the MSRP TSpec parameters into CSN QoS parameters and invokes the CSN's
- 10 Protocol Specific QoS transactions with the CSN Network Coordinator (C.2.2, C.3.3) as follows:
- 11 1) When the DMN receives a Talker Advertise message originated from an upstream CSN node,
- 12 the DMN invokes a bandwidth query transaction with the CSN Network Coordinator to check
- 13 whether the bandwidth advertised in the message's TSpec is available on each upstream to
- 14 downstream node link of the CSN network. In addition the DMN associates the MSRP
- 15 attributes with the CSN's native QoS records via the StreamID (which is included in the CSN
- 16 frames).

- 1        2) When the DMN receives a Listener Ready message originated from a downstream CSN node,  
2        the DMN invokes a bandwidth reservation transaction with the CSN QoS manager to reserve  
3        the bandwidth associated with the message's StreamID on the downstream to upstream CSN  
4        node link.
- 5        e) After the DMN completes the CSN QoS transactions, the DMN behaves as an MSRP application on  
6        a Bridge and propagates (MAP) and distributes (MAD) MSRP attributes (35.2).
- 7        NOTE—When the MAD function of the MSRP Service distributes attributes, it will deliver MSRPDUs to the  
8        DMN's non-CSN interface and/or send them to the appropriate MSRP-aware CSN nodes.

#### 9 **C.1.4 CSN bandwidth fluctuations**

10 Bandwidth on a CSN may fluctuate depending on interference experienced by the media. The MSRP  
11 Attribute Propagation (35.2.4) supports a *bandwidthAvailabilityChanged* notification when bandwidth  
12 increases or decreases across the media. When a bandwidth changed is encountered, MAP will reassess  
13 reservation requests to maintain appropriate bandwidth utilization.

### 14 **C.2 DMN on MoCA**

15 NOTE—The discussion that follows is based on terminology found in the MoCA MAC/PHY Specifications v1.1 and  
16 v2.0 [B57] and [B58].

#### 17 **C.2.1 DMN Selection on MoCA Network**

##### 18 **C.2.1.1 DMN-capable node discovery**

19 A DMN-capable node shall append the *IEEE DMN Device Attribute Information Element* (C.2.1.2) to the  
20 L2ME payload of the Device Discovery Protocol SUBMIT L2ME transaction message specified in the  
21 MoCA MAC/PHY Specification v2.0 [B58].

22 Upon completion of the L2ME Device Discovery transaction, all the DMN-capable nodes of the MoCA  
23 network share the same information as follows:

- 24        a) Which MoCA nodes are DMN capable  
25        b) Which MoCA node is selected as the DMN

26 If no DMN is selected, the DMN selection shall be performed (C.2.1.3).

## 1 C.2.1.2 IEEE DMN Device Attribute IE

### 2 C.2.1.2.1 General

3 The fields of the IEEE DMN Device Attribute IE are specified in Figure C-5 and C.2.1.2.2 through  
4 C.2.1.2.7. The general format of the Device Attribute Information Element is described in the MoCA MAC/  
5 PHY Specification v2.0 [B58].

| Bits                  |   |   |   |   |   |   |   | Octets | Offset<br>From<br>Start of<br>IE |
|-----------------------|---|---|---|---|---|---|---|--------|----------------------------------|
| 8                     | 7 | 6 | 5 | 4 | 3 | 2 | 1 |        |                                  |
| ATTRIBUTE_ID          |   |   |   |   |   |   |   | 1      | 0                                |
| LENGTH                |   |   |   |   |   |   |   | 1      | 1                                |
| ----- VENDOR_ID ----- |   |   |   |   |   |   |   | 2      | 2                                |
| TLV_TYPE              |   |   |   |   |   |   |   | 1      | 4                                |
| TLV_LENGTH            |   |   |   |   |   |   |   | 1      | 5                                |
| ----- TLV_VALUE ----- |   |   |   |   |   |   |   | 2      | 6                                |

Figure C-5—IEEE DMN Device Attribute IE

#### 6 C.2.1.2.2 ATTRIBUTE\_ID (Enumeration8)

7 The value of the ATTRIBUTE\_ID is 0xFF.

#### 8 C.2.1.2.3 LENGTH (UInteger8)

9 The value of the LENGTH is 1.

10 NOTE—The actual length of the Attribute IE in bits is  $(\text{LENGTH} + 1) \times 32$ .

#### 11 C.2.1.2.4 VENDOR\_ID (Enumeration16)

12 The value of VENDOR\_ID is 0x0090 (IEEE 802.1 AVB).

#### 13 C.2.1.2.5 TLV\_TYPE (Enumeration16)

14 The value of the TLV\_TYPE is 1 (SRP).

#### 15 C.2.1.2.6 TLV\_LENGTH (UInteger8)

16 The length of the TLV in octets is 4.

1 **C.2.1.2.7 TLV\_VALUE (Octet2)**

2 The meaning of the field of the TLV\_VALUE are specified as described in C.2.1.2.7.1 through C.2.1.2.7.3.

3 **C.2.1.2.7.1 DMNcapable (Bit 0 - Boolean)**

4 A value of 1 indicates the node is capable of acting as the DMN of the network. A value of 0 indicates the  
5 node is not capable to act as a DMN.

6 **C.2.1.2.7.2 DMNselected (Bit 1 - Boolean)**

7 A value of 1 indicates the node has been selected as the DMN of the network. A value of 0 indicates the  
8 node is not the selected DMN.

9 **C.2.1.2.7.3 Reserved (Bit 2..15)**

10 These bits are reserved for future use.

11 **C.2.1.3 DMN selection and confirmation**

12 If either 1) the *NODE\_BITMASK* field into MAP frames indicates that the selected DMN has been removed  
13 from the network (due to failure, power state/down, etc.) or 2) the DMN node discovery (C.2.1.1) does not  
14 indicate a DMN selected node, the DMN-capable node with the lowest node ID will start acting as the DMN  
15 and confirm the selection to the other DMN-capable nodes by generating a L2ME DMN Confirmation  
16 Transaction (C.2.1.3.1).

17 NOTE—"MAP frame" is defined in the MoCA MAC/PHY Specification v1.1 [B57].

18 **C.2.1.3.1 L2ME DMN Confirmation Transaction**

19 **C.2.1.3.1.1 Overview of DMN Confirmation Transaction**

20 Figure C-6 provides an overview of the signals exchanged among the nodes during an L2ME DMN  
21 Confirmation Transaction. As shown in the figure, the NC node starts the transaction either when it receives  
22 a Submit L2ME Frame from a node (called the DMN Selected Entry Node for that Transaction) or on its  
23 own. The transaction includes two L2ME Waves. The details of each message exchanged during the DMN  
24 Confirmation Transaction are provided below.

25 **C.2.1.3.1.2 DMN Confirmation Submit**

26 The DMN Confirmation Transaction starts when the DMN Selected Entry Node sends a Submit L2ME  
27 Frame to the NC.

28 The general fields of the Submit L2ME frame are as specified in section 2.2.3.1 of the MoCA MAC/PHY  
29 Specification v1.1 [B57]. The parameters in the Submit L2ME Frame are set as follows:

- 30 a) *VENDOR\_ID* (see C.2.1.2.4)
- 31 b) *TRANS\_TYPE* = 0x1 (SRP)
- 32 c) *TRANS\_SUBTYPE* = 0x1 (DMN Confirmation)
- 33 d) *WAVE0\_NODEMASK* = (DMN-capable nodes)
- 34 e) *MSG\_PRIORITY* = 0xF0
- 35 f) *TXN\_LAST\_WAVE\_NUM* = 0x1
- 36 g) *L2ME\_PAYLOAD* = 0 bytes

Figure C-6—DMN Confirmation Transaction

#### 1 C.2.1.3.1.3 Request L2ME Frame of Wave 0 of DMN Confirmation Transaction

2 In the Wave 0 that follows the DMN Confirmation Submit message, the NC node initiates a Request L2ME  
3 Frame based on the Submit L2ME Frame.

4 The general fields of the Request L2ME frame are as specified in section 2.2.3.2 of the MoCA MAC/PHY  
5 Specification v1.1 [B57].

#### 6 C.2.1.3.1.4 Response L2ME Frame of Wave 0 of DMN Confirmation Transaction

7 Each of the requested DMN-capable nodes sends a Response L2ME Frame to acknowledge the confirmation  
8 request.

9 The general fields of the Response L2ME frame are as specified in 2.2.3.3 of the MoCA MAC/PHY  
10 Specification v1.1 [B57]. The parameters in the Response L2ME Frame are set as follows:

- 11 a) RESP\_STATUS <INTERPRETED> = '1'
- 12 b) RESP\_STATUS <IN\_NEXT\_WAVE> = '1'
- 13 c) L2ME\_PAYLOAD = 0 bytes

#### 14 C.2.1.3.1.5 Request L2ME Frame of Wave 1 of DMN Confirmation Transaction

15 In Wave 1, the NC node informs the DMN-capable nodes about the acknowledgment results from Wave 0.  
16 The NC node initiates Wave 1 using a Request L2ME Frame with the “concatenated” type of  
17 L2ME\_PAYLOAD.

18 The general fields of the Request L2ME frame are as specified in section 2.2.3.1 of the MoCA MAC/PHY  
19 Specification v1.1 [B57]. The “concatenated” L2ME\_Payload is as specified in Table 2-4 of the MoCA  
20 MAC/PHY Specification v1.1 [B57].

### 1 C.2.1.3.1.6 Response L2ME Frame of Wave 1 of DMN Confirmation Transaction

2 The DMN Confirmation Transaction is completed when the DMN Selected Entry node and the other DMN-  
3 capable nodes send their final Response L2ME Frame to the NC node.

4 The general fields of the Response L2ME frame are as specified in section 2.2.3.3 of the MoCA MAC/PHY  
5 Specification v1.1 [B57]. The parameters in the Response L2ME Frame are set as follows:

- 6 a) RESP\_STATUS <INTERPRETED> = '1'
- 7 b) RESP\_STATUS <IN\_NEXT\_WAVE> = '0'
- 8 c) L2ME\_PAYLOAD = 0 bytes

### 9 C.2.2 MoCA network bandwidth management

10 The MSRP service within the MoCA network manages the MoCA bandwidth for the MSRP streams by  
11 invoking the MoCA native PQoS transactions. The DMN shall map the MSRP Attribute Declaration and the  
12 resultant MAD declarations as described in Table C-1.

**Table C-1—SRP to MoCA PQoS Transaction mapping**

| MSRP Attribute                                                                                                                                                                                                                                                                                                                    | MAD Primitive         | MoCA PQoS Transactions | Description                                                |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|------------------------|------------------------------------------------------------|
| Talker Advertise                                                                                                                                                                                                                                                                                                                  | MAD_Join.request(new) | Create PQoS Flow       | Query bandwidth without reservation (see NOTE)             |
| Listener Ready or Listener Ready Failed                                                                                                                                                                                                                                                                                           | MAD_Join.request(new) | Create PQoS Flow       | Reserve bandwidth for a stream                             |
| Listener Ready or Listener Ready Failed                                                                                                                                                                                                                                                                                           | MAD_Join.request()    | Update PQoS Flow       | Renew the bandwidth reservation (leased time) for a stream |
| Talker or Listener Leave                                                                                                                                                                                                                                                                                                          | MAD_Leave.request()   | Delete PQoS Flow       | Free bandwidth associated with a stream                    |
| NOTE—MoCA PQoS APIs do not include a Bandwidth Query-specific API. Therefore, bandwidth is queried by invoking a CreatePQoSFlow reservation for more bandwidth than the network could provide. The request will fail and CreatePQoSFlow will then return a failure status that includes the bandwidth available for reservations. |                       |                        |                                                            |

13 Table C-2 describes the mapping between SRP TSPEC components and MoCA PQoS TSPEC parameters.

**Table C-2—SRP TSPEC to MoCA TSPEC mapping**

| SRP TSPEC                                                                    | MoCA PQoS TSPEC  |
|------------------------------------------------------------------------------|------------------|
| MaxFrameSize                                                                 | Max Packet Size  |
| MaxFrameSize × MaxIntervalFrames                                             | Peak Data Rate   |
| MaxFrameSize × MaxIntervalFrames × Class B class measurement interval (34.4) | (Max) Burst Size |

14 Table C-3 describes the mapping of the SRP StreamID to MoCA PQoS Flow transactions. The MoCA Flow  
15 parameters includes a 32-bit field that allows an application, like SRP, to store application-specific  
16 information. SRP will use this field (FLOW\_TAG) to store the 16-bit unique ID portion of the StreamID.

**Table C-3—SRP StreamID to MoCA PQoS Flow transaction mapping**

| SRP StreamID     | MoCA PQoS Flow Transaction           |              |           |
|------------------|--------------------------------------|--------------|-----------|
|                  | Transaction                          | L2ME Payload | Field     |
| MAC Address      | Create PQoS Flow<br>Update PQoS Flow | Submit       | PACKET_DA |
|                  | Query PQoS Flow                      | Response     |           |
| 16-bit Unique ID | Create PQoS Flow<br>Update PQoS Flow | Submit       | FLOW_TAG  |
|                  | Query PQoS Flow                      | Response     |           |

### 1 C.3 DMNs on IEEE 802.11 media

2 NOTE—Even though IEEE Std 802.11 is not a CSN, it uses the same DMN concepts described below.

3 From the bandwidth reservation standpoint an IEEE 802.11 BSS network is modeled as a Bridge as  
4 illustrated by Figure C-7, Figure C-8, and Figure C-9. Each STA-AP link, STA-AP-STA link and optional  
5 STA-STA DLS direct link is equivalent to the path from an input to an output Bridge's port.

6 An IEEE 802.11 BSS provides a single entity called the Designated MSRP Node (DMN) (35.1.1) to manage  
7 the BSS bandwidth resources for the MSRP streams.

**Figure C-7—Bandwidth reservation—bridge model for IEEE 802.11 BSS (STA downstream Port)**

Figure C-10—MSRP/IEEE 802.11 query flows

1 Figure C-10 is an example of the reservation process associated with a Listener non-AP STA requesting a  
2 Stream from the Talker non-AP STA. The diagram at the left of the figure shows the Listener non-AP STA  
3 sending a Listener Ready (A) through the AP's MSRP Service, which then propagates that Listener Ready  
4 (B) to the Talker non-AP STA. The message flow on the right of the figure shows the corresponding  
5 IEEE 802.11 message exchanges associated with the two Listener Readys (A & B).

Figure C-11—MSRP/802.11 Talker STA to Listener STA reservation flows

1 There are two reservations (A & B) required to allow the Stream to flow from Talker to Listener. In  
2 Figure C-11, Figure C-12, and Figure C-13, the reservation process must be an atomic operation so, if either  
3 reservation fails, then both reservations shall be removed and the MSRP attributes updated accordingly.

4 Figure C-12 is an example of the reservation process associated with a “Bridged” Listener requesting a  
5 Stream from a Talker non-AP STA. The Listener sends a Listener Ready (A) from the “Bridged” side of the  
6 network and bandwidth is reserved as explained in SRP (Clause 35). The IEEE 802.11 message exchanges  
7 associated with the Listener Ready (B) propagating to the Talker non-AP STA are also shown.

**Figure C-12—MSRP/802.11 “Bridged” Listener to Talker STA reservation flows**

8 Figure C-13 is an example of the reservation process associated with a Listener non-AP STA requesting a  
9 Stream from a “Bridged” Talker. The Listener non-AP STA sends a Listener Ready (A) through the AP’s  
10 MSRP Service, resulting in the IEEE 802.11 message exchanges shown. The reservation process associated  
11 with the Listener Ready (B) sent to the “Bridged” Talker is explained in SRP (Clause 35).

**Figure C-13—MSRP/802.11 Listener STA to “Bridged” Talker reservation flows**

1 The IEEE 802.11 message exchanges shown in the preceding three figures are explained in more detail as  
2 follows:

- 3 a) BBS nodes identify MSRPDUs by their Group Destination Address (35.2.2.1) and EtherType  
4 (35.2.2.2) and send these PDUs to the AP.
- 5 b) The AP forwards the MSRPDUs to the MSRP service on the DMN.
- 6 c) The DMN translates the MSRP TSPEC parameters into an equivalent IEEE 802.11 TSPEC and  
7 invokes DMN-SME interface primitives with the AP as follows:
  - 8 1) When the DMN receives a Talker Advertise message that originated from an upstream BSS  
9 node, the DMN invokes QoS Query transactions (SME-QUERY.Request) with the BSS QoS  
10 AP (i.e., HC where dot11RobustAVStreamingImplemented is true) to check whether the  
11 bandwidth advertised in the message's TSPEC is available on each upstream to downstream  
12 node link of the BSS. In addition the DMN maps the MSRPDU's TSPEC with the message's  
13 StreamID.
  - 14 2) When the DMN receives a Listener Ready message originated from a downstream BSS node,  
15 the DMN invokes a QoS Reservation transaction (SME-ADDTS.Request) with the BSS QoS  
16 manager to reserve the bandwidth associated with the message's StreamID on the downstream  
17 to upstream BSS node link.

18 The IEEE 802.11 BSS QoS AP on receipt of a SME-ADDTS.Request from the DMN shall  
19 make a determination about whether to accept the request or deny the request. The algorithm to  
20 be used by the BSS QoS AP to make this determination is an implementation detail.

21 If the BSS QoS AP decides to accept the request, the AP shall derive a medium time value from  
22 the parameters specified in the SME-ADDTS.Request. The BSS QoS AP shall then generate an  
23 ADDTS Reserve Request frame in which the medium time value is included and transmit it to  
24 the appropriate SRP Talker (BSS upstream) and Listener (BSS downstream) nodes. The  
25 appropriate SRP Talker or Listener node replies to this ADDTS Reserve Request frame with an  
26 ADDTS Reserve Response frame indicating if the node accepts the reservation request. One or  
27 more ADDTS Request and ADDTS Response frames might be exchanged prior to the ADDTS  
28 Reserve Response frame.

29 If the BSS QoS AP or Listener/Talker node decides to reject the request, it shall respond to the  
30 DMN with SME-ADDTS.confirm with a ResultCode of Rejected. The confirm primitive may  
31 also include a TSPEC, which the BSS QoS AP can accept, if specified in a subsequent SME-  
32 ADDTS.request.

33 NOTE—The TSPEC included in the SME-ADDTS.confirm is based on the result of the negotiations  
34 (labeled optional in Figure C-11 through Figure C-13) with the upstream BSS node. As a result the  
35 TSPEC included in the SME-ADDTS.confirm may be different from the one in the SME-ADDTS.request  
36 from the DMN.
- 37 d) After the DMN completes the BSS QoS transactions (SME-QUERY.Confirm or SME-  
38 ADDTS.Confirm as appropriate), the DMN behaves as an MSRP application on a Bridge and  
39 propagates MSRP attributes (35.2).

### 40 C.3.2 BSS DMN selection

41 The DMN shall be co-located with the device that supports the QoS AP function in the BSS.

### 1 C.3.3 BSS network bandwidth management

2 The MSRP service within the IEEE 802.11 network manages the BSS bandwidth for the MSRP streams by  
3 invoking the MLME QoS services. The DMN shall map the MLME services as described in Table C-4.

**Table C-4—SRP to MLME QoS Services mapping**

| MSRP Attribute                          | MAD Primitive         | SME QoS Services       | Description                                                |
|-----------------------------------------|-----------------------|------------------------|------------------------------------------------------------|
| Talker Advertise                        | MAD_Join.request(new) | SME-QUERY              | Query bandwidth without reservation                        |
| Listener Ready or Listener Ready Failed | MAD_Join.request(new) | SME-ADDTS              | Reserve bandwidth for a stream                             |
| Listener Ready or Listener Ready Failed | MAD_Join.request()    | SME-ADDTS <sup>a</sup> | Renew the bandwidth reservation (leased time) for a stream |
| Talker or Listener Leave                | MAD_Leave.request()   | SME-DELTS              | Free bandwidth associated with a stream                    |

<sup>a</sup> Bandwidth renewal is not required as long as the reservation is already established.

#### 4 C.3.3.1 MSRPDU Encapsulation/De-encapsulation

5 In order to preserve the priority of an MSRPDU when traversing through an IEEE 802.11 network not using  
6 a Length/Type field in the MSDU, the priority shall be encapsulated while the MSRPDU is in the IEEE  
7 802.11 network and shall be de-encapsulated as it exits. See IEEE Std 802.11 for additional information.

8 NOTE—For example if the priority of the MSRPDU is 4, DEI=0 and VID = 1893 the equivalent VLAN tag field  
9 (32 bits) is 81-00-87-65. When the frame enters the IEEE 802.11 network, the encapsulated 802.11 LLC header is AA-  
10 AA-03-00-00-00-81-00-87-65-08-00, where AA-AA-03-00-00-00-81-00-87-65 is the SNAP encoded VLAN header.  
11 When the frame exits the IEEE 802.11 network a de-encapsulation operation is performed and the resulting VLAN tag  
12 field is 81-00-87-65.

#### 13 C.3.3.2 QoS Maintenance Report

14 An SRP DMN may obtain QoS Maintenance Report using IEEE 802.11 Transmit Stream/Category  
15 Measurement Requests and processing the corresponding Transmit Stream/Category Measurement Reports.  
16 The Transmit Stream/Category Measurement Request is sent to both the SRP Talker (BSS upstream) and the  
17 SRP Listener (BSS downstream) nodes. Triggers are set on appropriate conditions such that Transmit  
18 Stream/Category Measurement Reports are generated only when predefined thresholds are breached. See  
19 9.4.2.21.11 of IEEE Std 802.11-2016 [B16] for details.

20 NOTE—This provides an indication to SRP (35.2.4) that bandwidth has changed.

### 1 C.3.3.3 SRP TSpec to IEEE 802.11 TSPEC mapping

2 SR Class B traffic has three parameters associated with it, namely delay budget per IEEE 802.11 hop  
3 (20 ms), **MaxFrameSize** (?1500 bytes) and **MaxIntervalFrames** (units of 4000 frames per second).  
4 IEEE 802.11 TSPECs include a Minimum PHY rate that is derived from the SR Class B parameters as  
5 described below:

- 6 a) Overhead = 10-byte VLAN tag + 8 byte Protocol definition = 18 bytes.
- 7 b) Mean Data Rate = (SRP TSpec **MaxFrameSize** + overhead) × 4000 × SRP TSpec  
8 **MaxIntervalFrames** bytes/second.
- 9 c) The Mean Data Rate is also the Max Data Rate (since it is assumed that MSDU size is fixed).
- 10 d) Assuming 70% × efficiency between the MAC and the PHY this translates into  
11  $(10/7) \times (\text{SRP TSpec MaxFrameSize} + \text{overhead}) \times 4000 \times \text{SRP TSpec MaxIntervalFrames}$   
12 bytes/second, or  
13  $(10/7) \times 8 \times (\text{SRP TSpec MaxFrameSize} + \text{overhead}) \times 4000 \times \text{SRP TSpec MaxIntervalFrames}$   
14 bits/second.
- 15 e) Minimum PHY Rate is therefore  
16  $(10/7) \times 8 \times (\text{SRP TSpec MaxFrameSize} + \text{overhead}) \times 4000 \times \text{SRP TSpec MaxIntervalFrames}$   
17 bits/second.

18 NOTE—For example, with 1500 and 1 for **MaxFrameSize** the above turns into 69.394285 Mb/s. Or, with 64 and 1 for  
19 **MaxFrameSize** and **MaxIntervalFrames** the above turns into 3.748571 Mb/s.

20 Table C-5 describes the mapping between SRP TSpec components and IEEE 802.11 QoS TSPEC  
21 parameters for the mandatory EDCA-AC mode.

**Table C-5—EDCA-AC for AV Streams**

| TSPEC parameter                          |               | SR Class B                                                                                                          |
|------------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------|
| TSINFO                                   | TID           | 5                                                                                                                   |

<sup>c</sup> 20% surplus allocation.

## Annex D

(normative)

### IEEE 802.1 Organizationally Specific TLVs

#### D.1 Requirements of the IEEE 802.1 Organizationally Specific TLV sets

The IEEE 802.1 Organizationally Specific TLVs may be supported in conjunction with any of the destination MAC addresses identified by IEEE Std 802.1AB for LLDPDU transmission.

If any IEEE 802.1 Organizationally Specific TLV set is supported, all IEEE 802.1 Organizationally Specific TLVs that are identified as members of that TLV set shall be supported. All IEEE 802.1 Organizationally Specific TLVs shall conform to the LLDPDU bit and octet ordering conventions of IEEE Std 802.1AB.

The IEEE 802.1 Organizationally Specific TLVs specified in this standard are listed in Table D-1. Other standards can also define IEEE 802.1 Organizationally Specific TLVs. The “TLV set name” column identifies the TLV set to which each TLV belongs. Any additions or changes to these TLVs will be included in this annex.

**Table D-1—IEEE 802.1 Organizationally Specific TLVs**

| IEEE 802.1 subtype | TLV name                                      | TLV set name | TLV reference    | Feature clause reference |

## 1 D.2 Organizationally Specific TLV definitions

2 In the TLV definitions that follow, any fields that are labeled as “Reserved” are transmitted as zero and  
3 ignored on receipt.

4 NOTE—In the case of a Port supported by Link Aggregation (IEEE Std 802.1AX), these TLVs apply to the aggregation,  
5 not the individual links. Since sending multiple copies is allowed, an implementation can send these TLVs with the same  
6 values on each individual link, but a TLV received on any individual link applies to the aggregation.

### 7 D.2.1 Port VLAN ID TLV

8 The Port VLAN ID TLV is an optional fixed length TLV that allows a VLAN Bridge Port to advertise the  
9 port VLAN identifier (PVID) that is associated with untagged or priority tagged frames (see 6.9).

10 Figure D-1 shows the Port VLAN ID TLV format.

**Figure D-1—Port VLAN ID TLV format**

#### 11 D.2.1.1 port VLAN identifier (PVID)

12 The PVID field shall contain the VID for the Bridge Port as defined in 6.9. A value of zero shall be used if  
13 the system either does not know the PVID or does not support Port-based VLAN operation.

#### 14 D.2.1.2 Port VLAN ID TLV usage rules

15 An LLDPDU should contain no more than one Port VLAN ID TLV.

## 1 D.2.2 Port And Protocol VLAN ID TLV

2 The Port And Protocol VLAN ID TLV is an optional TLV that allows a Bridge Port to advertise a port and  
3 protocol VLAN identifier (PPVID). Figure D-2 shows the Port And Protocol VLAN ID TLV format.

**Figure D-2—Port And Protocol VLAN ID TLV format**

### 4 D.2.2.1 flags

5 The flags field shall contain a bit map indicating the port and protocol VLAN capability and status as  
6 defined in Table D-2.

**Table D-2—Port and protocol capability/status**

| Bit | Function                            | Value/meaning                      |
|-----|-------------------------------------|------------------------------------|
| 0   | Reserved for future standardization | —                                  |
| 1   | Port and protocol VLAN supported    | 1 = supported<br>0 = not supported |
| 2   | Port and protocol VLAN enabled      | 1 = enabled<br>0 = not enabled     |
| 3–7 | Reserved for future standardization | (set to zero)                      |

### 7 D.2.2.2 port and protocol VLAN identifier (PPVID)

8 The PPVID field shall contain the PPVID number for this IEEE 802 LAN station. If the port is not capable  
9 of supporting port and protocol VLANs and/or the port is not enabled with any port and protocol VLAN, the  
10 PPVID number should be zero.

### 11 D.2.2.3 Port And Protocol VLAN ID TLV usage rules

12 Port And Protocol VLAN ID TLVs are subject to the following rules:

- 13 a) If more than one Port And Protocol VLAN ID TLV is defined for a port, the PPVID value shall be  
14 different from any other PPVID defined for the port.
- 15 b) If the support bit (bit 1) of the flag field indicates that the port is not capable of supporting port and  
16 protocol VLANs but the enabled bit (bit 2) indicates that the port is enabled with one or more port  
17 and protocol VLANs, the Port And Protocol VLAN ID TLV is interpreted as containing an error and  
18 will be discarded.
- 19 c) If the PPVID reference number is greater than 4094, the Port And Protocol VLAN ID TLV is  
20 interpreted as containing an error and is discarded.

## 1 D.2.3 VLAN Name TLV

2 The VLAN Name TLV is an optional TLV that allows an IEEE 802.1Q-compatible IEEE 802 LAN station  
3 to advertise the assigned name of any VLAN with which it is configured.

4 Figure D-3 shows the VLAN Name TLV format.

Figure D-3—VLAN Name TLV format

### 5 D.2.3.1 TLV information string length

6 The TLV information string length field shall contain the length, in octets, of the (VLAN name + 7).

### 7 D.2.3.2 VLAN ID (VID)

8 The VLAN ID field shall contain the VID number associated with the VLAN name.

### 9 D.2.3.3 VLAN name length

10 The VLAN name length field shall contain the length, in octets, of the VLAN name. A VLAN name length  
11 of zero indicates that there is no VLAN name associated with this VLAN.

### 12 D.2.3.4 VLAN name

13 If present, the VLAN name field shall contain the VLAN's name. If implementations support  
14 IETF RFC 4363, the dot1QVLANStaticName object should be used for this field.

### 15 D.2.3.5 VLAN Name TLV usage rules

16 If more than one VLAN Name TLV is defined for a port, the VID and the associated VLAN name  
17 combination shall be different from any other VID and VLAN name combination defined for the port.

## 18 D.2.4 Protocol Identity TLV

19 The Protocol Identity TLV is an optional TLV that allows an IEEE 802 LAN station to advertise particular  
20 protocols that are accessible through the port. Figure D-4 shows the protocol identity TLV format.

Figure D-4—Protocol Identity TLV format

### 21 D.2.4.1 TLV information string length

22 The TLV information string length field shall contain the length, in octets, of the (protocol identity + 5).

#### 1 D.2.4.2 protocol identity length

2 The protocol identity length field shall contain the length, in octets, of the protocol identity.

#### 3 D.2.4.3 protocol identity

4 The protocol identity field shall contain the first  $n$  octets of the protocol after the layer 2 addresses (i.e., for  
5 example, starting with the EtherType field) that the sender would like to advertise. The value of  $n$  is  
6 determined by the need for the protocol to disambiguate itself. The protocol information string shall include  
7 enough octets to allow the receiver to correctly identify the protocol and its version. To advertise spanning  
8 tree protocols, for example, the protocol identity field would need to include at least eight octets:  
9 IEEE 802.3 length (two octets), LLC addresses (two octets), IEEE 802.3 control (one octet), Protocol ID  
10 (two octets), and the protocol version (one octet).

#### 11 D.2.4.4 Protocol Identity TLV usage rules

12 If more than one Protocol Identity TLV is defined for a port, the protocol identity field value shall be  
13 different from any other Protocol Identity TLV defined for the port.

#### 14 D.2.5 VID Usage Digest TLV

15 The VID Usage Digest TLV is an optional TLV that allows an IEEE Std 802.1Q-compatible IEEE 802 LAN  
16 station to advertise the value of a VID Usage Digest associated with the system. The value of the VID Usage  
17 Digest is obtained by applying the CRC32 function (see IEEE Std 802.3) to a VID Usage Table having a  
18 fixed length of 512 octets. A bit of the VID Usage Table contains the value PBB-TE-USAGE (binary 1) if  
19 the corresponding element of the MST Configuration Table (8.9.1) contains the value PBB-TE MSTID (hex  
20 FFE) and otherwise contains the value NON-PBB-TE-USAGE (binary 0).

21 Figure D-5 shows the VID Usage Digest TLV format.

Figure D-5—VID Usage Digest TLV format

#### 22 D.2.5.1 VID Usage Digest

23 The VID Usage Digest field shall contain a VID Usage Digest value obtained by applying the CRC32  
24 function to the 512-octet VID Usage Table. A bit of the VID Usage Table contains the value  
25 PBB-TE-USAGE (binary 1) if the corresponding element of the MST Configuration Table (8.9.1) contains  
26 the value PBB-TE MSTID (hex FFE) and otherwise contains the value NON-PBB-TE-USAGE (binary 0).

#### 27 D.2.6 Management VID TLV

28 The Management VID TLV is an optional TLV that allows an IEEE 802.1Q-compatible IEEE 802 LAN  
29 station to advertise the value of a Management VID associated with the system.

1 Figure D-6 shows the Management VID TLV format.

Figure D-6—Management VID TLV format

## 2 D.2.6.1 Management VID

3 The Management VID field shall contain the value configured for the Management VID, or the value 0 if a  
4 Management VID has not been provisioned.

## 5 D.2.7 Congestion Notification TLV

6 The TLV illustrated in Figure D-7 is encoded into each LLDP message transmitted by a system that is  
7 configured to support congestion notification on one or more priority values.

Figure D-7—Congestion Notification TLV format

8 A system shall transmit no more than one Congestion Notification TLV in a single LLDPDU. If a system  
9 receives an LLDPDU with more than one Congestion Notification TLV, the behavior of the receiving system  
10 is unspecified. A system shall not transmit a Congestion Notification TLV with all of the Per-priority CNPV  
11 indicators (D.2.7.3) clear (0).

### 12 D.2.7.1 TLV type

13 A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the  
14 value 127.

### 15 D.2.7.2 TLV information string length

16 A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information  
17 string length) and the entire second octet of the TLV, containing the total number of octets in the TLV  
18 information string of the Congestion Notification TLV. This does not count the TLV type and TLV  
19 information string length fields. It is equal to 6.

### 20 D.2.7.3 Per-priority CNPV indicators

21 A bit vector, one per priority value, containing all eight of the `cnpdXmitCnpvCapable` variables (32.4.7) for  
22 this port. The LSB of the octet carries priority 0's `cnpdXmitCnpvCapable` variable, and the MSB that of  
23 priority 7.

#### 1 D.2.7.4 Per-priority Ready indicators

2 A bit vector, one per priority value, containing all eight of the `cnpdXmitReady` variables (32.4.8) for this  
3 port. The LSB of the octet carries priority 0's `cnpdXmitReady` variable, and the MSB that of priority 7.

#### 4 D.2.8 ETS Configuration TLV

5 The TLV illustrated in Figure D-8 is encoded into each LLDP message and may be transmitted by a system  
6 in order to indicate the ETS configuration. Shall be sent using Asymmetric attribute passing (38.4.1).

Figure D-8—ETS Configuration TLV format

##### 7 D.2.8.1 TLV type

8 A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the  
9 value 127.

##### 10 D.2.8.2 TLV information string length

11 A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information  
12 string length) and the entire second octet of the TLV, containing the total number of octets in the TLV  
13 information string of the ETS Configuration TLV. This does not count the TLV type and TLV information  
14 string length fields. It is equal to 25.

##### 15 D.2.8.3 Willing

16 The Willing bit. A value of one indicates that the station is willing to accept configurations from the remote  
17 station.

##### 18 D.2.8.4 Credit-based Shaper

19 The Credit-based Shaper bit. A value of one indicates that the station supports the Credit-based Shaper  
20 transmission selection algorithm (see Table 8-6 and Clause 34).

##### 21 D.2.8.5 Max TCs

22 A 3-bit unsigned integer where the value of the integer is the maximum number of traffic classes that the  
23 implementation can support with the value 0 used when a device supports 8.

## 1 D.2.8.6 Priority Assignment Table

2 Table D-3 shows the layout of the priority assignment table.

**Table D-3—Priority assignment table**

| Octets: | 1          |   |            |   | 2          |   |            |   | 3          |   |            |   | 4          |   |            |   |
|---------|------------|---|------------|---|------------|---|------------|---|------------|---|------------|---|------------|---|------------|---|
|         | Priority 0 |   | Priority 1 |   | Priority 2 |   | Priority 3 |   | Priority 4 |   | Priority 5 |   | Priority 6 |   | Priority 7 |   |
| Bits:   | 7          | 4 | 3          | 0 | 7          | 4 | 3          | 0 | 7          | 4 | 3          | 0 | 7          | 4 | 3          | 0 |

3 The table consists of one 4-bit entry per Priority, where:

- 4 a) 0–7 indicate the Priority is mapped to the corresponding traffic class; and
- 5 b) All other values are Reserved.

## 6 D.2.8.7 TC Bandwidth Table

7 Table D-4 shows the layout of the traffic class bandwidth table.

**Table D-4—Traffic class bandwidth assignment table**

| Octets: | 1     | 2     | 3     | 4     | 5     | 6     | 7     | 8     |
|---------|-------|-------|-------|-------|-------|-------|-------|-------|
|         | TC% 0 | TC% 1 | TC% 2 | TC% 3 | TC% 4 | TC% 5 | TC% 6 | TC% 7 |

8 The table consists of one 8-bit entry per traffic class, and always contains 8 entries. Each entry:

- 9 a) Indicates the current TCBandwidth percentage configured for each traffic class N where N is 0 to 7.
- 10 b) Total shall equal 100 (implies valid range is 0–100 for each entry).

11 NOTE—While it is intended that only TCs configured for ETS will have a bandwidth value associated with them, it is  
12 possible, during configuration changes, to have situations where a TC is not configured for ETS but has a nonzero  
13 TCBandwidth percentage. In this case, the sum of all the TCBandwidth percentages is still equal to 100, but the TC  
14 bandwidth percentages of the non-ETS TCs would be unused bandwidth and reallocated to the ETS TCs.

## 15 D.2.8.8 TSA Assignment Table

16 Table D-5 shows the layout of the Transmission Selection Algorithm (TSA) Assignment Table.

**Table D-5—TSA Assignment Table**

| Octets: | 1               | 2               | 3               | 4               | 5               | 6               | 7               | 8               |
|---------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
|         | Traffic Class 0 | Traffic Class 1 | Traffic Class 2 | Traffic Class 3 | Traffic Class 4 | Traffic Class 5 | Traffic Class 6 | Traffic Class 7 |

17 The table consists of one 8-bit entry per traffic class. Each entry indicates the Transmission selection  
18 algorithm to be used for that traffic class as defined in Table 8-6. A value of 255 indicates a Vendor-specific  
19 Transmission selection algorithm.

## 1 D.2.9 ETS Recommendation TLV

2 The TLV illustrated in Figure D-9 is encoded into each LLDP message and may be transmitted by a system  
3 in order to indicate a recommendation on how ETS should be configured. A Willing system may receive a  
4 recommendation TLV that utilizes more Traffic Classes than the receiving system supports. In this case the  
5 receiving system may assign the received recommendations to match its capabilities. Shall be sent using  
6 Asymmetric attribute passing (38.4.1).

**Figure D-9—ETS Recommendation TLV format**

### 7 D.2.9.1 TLV type

8 A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the  
9 value 127.

### 10 D.2.9.2 TLV information string length

11 A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information  
12 string length) and the entire second octet of the TLV, containing the total number of octets in the TLV  
13 information string of the ETS Recommendation TLV. This does not count the TLV type and TLV  
14 information string length fields. It is equal to 25.

### 15 D.2.9.3 Priority Assignment Table

16 Table D-3 shows the layout of the priority assignment table.

17 See D.2.8.6 for description of table entries.

### 18 D.2.9.4 TC Bandwidth Table

19 Table D-4 shows the layout of the Traffic Class bandwidth assignment table.

20 See D.2.8.7 for description of table entries.

### 21 D.2.9.5 TSA Assignment Table

22 Table D-5 shows the layout of the TSA Assignment Table.

23 See D.2.8.8 for description of table entries.

1 **D.2.10 Priority-based Flow Control Configuration TLV**

2 The TLV illustrated in Figure D-10 is encoded into each LLDP message and may be transmitted by a system  
3 in order to indicate how PFC should be configured. Shall be sent using Symmetric attribute passing.

**Figure D-10—Priority-based Flow Control Configuration TLV format**

4 **D.2.10.1 TLV type**

5 A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the  
6 value 127.

7 **D.2.10.2 TLV information string length**

8 A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information  
9 string length) and the entire second octet of the TLV, containing the total number of octets in the TLV  
10 information string of the Priority-based Flow Control Configuration TLV. This does not count the TLV type  
11 and TLV information string length fields. It is equal to 6.

12 **D.2.10.3 Willing**

13 The Willing bit. A value of one indicates that the station is willing to accept configurations from the remote  
14 station.

15 **D.2.10.4 MBC**

16 The MACsec Bypass Capability Bit. If set to zero, the sending station is capable of bypassing MACsec  
17 processing when MACsec is disabled. If set to one, the sending station is not capable of bypassing MACsec  
18 processing when MACsec is disabled (see Clause 36).

19 **D.2.10.5 PFC cap**

20 A 4-bit unsigned integer, PFC cap (PFC capability) indicates the device’s limitation of how many traffic  
21 classes may simultaneously support PFC.

22 NOTE 1—PFC may be enabled on up to eight traffic classes allowing each priority to be independently paused.

23 NOTE 2—In a DCB environment at least one priority would generally have PFC enabled.

## 1 D.2.10.6 PFC Enable

2 Table D-6 shows the layout of the PFC Enable bit vector.

**Table D-6—PFC Enable bit vector**

|        |            |            |            |            |            |            |            |            |
|--------|------------|------------|------------|------------|------------|------------|------------|------------|
| Octet: | 1          |            |            |            |            |            |            |            |
|        | Priority 7 | Priority 6 | Priority 5 | Priority 4 | Priority 3 | Priority 2 | Priority 1 | Priority 0 |
| Bits:  | 7          | 6          | 5          | 4          | 3          | 2          | 1          | 0          |

3 A bit vector of 8 bits, one per priority:

- 4 a) A one indicates PFC is enabled on the priority.
- 5 b) A zero indicates that PFC is disabled on the priority.
- 6 c) Local policy in each end of the link decides whether to use the priority if the configuration does not
- 7 match.

## 8 D.2.11 Application Priority TLV

9 The TLV illustrated in Figure D-11 is encoded into each LLDP message and may be transmitted by a system  
10 in order to indicate the application priority table. This TLV is informational and used to indicate to a peer  
11 station the local configuration.

**Figure D-11—Application Priority TLV format**

### 12 D.2.11.1 TLV type

13 A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the  
14 value 127.

### 15 D.2.11.2 TLV information string length

16 A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information  
17 string length) and the entire second octet of the TLV, containing the total number of octets in the TLV  
18 information string of the Application Priority TLV. This does not count the TLV type and TLV information  
19 string length fields. The length for the Application Priority TLV is variable depending on the number of  
20 Application Priorities specified. The length shall be 5 plus a multiple of 3 octets.

### 1 D.2.11.3 Application Priority Table

2 Table D-7 shows the layout of a 3-octet entry in the Application Priority Table field.

**Table D-7—Application Priority Table Entry format**

| Octets: | 1        |   |          |   |     | 2           |   | 3 |   |   |
|---------|----------|---|----------|---|-----|-------------|---|---|---|---|
|         | Priority |   | Reserved |   | Sel | Protocol ID |   |   |   |   |
| Bits:   | 8        | 6 | 5        | 4 | 3   | 1           | 8 | 1 | 8 | 1 |

3 The priority field is a 3-bit unsigned integer indicating the priority for which the Protocol ID is being used.

4 The meaning of the Protocol ID field is determined by the Sel field. Allowed values for the Sel field are  
5 shown in Table D-8.

**Table D-8—Sel field values**

| Sel value | Protocol ID value                                                                                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | Reserved                                                                                                                                                                                                                                                                                                                                 |
| 1         | 0: Default application priority. For use when application priority is not otherwise specified.<br>1–1535: Reserved.<br>1536–65 535: An EtherType                                                                                                                                                                                         |
| 2         | Well Known Port number over TCP, or Stream Control Transmission Protocol (SCTP) [B36].                                                                                                                                                                                                                                                   |
| 3         | Well Known Port number over UDP, or Datagram Congestion Control Protocol (DCCP).                                                                                                                                                                                                                                                         |
| 4         | Well Known Port number over TCP, SCTP, UDP, or DCCP.                                                                                                                                                                                                                                                                                     |
| 5         | Differentiated Services Code Point (DSCP) value. The 6-bit DSCP value is stored in bits 1–6 of the low order octet of the Protocol ID field (octet 3 of the Application Priority Table Entry). Bits 7 and 8 and the high order octet of the Protocol ID field are set to zero. (See IETF RFC 2474 for the definition of the DSCP value.) |
| 6–7       | Reserved                                                                                                                                                                                                                                                                                                                                 |

6 NOTE—The port numbers shown are for identification (i.e., as assigned by IANA) instead of the actual port numbers  
7 being used in a particular deployment.

### 8 D.2.12 EVB TLV

9 The EVB TLV is used to:

- 10 a) Advertise a station or Bridge's EVB capabilities.
- 11 b) Negotiate and activate common capabilities.

12 The EVB TLV is exchanged via LLDP and conforms to the LLDP TLV specification. The LLDP database  
13 carrying the EVB TLV is addressed using the Nearest Customer Bridge address. One LLDP database is built  
14 at the URP of each ER. If the EVB TLV is used for VDP NVO3 support, the LLDP database carrying the  
15 EVB TLV can also be accessed using a unicast MAC address.

16 The EVB TLV allows setting the EVB Bridge's C-VLAN component Port to operate in reflective relay.  
17 Reflective relay is implemented by changing the active topology enforcement rules described in 8.6.1 to  
18 allow forwarding on the reception Bridge Port. When reflective relay is enabled on a given Bridge Port, that  
19 port is a potential transmission port for frames received on that port.

1 The EVB TLV structure is illustrated in Figure D-12.

Figure D-12—EVB TLV format

2 The EVB TLV information string fields are as defined in D.2.12.1 through D.2.12.10.

### 3 D.2.12.1 OUI

4 The OUI used to identify the EVB TLV is the 802.1 OUI 00-80-C2.

### 5 D.2.12.2 Subtype

6 The subtype used to identify the EVB TLV is as shown in Table D-1.

### 7 D.2.12.3 EVB Bridge status

8 The EVB Bridge status field describes EVB capabilities that are supported by the EVB Bridge. If the sender  
9 of the TLV is an EVB Bridge (EVB Mode = EVB Bridge—see D.2.12.7), then the field reflects its own  
10 capabilities; if the sender of the TLV is an EVB station (EVB Mode = EVB station), then the field reflects  
11 the capabilities received from an attached EVB Bridge, or a value of zero if no TLV has been received from  
12 an attached EVB Bridge.

13 If the sender of the TLV is an nNVE (EVB Mode = NVO3 and NVE Role = nNVE—see D.2.12.7 and  
14 D.2.12.10), then the field reflects its own capabilities; if the sender of the TLV is a tNVE (EVB Mode =  
15 NVO3 and NVE Role = tNVE), then the field reflects the capabilities received from an attached nNVE, or a  
16 value of zero if no TLV has been received from an attached nNVE.

17 Each capability is represented by a single bit flag; a value of TRUE (1) indicates that the capability is  
18 supported, a value of FALSE (0) indicates that the capability is not supported. The capabilities are as defined  
19 in D.2.12.3.1 through D.2.12.3.5.

#### 20 D.2.12.3.1 BGID

21 A value of TRUE indicates that the EVB Bridge wishes to control VID assignments and use the GroupID in  
22 VDP exchanges. A value of FALSE indicates that the EVB Bridge does not wish to make use of the Group  
23 ID in VDP exchanges.

24 If the EVB station sets SGID = TRUE, and the EVB Bridge also sets BGID = TRUE, then the EVB Bridge  
25 can control VID assignments and use the GroupID in VDP exchanges.

26 If the EVB station does not set SGID = TRUE, or the EVB Bridge does not set BGID = TRUE, then the  
27 EVB Bridge cannot control VID assignments or use the GroupID in VDP exchanges.

28 In an NVO3 Split-NVE scenario, BGID should always be set to TRUE by nNVE.

### 1 **D.2.12.3.2 RRCAP**

2 The RRCAP flag indicates the state of the EVB Bridge's reflectiveRelayCapable parameter (40.4.2).

3 If the EVB Bridge's reflectiveRelayCapable parameter is TRUE, and a TLV has been received by the EVB  
4 Bridge from an attached EVB station in which the value of RRREQ (D.2.12.4.2) is also TRUE, then the  
5 value of the EVB Bridge's operReflectiveRelayControl parameter (40.4.2) shall be set to TRUE. Otherwise,  
6 the value of the EVB Bridge's operReflectiveRelayControl parameter (40.4.2) shall be set to FALSE.

7 In an NVO3 Split-NVE scenario, RRCAP should be FALSE since reflective relay is not a required  
8 capability of nNVE.

### 9 **D.2.12.3.3 RRCTR**

10 The RRCTR flag indicates the state of the EVB Bridge's operReflectiveRelayControl parameter (40.4.2).

11 In an NVO3 Split-NVE scenario, RRCTR should be FALSE since RRREQ (D.2.12.4.2) received by nNVE  
12 is always FALSE.

### 13 **D.2.12.3.4 V6CAP**

14 This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the nNVE supports  
15 the use of IPv6 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates  
16 that the nNVE does not support the use of IPv6 addresses in that field. When both nNVE and tNVE set  
17 V6CAP = TRUE, then IPv6 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv6  
18 addresses cannot be used in the Filter Info field in VDP exchanges.

### 19 **D.2.12.3.5 V4CAP**

20 This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the nNVE supports  
21 the use of IPv4 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates  
22 that the nNVE does not support the use of IPv4 addresses in that field. When both nNVE and tNVE set  
23 V4CAP = TRUE, then IPv4 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv4  
24 addresses cannot be used in the Filter Info field in VDP exchanges.

### 25 **D.2.12.4 EVB station status**

26 The EVB station status field describes EVB capabilities that are supported by the EVB station. If the sender  
27 of the TLV is an EVB station (EVB Mode = EVB station—see D.2.12.7), then the field reflects its own  
28 capabilities; if the sender of the TLV is an EVB Bridge (EVB Mode = EVB Bridge), then the field reflects  
29 the capabilities received from an attached EVB station, or a value of zero if no TLV has been received from  
30 an attached EVB station.

31 If the sender of the TLV is a tNVE (EVB Mode = NVO3 and NVE Role = tNVE—see D.2.12.7 and  
32 D.2.12.10), then the field reflects its own capabilities; if the sender of the TLV is an nNVE (EVB Mode =  
33 NVO3 and NVE Role = nNVE), then the field reflects the capabilities received from an attached tNVE, or a  
34 value of zero if no TLV has been received from an attached tNVE.

35 Each capability is represented by a single bit flag; a value of TRUE (1) indicates that the capability is  
36 supported, a value of FALSE (0) indicates that the capability is not supported. The capabilities are as defined  
37 in D.2.12.4.1 through D.2.12.4.5.

### 38 **D.2.12.4.1 SGID**

39 A value of TRUE indicates that the EVB station can support the use of the GroupID.

1 If the EVB station sets SGID = TRUE, and the EVB Bridge also sets BGID = TRUE, then the EVB Bridge  
2 can control VID assignments and use the GroupID in VDP exchanges.

3 If the EVB station does not set SGID = TRUE, or the EVB Bridge does not set BGID = TRUE, then the  
4 EVB Bridge cannot control VID assignments or use the GroupID in VDP exchanges.

5 In an NVO3 Split-NVE scenario, SGID should always be set to TRUE by tNVE.

#### 6 **D.2.12.4.2 RRREQ**

7 The RRREQ flag indicates the state of the EVB station's adminReflectiveRelayRequest parameter (40.4.3).

8 In an NVO3 Split-NVE scenario, RRREQ should always be set to FALSE in order to make sure reflective  
9 relay is not enabled.

#### 10 **D.2.12.4.3 RRSTAT**

11 RRSTAT is a composite flag that indicates the state of the EVB station's operReflectiveRelayStatus  
12 parameter (40.4.3) as shown in Table D-9.

**Table D-9—RRSAT flag values and meanings**

| Bit 1 | Bit 2 | Meaning                              |
|-------|-------|--------------------------------------|
| TRUE  | FALSE | operReflectiveRelayStatus is TRUE    |
| FALSE | FALSE | operReflectiveRelayStatus is FALSE   |
| TRUE  | TRUE  | operReflectiveRelayStatus is Unknown |
| FALSE | TRUE  | operReflectiveRelayStatus is Unknown |

13 If a TLV has been received by the EVB station from an attached EVB Bridge in which the value of RRCTR  
14 (D.2.12.3.3) is TRUE, then the value of the EVB station's operReflectiveRelayStatus parameter (40.4.3)  
15 shall be set to TRUE. If a TLV has been received by the EVB station from an attached EVB Bridge in which  
16 the value of RRCTR (D.2.12.3.3) is FALSE, then the value of the EVB station's operReflectiveRelayStatus  
17 parameter (40.4.3) shall be set to FALSE. If no TLV has been received by the EVB station from an attached  
18 EVB Bridge, then the value of the EVB station's operReflectiveRelayStatus parameter (40.4.3) shall be set  
19 to Unknown.

20 In an NVO3 Split-NVE scenario, RRSTAT is always FALSE as RRCTR (D.2.12.3.3) received from nNVE  
21 is FALSE.

#### 22 **D.2.12.4.4 V6CAP**

23 This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the tNVE supports  
24 the use of IPv6 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates  
25 that the tNVE does not support the use of IPv6 addresses in that field. When both nNVE and tNVE set  
26 V6CAP = TRUE, then IPv6 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv6  
27 addresses cannot be used in the Filter Info field in VDP exchanges.

#### 28 **D.2.12.4.5 V4CAP**

29 This capability is valid only when NVE Mode is NVO3. A value of TRUE indicates that the tNVE supports  
30 the use of IPv4 addresses in the Filter Info field of the VDP association TLV. A value of FALSE indicates  
31 that the tNVE does not support the use of IPv4 addresses in that field. When both nNVE and tNVE set  
32 V4CAP = TRUE, then IPv4 addresses can be used in the Filter Info field in VDP exchanges; otherwise, IPv4  
33 addresses cannot be used in the Filter Info field in VDP exchanges.

#### 1 **D.2.12.5 R**

2 This field carries the maxRetries value for the ECP state machine (43.3.7.4). Both sides transmit the local  
3 value, and use the largest of the two values of R. If no remote value is available, then the local value is used.

#### 4 **D.2.12.6 RTE (retransmission exponent)**

5 RTE is an EVB link or S-channel attribute used to calculate the minimum ECPDU retransmission time,  
6 ackTimerInit. The value of ackTimerInit, in ECP timer tics of 10 usec, is calculated as:

$$7 \quad 2^{\text{RTE}} \text{ ECP timer tics}$$

8 Both sides transmit the local value, and use the largest of the two values of RTE for this calculation. If no  
9 remote value is available, then the greater of 2 ms and local value is used.

#### 10 **D.2.12.7 EVB Mode**

11 The EVB Mode field represents the value of the EVBMode parameter (40.4) for the sender of the TLV, as  
12 shown in Table D-10.

**Table D-10—EVB Mode values**

| <b>EVBMode (40.4)</b> | <b>Field value</b> |
|-----------------------|--------------------|
| Not Supported         | 0                  |
| EVB Bridge            | 1                  |
| EVB station           | 2                  |
| NVO3                  | 3                  |

#### 13 **D.2.12.8 ROL (remote or local) and RWD (resource wait delay)**

14 The RWD value transmitted by the EVB Bridge indicates the exponent value in use by the EVB Bridge for  
15 determining the value of the resourceWaitDelay variable (41.5.5.7). The value of resourceWaitDelay, in  
16 VDP timer tics of 10 usec, is calculated as:

$$17 \quad 2^{\text{RWD}} \text{ VDP timer tics}$$

18 Both sides transmit the local value, and use the largest of the local and remote values of RWD in calculation  
19 of resourceWaitDelay or respWaitDelay variable (41.5.5.9); if there is no remote value available, the local  
20 (proposed) value is used. The Remote or Local (ROL) flag indicates whether the remote RWD value is in  
21 use (TRUE) or the local value is in use (FALSE) at the sending node.

#### 22 **D.2.12.9 ROL (remote or local) and RKA (reinit keep alive)**

23 The RKA value transmitted by the EVB station indicates the exponent value in use by the EVB station for  
24 determining the value of the reinitKeepAlive variable (41.5.5.5). The value of reinitKeepAlive, in VDP  
25 timer tics of 10 usec, is calculated as:

$$26 \quad 2^{\text{RKA}} \text{ VDP timer tics}$$

27 Both sides transmit the local value, and use the largest of the local and remote values of RKA in calculation  
28 of reinitKeepAlive or toutKeepAlive variable (41.5.5.13); if there is no remote value available, the local  
29 (proposed) value is used. The Remote or Local (ROL) flag indicates whether the remote RKA value is in use  
30 (TRUE) or the local value is in use (FALSE) at the sending node.

## 1 D.2.12.10 NVE Role

2 NVE Role field represents the value of the NVERole parameter (40.5) for the sender of the TLV, as shown in  
3 Table D-11. This field is useful only when EVBMode = NVO3.

**Table D-11—NVE Role values**

| NVERole (40.5) | Field values |
|----------------|--------------|
| nNVE           | 00           |
| tNVE           | 01           |
| Reserved       | 10, 11       |

## 4 D.2.13 CDCP TLV

5 The EVB station and Bridge both use the same LLDP TLV to configure S-channels (see Figure D-13). This  
6 TLV is in LLDP Organizationally Specific TLV format (see IEEE Std 802.1AB). The S-channel's  
7 capabilities, requests, and running configuration is encoded in the information string of this TLV as defined  
8 in D.2.13.1 through D.2.13.8.

**Figure D-13—CDCP TLV structure**

## 9 D.2.13.1 OUI

10 The OUI used to identify the CDCP TLV is the 802.1 OUI 00-80-C2.

## 11 D.2.13.2 Subtype

12 The subtype used to identify the CDCP TLV is as shown in Table D-1.

## 13 D.2.13.3 Role

14 Role is a 1-bit field, defined as follows:

- 15 a) S(1)—Indicates the sender is operating in the station role, assigns channels numbers and a default SVID for the default channel 1, and requests SVID assignments from the neighboring 'B'.
- 16
- 17 b) B(0)—Indicates the sender is operating in the Bridge role, accepts S-channel configuration requests from its neighboring 'S' and that the sender will do the best it can to fill the SVID assignment requests from the neighboring 'S'.
- 18
- 19

## 20 D.2.13.4 RES1

21 RES1 is a 3-bit field, reserved for future standardization. This field is transmitted as zero and ignored on  
22 receipt.

### 1 D.2.13.5 SComp

2 SComp is a 1-bit field that indicates the presence or absence of an S-VLAN component for S-channel  
3 support. A value of 1 indicates TRUE, zero indicates FALSE.

4 NOTE—If this bit is zero, then the sender does not have a CDCP state machine, and the other fields in the TLV are not  
5 valid.

### 6 D.2.13.6 Res2

7 RES2 is a 15-bit field, reserved for future standardization. This field is transmitted as zero and ignored on  
8 receipt.

### 9 D.2.13.7 ChnCap

10 Channel capacity. Identifies the total number of S-channels, both assigned and available to be assigned, that  
11 the sender has.

### 12 D.2.13.8 SCID/SVID

13 An SCID/SVID pair exists for each S-channel that is currently supported by the sender. Each SCID/SVID  
14 pair consists of two 12-bit values, as follows:

- 15 a) SCID—indicates the index number of the S-channel. The station assigns S-channel numbers in the  
16 range 0–167. Zero is reserved. The S-channel index should be between 1 and the maximum number  
17 of S-channels supported by the port.
- 18 b) SVID—The VID assigned to the S-channel. The Bridge assigns SVIDs to channels in the range  
19 1–0xffe. A station uses the 0 SVID to request an SVID assignment from the Bridge.

20 After the station receives the SVID assignment from the Bridge, it uses the SVID assigned value in all  
21 subsequent exchanges for that specific SCID (SCID/SVID pair).

22 NOTE 1—The first entry in the list of SCID/SVID pairs contains the default S-channel. (i.e., the first channel pair is  
23 <1,1>).

24 NOTE 2—A maximum of 167 S-channels can be supported. Other formats (assuming sequential SVIDs) could be  
25 defined to allow support for 4K+ S-channels.

26 NOTE 3—This listing can be sparse (in order to indicate arrival and removal of S-channels). The S-channel going away  
27 is indicated by removing the SCID/SVID pair.

28 NOTE 4—The order of the list determines the priority of SVID assignments. If the Bridge does not have resources for  
29 all channels, it assigns the first channels in the list.

## 30 D.2.14 Application VLAN TLV

31 The TLV illustrated in Figure D-14 is encoded into each LLDP message and may be transmitted by a system  
32 in order to indicate the application VLAN table. This TLV is informational and used to indicate to a peer  
33 station the local configuration.

**Figure D-14—Application VLAN TLV format**

### 34 D.2.14.1 TLV type

35 A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the  
36 value 127.

## 1 D.2.14.2 TLV information string length

2 A 9-bit unsigned integer, occupying the LSB of the first octet of the TLV (the MSB of the TLV information  
3 string length) and the entire second octet of the TLV, containing the total number of octets in the TLV  
4 information string of the Application VLAN TLV. This does not count the TLV type and TLV information  
5 string length fields. The length for the Application VLAN TLV is variable depending on the number of  
6 Application VLANs specified. The length shall be 4 plus a multiple of 4 octets.

## 7 D.2.14.3 Application VLAN Table

8 Table D-12 shows the layout of a 4-octet entry in the Application VLAN Table.

**Table D-12—Application VLAN Table Entry format**

| Octets: | 1   | 2 | 3        | 4   |
|---------|-----|---|----------|-----|
| Field:  | VID |   | Reserved | Sel |
| Bits:   | 8   | 1 | 8        | 5   |
|         |     |   | 4        | 3   |
|         |     |   | 1        | 8   |
|         |     |   |          | 1   |

9 The VID field is a 12-bit unsigned integer indicating the VID of the VLAN for which the Protocol ID is  
10 being used.

11 The meaning of the Protocol ID field is determined by the Sel field. Allowed values for the Sel field are  
12 shown in Table D-13.

**Table D-13—Sel field values**

| Sel value | Protocol ID value                                                                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | Reserved                                                                                                                                                                                                                                                                                                                                      |
| 1         | 0: PVID. For use when an application VLAN is not otherwise specified.<br>1–1535: Reserved<br>1536–65 535: An EtherType.                                                                                                                                                                                                                       |
| 2         | Well Known Port number over TCP, or SCTP.                                                                                                                                                                                                                                                                                                     |
| 3         | Well Known Port number over UDP, or DCCP.                                                                                                                                                                                                                                                                                                     |
| 4         | Well Known Port number over TCP, SCTP, UDP, or DCCP.                                                                                                                                                                                                                                                                                          |
| 5         | Differentiated Services Code Point (DSCP) value. The 6-bit DSCP value is stored in bits 1–6 of the low<br>order octet of the Protocol ID field (octet 4 of the Application VLAN Table Entry). Bits 7 and 8 and the<br>high order octet of the Protocol ID field are set to zero.<br>(See IETF RFC 2474 for the definition of the DSCP value.) |
| 6–7       | Reserved                                                                                                                                                                                                                                                                                                                                      |

13 The Application VLAN TLV may be exchanged between EVB station ERs (5.24.1) and EVB Bridges (5.23)  
14 with LLDP using the Nearest Customer Bridge address. This allows ERs sharing a LAN using S-channels  
15 (40.2) to use different VLANs for the same application.

16 NOTE 1—The Application VLAN TLV allows multiple VLANs to be associated with an application on a port. Issues  
17 involved with using multiple VLANs for an application on a port, such as resolving which IP subnetwork corresponds to  
18 which VLAN, are beyond the scope of this standard.

19 NOTE 2—Selection of different IEEE 802.1 paths may use different VLANs, which could be associated with different  
20 quality of service levels. This TLV may not apply to deployment cases where the VID is implied by other attributes of  
21 the frame, for example, by the IP subnet of the source IP address.

## 1 D.2.15 Congestion Isolation TLV

2 The Congestion Isolation TLV is an optional TLV that allows an IEEE 802.1Q-compliant Bridge and an  
3 IEEE 802.1Q-compatible IEEE 802 LAN station to discover each other and exchange configuration  
4 information for congestion isolation.

5 Figure D-15 shows the Congestion Isolation TLV format.

**Figure D-15—Congestion Isolation TLV format**

**Figure D-15—Congestion Isolation TLV format**

### 6 D.2.15.1 TLV type

7 A 7-bit integer value occupying the most-significant bits of the first octet of the TLV. Always contains the  
8 value 127.

### 9 D.2.15.2 TLV information string length

10 The TLV information string length field of the Congestion Isolation TLV depends on the Address Family  
11 specified for the IP Address field and shall contain the value 25 if the Address Family is 1 (IPv4), the value  
12 37 if the Address Family is 2 (IPv6), or the value 21 if the Address Family is anything other than 1 or 2.

### 13 D.2.15.3 Queue Map

14 Eight octets, one for each traffic class supported by the Bridge or end station. The least significant octet  
15 represents traffic class 0 and the most significant octet represents traffic class 7. The content of each octet  
16 specifies a signed numeric value that can be translated to the value of the traffic class to be used as either the  
17 congesting queue or the monitored queue for the represented traffic class. The contents of each octet is a  
18 signed numeric value between –8 and 8. A value of 0 specifies that there is no mapping for the traffic class  
19 and that it is not participating in congestion isolation. A positive number specifies a traffic class for a  
20 monitored queue that is one less than the value (e.g., a value of 5 represents traffic class 4). A negative  
21 number specifies a traffic class for a congesting queue that is one less than the absolute value (e.g., a value  
22 of –4 represents traffic class 3).

### 23 D.2.15.4 CIM Encap Length

24 A 2-octet unsigned integer representing the requested length in octets of the data from the frame of a  
25 congesting flow to be encapsulated into a CIM by a peer. The default and minimum required value is 48. The  
26 maximum value is 512.

### 27 D.2.15.5 MAC Address

28 The 6-octet MAC address that can be used as the destination MAC address for a CIM to the Bridge or end  
29 station sending this TLV.

## 1 D.2.15.6 UDP Port Number

2 An integer value indicating the UDP port number to be used by the peer when creating a layer-3 CIM. The  
3 value of the UDP port number is within the dynamic port number range of 49152 to 65535 as specified by  
4 IETF RFC 6335 (e.g., 58622).

## 5 D.2.15.7 Address Family

6 An integer value indicating the type of address that is listed in the address field. Enumeration for this field is  
7 contained in the ianaAddressFamilyNumbers module of the IETF RFC 3232 on-line database that is  
8 accessible through a web page (<http://www.iana.org>). Only two types are recognized with the following  
9 definitions; 1=IPv4 and 2=IPv6.

## 10 D.2.15.8 IP Address

11 An octet string with length of 0, 4, or 16 octets dependent upon the Address Family specified. If the Address  
12 Family is 1, the address shall be an IPv4 address as specified in IETF RFC 791. If the Address Family is 2,  
13 the address shall be an IPv6 address as specified in IETF RFC 8200. No address shall be provided for any  
14 other Address Families.

15 NOTE—If the CIM PDU is layer 2 encapsulated, the MAC address field is already provided and the Address Family  
16 should be anything other than 1 or 2. For layer 2 encapsulated CIM PDUs, it is recommended to use the Address Family  
17 value of 6 for IEEE 802 addresses.

## 18 D.2.15.9 Congestion Isolation TLV usage rules

19 The priority of a congesting queue shall be lower than the priority of all monitored queues.

## 20 D.2.16 Topology Recognition TLV

21 The Topology Recognition TLV is an optional TLV that allows an IEEE 802.1Q-compliant Bridge and an  
22 IEEE 802.1Q-compatible IEEE 802 LAN station to discover and determine the position of the system in the  
23 data center topology. End-stations are always at level 0 and Bridges or routers are at levels greater than 0  
24 depending upon the number of links between the Bridge or router and the end-station.

25 Figure D-16 shows the Topology Recognition TLV format:

**Figure D-16—Topology Recognition TLV Format**

### 26 D.2.16.1 TLV Type

27 A 7-bit integer value occupying the most-significant bits of the first octet of the TLV. Always contains the  
28 value 127.

## 1 D.2.16.2 TLV information string length

2 The TLV information string length field of the Congestion Isolation TLV is fixed and shall contain the  
3 value 7.

## 4 D.2.16.3 Device Type

5 The Device Type field indicates what type of device is sending the Topology Recognition TLV. End-stations  
6 or servers that are non-relay systems are at the edge of the topology and shall use the value 0. Table D-14  
7 specifies valid values for the Device Type field.

**Table D-14—Device Type field values**

| Device Type | Value/meaning      |
|-------------|--------------------|
| 0           | end-station/server |
| 1           | bridge             |
| 2           | router             |
| 3–254       | reserved           |
| 255         | unknown            |

## 8 D.2.16.4 Topology Level

9 An integer indicating the system’s understanding of its current level in the topology. The value of 0 indicates  
10 the edge of the topology and the value 255 indicates the level is currently unknown. Other non-zero values  
11 indicate the minimum number of links between the system and the edge of the topology. Initially systems  
12 may not know their position in the topology and will use the value of unknown by default. As systems  
13 discover the device type and topology level of their peers the topology level of the sending system may  
14 change. The procedures that implement the recognition of the topology level are described in 49.5.3.

## 15 D.2.16.5 Port Orientation

16 The Port Orientation field indicates whether the port is facing an *uplink*, *downlink*, *crosslink*, or the  
17 orientation is *unknown*. An *uplink* is a port that is facing a system that is deeper in the topology (i.e., has a  
18 Topology Level greater than the sending system). A *downlink* is a port that is facing a system closer to the  
19 edge of the topology (i.e., has a Topology Level less than the sending system). A *crosslink* is a port that is  
20 facing a system at the same level of the topology. Initially systems may not know whether the port  
21 orientation is an *uplink*, *downlink*, or *crosslink* and will use the value of *unknown* by default. The procedures  
22 that implement the recognition of the Port Orientation are described in 49.5.3. Table D-15 specifies valid  
23 values for the Port Orientation field.

**Table D-15—Port Orientation field values**

| Port Orientation | value/meaning |
|------------------|---------------|
| 0                | uplink        |
| 1                | downlink      |
| 2                | crosslink     |
| 3–254            | reserved      |
| 255              | unknown       |

## 1 D.2.17 PBBN Auto Attach System TLV

2 The PBBN Auto Attach System TLV is an optional TLV that allows Bridges and IEEE 802 LAN stations to  
3 discover each other and exchange type and configuration information. Refer to Clause 50 for usage of Auto  
4 Attach TLVs.

5 Figure D-17 shows the format of the PBBN Auto Attach System TLV.

Figure D-17—PBBN Auto Attach System TLV format

### 6 D.2.17.1 TLV type

7 A 7-bit integer value occupying the most significant bits of the first octet of the PBBN Auto Attach System  
8 TLV. Always contains the value 127.

### 9 D.2.17.2 TLV information string length

10 The TLV information string length field contains the length, in octets, of the fixed length PBBN Auto Attach  
11 System TLV fields, which is 19 octets.

### 12 D.2.17.3 802.1 OUI

13 The 3-octet OUI assigned to IEEE 802.1 (00-80-C2).

### 14 D.2.17.4 IEEE 802.1 subtype

15 An octet field containing the PBBN Auto Attach System TLV subtype as specified in Table D-1.

### 16 D.2.17.5 Assoc State

17 An octet field that identifies the current state of the association (Table D-16).

### 18 D.2.17.6 Rsvd1

19 Three reserved bits, set to zero on transmission. The Rsvd1 field is ignored on receipt.

### 20 D.2.17.7 System Type

21 The System Type field (Table D-17) is a 3-bit unsigned integer used by all AASs to identify the advertising  
22 system's type.

23 An AAB advertises itself as an AAB system so that connected AADs know that it performs the AAB  
24 function of receiving and processing VID/I-SID assignment requests and provides responses to such  
25 requests.

26 An AAD could be a VLAN-aware or VLAN-unaware system. A VLAN-aware system can be a  
27 VLAN-aware Bridge, a VLAN-aware wireless LAN access point, or VLAN-aware end station. A  
28 VLAN-unaware system can be a MAC Bridge or an end station.

**Table D-16—PBBN Auto Attach association states**

| Assoc State        | Value     | Notes                                                                 |
|--------------------|-----------|-----------------------------------------------------------------------|
| NOT_READY          | 0x00      | Not ready to associate                                                |
| READY_TO_ASSOC     | 0x01      | Ready to associate                                                    |
| READY_TO_ATTACH    | 0x02      | Associated, viable partner                                            |
| ASSOC_FAILED_TYPES | 0x12      | Not AAD to AAB                                                        |
| ASSOC_FAILED_TAGS  | 0x22      | Tagging mismatched                                                    |
| ASSOC_FAILED_TOPO  | 0x32      | Multi-point link detected                                             |
| ASSOC_FAILED_OTHER | 0x42      | Parsing or resourcing error                                           |
| ASSOC_ATTACHED     | 0x03      | Association attached                                                  |
| ASSOC_STANDBY      | 0x13      | Association not attached, AAD already attached                        |
| ASSOC_INVALID      | 0x23      | Association rejected at AAB because AAD is already attached elsewhere |
| Reserved           | All other |                                                                       |

**Table D-17—PBBN Auto Attach System Type values**

| System Type                           | Value  |
|---------------------------------------|--------|
| Auto Attach BEB (AAB)                 | 1      |
| C-VLAN aware Auto Attach Device (AAD) | 2      |
| VLAN unaware Auto Attach Device (AAD) | 3      |
| S-VLAN aware Auto Attach Device (AAD) | 4      |
| Reserved for future standardization   | 0, 5–7 |

#### **1 D.2.17.8 Tagging**

2 The Tagging field (Table D-18) indicates AAD link tagging requirements in AAD-sourced frames and  
3 current provisioning mode information. AABs adhere to the Tagging field setting requested by the  
4 AAD.

**Table D-18—PBBN Auto Attach Tagging field values**

| Bit Numbers | Name                           | Value                                                                                                                          |
|-------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0–1         | Link VLAN Tagging requirements | 0 - All traffic tagged on link<br>1 - Untagged and Tagged traffic on Link<br>2 - Untagged traffic only on Link<br>3 - Reserved |

#### **5 D.2.17.9 Rsvd2**

6 One octet reserved for future alternative formats. The octet is set to zero on transmission. All other values  
7 are reserved for future standardization. The Rsvd2 field is ignored on receipt.

## 1 D.2.17.10 PortNetId

2 A 12-octet field (Table D-19) that uniquely identifies an Auto Attach port within the administrative domain  
3 used for Auto Attach connection management. This information is particularly important to an AAD to  
4 determine to which AAB in a given network it is attached. AADs only form an association to one AAB, and  
5 an AAB forms an association to one AAD per AAB port.

6 When the AAB function resides on two physical BEBs comprising a DRNI (IEEE Std 802.1AX), the AAD  
7 requires an association with a single logical AAB system. AABs in a DRNI configuration use a single  
8 unique PortNetId to ensure the AAD is associated logically with one AAB.

**Table D-19—PBBN Auto Attach PortNetId values**

| Octets | Type               | Values                                    |
|--------|--------------------|-------------------------------------------|
| 6      | System MAC Address |                                           |
| 2      | Reserved           | 0 on transmit, can be anything on receive |
| 4      | Integer            | Port IfIndex, Aggregator IfIndex          |

## 9 D.2.17.11 PBBN Auto Attach System TLV usage rules

10 An LLDPDU shall contain no more than one PBBN Auto Attach System TLV.

## 11 D.2.18 PBBN Auto Attach Assignment TLV

12 The PBBN Auto Attach Assignment TLV is an optional TLV that allows an AAD to request VID/I-SID  
13 assignments that it would like enabled by a directly connected AAB.

14 Figure D-18 depicts a PBBN Auto Attach Assignment TLV containing multiple VID/I-SID assignments.  
15 The minimum number of assignments is zero. The maximum number of assignments is determined by the  
16 maximum TLV information string size of 511 bytes. This allows 101 VID/I-SID assignments resulting in a  
17 TLV size of 510 bytes.

**Figure D-18—PBBN Auto Attach Assignment TLV format**

### 18 D.2.18.1 TLV type

19 A 7-bit integer value occupying the most significant bits of the first octet of the TLV. Always contains the  
20 value 127.

### 21 D.2.18.2 TLV information string length

22 The TLV information string length field contains the length, in octets, of the TLV. The length of this TLV is  
23 variable between 5 and 510 octets depending on the number of VID/I-SID assignments carried.

### 24 D.2.18.3 802.1 OUI

25 The 3-octet OUI assigned to IEEE 802.1 (00-80-C2).

## 1 D.2.18.4 802.1 TLV subtype

2 An octet containing the PBBN Auto Attach Assignment TLV subtype specified in Table D-1.

## 3 D.2.18.5 Number of assignments

4 An octet containing the number *n* of Status/VID/I-SID triples in this TLV. The number can range from  
5 0 to 101. Zero indicates no Status/VID/I-SID triples are present while 101 is the maximum number allowed  
6 in a PBBN Auto Attach Assignment TLV.

## 7 D.2.18.6 Assignment Status

8 The Assignment Status (Table D-20) is returned by the AAB for each VID/I-SID assignment request. If  
9 multiple AADs are connected to the AAB, Assignment Status is returned independently on each port. This  
10 field is only valid when generated by an AAB.

**Table D-20—PBBN Auto Attach Assignment Status values**

| Assignment Status                           | Value |
|---------------------------------------------|-------|
| Pending                                     | 1     |
| Accepted                                    | 2     |
| Rejected: Generic                           | 3     |
| Rejected: Auto attach resources unavailable | 4     |
| Rejected: Invalid VLAN ID                   | 5     |
| Rejected: VLAN resources unavailable        | 6     |
| Rejected: Invalid I-SID                     | 7     |
| Rejected: I-SID resources unavailable       | 8     |
| Rejected: Application interaction issue     | 9     |
| Rejected: Assignment not allowed            | 10    |

11 Pending—AAB is processing assignment; used by the AAD while waiting for a response from the AAB.

12 Accepted—AAB assignment request processing is complete for the VID / I-SID and the VLAN to BSI  
13 connection has been established.

14 Rejected: Generic—used when an undefined rejection occurs.

15 Rejected: Auto attach resources unavailable—used when the Auto Attach process is unable to process a  
16 request due to system resources being unavailable. For example, memory or CPU processing.

17 Rejected: Invalid VLAN ID—used when the VID value is outside the range of 1 to 4094.

18 Rejected: VLAN resources unavailable—used when VID resource limits have been reached. For example,  
19 maximum number of VLANs are already in use for the port or AAB.

20 Rejected: Invalid I-SID—used when the I-SID value is outside the allowed values of 1 or 256 through  
21 16 777 214.

22 Rejected: I-SID resources unavailable—used when I-SID resource limits have been reached. For example,  
23 the maximum number of I-SIDs are already in use for the port or AAB.

24 Rejected: Application interaction issue—used when Auto Attach assignment processing is not able to  
25 complete due to an issue with Auto Attach agent functions on the AAB. For example, a state machine issue.

1 Rejected: Assignment not allowed—used when Auto Attach assignment processing is subject to a policy or  
2 rule on the AAB where the assignment requested is not permitted or denied.

### 3 **D.2.18.7 VLAN ID**

4 The VLAN ID of the VLAN being mapped by this attachment. If this is an attachment with a  
5 VLAN-unaware AAD, this field is transmitted as zero and ignored on receive. If this is a C-VLAN aware  
6 AAD, then this field is a valid C-VID. If this is an S-VLAN aware AAD, then this field is a valid S-VID.

### 7 **D.2.18.8 I-SID**

8 The I-SID for the PBBN backbone service instance (BSI).

### 9 **D.2.18.9 PBBN Auto Attach Assignment TLV usage rules**

10 An LLDPDU shall contain no more than one PBBN Auto Attach Assignment TLV.

## 11 **D.3 IEEE 802.1 Organizationally Specific TLV management**

### 12 **D.3.1 IEEE 802.1 Organizationally Specific TLV selection management**

13 TLV selection management consists of providing the network manager with the means to select which  
14 specific IEEE 802.1 Organizationally Specific TLVs are enabled for inclusion in an LLDPDU. The  
15 following LLDP variables cross reference to LLDP local systems configuration MIB tables indicate which  
16 specific TLVs are enabled for the particular port(s) on the system. The specific port(s) through which each  
17 TLV is enabled for transmission may be set (or reset) by the network manager:

- 18 a) **mibXdot1PortVlanTxEnable:** This variable lists the VID of the port through which the referenced  
19 TLV is enabled for transmission.
- 20 b) **mibXdot1VlanNameConfigTxEnable:** This variable lists the different VLAN name/PPVID TLVs  
21 that are defined for the system, each with a bit map indicating the system ports through which the  
22 particular VLAN name TLV is enabled for transmission.
- 23 c) **mibXdot1ProtoVlanConfigTxEnable:** This variable lists the Port And Protocol VLAN TLVs that  
24 are defined for the system, each with a bit map indicating the system ports through which the  
25 particular Port And Protocol VLAN TLV is enabled for transmission.
- 26 d) **mibXdot1ProtocolConfigTxEnable:** This variable lists the protocol identity TLVs that are defined  
27 for the system, each with a bit map indicating the system ports through which the particular protocol  
28 TLV is enabled for transmission.

### 29 **D.3.2 IEEE 802.1 managed objects—TLV variables**

#### 30 **D.3.2.1 Port VLAN ID TLV managed objects**

- 31 a) **PVID:** The port VLAN identifier (see D.2.1.1).

#### 32 **D.3.2.2 Port And Protocol VLAN ID TLV managed objects**

- 33 a) **Port and protocol VLAN supported:** A flag indicating whether port and protocol VLANs are  
34 supported (see D.2.2.1).
- 35 b) **Port and protocol VLAN enabled:** A flag indicating whether port and protocol VLANs are  
36 enabled (see D.2.2.1).
- 37 c) **PPVID:** The advertised port and protocol VLAN identifier (see D.2.2.2).

1 **D.3.2.3 VLAN Name TLV managed objects**

- 2 a) **VID:** The VLAN identifier associated with the VLAN name (see D.2.3.2).
- 3 b) **VLAN name length:** The length of the VLAN name (see D.2.3.3).
- 4 c) **VLAN name:** The VLAN's name (see D.2.3.4).

5 **D.3.2.4 Protocol Identity TLV managed objects**

- 6 a) **protocol identity length:** The length of the protocol identity (see D.2.4.2).
- 7 b) **protocol identity:** The protocol's identity (see D.2.4.3).

8 **D.3.2.5 VID Usage Digest TLV managed objects**

- 9 a) **VID Usage Digest:** The VID Usage Digest value (see D.2.5.1)

10 **D.3.2.6 Management VID TLV managed objects**

- 11 a) **Management VID:** The Management VID value (see D.2.6.1)

12 **D.3.2.7 Link Aggregation TLV managed objects**

- 13 a) **aggregation status:** The capability and current aggregation status of the link (see
- 14 IEEE Std 802.1AX).
- 15 b) **aggregated port ID:** The aggregated port identifier (see IEEE Std 802.1AX).

16 **D.3.2.8 Congestion Notification TLV managed objects**

- 17 a) **CNPV indicators:** A per-priority CNPV indicator vector (see D.2.7.3).
- 18 b) **CN ready indicators:** A per-priority ready indicator vector (see D.2.7.4).

19 **D.3.2.9 EVB TLV managed objects**

- 20 a) **EVB TLV:** see D.2.12.

21 **D.3.2.10 CDCP TLV managed objects**

- 22 a) **CDCP TLV:** see D.2.13.

23 **D.3.2.11 Congestion Isolation TLV managed objects**

- 24 a) **queue map:** see D.2.15.3.
- 25 b) **CIM Encap Length:** see D.2.3.3.
- 26 c) **MAC Address:** see D.2.15.5
- 27 d) **Address Family:** see D.2.15.7
- 28 e) **IP Address:** see D.2.15.8

29 **D.3.2.12 Topology Recognition TLV managed objects**

- 30 a) **Device Type:** see D.2.16.3.
- 31 b) **Topology Level:** see D.2.16.4.
- 32 c) **Port Orientation:** see D.2.16.5

33 **D.3.2.13 PBBN Auto Attach TLV managed objects**

- 34 a) **PBBN Auto Attach System TLV** (D.2.17).
- 35 b) **PBBN Auto Attach Assignment TLV** (D.2.18).

## 1 D.5 IEEE 802.1/LLDP extension MIB

### 2 D.5.1 Internet Standard Management Framework

3 LLDP MIBs are designed to operate in a manner consistent with the principles of the Internet Standard  
4 Management Framework, which describes the separation of a data modeling language (for example, SMIV2)  
5 from content-specific data models (for example, the LLDP remote systems MIB), and from messages and  
6 protocol operations used to manipulate the data (for example, SNMPv3).

7 For a detailed overview of the documents that describe the current Internet Standard Management  
8 Framework, refer to section 7 of IETF RFC 3410 (2002).

9 Managed objects are accessed via a virtual information store, termed the *Management Information Base* or  
10 *MIB*. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP).  
11 Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information  
12 (SMI). This clause specifies a MIB module that is compliant to the SMIV2, which is described in  
13 IETF STD 58, IETF RFC 2578, IETF RFC 2579, and IETF RFC 2580.

### 14 D.5.2 Structure of the IEEE 802.1/LLDP extension MIB

15 Table D-21 summarizes the particular object groups that are required for each operating mode. The  
16 implemented MIB shall comply with the MIB conformance section for the particular operating mode being  
17 supported.

**Table D-21—IEEE 802.1 extension MIB object group conformance requirements**

| MIB group                             | Rx mode        | Tx mode | Tx/Rx mode |
|---------------------------------------|----------------|---------|------------|
| lldpV2Xdot1ConfigGroup                | M <sup>a</sup> | M       | M          |
| lldpV2Xdot1LocSysGroup                | M              | —       | M          |
| lldpV2Xdot1RemSysGroup                | —              | M       | M          |
| ifGeneralInformationGroup             | M              | M       | M          |
| lldpXdot1dcbxETSGroup                 | DCBX:M         | DCBX:M  | DCBX:M     |
| lldpXdot1dcbxPFCGroup                 | DCBX:M         | DCBX:M  | DCBX:M     |
| lldpXdot1dcbxApplicationPriorityGroup | DCBX:M         | DCBX:M  | DCBX:M     |
| lldpXdot1dcbxApplicationVlanGroup     | DCBX:M         | DCBX:M  | DCBX:M     |
| lldpXdot1CiGroup                      | CI:M           | CI:M    | CI:M       |
| lldpXdot1TrGroup                      | TR:M           | TR:M    | TR:M       |
| lldpXdot1AaGroup                      | —              | —       | AA:M       |

<sup>a</sup>M=Mandatory.

<sup>1</sup> Table D-22 shows the structure of the MIB and the relationship of the MIB objects to the LLDP operational  
<sup>2</sup> status/control variables, LLDP statistics variables, and TLV variables.

**Table D-22—IEEE 802.1/LLDP extension MIB object cross reference**

| MIB table                            | MIB object                              | LLDP reference                                |

<sup>a</sup> The term Extension Group is used here to be consistent with LLDP (see IEEE Std 802.1AB).

### 1 D.5.3 Relationship to other MIBs

2 Version 2 of the IEEE 802.1 LLDP extension MIB module appears in D.5.5. Version 1 of the MIB module  
3 that was published in IEEE Std 802.1AB-2005 [B8] has been superseded by version 2 of the MIB module,  
4 and support of the version 2 module is a requirement for conformance to the required or optional capabilities  
5 (Clause 5 of IEEE Std 802.1AB-2009 [B9]) in IEEE Std 802.1AB-2009. The version 2 MIB module reflects  
6 changes in indexation of the MIB objects that support the use of LLDP with multiple destination MAC  
7 addresses, as discussed in Clause 6 of IEEE Std 802.1AB-2009 [B9].

8 The relationship of the IEEE 802.1 LLDP extension MIB module to other MIBs, and coexistence between  
9 version 1 and version 2 implementations, is further discussed in 11.3 of IEEE Std 802.1AB-2009 [B9].

### 10 D.5.4 Security considerations for IEEE 802.1 LLDP extension MIB module

11 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
12 read-write.<sup>74</sup> Such objects may be considered sensitive or vulnerable in some network environments. The  
13 support for SET operations in a nonsecure environment without proper protection can have a negative effect  
14 on network operations.

<sup>74</sup> In IETF MIB definitions, the MAX-ACCESS clause defines the type of access that is allowed for particular data elements in the MIB. An explanation of the MAX-ACCESS mappings is given in section 7.3 of IETF RFC 2578 (1999).

1 Setting the following objects to incorrect values can result in improper operation of LLDP when in the  
2 transmit mode:

- 3 a) lldpV2Xdot1ConfigPortVlanTxEnableV2
- 4 b) lldpV2Xdot1ConfigVlanNameTxEnable
- 5 c) lldpV2Xdot1ConfigProtoVlanTxEnable
- 6 d) lldpV2Xdot1ConfigProtocolTxEnable
- 7 e) lldpV2Xdot1ConfigVidUsageDigestTxEnable
- 8 f) lldpV2Xdot1ConfigManVidTxEnable

9 The following readable objects in this MIB module may be considered to be sensitive or vulnerable in some  
10 network environments:

- 11 g) MIB objects that are related to the transmit mode:
  - 12 1) lldpV2Xdot1LocPortVlanId
  - 13 2) lldpV2Xdot1LocProtoVlanSupported
  - 14 3) lldpV2Xdot1LocProtoVlanEnabled
  - 15 4) lldpV2Xdot1LocVlanName
  - 16 5) lldpV2Xdot1LocProtocolId
  - 17 6) lldpV2Xdot1LocVidUsageDigest
  - 18 7) lldpV2Xdot1LocManVidTxEnable
  - 19 8) lldpV2Xdot1LocLinkAggStatus
  - 20 9) lldpV2Xdot1LocLinkAggPortId
  - 21 10) lldpXdot1dcbxConfigETSConfigurationEntry
  - 22 11) lldpXdot1dcbxConfigPFCtable
  - 23 12) lldpXdot1dcbxLocETSConfigurationTable
  - 24 13) lldpXdot1dcbxLocETSConPriorityAssignmentTable
  - 25 14) lldpXdot1dcbxLocETSConTrafficSelectionAlgorithmTable
  - 26 15) lldpXdot1dcbxLocPFCBasicTable
  - 27 16) lldpXdot1dcbxLocPFCEnableTable
  - 28 17) lldpXdot1dcbxAdminETSConfigurationTable
  - 29 18) lldpXdot1dcbxAdminETSConPriorityAssignmentTable
  - 30 19) lldpXdot1dcbxAdminETSConTrafficSelectionAlgorithmTable
  - 31 20) lldpXdot1dcbxAdminPFCBasicTable
  - 32 21) lldpXdot1dcbxAdminPFCEnableTable
  - 33 22) lldpXdot1dcbxLocApplicationPriorityAppTable
  - 34 23) lldpXdot1dcbxLocApplicationVlanAppTable
  - 35 24) lldpXdot1dcbxAdminApplicationPriorityAppTable
  - 36 25) lldpXdot1dcbxAdminApplicationVlanAppTable
  - 37 26) lldpXdot1LocCiBasicTable
  - 38 27) lldpXdot1CiLocQueueMapTable
  - 39 28) lldpXdot1LocTrTable
  - 40 29) lldpV2Xdot1LocAaTlvTable
- 41 h) MIB objects that are related to the receive mode:
  - 42 1) lldpV2Xdot1RemPortVlanId
  - 43 2) lldpV2Xdot1RemProtoVlanSupported
  - 44 3) lldpV2Xdot1RemProtoVlanEnabled
  - 45 4) lldpV2Xdot1RemVlanName
  - 46 5) lldpV2Xdot1RemProtocolId
  - 47 6) lldpV2Xdot1RemVidUsageDigest
  - 48 7) lldpV2Xdot1RemManVidTxEnable

- 1        8) lldpV2Xdot1RemLinkAggStatus
- 2        9) lldpV2Xdot1RemLinkAggPortId
- 3        10) lldpXdot1dcbxConfigETSConfigurationEntry
- 4        11) lldpXdot1dcbxConfigPFCTable
- 5        12) lldpXdot1dcbxRemETSConfigurationTable
- 6        13) lldpXdot1dcbxRemETSConPriorityAssignmentTable
- 7        14) lldpXdot1dcbxRemETSConRecoTrafficSelectionAlgorithmTable
- 8        15) lldpXdot1dcbxRemPFCBasicTable
- 9        16) lldpXdot1dcbxRemPFCEnableTable
- 10       17) lldpXdot1dcbxAdminETSConfigurationTable
- 11       18) lldpXdot1dcbxAdminETSConPriorityAssignmentTable
- 12       19) lldpXdot1dcbxAdminETSConRecoTrafficSelectionAlgorithmTable
- 13       20) lldpXdot1dcbxAdminPFCBasicTable
- 14       21) lldpXdot1dcbxAdminPFCEnableTable
- 15       22) lldpXdot1dcbxRemApplicationPriorityAppTable
- 16       23) lldpXdot1dcbxRemApplicationVlanAppTable
- 17       24) lldpXdot1dcbxAdminApplicationPriorityAppTable
- 18       25) lldpXdot1dcbxAdminApplicationVlanAppTable
- 19       26) lldpXdot1RemCiBasicTable
- 20       27) lldpXdot1CiRemQueueMapTable
- 21       28) lldpXdot1RemTrTable
- 22       29) lldpV2Xdot1RemAaTlvTable

23 This concern applies both to objects that describe the configuration of the local host, as well as for objects  
24 that describe information from the remote hosts, acquired via LLDP and displayed by the objects in this  
25 MIB module. It is thus important to control even GET and/or NOTIFY access to these objects and possibly  
26 to even encrypt the values of these objects when sending them over the network via SNMP.

27 SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for  
28 example, by using IPSec), there is no control about who on the secure network is allowed to access and  
29 GET/SET (read/change/create/delete) the objects in this MIB module.

30 Implementers should consider the security features as provided by the SNMPv3 framework (see  
31 IETF RFC 3410 (2002), section 8), including full support for the SNMPv3 cryptographic mechanisms (for  
32 authentication and privacy).

33 Further, implementers should not deploy SNMP versions prior to SNMPv3. Instead, implementers should  
34 deploy SNMPv3 to enable cryptographic security. It is then a customer/operator responsibility to ensure that  
35 the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the  
36 objects only to those principals (users) that have legitimate rights to indeed GET or SET  
37 (change/create/delete) them.

## 1 D.5.5 IEEE 802.1 LLDP extension MIB module—version 2<sup>75</sup> 76

2 In the following MIB definition, should any discrepancy between the DESCRIPTION text and the  
3 corresponding definition in D.2.1 through D.5 occur, the definition in D.2.1 through D.5 shall take  
4 precedence.

53     DESCRIPTION
54         "The LLDP Management Information Base extension module for
55         IEEE 802.1 organizationally defined discovery information.
56
57         In order to ensure the uniqueness of the LLDP-V2-MIB,
58         lldpV2Xdot1MIB is branched from lldpV2Extensions using an
59         Organizationally Unique Identifier (OUI) value as the node.
60         An OUI is a 24 bit globally unique number assigned by the
61         IEEE Registration Authority - see:

```

10  
11      REVISION "202306050000Z" -- June 5, 2023  
12      DESCRIPTION  
13          "Published as part of IEEE Std 802.1Qcz-2023.  
14          Congestion Isolation objects added."  
15  
16      REVISION "202211080000Z" -- November 8, 2022  
17      DESCRIPTION  
18          "Published as part of IEEE Std 802.1Q-2022.  
19          Cross references and contact information updated."  
20  
21      REVISION "201807010000Z" -- July 1, 2018  
22      DESCRIPTION  
23          "Published as part of IEEE Std 802.1Q 2018 revision.  
24          Cross references updated and corrected.  
25          Changes introduced by IEEE Std 802.1Qcd-2015 and  
26          IEEE Std 802.1Q-2014 Cor 1-2015 merged. "  
27  
28      REVISION "201502160000Z" -- February 16, 2015  
29      DESCRIPTION  
30          "Published as part of IEEE Std 802.1Q 2014 Cor-1.  
31          Updated as a result of maintenance items #0132 and #0152"  
32  
33      REVISION "201502160000Z" -- February 16, 2015  
34      DESCRIPTION  
35          "Published as part of IEEE Std 802.1Qcd.  
36          Adds Application VLAN TLV objects to the DCBX groups of  
37          the MIB module."  
38  
39      REVISION "201412150000Z" -- December 15, 2014  
40      DESCRIPTION  
41          "Published as part of IEEE Std 802.1Q 2014 revision.  
42          Cross references updated and corrected.  
43          New tables lldpV2Xdot1RemVidUsageDigestV2Table  
44          and lldpV2Xdot1RemManVidV2Table inserted; old  
45          versions deprecated. New versions add an index for  
46          lldpV2RemIndex. "  
47  
48      REVISION "201103250000Z" -- March 25, 2011  
49      DESCRIPTION  
50          "Published as part of IEEE Std 802.1Qaz-2011. Adds the DCBX  
51          objects to the MIB module"  
52  
53      REVISION "201103230000Z" -- March 23, 2011  
54      DESCRIPTION  
55          "Published as part of IEEE Std 802.1Q-2011 revision.  
56          This revision contains changes associated with  
57          relocating the extension MIB from IEEE Std 802.1AB to  
58          IEEE Std 802.1Q, minor tweaks to the text of the  
59          DESCRIPTION statement above to fix references to  
60          IEEE Std 802.1Q, updating of references to refer to  
61          Annex D, and addition of object definitions for  
62          Congestion Notification TLVs and corresponding  
63          compliance statements."  
64  
65      REVISION "200906080000Z" -- June 08, 2009  
66      DESCRIPTION  
67          "Published as part of IEEE Std 802.1AB-2009 revision.  
68          This revision incorporated changes to the MIB to  
69          support the use of LLDP with multiple destination MAC  
70          addresses, and to import the Link Aggregation TLV  
71          from the IEEE 802.3 extension MIB"  
72

25     STATUS      current
26     DESCRIPTION
27         "This TC describes the link aggregation status.
28
29         The bit 'aggCapable(0)' indicates the link is capable of being
30         aggregated if 1, not capable if 0.
31
32         The bit 'aggEnabled(1)' indicates the link is currently in
33         an aggregation if 1, not in an aggregation if 0.
34
35         The bits 'portTypeLS(1)' and portTypeMS(2)' form the LS
36         and MS bits of a Port Type value respectively:
37         00 = no port type specified
38         01 = transmitted from Aggregation Port
39         10 = transmitted from Aggregator
40         11 = transmitted from an Aggregator with a single
41             Aggregation Port.
42
43         The remaining bits are reserved for future standardization."
44     SYNTAX BITS {
45         aggCapable(0),
46         aggEnabled(1),
47         portTypeLS(2),
48         portTypeMS(3)
49     }

49  STATUS          current
50  DESCRIPTION
51     "Indicates the bandwidth assigned to this traffic class.
52     The sum of the bandwidths assigned to a given port is
53     required at all times to equal 100. An operation that
54     attempts to change this table such that the bandwidth
55     entires do not total 100 shall be rejected. An implication
56     of this is that modification of this table requires that
57     multiple set operations be included in a single SNMP PDU,
58     commonly referred to as an MSET operation, to perform
59     simultaneous set operations to keep the sum at 100. Any
60     attempt to change a single entry in this table will result
61     in the operation being rejected since entries in the
62     table referring to the given port will no longer
63     sum to 100."

28     STATUS          current
29     DESCRIPTION
30         "Indicates the bandwidth assigned to this traffic class.
31         The sum of the bandwidths assigned to a given port is
32         required at all times to equal 100. An operation that
33         attempts to change this table such that the bandwidth
34         entries do not total 100 shall be rejected. An implication
35         of this is that modification of this table requires that
36         multiple set operations be included in a single SNMP PDU,
37         commonly referred to as an MSET operation, to perform
38         simultaneous set operations to keep the sum at 100. Any
39         attempt to change a single entry in this table will result
40         in the operation being rejected since entries in the
41         table referring to the given port will no longer
42         sum to 100."

34     DESCRIPTION
35         "The lldpXdot1AaConfigAsgnsTxEnable, which is
36         defined as a truth value and configured by the PBBN Auto Attach
37         state machines, determines whether the IEEE 802.1 organizationally
38         defined PBBN Auto Attach Assignment TLV transmission is allowed
39         on a given LLDP transmission-capable port.
40
41         The value of this object is returned to FALSE after a re-initialization
42         of the management system."

## 1 D.6 IEEE 802.1/LLDP extension YANG

2 This clause specifies YANG data models that provide objects for managing the operation of IEEE 802.1  
3 Organizationally Specific TLVs. The YANG modules defined here extend the basic YANG module for  
4 controlling and monitoring the LLDP agent defined in IEEE Std 802.1AB.

### 5 D.6.1 YANG framework

6 This clause has been developed in a manner consistent with the principles of the Internet Standard  
7 Management Framework and according to the YANG guidelines published in IETF RFC 7950 as applicable  
8 to IEEE standards.

9 The YANG framework for the Organizationally Specific TLV YANG follows the framework described in  
10 48.1 and as extended by IEEE Std 802.1AB. Each of the TLV sets shown in Table D-1 has an associated  
11 YANG module that augments the base and per-port LLDP YANG defined in IEEE Std 802.1AB.  
12 Figure D-19 shows the high-level arrangement of IEEE 802.1 Organizationally Specific TLV YANG in the  
13 general YANG framework.

Figure D-19—YANG hierarchy with IEEE 802.1Q Extension TLV YANG

### 14 D.6.2 IEEE 802.1 Organizationally Specific TLV YANG data models

15 The YANG data models are based on the management model outline in D.3. A UML representation of the  
16 management model for each TLV set is provided in D.6.2.1 to D.6.2.6.

### 1 D.6.2.1 IEEE 802.1/LLDP extension basicSet TLV model

2 The attributes for the TLVs in the basicSet are obtained from both system wide and per-port managed  
3 objects. The model augments both the LLDP base model and the LLDP port model. The UML for the  
4 IEEE 802.1/LLDP extension basicSet is derived from the UML specified in IEEE Std 802.1AB and is  
5 shown in Figure D-20. The highlighted portions of the UML show how the LLDP models have been  
6 augmented.

**Figure D-20—basicSet TLV model**

1 **D.6.2.2 IEEE 802.1/LLDP extension cnSet YANG model**

2 The attributes for the TLV in the cnSet are obtained from per-port managed objects. The model augments the  
3 LLDP port model. The UML for the IEEE 802.1/LLDP extension cnSet is derived from the UML specified  
4 in IEEE Std 802.1AB and is shown in Figure D-21. The highlighted portions of the UML show how the  
5 LLDP model has been augmented.

**Figure D-21—cnSet TLV model**

### 1 D.6.2.3 IEEE 802.1/LLDP extension dcbxSet YANG model

2 The attributes for the TLV in the dcbxSet are obtained from per-port managed objects. The model augments  
3 the LLDP port model. The UML for the IEEE 802.1/LLDP extension dcbxSet is derived from the UML  
4 specified in IEEE Std 802.1AB and is shown in Figure D-22. The highlighted portions of the UML show  
5 how the LLDP model has been augmented.

Figure D-22—dcbxSet TLV model

#### 1 D.6.2.4 IEEE 802.1/LLDP extension evbSet YANG model

2 The attributes for the TLVs in the evbSet are obtained from per-port managed objects. The model augments  
3 the LLDP port model. The UML for the IEEE 802.1/LLDP extension evbSet is derived from the UML  
4 specified in IEEE Std 802.1AB and is shown in Figure D-23. The highlighted portions of the UML show  
5 how the LLDP model has been augmented.

Figure D-23—evbSet TLV model

#### 6 D.6.2.5 IEEE 802.1/LLDP extension ciSet TLV model

7 The attributes for the Congestion Isolation TLV in the ciSet are obtained from per-port managed objects and  
8 augment the LLDP port. The UML for the IEEE 802.1/LLDP extension ciSet is derived from the UML  
9 specified in IEEE Std 802.1AB and is shown in Figure D-24. The highlighted portions of the UML show  
10 how the LLDP models have been augmented..

Figure D-24—ciSet TLV model

1 **D.6.2.6 IEEE 802.1/LLDP extension trSet TLV model**

2 The attributes for the Topology Recognition TLV in the trSet are obtained from both system wide and  
3 per-port managed objects. The model augments both the LLDP system and the LLDP port. The UML for the  
4 IEEE 802.1/LLDP extension trSet is derived from the UML specified in IEEE Std 802.1AB and is shown in  
5 Figure D-25. The highlighted portions of the UML show how the LLDP models have been augmented.  
6

**Figure D-25—trSet TLV model**

## 1 D.6.2.7 IEEE 802.1/LLDP extension aaSet TLV model

2 The attributes for the TLVs in the aaSet are obtained from both system wide and per-port managed objects of  
3 the IEEE8021-PBBN-AA-MIB. The model augments the LLDP port model. The UML for the IEEE  
4 802.1/LLDP extension aaSet is derived from the UML specified in IEEE Std 802.1AB and is shown in  
5 Figure D-26. The highlighted portions of the UML show how the LLDP model has been augmented.

Figure D-26—PBBN Auto Attach aaSet TLV model

## 6 D.6.3 Structure of the IEEE 802.1/LLDP extension YANG models

7 IEEE 802.1/LLDP extension YANG models are divided into a number of YANG modules, one for each TLV  
8 set defined in Table D-1. Each YANG module augments the LLDP base module and/or the LLDP port  
9 module with objects needed to generate the IEEE 802.1 Organizationally Specific TLVs. Each YANG  
10 module augments the LLDP port module's remote-systems-data to create space to hold the objects received  
11 from a peer LLDP agent. Table D-23 summarizes the modules in this Annex.

## 12 D.6.4 Security considerations

13 The general security considerations specified in 48.4 apply to the YANG modules defined in this clause.  
14 There are a number of management objects defined in the Organizationally Specific TLV extension YANG  
15 modules that are configurable (i.e., read-write) and/or operational (i.e., read-only). Such objects may be  
16 considered sensitive or vulnerable in some network environments. A network configuration protocol, such  
17 as NETCONF (IETF RFC 6241 [B51]), can support protocol operations that can edit or delete YANG  
18 module configuration data (e.g., edit-config, delete-config, copy-config). If this is done in a non-secure  
19 environment without proper protection, then negative effects on the network operation is possible.

20 The following subclauses define module specific security considerations for each of the Organizationally  
21 Specific TLV sets.

**Table D-23—Summary of the YANG modules**

| Module                         | References | Notes                                                                     |
|--------------------------------|------------|---------------------------------------------------------------------------|
| ieee802-dot1q-lldp-basic-tlv   | D.6.6.1    | Basic set of IEEE 802.1 Organizationally Specific TLVs.                   |
| ieee802-dot1q-lldp-cn-tlv      | D.6.6.2    | Congestion Notification set of IEEE 802.1 Organizationally Specific TLVs. |
| ieee802-dot1q-lldp-dcbx-tlv    | D.6.6.3    | DCBX set of IEEE 802.1 Organizationally Specific TLVs.                    |
| ieee802-dot1q-lldp-evb-tlv     | D.6.6.4    | Edge Virtual Bridging set of IEEE 802.1 Organizationally Specific TLVs.   |
| ieee802-dot1q-lldp-ci-tlv      | D.6.6.5    | Congestion Isolation set of IEEE 802.1 Organizationally Specific TLVs.    |
| ieee802-dot1q-lldp-tr-tlv      | D.6.6.6    | Topology Recognition set of IEEE 802.1 Organizationally Specific TLVs.    |
| ieee802-dot1q-lldp-pbbn-aa-tlv | D.6.6.7    | PBBN Auto Attach set of IEEE 802.1 Organizationally Specific TLVs.        |

#### 1 D.6.4.1 Security considerations of the ieee802-dot1q-lldp-basic-tlv YANG module

2 The following objects in the ieee802-dot1q-lldp-basic-tlv YANG module could be manipulated to interfere  
3 with the operation of IEEE 802.1 organizationally specific functionality using LLDP on a port and, for  
4 example, be used to cause network instability:

5       /lldp/vid-usage-digest-tlv-extension/vid-usage-digest  
6       /lldp/management-vid-tlv-extension/management-vid  
7       /lldp/port/tlvs-tx-org-basic-enable  
8       /lldp/port/port-vlan-id-tlv-extension/port-vlan-id  
9       /lldp/port/port-and-protocol-vlan-id-extension/port-vlan-id  
10      /lldp/port/port-and-protocol-vlan-id-extension/flags  
11      /lldp/port/port-vlan-name-tlv-extension/vlan-id  
12      /lldp/port/port-vlan-name-tlv-extension/port-vlan-name  
13      /lldp/port/protocol-identity-tlv-extension/protocol-identity  
14      /lldp/port/link-aggregation-tlv-extension/aggregation-status  
15      /lldp/port/link-aggregation-tlv-extension/aggregated-port-id

#### 16 D.6.4.2 Security considerations of the ieee802-dot1q-lldp-cn-tlv YANG module

17 The following objects in the ieee802-dot1q-lldp-cn-tlv YANG module could be manipulated to interfere  
18 with the operation of IEEE 802.1 organizationally specific functionality using LLDP on a port and, for  
19 example, be used to cause network instability:

20       /lldp/port/congestion-notification-tlv-extension/per-priority-xmit-cnpv-enable  
21       /lldp/port/congestion-notification-tlv-extension/per-priority-xmit-ready

#### 1 **D.6.4.3 Security considerations of the ieee802-dot1q-lldp-dcbx-tlv YANG module**

2 The following objects in the ieee802-dot1q-lldp-dcbx-tlv YANG module could be manipulated to interfere  
3 with the operation of IEEE 802.1 organizationally specific functionality using LLDP on a port and, for  
4 example, be used to cause network instability:

5       /lldp/port/ets-configuration-tlv-extension/ets-config-willing  
6       /lldp/port/ets-configuration-tlv-extension/ets-config-credit-based-shaper  
7       /lldp/port/ets-configuration-tlv-extension/ets-config-traffic-classes-supported  
8       /lldp/port/ets-configuration-tlv-extension/ets-config-priority-assignment-table  
9       /lldp/port/ets-configuration-tlv-extension/ets-config-tc-bandwidth-table  
10       /lldp/port/ets-configuration-tlv-extension/ets-config-tsa-assignment-table  
11       /lldp/port/ets-recommendation-tlv-extension/ets-recommend-priority-assignment-table  
12       /lldp/port/ets-recommendation-tlv-extension/ets-recommend-tc-bandwidth-table  
13       /lldp/port/ets-recommendation-tlv-extension/ets-recommend-tsa-assignment-table  
14       /lldp/port/pfc-tlv-extension/pfc-willing  
15       /lldp/port/pfc-tlv-extension/pfc-macsec-bypass-capable  
16       /lldp/port/pfc-tlv-extension/pfc-number-tc-capable  
17       /lldp/port/pfc-tlv-extension/pfc-enable  
18       /lldp/port/application-priority-tlv-extension/application-priority-table  
19       /lldp/port/application-vlan-tlv-extension/application-vlan-table

#### 20 **D.6.4.4 Security considerations of the ieee802-dot1q-lldp-evb-tlv YANG module**

21 The following objects in the ieee802-dot1q-lldp-evb-tlv YANG module could be manipulated to interfere  
22 with the operation of IEEE 802.1 organizationally specific functionality using LLDP on a port and, for  
23 example, be used to cause network instability:

24       /lldp/port/evb-tlv-extension/evb-tlv-info-string  
25       /lldp/port/evb-tlv-extension/cdcp-tlv-info-string

#### 26 **D.6.4.5 Security considerations of the ieee802-dot1q-lldp-ci-tlv YANG module**

27 The following objects in the ieee802-dot1q-lldp-ci-tlv YANG module could be manipulated to interfere with  
28 the operation of IEEE 802.1 organizationally specific functionality using LLDP on a port and, for example,  
29 be used to cause network instability:

30       /lldp/port/tlvs-tx-org-ci-enable  
31       /lldp/port/congestion-isolation-tlv-extension/queue-map  
32       /lldp/port/congestion-isolation-tlv-extension/cim-encap-length  
33       /lldp/port/congestion-isolation-tlv-extension/address-family-subtype  
34       /lldp/port/congestion-isolation-tlv-extension/ip-address

#### 35 **D.6.4.6 Security considerations of the ieee802-dot1q-lldp-tr-tlv YANG module**

36 The following objects in the ieee802-dot1q-lldp-tr-tlv YANG module could be manipulated to interfere with  
37 the operation of IEEE 802.1 organizationally specific functionality using LLDP on a port and, for example,  
38 be used to cause network instability:

39       /lldp/topology-recognition-tlv-extension/topology-level  
40       /lldp/port/tlvs-tx-org-tr-enable  
41       /lldp/port/topology-recognition-tlv-extension/port-orientation

1 *Insert D.6.4.7 after D.6.4.6 as follows:*

## 2 **D.6.4.7 Security considerations of the ieee802-dot1q-lldp-pbbn-aa-tlv YANG module**

3 All objects in ieee802-dot1q-lldp-pbbn-aa-tlv are read only and so cannot be manipulated. The objects:

- 4       /lldp/port/aa-system-tlv-extension/assoc-state
- 5       /lldp/port/aa-system-tlv-extension/system-type
- 6       /lldp/port/aa-system-tlv-extension/tagging
- 7       /lldp/port/aa-system-tlv-extension/portnetid
- 8       /lldp/port/aa-assign-tlv-extension/assignments

9 provide information about attachments between AADs and AABs which could be useful to an attacker.

## 10 **D.6.5 Definition of the IEEE 802.1/LLDP extension YANG modules**

11 The structure of the IEEE 802.1/LLDP extension YANG modules is described in D.6.4. In the following  
12 YANG module definitions, if any discrepancy between the DESCRIPTION text and the corresponding  
13 definition in any other part of this standard occur, the definitions outside this subclause take precedence.

14 The simplified graphical representation of the data model described in 48.5 is used in the following  
15 subclauses to describe the data schema for the IEEE 802.1/LLDP extension YANG modules.

### 16 **D.6.5.1 Schema for the ieee802-dot1q-lldp-basic-tlv YANG module**

```

17 module: ieee802-dot1q-lldp-basic-tlv

## **Annex E**

### **(normative)**

### **Notational conventions used in state diagrams**

State diagrams are used to represent the operation of the protocol by a number of cooperating state machines each comprising a group of connected, mutually exclusive states. Only one state of each machine can be active at any given time.

Each state is represented in the state diagram as a rectangular box, divided into two parts by a horizontal line. The upper part contains the state identifier, written in upper case letters. The lower part contains any procedures that are executed on entry to the state.

All permissible transitions between states are represented by arrows, the arrowhead denoting the direction of the possible transition. Labels attached to arrows denote the condition(s) that must be met in order for the transition to take place. All conditions are expressions that evaluate to TRUE or FALSE; if a condition evaluates to TRUE, then the condition is met. The label UCT denotes an unconditional transition (i.e., UCT always evaluates to TRUE). A transition that is global in nature (i.e., a transition that occurs from any of the possible states if the condition attached to the arrow is met) is denoted by an open arrow, i.e., no specific state is identified as the origin of the transition. When the condition associated with a global transition is met, it supersedes all other exit conditions including UCT. The special global condition BEGIN supersedes all other global conditions, and once asserted remains asserted until all state blocks have executed to the point that variable assignments and other consequences of their execution remain unchanged.

On entry to a state, the procedures defined for the state (if any) are executed exactly once, in the order that they appear on the page. Each action is deemed to be atomic, i.e., execution of a procedure completes before the next sequential procedure starts to execute. No procedures execute outside of a state block. The procedures in only one state block execute at a time, even if the conditions for execution of state blocks in different state machines are satisfied. All procedures in an executing state block complete execution before the transition to and execution of any other state block occurs, i.e., the execution of any state block appears to be atomic with respect to the execution of any other state block and the transition condition to that state from the previous state is TRUE when execution commences. The order of execution of state blocks in different state machines is undefined except as constrained by their transition conditions. A variable that is set to a particular value in a state block retains this value until a subsequent state block executes a procedure that modifies the value.

On completion of all of the procedures within a state, all exit conditions for the state (including all conditions associated with global transitions) are evaluated continuously until one of the conditions is met. The label ELSE denotes a transition that occurs if none of the other conditions for transitions from the state are met (i.e., ELSE evaluates to TRUE if all other possible exit conditions from the state evaluate to FALSE). Where two or more exit conditions with the same level of precedence become TRUE simultaneously, the choice about which exit condition causes the state transition to take place is arbitrary.

Where it is necessary to split a state machine description across more than one diagram, a transition between two states that appear on different diagrams is represented by an exit arrow drawn with dashed lines, plus a reference to the diagram that contains the destination state. Similarly, dashed arrows and a dashed state box are used on the destination diagram to show the transition to the destination state. In a state machine that has been split in this way, any global transitions that can cause entry to states defined in one of the diagrams are deemed to be potential exit conditions for all of the states of the state machine, regardless of which diagram the state boxes appear in.

Should a conflict exist between a state diagram and either the corresponding global transition tables or the textual description associated with the state machine, the state diagram takes precedence. The interpretation of the special symbols and operators used in the state diagrams is as defined in Table E-1; these symbols and operators are derived from the notation of the “C++” programming language, ISO/IEC 14882. If a Boolean variable is described in this clause as being set it has or is assigned the value TRUE, if reset or clear the value FALSE.

**Table E-1—State machine symbols**

| Symbol                | Interpretation                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ()                    | Used to force the precedence of operators in Boolean expressions and to delimit the argument(s) of actions and conditional actions within state boxes.                                                                                                                                                                                                                                                            |
| { }                   | Used to group multiple actions.                                                                                                                                                                                                                                                                                                                                                                                   |
| ;                     | Used as a terminating delimiter for actions within state boxes. Where a state box contains multiple actions, the order of execution follows the normal English language conventions for reading text.                                                                                                                                                                                                             |
| =                     | Assignment action. The value of the expression to the right of the operator is assigned to the variable to the left of the operator. Where this operator is used to define multiple assignments, e.g., a = b = X the action causes the value of the expression following the right-most assignment operator to be assigned to all of the variables that appear to the left of the right-most assignment operator. |
| !                     | Logical NOT operator.                                                                                                                                                                                                                                                                                                                                                                                             |
| &&                    | Logical AND operator.                                                                                                                                                                                                                                                                                                                                                                                             |
|                       | Logical OR operator.                                                                                                                                                                                                                                                                                                                                                                                              |
| if <expr><br><action> | Conditional action. If the Boolean expression, <expr>, evaluates to TRUE, then the <action> following the expression is executed. If multiple actions are to be executed, they are grouped together by means of {}.                                                                                                                                                                                               |
| !=                    | Inequality. Evaluates to TRUE if the expression to the left of the operator is not equal in value to the expression to the right.                                                                                                                                                                                                                                                                                 |
| ==                    | Equality. Evaluates to TRUE if the expression to the left of the operator is equal in value to the expression to the right.                                                                                                                                                                                                                                                                                       |
| *                     | Arithmetic multiplication operator.                                                                                                                                                                                                                                                                                                                                                                               |
| -                     | Arithmetic subtraction operator.                                                                                                                                                                                                                                                                                                                                                                                  |

## 1 **Annex F**

### 2 (informative)

### 3 **Shared and Independent VLAN Learning (SVL and IVL)**

4 This standard provides for a variety of approaches to the implementation of Bridges from the point of view  
5 of the way that individual MAC addresses are learned, and how that learned information is used in  
6 subsequent forwarding/filtering decisions. Two mechanisms are used as a basis for these variants:

- 7 a) Making use of address information learned across a number of VIDs in order to make learning  
8 decisions relative to any one of those VIDs. This is referred to as Shared VLAN Learning (SVL,  
9 3.247).
- 10 b) Making use of address information learned in association with one VID only in order to make  
11 learning decisions relative to that VID, and ensuring that it is not used in learning decisions relative  
12 to any other VID. This is referred to as *Independent VLAN Learning* (IVL, 3.120).

13 These mechanisms lead to the SVL/IVL model for how a Bridge implements learning and filtering for MAC  
14 addresses. Using the terminology of 8.8.8, an SVL/IVL Bridge supports multiple FIDs (which effectively  
15 equates to supporting multiple FDBs), and multiple VIDs can use each FID. By varying the number of FIDs  
16 supported, and the number of VIDs that can share each FID, the following simplifications of the SVL/IVL  
17 model can be created:

- 18 c) *SVL only*. The implementation supports only one FID, so all VIDs share the same learned MAC  
19 address information, regardless of which VID the information was learned in.
- 20 d) *IVL only*. Multiple FIDs are supported, but each FID can support only one VID, so each VID makes  
21 use only of MAC address information learned within the context of that VID.

22 All three approaches are permitted by this standard, and each has advantages in particular circumstances.  
23 The remainder of this annex discusses the following:

- 24 e) The requirements for IVL, SVL, or both.
- 25 f) How Bridges are made aware of the requirement for particular VLANs to be “shared” or  
26 “independent.”
- 27 g) How Bridges based on one of these models can interoperate with Bridges based on a different  
28 model, in the same network.

### 29 **F.1 Requirements for Shared and Independent Learning**

30 Under most circumstances, the SVL and IVL approaches work equally well, and Bridges adopting either  
31 approach can be freely intermixed within a network. There are, however, a small number of configuration  
32 cases where, in order to prevent undue flooding of unicast frames, and in some cases, to make  
33 communication between the affected end systems possible, it is necessary to make specific choices about  
34 how Bridges that adopt these different learning models are deployed in a network. The following subclauses  
35 give examples of some of these configurations and provide a generic statement of the requirements that must  
36 be met in order for each learning model to be successfully deployed.

## 1 F.1.1 Connecting independent VLANs

2 Figure F-1 illustrates how a device that connects two VLANs together, and which therefore itself shares  
3 learning between those VLANs, creates a need for those VLANs to be independent in other Bridges.

**Figure F-1—Connecting independent VLANs—1**

4 Clients A and B are connected via the protocol sensitive Bridge-Router (Connector), with an intervening  
5 VLAN Bridge. The fact that all Ports of the Bridge carry untagged traffic neatly conceals the fact that the  
6 Connector has the effect of connecting VLANs Red and Blue together with regard to bridged traffic. The  
7 Connector learns A and B in the same database, as it has no knowledge of VLANs Red and Blue. This  
8 prevents any traffic transmitted on the Red VLAN (Port X of the Connector) that is destined for A, from  
9 being bridged to Port Y and transmitted on the Blue VLAN.

10 The VLAN Bridge must keep its learning separate for Red and Blue; otherwise, the addresses of the two  
11 clients would be alternately learned on diagonally opposite Ports as, for example, traffic sourced by A  
12 reenters the Bridge on Port 4 having previously been seen on Port 1.

13 NOTE—This example assumes that the spanning tree protocol is disabled in the Connector, so that the VLAN Bridge  
14 does not attempt to suppress the loop that apparently exists if VLANs are not taken into account.

15 A simpler example can be constructed, with a single Port connecting the Connector and the VLAN Bridge, if  
16 the Connector is itself VLAN aware and transmits and receives only VLAN-tagged traffic. In this case, the  
17 Connector would allocate a single FID for use by Red and Blue. This is shown in Figure F-2.

**Figure F-2—Connecting independent VLANs—2**

## 1 F.1.2 Duplicate MAC addresses

2 The simplest example of a need for IVL occurs where two (or more) distinct devices in different parts of the  
3 network reuse the same individual MAC address, or where a single device is connected to multiple LANs,  
4 and all of its LAN interfaces use the same individual MAC address. This is shown in Figure F-3.

**Figure F-3—Duplicate MAC addresses**

The example shows two clients with access to the same server; both clients are using the same individual MAC address, X. If the Bridge shares learning between VLAN Red (which serves Client A) and VLAN Blue (which serves Client B), i.e., the Bridge uses the same FID for both VLANs, then Address X will appear to move between Ports 1 and 2 of the Bridge, depending on which client has most recently transmitted a frame. Communication between these Clients and the server will therefore be seriously disrupted. Assignment of distinct FIDs for Red and Blue ensures that communication can take place correctly.

Hence, in order to construct this particular VLAN configuration, either an IVL Bridge or an SVL/IVL Bridge would be required.

### F.1.3 Asymmetric VLANs and Rooted-Multipoint connectivity

A primary example of the requirement for SVL is found in “asymmetric” uses of VLANs. Under normal circumstances, a pair of devices communicating in a VLAN environment will both send and receive using the same VID; however, there are some circumstances in which it is convenient to make use of two distinct VLANs, one used for A to transmit to B and the other used for B to transmit to A. Examples of such applications include configuring multi-netted servers, and configuring rooted-multipoint services.

#### F.1.3.1 Multi-netted Server

An example of Multi-netted Server application of asymmetric VLANs is shown in Figure F-4. Note that:

- In the example, the server and both clients are assumed to be VLAN-unaware devices, i.e., they transmit and receive untagged frames only.
- The ingress classification rules assumed by the example are as defined in this standard, i.e., Port-based classification only.
- The configuration shown can only be achieved by management configuration of appropriate values in Static VLAN Registration Entries (8.8.10) in order to configure the indicated member sets and untagged sets.

Figure F-4—Asymmetric VID use: “multi-netted server”

1 In the example, Port-based tagging and an asymmetric VLAN configuration is used in order to permit  
2 Clients A and B access to a common server, but to prohibit Clients A and B from talking to each other.  
3 Examples of where this type of configuration might be required are if the clients are on distinct IP subnets,  
4 or if there is some confidentiality-related need to segregate traffic between the clients.

5 Client A transmits to the server via Port 1, which will classify this traffic as belonging to VLAN Red; the  
6 Bridge therefore learns Client A's MAC address on Port 1 in association with VLAN Red's VID. The Server  
7 transmits its responses to Client A via Port 3, which classifies the return traffic as belonging to VLAN  
8 Purple. If individual MAC address learning is configured in the Bridge such that learning is independent  
9 between Red and Purple (the VIDs for Red and Purple are allocated to distinct FIDs), then the Bridge will  
10 have no knowledge of A in VLAN Purple and will therefore flood the server's responses to Client A on both  
11 Port 1 and Port 2. Conversely, if the VIDs for Red and Purple are defined to share the same FID, then the  
12 address information learned in Red will be available for use in forwarding the Purple traffic, and the  
13 responses to Client A are forwarded only through Port 1.

14 Similarly, there is a need in this configuration for Blue and Purple to share learning information; hence, in  
15 order for this configuration to achieve its objectives, the Red, Blue, and Purple VIDs must be allocated to the  
16 same FID in the Bridge.

17 Hence, in order to construct this particular VLAN configuration, either an SVL Bridge or an SVL/IVL  
18 Bridge would be required.

19 NOTE—The example has been deliberately simplified; in practical applications, the central Bridge would likely be  
20 replaced by a number of VLAN Bridges, interconnected with links that would carry the traffic between clients and server  
21 as VLAN-tagged frames, with VLAN-tagging and untagging occurring only at the "edge" Ports of the network. An  
22 alternative approach to the one described here could also be achieved either by using a VLAN-aware server or by use of  
23 more sophisticated ingress classification rules.

#### 24 **F.1.3.2 Rooted-Multipoint**

25 An example of a rooted-multipoint application of asymmetric VLANs is shown in Figure F-5. The defining  
26 characteristic of a rooted-multipoint service is that all Bridge Ports that provide access points to the service  
27 are designated as either a Root Port or a Leaf Port, and that the Root Ports can communicate with all other  
28 Root Ports and all Leaf Ports, whereas the Leaf Ports can communicate with all Root Ports but not with any  
29 other Leaf Ports. Services based on rooted-multipoint connectivity are also known as "Rooted-Multipoint  
30 EVC" services as defined in MEF 10.3. Rooted-multipoint connectivity would typically be used by an  
31 Internet access provider or a video content provider, where the provider of the service connects to Root  
32 Ports, and the subscribers of the service connect to Leaf Ports. This connectivity can be achieved with  
33 the "multi-netted server" configuration shown in Figure F-4, but it consumes one VID per subscriber.  
34 Figure F-5 shows an alternative that uses just two VIDs: a "Trunk" VID for traffic from Root Ports to Leaf  
35 Ports (and to other Root Ports) and a "Branch" VID for traffic from Leaf Ports to Root Ports.

36 To allow the servers to communicate with all other servers and all subscribers, and to allow the subscribers  
37 to communicate with all servers but not with other subscribers, the rooted-multipoint connectivity requires  
38 the following configuration:

- 39 a) The server(s) and all subscribers transmit and receive untagged frames only. Note that for a rooted-  
40 multipoint service on a PBN, this means the frames do not contain S-TAGs at the customer service  
41 interface (in other words, the User Network Interface (UNI)). Therefore, rooted-multipoint can be  
42 supported at Port-based service interfaces (15.3) and C-tagged service interfaces (15.4).
- 43 b) The ingress C-VLAN classification may be Port-based or Port-and-Protocol-based for rooted-  
44 multipoint on CBNs. The ingress S-VLAN classification may be Port-based or C-TAG-based for  
45 rooted-multipoint on PBNs.
- 46 c) In Customer Bridges and S-VLAN Bridges, the indicated values of the member sets and untagged  
47 sets (8.8.10) are achieved by management configuration of Static VLAN Registration Entries

- (8.8.2). In Provider Edge Bridges the Trunk and Branch VIDs are also mapped to the appropriate CNP/PEP pair by management configuration of the PEP Table (12.13.2.4, ieee8021PbEdgePortTable 17.6.1.2). Note that connectivity between Leaf Ports is blocked by not including Leaf Ports in the member set associated with the Branch VID.
- d) In Customer Bridges and S-VLAN Bridges the indicated values of the PVID parameters are configured by management. In Provider Edge Bridges the equivalent configuration is achieved by management configuration of the C-VID Registration Table (12.13.2.2, ieee8021PbCvidRegistrationTable 17.6.1.2).
- e) The Enable Ingress Filtering parameter (8.6.2) is reset, i.e., ingress VLAN filtering is disabled, on Leaf Ports.
- f) The Trunk and Branch VIDs share the same FID (to enable SVL).

**Figure F-5—Asymmetric VLAN use: “Rooted-Multipoint”**

NOTE 1—The example has been deliberately simplified; in practical applications, the central Bridge would likely be replaced by a number of VLAN Bridges, interconnected with links that would carry the traffic between subscribers and servers as VLAN-tagged frames, with only the Root and Leaf Ports of the network carrying untagged frames.

Rooted-multipoint services can be carried on PBBNs by configuring Trunk and Branch S-VIDs as described above, with the Root and Leaf Ports at CNPs either at an I-component of a BEB, or at a Provider Edge Bridge of a PBN that then connects to the PBBN. The I-component of a BEB can then either map the Trunk and Branch S-VIDs to separate backbone service instances (i.e., mapped to separate I-SIDs) or bundle them into a single backbone service instance.

Rooted-multipoint connectivity can also be created on a PBBN by configuring Trunk and Branch B-VIDs as described above, with the Root and Leaf Ports at CBPs of a B-component in a BEB. One or more backbone service instances can then be mapped to the Trunk and Branch B-VIDs to take advantage of the rooted-multipoint connectivity.

As noted in item a) above, the configurations described above apply to scenarios where the ingress and egress frames at a Root or Leaf Port on a Customer Bridge or S-VLAN Bridge are untagged. Customer Bridges and S-VLAN Bridges that support both the VID Translation Table and Egress VID Translation Table (6.9) can support tagged ingress and egress frames at a Root or Leaf Port. Figure F-6 shows the configuration where the server(s) and subscribers transmit and receive tagged frames. The server uses VID R for frames associated with the rooted-multipoint service, and the subscribers use VIDs L1 and L2. The values of R, L1, and L2 could be, but are not necessarily, the same. The configuration of the Bridge(s) with Root and Leaf Ports are shown in the diagram. All Root and Leaf Ports are included in the member set of the Trunk and Branch VIDs, but not in the untagged set (including the Leaf Ports in the member set of the Branch VID allows ingress VLAN filtering to be enabled at these ports if desired). The VID translation at a Root Port ensures that ingress frames go to the Trunk VID, and egress frames come from both the Trunk and Branch VIDs. The VID translation at a Leaf Port ensures that ingress frames go to the Branch VID, and egress frames come from the Trunk VID (translating the Branch VID to 0xFFFF on egress frames at Leaf Ports causes these frames to be discarded).

Figure F-6—Rooted-Multipoint with tagged interfaces

NOTE 2—The example has been deliberately simplified; in practical applications, the central Bridge would likely be replaced by a number of VLAN Bridges, interconnected with links that would carry the traffic between subscribers and servers as frames tagged with either the Trunk or Branch VID. VLAN translation occurs only at the Root and Leaf Ports of the network.

#### F.1.4 Shared learning and Shortest Path Bridging VID (SPBV) mode

SPBV mode uses shared learning among the set of SPVIDs that support a given SPBV VLAN. Each SPT Bridge supporting an SPBV VLAN is assigned a unique VID (SPVID) for transmitting VLAN frames into the SPT Region. This SPVID is registered by the ISIS-SPB control plane along an SPT rooted at the SPT Bridge to which it is assigned. The SPTs determined by ISIS-SPB provide symmetric bidirectional paths (i.e., congruent paths) between any pair of SPT Bridges within an SPT Region. The congruency of the paths is essential to allow shared learning. Shared learning is required because frames forwarded from a given SPT Bridge will contain a different SPVID from frames being forwarded to that SPT Bridge.

Figure F-7 shows an example of a simple SPBV VLAN operating in an SPT Region comprising three Bridges A, B, and C. Each of the Bridges is assigned an SPVID, in this example using the same letter designation as the Bridge to which it is assigned. ISIS-SPB maintains the VID member sets such that the SPVID of an SPT Bridge follows an SPT rooted at that particular SPT Bridge. The SPT includes all boundary ports participating in the SPBV VLAN (in this example the ports connected to stations A, B, and C).

Figure F-7—SPBV VLAN Shared Learning and VID Translation

Shared learning is used among all the SPVIDs belonging to the SPBV VLAN. This enables the filtering information learned from frames transmitted from a Bridge (with that Bridge's SPVID) to be applied to frames being transmitted to that Bridge from other Bridges using the other Bridges' SPVIDs. For example, a frame sent from station A to station B will be transmitted by Bridge A using SPVID A. At Bridge B the frame's source address will be learned at port B2. When station B later sends a frame to station A, Bridge B will assign the frame SPVID B. Shared learning enables Bridge B to use the MAC address previously learned from the frame with SPVID A to filter the frame with SPVID B to transmit only on port B2.

Enhanced VID translation capabilities allow a single VID to be used for VLANs on boundary ports connected to an SPT Region even though many SPVIDs with shared learning are used within the SPT Region. In this example stations A, B, and C all use VID X. At each boundary port ingress translation is set to translate the external VID (usually the Base VID) to the SPVID for the Bridge on which the boundary port resides. Egress VID translation is set to translate all the SPVIDs belonging to the SPBV VLAN to the external VID.

## 1 F.1.5 Generic constraints on SVL and IVL use

2 This subclause describes the general constraints on the mapping of VIDs to FIDs, from the point of view of  
3 a given Bridge that learns from or forwards frames on a set of VIDs (the Bridge’s “active set” of VIDs). If:

- 4 a) The individual MAC addresses associated with each point of attachment to the active set of VIDs  
5 are unique (i.e., the “Duplicate MAC Address problem” is not present), and
- 6 b) There is no Bridge or Bridge-like device that takes frames from one VID in the active set and  
7 subsequently transmits them on another VID in the active set, then

8 every VID in the active set may share the same FID; in other words, individual MAC address information  
9 learned in the context of any one VID may be used in forwarding decisions taken relative to any of the  
10 others, so the SVL approach can be used in that Bridge.

11 Furthermore, if:

- 12 c) Each bidirectional, individual MAC-Addressed, conversation between pairs of end stations makes  
13 use of the same VID in both directions, then

14 every VID in the active set may be allocated a distinct FID (with the possibility of a little extra flooding as  
15 learning of addresses in the context of one VID does not contribute to forwarding decisions for that address  
16 relative to any other VID). Under these circumstances, rule b) may also be relaxed and restated as follows:

- 17 d) Frames associated with one VID in the active set may be received by (up to) one Bridge and  
18 transmitted using another VID in the active set, provided that there is no loop in such VLAN to  
19 VLAN forwarding, e.g., for a set of VIDs Red, Blue, and Green, there is no logical loop in copying  
20 frames between VIDs, such as copying from Red to Green by one Bridge, Green to Blue by another,  
21 and Blue back to Red by a third.

22 So:

- 23 e) If rules a), b), and c) are true, and d) is false, for all VIDs in the active set, then either an SVL or an  
24 IVL Bridge can be deployed;
- 25 f) If rules a) and b) are true, and c) and d) are false for all VIDs in the active set, then only an SVL  
26 Bridge can be deployed;
- 27 g) If rules a) or b) or d) are false, and c) is true for all VIDs in the active set, then only an IVL Bridge  
28 can be deployed.

29 These conditions are all on the basis that they apply “for all VIDs in the active set.” Clearly, in more  
30 complex scenarios, some VIDs in the active set will have requirements that dictate SVL behavior on the part  
31 of a given Bridge, while others will have requirements that dictate IVL behavior. Under such circumstances,  
32 an SVL/IVL Bridge is required, allowing those VIDs that need to be shared to be mapped to a single FID,  
33 while those that need to be independent are mapped to distinct FIDs. Needless to say, wherever an SVL or  
34 IVL Bridge can be deployed, it can successfully be replaced by an appropriately configured SVL/IVL  
35 Bridge.

## Annex G

### (informative)

## MAC method-dependent aspects of VLAN support

### G.1 Example tagged IEEE 802.3 EtherType-encoded frame format

Figure G-1 provides an illustrative example of a single tagged EtherType-encoded frame format as used in an Ethernet to Ethernet Bridge. This illustration is only of the simplest case, that is, a single-level, fixed-size tagging between identical MACs.<sup>77</sup>

Figure G-1—Example of IEEE 802.3 MAC frame format

### G.2 Padding and frame size considerations

#### G.2.1 Treatment of PAD fields in IEEE 802.3 frames

The minimum frame size constraint placed on IEEE 802.3/Ethernet frames requires frames to carry zero or more pad octets following the MAC client data, in order to ensure that no frame of total length less than 64 octets is transmitted on the medium. This requirement means that frames whose overall length would otherwise be less than 64 octets in length have (64-len) octets of padding added after the MAC client data, where len is the size of the frame before padding.

<sup>77</sup> Figure G-1 was part of Clause 3 of IEEE Std 802.3-2005.

1 When tagged frames are transmitted by a Bridge on an IEEE 802.3 MAC, there are two permissible  
2 approaches, as follows:

- 3 a) Keep the minimum frame size generated by the Bridge equal to 64 octets. This implies that the  
4 number of pad octets in a received untagged IEEE 802.3 frame would be reduced by up to 4 octets  
5 when that frame was tagged.
- 6 b) Adopt a minimum tagged frame length of 68 octets. This implies that the number of pad octets in a  
7 received untagged IEEE 802.3 frame would not be adjusted when tagging such frames; equally, if  
8 subsequently untagged, no pad adjustment would be necessary before transmission on IEEE 802.3/  
9 Ethernet.

10 There is a similar choice to be made in end stations that generate tagged frames:

- 11 c) In some existing implementations, the decision about whether pad octets are needed will be made at  
12 a point where it is impractical to distinguish between tagged and untagged frames. In these cases, the  
13 end station will use a minimum frame size of 64 octets for all frames.
- 14 d) In other cases, the padding decision will be taken at a point before it is known whether the frame will  
15 be transmitted tagged or untagged. In these cases, the end station will use a minimum tagged frame  
16 size of 68 octets and a minimum of 64 octets for untagged frames.

17 These approaches are all consistent with the IEEE 802.3 frame specification.

18 The implication is that, for correct operation on IEEE 802.3/Ethernet, all devices have to be capable of  
19 correctly handling tagged frames of less than 68 octets in length (G.2.3).

## 20 **G.2.2 Maximum PDU size**

21 VLAN tagging of an untagged frame, or relaying frames in tagged frame format, can result in an increase in  
22 the length of the original frame. If transmission of a given frame in tagged frame format through a given  
23 destination Port would result in violation of the maximum PDU size for the destination MAC method, the  
24 Bridge discards the frame for that destination Port.

25 NOTE—Violation of the maximum PDU sizes for destination MAC methods can produce undefined results in networks  
26 that contain devices that adhere strictly to these maxima, or in MAC methods where these maxima are inherently  
27 constrained by the operation of the MAC method itself (e.g., constrained by timing considerations in the MAC state  
28 machines).

29 IEEE Std 802.3 defines an extension to the normal IEEE 802.3 maximum frame size for the specific purpose  
30 of accommodating the additional octets of the VLAN tag header. The example frame translations in this  
31 annex make use of this extension to the IEEE 802.3 frame size.

## 32 **G.2.3 Minimum PDU size**

33 VLAN untagging of a tagged frame results in the original frame decreasing in length.

34 Where the destination MAC is Ethernet:

- 35 a) If untagging a given frame would result in violation of the minimum frame length requirements of  
36 Ethernet, the Bridge is required to adjust the PAD field to ensure that the frame length equals the  
37 minimum length of 64 octets (G.2.1).
- 38 b) If a frame is transmitted in tagged frame format, the Bridge may adopt a minimum tagged frame  
39 length of either 64 or 68 octets, as an implementation option. If the latter is chosen, the Bridge  
40 adjusts the size of the PAD field on transmission for any tagged frame that is less than 68 octets in  
41 length (G.2.1).

## 1 **G.3 Tag insertion and removal for LLC media**

2 In IEEE Std 802.1Q-2014 and all previous revisions of IEEE Std 802.1Q, the method of inserting and  
3 deleting tags was independent of whether a Length/Type field is used for protocol type encoding. The tag  
4 was inserted into or deleted from the first octets of the `mac_service_data_unit` and the remainder of the  
5 `mac_service_data_unit` was unchanged.

6 That deletion/insertion method did not provide for interoperability between VLAN-aware end stations  
7 where only one used a Length/Type field to encode protocol identifiers. It specified that the station on the  
8 LLC media used a SNAP-encoded VLAN tag followed by a SNAP-encoded data unit, whereas on the  
9 station using Length/Type, the VLAN tag was followed by an EtherType protocol identifier. These multiple  
10 encodings required a bridge to translate both the VLAN tag and the following protocol identifier, along with  
11 any other tags defined previously or subsequently. Translation of the second and any subsequent protocol  
12 identifiers is impossible if the contents of the frame are protected against modification or rendered  
13 confidential, as in the case of a frame protected by MAC Security (IEEE Std 802.1AE).

14 To avoid this problem, revisions of IEEE Std 802.1Q subsequent to 2014, and IEEE Std 802.1AC  
15 subsequent to 2012, specify that following the first protocol identifier, all subsequent protocol identifiers (if  
16 any) use Length/Type encoding.

17 The net result was that the expected format for a tagged frame changed. For example, on LLC media, the  
18 first 18 octets of a VLAN-tagged SNAP-encoded MSDU carrying an EtherType of 08-00 (hexadecimal) for  
19 the user data, priority 0, VLAN 123, was, in revisions prior to IEEE Std 802.1Q-2018:

20 AA-AA-03-00-00-00-81-00-01-23-AA-AA-03-00-00-00-08-00

21 and subsequently, is:

22 AA-AA-03-00-00-00-81-00-01-23-08-00

23 The underlined octets are no longer present. That is, on LLC media, all tags and protocol identifiers after the  
24 first are Length/Type encoded.

## 25 **G.4 IEEE 802.11 and PMPN media**

26 Figure G-2 illustrates an example of a five-port Bridge that uses three of the methods defined by  
27 IEEE Std 802.1AC whereby a Bridge can connect to an IEEE 802.11 medium, or to a Point-to-Multipoint  
28 Network (PMPN). The following subclauses describe these methods.

### 29 **G.4.1 IEEE 802.11 Portal convergence**

30 A Bridge, along with the portal convergence function defined in 13.2.1 of IEEE Std 802.1AC-2016 [B10],  
31 together constitute an example of an IEEE 802.11 Portal.

### 32 **G.4.2 Point-to-Multipoint Network convergence: multiple connections**

33 The PMPN convergence function, defined in 13.6.2 of IEEE Std 802.1AC-2016 [B10], provides a set of  
34 virtual point-to-point instances of the ISS, one to each PMPN node to which an underlying PMPN node is  
35 associated. The convergence function maps this set of ISS instances to a single instance of the service  
36 defined for the PMPN node. This interface supports PMPN media interior to a Bridged Network or Virtual  
37 Bridged Network. In Figure G-2, the center block in the diagram has three Bridge Ports connecting to three  
38 of these instances.

**Figure G-2—Methods for Bridge access to IEEE 802.11 and PMPN media: example**

**1 G.4.3 Point-to-Multipoint Network convergence: single connection**

2 The PMPN convergence function, defined in 13.6.2 of IEEE Std 802.1AC-2016 [B10], is also used between  
3 the ISS and the MAC service interface defined for a PMPN node that has, or is capable of, only a single  
4 connection.

## **1 Annex H**

### **2 (informative)**

### **3 Interoperability considerations**

4 VLAN Bridges are able to interoperate in networks with other VLAN Bridges. However, the VLAN-based  
5 filtering service defined in this standard, as provided in the context of a single spanning tree for the network,  
6 involves some constraints on the network topology and individual device configurations that differ from the  
7 set of constraints that apply to the building and configuration of networks based only on MAC Bridges.

8 In addition, VLAN Bridges are able to interoperate with MAC Bridges, as well as with both priority-aware  
9 and VLAN-aware end systems. Both the VLAN-based filtering service and the tag insertion and removal  
10 service specified in this standard cause constraints on intermixed network topologies and device  
11 configurations that again differ from the building and configuration of networks containing MAC Bridges.

12 The implications of certain device configurations may not be immediately apparent from the technical detail  
13 of this standard. In order to clarify the nature of the additional constraints, H.1 through H.4

- 14 a) Describe the basic requirements for interoperability.
- 15 b) Discuss those requirements in the context of homogeneous and heterogeneous configurations, with  
16 examples of some of the problems that can occur if these requirements are not adhered to.

### **17 H.1 Requirements for interoperability**

18 Two primary aspects of the configuration of a network are of concern from the point of view of  
19 interoperability:

- 20 a) Establishing a consistent view of the static filtering configuration of Bridges in the network.
- 21 b) Ensuring that untagged frames are VLAN-tagged (and that the tag is subsequently removed)  
22 consistently regardless of spanning tree reconfigurations.

#### **23 H.1.1 Static filtering requirements**

24 Static filtering controls allow the network administrator to impose a level of control over the permitted  
25 connectivity in the network, by setting static MAC address filters in the FDBs of Bridges, and by controlling  
26 the extent of particular VLANs by manipulation of Static VLAN Registration Entries (8.8.2).

27 In order to ensure that end station-to-end station connectivity (or the lack of it) is consistent in all possible  
28 spanning tree configurations, any static filters need to be established taking account of the full mesh  
29 topology of the physical interconnections between Bridges in the network, not just the “normal” spanning  
30 tree topology to which the network is configured when all Bridges and LANs are operating correctly. An  
31 example of the consequences of failure to establish consistent controls for static VLAN filtering is given in  
32 H.2.1.

#### **33 H.1.2 Configuration requirements for VLAN-tagging**

34 VLAN Bridges classify incoming untagged frames by applying either a Port-based tagging rule on ingress  
35 that uses the PVID for the reception Port as the VLAN classification for such frames or a  
36 Port-and-Protocol-based rule that uses the frame’s ULP to select one of a port’s VIDs. Maintaining

1 consistent connectivity between any pair of end stations that are on the same VLAN, and where one or both  
2 of those end stations is VLAN-unaware, requires that:

- 3 a) All VLAN Bridge Ports that are connected to the same LAN apply a consistent set of ingress rules  
4 (8.6).
- 5 b) All VLAN Bridge Ports that are connected to the same *legacy region* of a network apply a consistent  
6 set of ingress rules.
- 7 c) All VLAN Bridge Ports that serve LANs to which members of the same VLAN are (or can be)  
8 attached apply a consistent set of ingress rules.

9 A legacy region of a network consists of any set of LANs that are physically interconnected via MAC  
10 Bridges. A legacy region has the property that, by appropriate configuration of the spanning tree, a spanning  
11 tree path could be created between any pair of LANs in the region such that the path would pass only  
12 through MAC Bridges.

13 NOTE—In case b), spanning tree reconfiguration within the legacy region can change the logical connectivity between  
14 the VLAN Bridge Ports and the LANs that they (directly or indirectly) serve. Hence, a spanning tree reconfiguration  
15 could result in any end stations connected to the legacy region being serviced via any VLAN Bridge Port. In effect, such  
16 a reconfiguration reduces case b) to case a). Figure H-2 and Figure H-3 give examples of this type of configuration. In  
17 Figure H-2, the legacy region consists of all three LANs and both MAC Bridges. In Figure H-3, the legacy region  
18 consists of the MAC Bridge and both LANs to which it is attached. An example of case c) is where an end station  
19 attached to a leaf LAN is in the same VLAN as a server that is attached to a distinct LAN, i.e., all possible spanning tree  
20 paths between the two stations pass through a VLAN-aware region of the network.

21 The essence of what these rules express is that if a given untagged frame belongs on a given VLAN, then the  
22 classification and tagging behavior of any VLAN Bridges that are required to tag that frame needs to be the  
23 same, regardless of the logical connectivity that is created by the spanning tree configuration of the network.  
24 Examples of the consequences of failure to apply these rules appear in H.3 and H.4.

## 25 H.2 Homogeneous VLAN-aware networks

26 This standard requires new considerations in building a network in which all Bridges are VLAN Bridges.  
27 The arbitrary plug-and-play capability of MAC Bridges in creating a network topology is restricted when  
28 making use of the VLAN extensions defined in this standard.

### 29 H.2.1 Consistency of static VLAN filtering

30 In order for stations that are members of a given VLAN to be able to reach other members of the same  
31 VLAN elsewhere in the network, all Bridge Ports that are part of the spanning tree active topology (i.e., all  
32 Bridge Ports that are in a forwarding state) connecting the stations must be included in the member set  
33 (8.8.10) for the VID that identifies that VLAN. In order for this connectivity to be independent of any  
34 reconfiguration of the spanning tree topology, all paths among those stations, both forwarding and blocked,  
35 must have this characteristic. Use of management controls to manipulate the member set (e.g., filters for  
36 security) must be applied in a manner consistent with requirements of the full mesh topology of the network.

37 An inconsistency occurs, for example, if a VID is restricted from an active path, but not from a redundant  
38 path currently blocked by the operation of spanning tree. Should a spanning tree reconfiguration enable the  
39 previously blocked path, the restriction will no longer be in place. In the reverse, a spanning tree  
40 reconfiguration may suddenly impose a restriction that had not existed. A common use of such management  
41 restriction will likely arise from managers who make use of an “access” port construct. An access port may  
42 be a port that is absent from the member set (8.8.10) for all VIDs but the untagged, default VID. Should such  
43 an access port become the active connection between two portions of the network as a result of a spanning  
44 tree reconfiguration, all VLANs but the one identified by the default VID will be partitioned at that point in  
45 the topology.

1 In Figure H-1, the trunk style link and access style link cause a loop through the left and right portions of the  
2 network. STP will block one or the other. Should the spanning tree block at point #1, all 2000 users may  
3 communicate on any of the 50 VLANs. However, should the spanning tree block at point #2, the left and  
4 right portions of the network will be partitioned on all VLANs excepting VLAN 3 (the VLAN carried via  
5 the access style link.)

**Figure H-1—Static filtering inconsistency**

## 6 H.2.2 Consistent view of the “untagged VLAN(s)” on a given LAN

7 In the Port-based VLAN model defined in this standard, the PVID for a Bridge Port provides the VLAN  
8 classification for all frames on the attached LAN that are received in untagged form. Any LAN with more  
9 than one VLAN Bridge attached has such an “untagged VLAN” for each VLAN Bridge. No explicit  
10 requirement that PVID be consistent for all VLAN Bridges on the same LAN, nor mechanism to ensure  
11 such, has been included in this standard.

12 Similarly, in the Port-and-Protocol-based VLAN model defined in this standard, one member of the VID Set  
13 for a Bridge Port provides the VLAN classification for all frames on the attached LAN that are received in  
14 untagged form with a particular ULP. Any LAN with more than one such VLAN Bridge attached has such a  
15 set of “untagged VLANs” for each VLAN Bridge. No explicit requirement that these be consistent for all  
16 VLAN Bridges on the same LAN, nor mechanism to ensure such, has been included in this standard.

17 Consider the case of a LAN to which are attached three VLAN Bridges, each of which is using Port-based  
18 classification and is capable of transmission of untagged frames onto the LAN. An untagged frame placed  
19 on that LAN by any one of the VLAN Bridges will be associated by each of the other two VLAN Bridges  
20 with its own configured PVID for its reception Port on that LAN. The VLAN model requires that each frame  
21 have a unique VLAN association, and that association is represented by a single, global VID value.  
22 Therefore, it follows that all VLAN Bridges on that LAN must make use of the same classification rules (in  
23 this case, the same PVID) for their ports connected to that LAN.

24 It has been suggested that in the special case of a direct point-to-point connection between two VLAN  
25 Bridges or other VLAN-aware devices, other rules might apply. No mechanism for identifying such links  
26 has yet been suggested.

27 This creates a configuration challenge for installers of VLAN Bridges that conform to this standard. Initial  
28 management configuration of the VLAN Bridges (the setting of PVIDs, VID Sets, and Protocol Group  
29 Databases) must be made consistent among the VLAN Bridges, in a manner that takes into account the  
30 actual physical topology. Changes to the physical topology may require specific changes to the configuration  
31 of all affected switches. These requirements effectively disallow a plug-and-play installation as supported by  
32 MAC Bridges, unless all VLAN Bridges are left with their default Port-based classification rules and with  
33 each PVID = 1.

## 1 H.3 Heterogeneous networks: Intermixing MAC Bridges (M) and VLAN 2 Bridges (V)

3 This subclause discusses networks in which VLAN Bridges are intermixed with MAC Bridges.

4 A principal limitation in intermixing VLAN Bridges with MAC Bridges is that the VLAN filtering services  
5 are not universally available throughout the network. Also, services for the insertion and removal of tags are  
6 not universally available. Furthermore, spanning tree reconfigurations may cause filtering services, as well  
7 as tag insertion and removal services, to become available or become unavailable independent of actions of  
8 affected users.

### 9 H.3.1 Example: Adding a VLAN Bridge to provide filtering to a MAC Bridged 10 Network

11 Example problems can be shown with the following topology diagrams. Figure H-2 includes one V Bridge  
12 and two M Bridges.

**Figure H-2—Interoperability with MAC Bridges: example 1**

13 If the spanning tree protocol determines to break the loop among the three Bridges by blocking at point #1,  
14 connectivity within each VLAN is as desired. However, should the block occur at point #2, traffic from  
15 VLAN A users will pass through both M Bridges and be treated as VLAN B traffic upon arrival in the V  
16 Bridge. Connectivity to the A server will be lost for the A users.

### 1 H.3.2 Example: Adding a MAC Bridge to a (previously) Homogeneous VLAN 2 Bridged Network

3 A similar problem, demonstrating the impact of placing an M Bridge within an otherwise homogeneous V  
4 topology, can be shown by the configuration in Figure H-3. This figure includes two V Bridges and adds a  
5 single redundant M Bridge.

**Figure H-3—Interoperability with MAC Bridges: example 2**

6 If STP determines to break the loop among the three Bridges by blocking at point #1, connectivity within  
7 each VLAN is as desired. The two V switches operate as expected. A and B VLAN frames are  
8 VLAN-tagged on arrival in either V Bridge and forwarded only to the appropriate servers. Now suppose an  
9 STP reconfiguration results in a block at point #2, but not at #1. This redirects VLAN B user traffic through  
10 the M Bridge. VLAN B users no longer have their traffic identifiably distinct from VLAN A. An immediate  
11 consequence is that the VLAN B users will no longer have access to the “B server.”

### 12 H.4 Intermixing Port-based classification and Port-and-Protocol-based 13 classification or future enhancements in VLAN Bridges

14 Intermixing V Bridges with M Bridges has a direct analogue in the mixing of Bridges implementing only  
15 Port-based and Port-and-Protocol-based classification of frames in VLAN Bridged networks. This revision  
16 and potential subsequent editions of this standard extend the VLAN classification capabilities to support  
17 more sophisticated ingress rules for frame classification.

18 In VLAN configurations that use both Port-based and Port-and-Protocol-based VLAN classification, a  
19 Bridge that supports only Port-based VLAN classification will merge VLANs that would otherwise be  
20 classified separately by a Bridge that supports Port-and-Protocol-based VLAN classification. To get around  
21 this problem, it may be possible to dedicate specific Ports to specific protocols in Bridges that support only  
22 Port-based VLAN classification, as in the example shown in Figure H-4. However, such solutions may not  
23 be possible where there are multiprotocol end stations in the network.

## 1 H.4.1 Example: Intermixing Protocol-based ingress rules

2 Consider the case where Bridges implement a configuration mechanism to select between Port-based  
3 classification rules (a “V-Port Bridge”) and Port-and-Protocol-based rules (a “V-Port/Protocol Bridge”).  
4 This case would allow, for example, for support for IP and IPX as distinct VLANs. The topology shown in  
5 Figure H-4 might apply when a V-Port/Protocol Bridge is added to a topology; otherwise, using only V-Port  
6 Bridges allows users of two protocols to participate in two separate VLANs.

**Figure H-4—Interoperability between Port-based and Port-and-Protocol-based classification**

7 Consider this network, when STP has blocked at point #1, and not at #2. The upper V-Port Bridge operates  
8 as expected, and the V-Port/Protocol Bridge provides Port-and-Protocol-based classification for the frames  
9 received from the dual protocol users on the right-hand LAN. IP-VLAN and IPX-VLAN frames are  
10 VLAN-tagged on the trunks to and from the uppermost Bridges and servers. But if a STP reconfiguration  
11 should result in a block at point #2, but not at #1, activating traffic through the lower V-Port Bridge, dual  
12 protocol users will have all their traffic treated as part of the IP-VLAN. An immediate consequence is that  
13 the uppermost Bridge will no longer provide them access to the “IPX server.” It is the fact that the lower  
14 V-Port Bridge must have just one of the two VLANs configured for all untagged traffic, regardless of its  
15 protocol, that leads to this lack of connectivity.

## 16 H.4.2 Differing views of untagged traffic on a given LAN

17 Further challenges arise when one considers the case where several V Bridges, some implementing  
18 Port-based and some implementing Port-and-Protocol-based classification, all attach to the same LAN.  
19 Again, the rule that any given frame exists in exactly one VLAN requires that all of these Bridges be  
20 configured with consistent ingress rules. In this case, the V-Port Bridges will provide a least common  
21 capability, and this further requires common configuration of the PVID in the V-Port and V-Port/Protocol  
22 Bridges.

# **Annex I**

(informative)

## **Priority and drop precedence**

This standard allows management of priorities, flow metering, queue assignment, and queue servicing. This annex documents the rationale for the recommended and default priority to traffic class mappings in Table 8-5 and the encoding of priority and drop eligibility in Table 6-2 and Table 6-3.

Classification of user data frames into a small number of behavior aggregates, together with aggregate dependent forwarding behavior in each Bridge, allows signaling of application requirements to the network. Frame classification, aggregate bandwidth metering, policing, and drop precedence marking also facilitate network scaling and provision of services to independent customers through allocation of those functions to appropriate Bridges in the network.

While there are many possible ways to classify frames and to specify forwarding behaviors, it is widely appreciated that a set of well-known and easily understood defaults can facilitate interoperability and the deployment of services. The defaults described in this annex and supported by this standard were chosen to support integrated and differentiated services, to minimize the burden of management, to reduce the possibility of misconfiguration and out-of-order frame delivery, and to provide useful service without management in many networks.

This standard mandates support for strict priority frame transmission (8.6.6) but permits the use of additional traffic class-based transmission selection algorithms. The default assignments of frames to traffic classes on the basis of frame priority, as described in this annex, also support the use of frame priority to select general traffic class-based forwarding behavior.

NOTE—Annex X provides references to the IETF work on integrated and differentiated services ([B21] through [B25] and [B26] through [B33]).

### **I.1 Traffic types**

A full description of the QoS needs of applications and network services is too complex to be represented by a simple number 0 through 7. The pragmatic aim of traffic classification is to simplify requirements to preserve the high-speed, low-cost characteristics of Bridges. At the margin, potential bandwidth efficiency is traded for simplicity and higher speed operation—historically a good decision in the LAN.

The following list of traffic types, each of which can benefit from simple segregation from the others, are of general interest:

- a) Network Control—characterized by a guaranteed delivery requirement to support configuration and maintenance of the network infrastructure.
- b) Internetwork Control—in large networks comprising separate administrative domains there is typically a requirement to distinguish traffic supporting the network as a concatenation of those domains from the Network Control of the immediate domain.
- c) Voice—characterized by less than 10 ms delay and, hence, maximum jitter (one way transmission through the LAN infrastructure of a single campus).
- d) Video—characterized by less than 100 ms delay, or other applications with low latency as the primary QoS requirement.
- e) Critical Applications—characterized by having a guaranteed minimum bandwidth as their primary QoS requirement and subject to some form of admission control to ensure that one system or application does not consume bandwidth at the expense of others. The admission control mechanism

- 1 can range from preplanning of the network requirement at one extreme to bandwidth reservation per  
2 flow at the time the flow is started at the other.
- 3 f) Excellent Effort—or “CEO’s best effort,” the best-effort type services that an information services  
4 organization would deliver to its most important customers.
- 5 g) Best Effort—for default use by unprioritized applications with fairness only regulated by the effects  
6 of TCP’s dynamic windowing and retransmission strategy.
- 7 h) Background—bulk transfers and other activities that are permitted on the network but that should  
8 not impact the use of the network by other users and applications.

## 9 I.2 Managing latency and throughput

10 Use of priorities and queuing by traffic classes, each class encompassing one or more priorities, facilitates  
11 improvement and management of latency and throughput, allowing QoS goals to be supported at higher  
12 levels of network loading than would otherwise be possible.

13 Congestion, resulting in QoS degradation, is not equally likely at all Bridges in a network. Transient traffic  
14 patterns are likely to result in congestion in only a few Bridges at a time, while over an extended period,  
15 momentary congestion is more likely to occur in the network core than at Bridge Ports attached to one or a  
16 relatively small number of end stations. Use of fewer traffic classes for those Ports can lower the cost of  
17 implementation and management, and this standard facilitates the use of Bridges supporting differing  
18 numbers of classes within a single network that delivers a consistent set of QoS parameters for each frame  
19 priority level. Although the number of traffic classes supported by each Bridge Port along the path taken by  
20 a given flow of data can vary, the default mappings of priorities to classes ensures that frame ordering is  
21 preserved as required by 8.6.6.

22 With few classes, the focus is on meeting latency requirements—the bandwidth surplus required in a bursty  
23 data environment to guarantee sub-10 ms delays without a distinct traffic classification is uneconomically  
24 large. As the number of traffic classes that can be used increases, the focus shifts to managing throughput.

25 The simple default queue servicing policy defined in this standard, strict priority, supports latency  
26 management. Active management of bandwidth sharing necessarily requires some management.

## 27 I.3 Traffic type to traffic class mapping

28 Table I-1 is an example of how traffic types can be grouped to match the number of traffic class queues  
29 supported by a Bridge Port. Each grouping of types is shown as *{Distinguishing type, Type, Type, . . .}*. The  
30 “distinguishing type” is not treated in any way differently in a Bridge but is italicized here to illustrate, for  
31 any given number of queues, which traffic types have driven the allocation of types to classes.

32 The step-by-step breaking out of traffic types as more classes are available proceeds as follows:

- 33 a) With a single queue, there are no choices. All traffic is Best Effort.
- 34 b) To support integrated services in the presence of bursty best effort data, it is necessary to segregate  
35 all time-critical traffic. The amount of high-priority traffic will be restricted by the need to support  
36 low latency for Voice, which becomes the defining type for the additional queue.
- 37 c) Two queues may be adequate for Bridge Ports attaching to end stations. The stability of the network  
38 as a whole may be unaffected by the performance of configuration protocols on those Ports, and in-  
39 band management of the Bridge is likely to occur through another Port. For Bridges within the  
40 network infrastructure, a further queue is used to isolate Network Control from the user data traffic.
- 41 d) Traffic for business Critical Applications is separated from Best Effort to allow a bandwidth  
42 guarantee to be provided.

- 1 e) The queue separation so far provided can support a large network. The next queue is allocated to  
2 distinguishing Internetwork Control traffic from local Network Control.
- 3 f) Background is separated from Best Effort to minimize the effect of bulk transfers on ordinary  
4 network use.
- 5 g) Excellent Effort is separated from Critical Applications, either to provide a simple superior service  
6 based on policy controlled access or to provide an additional segregated bandwidth guarantee.
- 7 h) The final provides increased network utilization as the higher bandwidth traffic associated with  
8 Video is no longer given the same latency guarantee as Voice. This description is illustrative rather  
9 than definitive of the logic of allocating traffic types to classes. The mappings in Table 8-5 support  
10 the assignment of other semantics to each traffic type identified by priority values, e.g., the  
11 identification of all three illustrative types “Video,” “Critical Applications,” and “Excellent Effort”  
12 with ensured forwarding classes that provide segregated bandwidth guarantees. However, alternate  
13 semantics should take into account the service provided by Bridges with limited traffic class  
14 queuing; e.g., of the foregoing, only “Video” would receive priority treatment by default at a Bridge  
15 Port supporting queuing for only two classes.

**Table I-1—Traffic type to traffic class mapping**

| Number of queues | Traffic types                                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                | { <i>Best Effort</i> , Background, Excellent effort, Critical Applications, Voice, Video, Internetwork Control, Network Control}                                                                               |
| 2                | { <i>Best Effort</i> , Background, Excellent effort, Critical Applications}<br>{ <i>Voice</i> , Video, Internetwork Control, Network Control}                                                                  |
| 3                | { <i>Best Effort</i> , Background, Excellent effort, Critical Applications}<br>{ <i>Voice</i> , Video}<br>{ <i>Network Control</i> , Internetwork Control}                                                     |
| 4                | { <i>Best Effort</i> , Background}<br>{ <i>Critical Applications</i> , Excellent effort}<br>{ <i>Voice</i> , Video}<br>{ <i>Network Control</i> , Internetwork Control}                                        |
| 5                | { <i>Best Effort</i> , Background}<br>{ <i>Critical Applications</i> , Excellent effort}<br>{ <i>Voice</i> , Video}<br>{ <i>Internetwork Control</i> }<br>{ <i>Network Control</i> }                           |
| 6                | { <i>Background</i> }<br>{ <i>Best Effort</i> }<br>{ <i>Critical Applications</i> , Excellent effort}<br>{ <i>Voice</i> , Video}<br>{ <i>Internetwork Control</i> }<br>{ <i>Network Control</i> }              |
| 7                | { <i>Background</i> }<br>{ <i>Best Effort</i> }<br>{ <i>Excellent effort</i> }<br>{ <i>Critical Applications</i> }<br>{ <i>Voice</i> , Video}<br>{ <i>Internetwork Control</i> }<br>{ <i>Network Control</i> } |
| 8                | { <i>Background</i> } { <i>Best Effort</i> } { <i>Excellent effort</i> } { <i>Critical Applications</i> }<br>{ <i>Video</i> } { <i>Voice</i> } { <i>Internetwork Control</i> } { <i>Network Control</i> }      |

## 1.4 Traffic types and priority values

Table I-2 shows the correspondence between traffic types and priority values used to select the defaults in Table 8-5. The default priority used for transmission by end stations is 0. Changing this default would result in confusion and likely in interoperability problems. At the same time, the default traffic type is definitely Best Effort. 0 is thus used both for default priority and for Best Effort, and Background is associated with a priority value of 1. This means that the value 1 effectively communicates a lower priority than 0.

**Table I-2—Traffic type acronyms**

| Priority    | Acronym | Traffic type                         |
|-------------|---------|--------------------------------------|
| 1           | BK      | Background                           |
| 0 (Default) | BE      | Best Effort                          |
| 2           | EE      | Excellent Effort                     |
| 3           | CA      | Critical Applications                |
| 4           | VI      | “Video,” < 100 ms latency and jitter |
| 5           | VO      | “Voice,” < 10 ms latency and jitter  |
| 6           | IC      | Internetwork Control                 |
| 7           | NC      | Network Control                      |

Table I-3 summarizes Table I-1, showing just the defining traffic types. By maintaining the groupings of types established for a given number of queues for all less numbers, the table preserves the order of frames of any given type, independent of the number of queues.

**Table I-3—Defining traffic types**

| Number of queues | Defining traffic type |    |    |    |    |    |    |    |
|------------------|-----------------------|----|----|----|----|----|----|----|
| 1                | BE                    |    |    |    |    |    |    |    |
| 2                | VO                    |    |    |    | BE |    |    |    |
| 3                | NC                    |    | VO |    | BE |    |    |    |
| 4                | NC                    |    | VO |    | CA | BE |    |    |
| 5                | NC                    | IC | VO |    | CA | BE |    |    |
| 6                | NC                    | IC | VO |    | CA | BE | BK |    |
| 7                | NC                    | IC | VO |    | CA | EE | BE | BK |
| 8                | NC                    | IC | VO | VI | CA | EE | BE | BK |

This discussion of traffic types, and the suggested association of each with a priority value, differs from the similar discussion in Annex G of IEEE Std 802.1D-2004 [B14] and prior revisions of that standard. The latter was developed contemporaneously with IETF Intserv and predates Diffserv. The discussion in this

1 annex better aligns with current practice; in particular, Voice is associated with priority 5, matching the  
2 setting of the relevant bits for Expedited Forwarding (EF) in the DSCP (Differentiated Services Code Point)  
3 for IP and in the common use of the EXP bits for MPLS. Standards for DSCPs are believed to be the prime  
4 reference for use of priority by end stations, and there is no direct change to the behavior of Bridge  
5 implementations conforming to this standard as a result of this change.

6 The priority to traffic class mappings in Table 8-5 differ in one minor respect from those specified in prior  
7 revisions of this standard and in IEEE Std 802.1D-2004 [B14] and its prior revisions. Priority value 2 was  
8 previously described as ‘Spare’ and positioned lower than 0 (Best Effort) in priority order. This change may  
9 result in networks, including Bridges, conformant to prior revisions of this standard, and implementing four  
10 or more traffic classes, providing less-than-expected priority to traffic described in this annex as Excellent  
11 Effort, and misordering drop eligible traffic for Critical Applications. The change allows better use of the  
12 available traffic classes, given the low demand for two distinct priorities of lesser importance than Best  
13 Effort, and the best use of Priority Code Point when encoding drop eligibility.

## 14 I.5 Supporting the credit-based shaper algorithm

15 Table 34-1 and Table 34-2 define a set of recommended priority to traffic class mappings where the credit-  
16 based shaper algorithm (8.6.8.1) is supported by one or two of the available traffic classes; the recommended  
17 mappings shown are intended for use where priority 3 is used to support SR class A and priority 2 is used to  
18 support SR class B.

19 In order for the credit-based shaper algorithm to operate in the way it is intended, it is necessary to ensure  
20 that the shaper algorithm is supported on the numerically highest traffic class(es). Hence, if two traffic  
21 classes are used to support the shaper algorithm, it follows that the minimum useful number of traffic classes  
22 that a Port could support is three.

23 Table I-4 redraws Table I-3 for the case where only SR class B (SR-B) is supported. The defining traffic type  
24 for the numerically highest traffic class is SR-B in all cases. VI does not appear in this table since SR-B is  
25 used for the video traffic.

**Table I-4—Defining traffic types—Credit-based shaper support of SR class B only**

| Number of queues | Defining traffic type |    |    |    |    |    |    |    |
|------------------|-----------------------|----|----|----|----|----|----|----|
| 2                | SR-B                  | BE |    |    |    |    |    |    |
| 3                | SR-B                  | NC |    |    | BE |    |    |    |
| 4                | SR-B                  | NC |    |    | CA |    | BE |    |
| 5                | SR-B                  | NC | IC |    | CA |    | BE |    |
| 6                | SR-B                  | NC | IC |    | CA |    | BE | BK |
| 7                | SR-B                  | NC | IC |    | CA | EE | BE | BK |
| 8                | SR-B                  | NC | IC | VO | CA | EE | BE | BK |

26 NOTE—When one or more SR classes are supported, the primary distinction being made is between traffic that requires  
27 bandwidth reservation and latency guarantees on the one hand, and different types of “best effort” traffic on the other.  
28 The audio and video traffic types identified in Table I-1 are therefore not applicable.

Table I-5 redraws Table I-3 for the case where SR classes A (SR-A) and B (SR-B) are supported in place of VO and VI. The defining traffic types for the two numerically highest traffic classes are SR-A and SR-B in all cases; for 4 through 8 traffic classes, the remaining traffic types are broken out in the same order as in Table I-3.

**Table I-5—Defining traffic types—Credit-based shaper support of SR classes A and B**

| Number of queues | Defining traffic type |      |    |    |    |    |    |    |
|------------------|-----------------------|------|----|----|----|----|----|----|
| 3                | SR-A                  | SR-B | BE |    |    |    |    |    |
| 4                | SR-A                  | SR-B | NC |    | BE |    |    |    |
| 5                | SR-A                  | SR-B | NC |    | CA |    | BE |    |
| 6                | SR-A                  | SR-B | NC | IC | CA |    | BE |    |
| 7                | SR-A                  | SR-B | NC | IC | CA |    | BE | BK |
| 8                | SR-A                  | SR-B | NC | IC | CA | EE | BE | BK |

## 5 I.6 Supporting drop precedence

It is often desirable to meter traffic from different users to ensure fairness or to meet bandwidth guarantees; however, dropping all traffic in excess of a committed rate is likely to result in severe under-utilization of the networks, because most traffic sources are bursty in nature. At the same time, it is burdensome to meter traffic at all points in the network where bandwidth contention occurs. One solution is to mark those frames in excess of the committed rate as drop eligible on admission to the network.

This standard allows drop eligibility to be conveyed separately from priority in VLAN tags so that all previously introduced traffic types can be marked as drop eligible. To provide compatibility with previous revisions of this standard while allowing drop eligibility to be conveyed in C-TAGs, this standard also allows a subset of the priorities to be conveyed along with drop eligibility marking for some of those priorities within the PCP field of both S-TAGs and C-TAGs.

## 16 I.7 Priority Code Point allocation

The Priority Code Point of VLAN tags allows encoding of five, six, seven, or eight distinct priorities, with a single level of drop eligibility on three, two, one, or zero of those priorities, respectively. Table 6-2 and Table 6-3 specify encoding and decoding for five through eight priorities. The tables are consistent with the following step-by-step reduction in the number of distinct priorities to provide drop eligibility for certain traffic types:

- a) If eight distinct priorities are required, drop eligibility cannot be encoded in the Priority Code Point (but may be encoded in VLAN tags using the DEI).
- b) Drop eligibility in support of QoS maintenance for traffic conforming to a committed rate is most effective when used to support time-critical traffic. If seven priorities, one of which can be marked as drop eligible, are required, then the traffic class queuing distinction between Voice and Video is sacrificed to providing drop eligibility for the combined traffic types. This does not preclude marking all Video traffic as drop eligible upon ingress to a network to provide the same guarantee to Voice as a distinct priority.

- 1 c) The distinctions between Critical Applications and Excellent Effort, and between Best Effort and  
2 Background traffic types, is removed to provide drop eligibility for Critical Applications and for  
3 Best Effort.
- 4 d) Although the use of four priorities, each with drop eligibility, is possible, it is not recommended.  
5 Combining Network Control with Internetwork Control could only serve to increase the guarantees  
6 provided to the latter at the expense of the former, which if not delivered threatens the stability of the  
7 overall network in any case. Moreover, both traffic types should be supportable with guaranteed  
8 bandwidth if the network is to be operated successfully.

9 Choosing first to combine Video and Voice, and then Critical Applications with Excellent Effort (for six  
10 queues), provides consistency with the allocation of priorities to traffic classes in the absence of drop  
11 eligibility. Bridges that do not implement drop eligibility, but are configured to use the same number or  
12 fewer traffic classes, will not misorder frames. If such a Bridge is configured to use only five traffic classes,  
13 and in accordance with Table 8-5, it will not misorder frames with a Priority Code Point encoded using any  
14 of the alternatives provided by Table 6-2.

## 15 **1.8 Interoperability**

16 Encoding of drop eligibility within the Priority Code Point, as opposed to explicitly with the DEI, provides  
17 interoperability with Bridges that are not capable of supporting the DEI. It also provides compatibility with  
18 the use of the MPLS EXP bits to convey priority and drop eligibility.

19 However, the requirement to provide different combinations of priorities with drop eligibility within the  
20 confines of the Priority Code Point means that priority and drop eligibility information can be lost for frames  
21 traversing a network if the combinations used on individual LANs differ. Use of the DEI does not suffer  
22 from this problem. In some cases, loss of drop eligibility information at the boundary between  
23 administrative domains risks impacting profile conformant traffic from some users with out-of-profile drop  
24 eligible traffic from others; in other cases, the drop eligible marking has already done its job (the next LAN,  
25 for example, might deliver traffic to a single customer). Without explicit management, a Bridge Port cannot  
26 decide, so the Require Drop Encoding parameter (8.6.7) has been provided.

27 If Bridges attached to the same LAN encode and decode the Priority Code Point differently, then incorrect  
28 priority values can be attributed and subsequent misordering of frames can occur. Misordering will not  
29 occur, with the recommended priority to traffic class mappings of Table 8-5 and the recommended Priority  
30 Code Point encoding and decoding in Table 6-2 and Table 6-3, if the Bridge performing the incorrect  
31 decoding assumes fewer priorities than are actually encoded or if all Bridges subsequently transited by the  
32 frame use the same number or fewer traffic classes than those used for the encoding. However, incorrect  
33 decoding will in all probability affect other service guarantees that the network is intended to support. If a  
34 Bridge can be used in a network that encodes drop eligibility in the Priority Code Point, and there is any  
35 likelihood of the Bridge being brought into service prior to the network-dependent service-level  
36 configuration, then five priorities, three with drop eligibility (5P3D encoding and decoding), should be used.  
37 Bridges that do not support drop precedence should be configured to support five or fewer traffic classes in  
38 the same circumstances.

39 The use of separate Priority Code Point Encoding and Priority Code Point Decoding Tables for each Bridge  
40 Port allows adaptation between the encoding scheme in one domain of the network and the encoding scheme  
41 used in another to be accomplished in only one of any pair of Bridges, each serving as a boundary of its  
42 domain, connected by a point-to-point LAN. However, if more than two Bridges are attached to a LAN, all  
43 need to use the same encoding so that each of its recipients can assign the correct priority to the frame.

1 The default Priority Code Point encoding and decoding, as documented in Table 6-2 and Table 6-3, are  
2 reproduced in Table I-6 and Table I-7, with the addition of the default allocation of priorities to traffic  
3 classes to the latter.

4 NOTE—The sequence of the columns for the priority values of 0 and 1 in Table I-6 and Table I-7 are reversed from the  
5 sequence in Table 6-2 and Table 6-3 in order to show the alignment with the traffic classes in Table I-3.

**Table I-6—Priority Code Point encoding**

## 1 **Annex J**

### 2 (informative)

## 3 **CFM protocol design and use**

### 4 **J.1 Origin of CFM**

5 Operations, Administration, and Maintenance (OAM) functions are a product of the world of telephony. As  
6 Ethernet, which has traditionally been an Enterprise network technology, expands into the realm of service  
7 providers, such useful notions as OAM become important. The OAM work conducted in various standards  
8 bodies and in various vendors' products can be classified into five groups:

- 9 a) Provider Edge OAM, as defined by IEEE Std 802.3.
- 10 b) Ethernet Local Management Interface (E-LMI), as defined by MEF 16 [B54].
- 11 c) Underlying layers of OAM, such as MPLS OAM [B59] or ATM OAM [B2], used on various sorts of  
12 emulated Ethernet links, carrying Ethernet frames as a higher layer.
- 13 d) Ethernet frames carrying End-to-End CFM PDUs, defined by this standard and by  
14 ITU-T G.8013/Y.1731.
- 15 e) Network performance measurement, defined by the MEF Forum in MEF 35.1 [B56] and ITU-T,  
16 including ITU-T G.8013/Y.1731.

17 CFM is one part of the whole OAM picture. It defines group in item d), Ethernet frames carrying  
18 End-to-End CFM PDUs, defined by this standard and by ITU-T G.8013/Y.1731. This standard does not  
19 explicitly address the subject of the configuration or provisioning of MEF services, but it does generate  
20 significant requirements on configuration and provisioning. Certain CFM PDU formats are also useful for  
21 network performance measurement [item e)] and are defined in this standard. Additional PDUs for these  
22 operations are defined in ITU-T G.8013/Y.1731.

23 Finally, unlike OAM in the telephony world, CFM does not address recovery from a loss of connectivity.  
24 That is the function of the various Layer 2 control protocols such as spanning tree (see Clause 13).

### 25 **J.2 Deployment of CFM**

26 It is critical to the early deployment of CFM that no hardware changes be required to achieve a significant  
27 level of CFM functionality. However, if the MEPs in a large number of large MAs issue Continuity Check  
28 Messages (CCMs) at the highest allowed rates, a Provider Bridge's ability to generate and/or absorb these  
29 CCMs could be overwhelmed. To achieve its full potential, CFM could require hardware modifications to  
30 existing Provider Bridges.

- 31 a) The CFM shims shown in Figure 22-4 are an abstract concept. They have been defined so that it  
32 should be possible to emulate their functions on most existing platforms, though perhaps not at high  
33 rates of CFM PDU transmission and reception. Hardware assistance can enable higher CFM PDU  
34 rates and can enable the implementation of the Shared MP address model of operation instead of the  
35 Individual MP address model (J.6).
- 36 b) Directing CFM PDUs to the appropriate ports of a Provider Bridge could necessitate a separate  
37 MAC Address Registration Entry for each VID in the FDB. Some means whereby this large number  
38 of entries could be abstracted would reduce the load on the FDB and enable the use of a larger  
39 number of MD Levels.
- 40 c) The reception of an LBM and generation of the corresponding LBR have been defined in a manner  
41 that is amenable to implementation in hardware. If so implemented, then the providers' ability to  
42 support a particular requirement for bandwidth in a service instance can easily be tested.

### 1 J.3 MD Level allocation alternative

2 There are eight Maintenance Domain Levels (MD Levels) as shown in Table J-1. In order to allow  
3 administrations to configure different Maintenance Domains in the same Bridge without having to resort to  
4 detailed inter-organizational agreements about which MD Levels are available for use, an administrator of a  
5 Maintenance Domain can decide which of three roles that Maintenance Domain will play: the “customer”  
6 role, the “service provider” role, or the “operator” role. The administrator would then be free to assign an  
7 MD Level to a Maintenance Domain within the range shown in Table J-1 according to the Maintenance  
8 Domain’s role. If two administrations can operate Maintenance Domains using the same role in one Bridge  
9 at different MD Levels.

**Table J-1—Provider MD Level allocation**

| MD Level | 7        | 6                    | 5 | 4                | 3 | 2        | 1 | 0      |
|----------|----------|----------------------|---|------------------|---|----------|---|--------|
| Use      | customer |                      |   | service provider |   | operator |   |        |
|          | Highest  | <- Higher<br>lower-> |   |                  |   |          |   | Lowest |

10 This method of MD Level allocation attempts to minimize the likelihood of incompatibilities caused by MD  
11 Level selection among separate administrative organizations that interconnect in a manner such that their  
12 MD Levels are visible to each other. Due to the addition of encapsulations such as VLAN tags that can hide  
13 one organization’s MD Levels from another, it is considered unlikely that the allocation method shown in  
14 Table J-1 will be necessary and that the method described in 22.3 will be sufficient.

### 15 J.4 Relationship of IEEE Std 802.1Q CFM to other standards

16 ITU-T G.8013/Y.1731 is a compatible extension of CFM. Certain terminology is different between ITU-T  
17 G.8013/Y.1731 and this standard. These differences are summarized in Table J-2 .

**Table J-2—IEEE / ITU-T terminology differences**

| IEEE Std 802.1Q                           | ITU-T G.8013/Y.1731                         |
|-------------------------------------------|---------------------------------------------|
| Maintenance Association (MA)              | Maintenance Entity Group (MEG)              |
| Maintenance Association Identifier (MAID) | Maintenance Entity Group Identifier (MEGID) |
| Maintenance Domain                        | (No such construct present)                 |
| Maintenance Domain Level (MD Level)       | Maintenance Entity Group Level (MEG Level)  |

18 ITU-T G.8013/Y.1731 includes a number of OpCodes in addition to the CCM, LBM, LBR, LTM, and LTR  
19 defined in this standard. ITU-T G.8013/Y.1731 also specifies that the LBM can have a Group  
20 destination\_address, in addition to the ability of using an Individual destination\_address, as defined in this  
21 standard. It is for this reason that the MP Loopback Responder’s ProcessLBM() procedure (20.28.1) is  
22 required to respond to an LBM whose destination\_address is the appropriate CCM Group address, even  
23 though this standard specifies no means for generating such a frame.

1 The MIP is defined as two MHFs in this standard, but not in ITU-T G.8013/Y.1731. This is because  
2 ITU-T G.8013/Y.1731 is not concerned with the details of the implementation.

3 ITU-T G.8013/Y.1731 does not include an LTM Egress Identifier TLV (21.8.8) or LTR Egress Identifier  
4 TLV (21.9.7). For compatibility with early implementations of ITU-T G.8013/Y.1731, this standard does not  
5 require that these TLVs be present on received LTMs or LTRs. However, this standard does require these  
6 TLVs to be transmitted in LTMs and LTRs.

7 ITU-T G.8013/Y.1731 specifies that, if an LTM passes through MPs on both the ingress and egress ports, the  
8 TTL field of the LTM will be decremented twice. This standard requires, in that case, that the Bridge  
9 decrement the TTL field only once, and return a single LTR. The ITU-T G.8013/Y.1731 behavior is  
10 compatible with the LTR analysis presented in J.5, as long as each of the MPs that decrement the LTM's  
11 TTL field also return an LTR. If a Bridge decremented the TTL twice, but returned only a single LTR, it  
12 would be impossible for the originating MEP to tell whether an LTR was lost in transit.

13 The Flags field (21.9.1) returned in the LTR contains two extra bits of information in this standard that are  
14 not in ITU-T G.8013/Y.1731.

## 15 J.5 Interpreting Linktrace results

16 The LTR entries are retrieved from the Linktrace Database in the order the LTRs were received by the MEP.  
17 There is no way to determine when the last LTR has been received, except to wait for some number of  
18 seconds (e.g., long enough for a worst-case delay through the Bridged Network plus a few seconds), after  
19 the successful completion of the Transmit Linktrace Message command, before assuming that no further  
20 LTRs are likely to be received.

21 Because of the timer used by the LTR Transmitter state machine (20.5.1), the order in which the LTRs are  
22 received (time order) is likely to be different from the order of the MPs reached by the LTM as it was  
23 forwarded, MP by MP (path order). It is possible for an LTM to take more than one path, so that the LTRs  
24 report a tree, rooted at the originating MEP, rather than a simple linear series of zero or more MHFs  
25 terminating at a MEP or an MHF. If there are no network topology changes during the Linktrace operation,  
26 and if all systems' behavior conforms to this standard, the following can be said about constructing this path  
27 tree from the list of LTR entries returned by the Read Linktrace Reply command:

- 28 a) Sort the returned LTR entries by decreasing value of `ltrReplyTTL` (20.41.2.2). The highest reported  
29 value is one less than the initial LTM TTL field value [item d) in 12.14.7.4.2] used in the Transmit  
30 Linktrace Message command, and corresponds to the first Linktrace Responder reached by the  
31 initial LTM. This Linktrace Responder resides in the same Bridge as the MEP, in the case of an LTM  
32 originated by an Up MEP. The next-lower value corresponds to the MHF(s) or MEP(s) reached by  
33 the first forwarded copy of that LTM, and so on. Any gaps in the sequence of Reply TTL values  
34 indicate lost LTRs.
- 35 b) The `ltrNextEgressId` variable (20.41.2.4) in every LTR entry returned from a given Transmit  
36 Linktrace Message command is unique among the LTR entries in a given LTM entry in the Linktrace  
37 database, since no Linktrace Responder transmits more than one copy of an LTM.
- 38 c) The `ltrLastEgressId` variable (20.41.2.3) in any LTR entry is unique only over those LTR entries  
39 with matching values of the `ltrReplyTTL` variable.
- 40 d) The `ltrLastEgressId` variable (20.41.2.3) in any LTR entry whose `ltrReplyTTL` variable is one less  
41 than the initial LTM TTL field also matches the original LTM's LTM Egress Identifier TLV value, as  
42 returned from the Transmit Linktrace Message command [item c) in 12.14.7.4.3].
- 43 e) In the absence of lost LTRs, the `ltrLastEgressId` variable of any LTR whose `ltrReplyTTL` variable  
44 contains  $x$  will match the `ltrNextEgressId` variable of one of the LTRs whose `ltrReplyTTL` variable  
45 contains  $(x + 1)$ . For LTR entry  $x$ , this match indicates which of the Linktrace Responders  $(x + 1)$   
46 forwarded the LTM that was received by the Linktrace Responder that returned LTR entry  $x$ , and  
47 thus turns the list of LTR entries at each `ltrReplyTTL` value into a tree.

- 1 f) Along any given path from the root of the reply tree, the last reply can report any of the following  
2 conditions that terminate the forwarding of the LTM:
- 3 1) FwdYes bit of the ltrFlags variable is reset (false); or  
4 2) TerminalMEP of the ltrFlags variable is set (true); or  
5 3) ltrRelayAction variable contains the value, RlyHit; or  
6 4) ltrReplyTTL variable contains 0.
- 7 g) If any path does not terminate with one of the conditions 1) through 3) in the previous item f), then  
8 either the initial LTM TTL field was insufficiently large to trace the complete path (and the last  
9 ltrReplyTTL variable of the end MP in the path contains 0), or a data frame addressed to the target  
10 MAC address of the LTM would be flooded after being forwarded from the Bridge that returned the  
11 last LTR in the path.
- 12 h) If the first Bridge encountered by the original LTM (which is the Bridge on which the LTM was  
13 originated, if originated from an Up MEP) would have flooded a data frame addressed to the target  
14 MAC address of the LTM, no LTRs will be returned in response to the LTM.
- 15 i) A gap in the ltrReplyTTL value sequence indicates the loss of (or failure to transmit) one or more  
16 LTRs. Similarly, a gap in the chain of ltrNextEgressId and ltrLastEgressId variables can be caused  
17 by the loss of LTRs. These conditions can make the construction of a reply tree impossible, if  
18 multiple LTRs have been returned with the same ltrReplyTTL value. If the last LTR along the path is  
19 lost, there is no gap in the ltrReplyTTL sequence to indicate the loss.
- 20 j) The Transmit Linktrace Message command can be reissued, and the resultant LTRs correlated with  
21 the results of a previous LTM, to improve the reliability of the results.

22 Diagnosing whether an anomalous result from a Read Linktrace Reply command, i.e., one that violates any  
23 of the prior assertions, is the result of ordinary frame loss (caused, e.g., by congestion), transitory network  
24 behavior (e.g., the loss of a LAN during the Linktrace procedure), a permanent malfunction (e.g., a Bridge is  
25 behaving in a noncompliant manner due to a hardware or software malfunction), or some other reason, is  
26 beyond the scope of this standard.

## 27 J.6 MP addressing: Individual and Shared MP addresses

28 It is stated in 21.3.2 that the source MAC address for a frame carrying a CFM PDU is the MAC address of  
29 the MP transmitting the PDU. This does not necessarily mean that the MP's physical implementation is tied  
30 to a particular Bridge Port, and that the MAC addresses used in the frames carrying CFM PDUs are the  
31 MAC addresses of those Bridge Ports. While this method of MAC address assignment produces the best  
32 protection that this standard can provide for a network, it is not required that every MP use its Bridge Port's  
33 MAC address.

34 CFM does not require the MPs configured on a single Bridge Port, e.g., all of the MPs illustrated in  
35 Figure 22-4, to have MAC addresses that are different from each other, nor does CFM require that they be  
36 the same. If the MPs in Figure 22-4 all have the same MAC address, CFM frames can be directed to the  
37 different MPs on that Bridge Port based on VID and MD Level. Choices can be made, however, with regard  
38 to whether MPs on different Bridge Ports can share the same MAC address. Two models are presented in  
39 this subclause for the assignment of MAC addresses to MPs:

- 40 a) **Individual MP address model:** The individual MAC address assigned to an MP associated with a  
41 particular MA, and hence that MA's MD Level and set of VIDs, is unique over all service instances  
42 associated with that same set of VIDs, such that those service instances' CFM PDUs can be  
43 distinguished only by their MD Levels that can pass through that MP's Bridge Port.
- 44 b) **Shared MP address model:** The same as the Individual MP address model, except that Up MPs  
45 (but not Down) in the same MA and in the same Bridge can share a (i.e., can all have the same)  
46 MAC address.

1 Down MPs in different Bridge Ports have different MAC addresses. If two Bridge Ports are connected to the  
2 same LAN, but have the same MAC address, then both would respond to an LBM sent to that MAC  
3 address.<sup>78</sup> This is true, even though one of those two Bridge Ports would be Blocked (it would be either a  
4 Backup or an Alternate Port, see 13.12), because Down MEPs are between the LAN and the Port filtering  
5 entities (8.6.1, 8.6.2, 8.6.4) that enforce the blocking. This placement allows Down MEPs to test their  
6 service instances even when their Port is blocked, so that the system administrator knows that the failover  
7 links will be ready to carry data when a network event causes the Port to become Forwarding.

8 A Bridge can use the Shared MP address model, or the Individual MP address model, on any given Bridge  
9 Port. This is an implementation decision; no managed objects are provided to select one or the other model  
10 of operation.

11 A Bridge using either of these two models can also make use of a third scheme for configuring MPs:

12 c) **Management Port MEPs:** Up MEPs (not Up MHFs, not Down MPs) are configured on a  
13 Management Port, a Bridge Port that does not connect to any LAN exterior to the Bridge. (See 8.3  
14 and Figure 8-8.) Typically, this would be the same MAC address, and the same Bridge Port, that  
15 used for the Bridge's Management Port (see Figure 8-8).

16 The Individual MP address model is described in J.6.1, Shared MP address model in J.6.2, and Management  
17 Port MEPs in 22.7.

## 18 J.6.1 Individual MP address model

19 The purpose of CFM is to detect and diagnose connectivity errors. If a Bridge implements its Up MPs as  
20 close to the physical layer hardware as possible, it maximizes the capability of CFM to detect connectivity  
21 errors caused by malfunctions in that Bridge. In particular, giving each Up MP a MAC address that is tied to  
22 its particular Bridge Port means that an LBM/LBR exchange tests the Frame filtering entity (8.6.3) at both  
23 ends of the path. Figure 22-5 illustrates this fact. Any LBMs or LBRs passing between the Up MEPs and  
24 MHFs at the ends of the grayed service instance traverse exactly the same path through the Frame filtering  
25 entity as ordinary data frames carried from the left-most LAN to the right-most LAN.

## 26 J.6.2 Shared MP address model and the CFM Port

27 Although the Individual MP address model (J.6.1) gives the best detection and diagnostic capabilities, not  
28 all Bridge implementations are capable of inserting and removing CFM PDUs at points close to the physical  
29 layer. For example, the reflection of a high-speed LTM/LTR test stream by an Up MEP configured on a Port  
30 that is also receiving normal traffic from its LAN implies the presence of prioritization, data path, queuing,  
31 and bandwidth resources not otherwise required by this standard. This does not mean that Bridges lacking  
32 those resources cannot support CFM. The Shared MP address model provides one way for these Bridges to  
33 maximize their CFM capabilities.

34 Consider Figure 20-16, case c), but assume that the PDU entering Port 5, instead of being an LTM, is an  
35 LBM addressed to the Up MEP on Port 3. One cannot discern, from observing the external behavior of a  
36 Bridge, whether that LBM was actually delivered to the Up MEP on Port 3 or to some other entity within the  
37 Bridge. The Shared MP address model takes advantage of this fact by allowing Up MPs in different Bridge  
38 Ports to share the same MAC address. The Up MPs are still configured on different Bridge Ports according  
39 to the managed objects in Clause 12. For the most part, they have distinct identities. They share their MAC  
40 addresses and, as discussed more fully in 20.53, certain state machines and variables.

<sup>78</sup> Bridge implementations are known that use the same source MAC address for different Bridge Ports. As long as the Bridge Port or Management Port to which higher layer entities (e.g., an IP/TCP stack) are attached has its own unique MAC address, and as long as those Bridge Ports that share an address transmit only frames, such as BPDUs that do not traverse other Bridges, and as long as those Ports are not running any protocols that expect unicast frames to pass through a Bridge to reach them, Bridges of this description can interoperate each other and can interoperate with Bridges that follow the requirement to have a different MAC address for every Port. However, CFM PDUs do traverse other Bridges, and the LBM protocol does utilize individual MAC addresses. Therefore, the CFM protocols do not meet the goals of Clause 18 in all network topologies if Bridge Ports' Down MPs share MAC addresses.

1 In a Bridge configured according to the Shared MP address model, whether an LBM (or other PDU) that  
2 enters Port 5 in Figure 20-16 is addressed to the Up MEP on Port 3, or the Up MHF on Port 2, it is delivered  
3 to the same physical Bridge Port, called a “CFM Port.” This could be a normal Bridge Port, e.g., one with  
4 more capability than the Bridge Port on which the addressed MP is configured, or it could be a Port that is  
5 attached to no LAN, in the manner of a Management Port (8.3, 22.7). A Bridge can have more than one  
6 CFM Port, but within that Bridge, each CFM Port has a MAC address that is different from the other CFM  
7 Ports. In the limiting case, each CFM Port is also a Bridge Port, and is associated with only its own Up MPs;  
8 this is indistinguishable from the Individual MP address model. A CFM Port, for which the MPs of three  
9 different Bridge Ports are residing, is illustrated in Figure J-1.

**Figure J-1—Up MPs in a CFM Port**

10 NOTE 1—Unlike normal Bridge Ports or a Management Port, multiple levels of MHFs can be present on a CFM Port  
11 for the same service instance, because they belong to different MAs on different Bridge Ports.

12 MPs on this CFM Port are distinguished by VID and by MD Level. However, those criteria are insufficient  
13 when Up MPs configured on different Bridge Ports are in the same MA, and thus in the same VID and at the  
14 same MD Level. There is no way of distinguishing, in that case, to which of those Up MPs a given CFM  
15 PDU is addressed. For the PDUs defined in this standard, this is not a problem.

16 Each MEP, even when multiple MEPs reside on a single CFM Port, has its own MEP Continuity Check  
17 Initiator state machine (20.12) and associated variables. Each MEP is responsible for transmitting its own  
18 CCMs, carrying information (e.g., the optional Sender ID TLV, 21.5.3) peculiar to its configured Bridge  
19 Port.

20 On the other hand, otherwise indistinguishable MEPs sharing a MAC address share a single LTR  
21 Transmitter state machine (20.50) and a single MEP Loopback Initiator transmit state machine (20.32), and  
22 their associated variables. The managed objects in 12.14.7.1.3 support this sharing.

1 When any CFM PDU arrives at the CFM Port, it is copied and delivered to each of the MPs that share the  
2 same MA. Each of these MPs responds to the CFM PDU separately and responds as if it resided in its  
3 configured Bridge Port. Since a multicast would be delivered to all of the MPs anyway, there is no harm in  
4 placing all of them in a single CFM Port, with a single MAC address.

5 Unicast CCMs, LTMs, LBRs, and LTRs present no issues. CCMs require no response. The LTMs all go to  
6 the Bridge's single Linktrace Responder. Even when an LTM is multicast, only one LTR and/or forward  
7 LTM is produced, so delivering a unicast LTM to multiple MPs causes no additional problems. Since the  
8 MEPs sharing a single CFM Port also share a single MEP Loopback Initiator transmit state machine (20.32)  
9 and a single MEP Loopback Initiator receive state machine (20.34), and since they all share a single set of  
10 variables, particularly those related to the LTM Transaction Identifier fields in these PDUs, there is no  
11 confusion about which MEP the LBR or LTR is directed.

12 The remaining PDU type is the LBM. Consider what would happen if the MEPs and their associated MP  
13 Loopback Responders (19.2.10) resided on separate Bridge Ports, but all shared the same MAC address.  
14 Assuming that the Frame filtering entity had learned that MAC address, the LBM would be forwarded to  
15 exactly one of those MEPs, namely the one that, by chance, last happened to transmit a frame, thus causing  
16 the Learning Process (8.7) to associate the shared MAC address with that transmitter's Bridge Port. Thus,  
17 exactly one LBR would be returned, not one per Bridge Port. The MEP receiving that LBR would not know  
18 from which MP the LBR was returned, because there is nothing in the LBR to indicate the identity of the  
19 responding MP. Therefore, only one response to a unicast LBM is returned from a CFM Port, no matter how  
20 many MPs on that LBM's MA reside on the CFM Port.

21 On the other hand, a multicast LBM could cause any number of Up MPs configured in the same MA, but on  
22 different Bridge Ports in a single Bridge, to respond. Thus, a high-speed stream of multicast LBMs could  
23 impose an arbitrarily large burden upon a single CFM Port that is supporting a large number of Bridge Ports'  
24 MPs, if each MP responded to that LBM. Therefore, among a set of MPs for a single MA that all share the  
25 same MAC address (i.e., reside on the same CFM Port), one or more, but not all, of their MP Loopback  
26 Responders (19.2.10) can be disabled by not configuring any group MAC address for them to recognize.  
27 This configuration is accomplished automatically by a Bridge that utilizes CFM Ports and is not controlled  
28 by any managed object.

29 The externally visible behaviors that can be discerned from outside a Bridge that uses the Shared MP  
30 address model are as follows:

- 31 a) An external MEP can regularly receive CFM PDUs other than LTRs, from two different MPs in the  
32 same MA that have the same source\_address.
- 33 b) A multicast LBM can regularly receive only one reply from among a set of MPs that normally all  
34 respond to unicast LBMs, but all with the same source\_address, without implying the presence of an  
35 intermittent network failure.
- 36 c) A system administrator can see unexpected advances in a MEP's managed objects that count LBMs  
37 and LBRs, apparently due to activity on another MEP.
- 38 d) If conceptual rows in the Interface MIB module of IETF RFC 2863 are instantiated for individual  
39 MPs, the packet and frame counts of those interfaces count both CFM PDUs and ordinary data  
40 frames passing through the Active and Passive SAPs, and thus can indicate whether an MP is  
41 instantiated on the Bridge Port on which it is configured, or on a separate CFM Port through which  
42 no ordinary data frames pass.

43 NOTE 2—None of these behaviors is impossible for a Bridge using the Individual MP address model; MAC addresses  
44 can change faster than CCMs time out, momentary congestion can cause frame loss, multiple administrators can access  
45 different MEPs' managed objects, and ordinary data frames can be absent. It is only the frequency of these behaviors  
46 that distinguishes the Individual MP address model from the Shared MP address model.

## Annex K

(informative)

### TPMR use cases

This material is intended to assist the reader of this standard in putting the operation of a TPMR in context with the operation of Bridged Networks as a whole, by illustrating some of the uses of a TPMR in conjunction with other types of Bridge. The set of cases is not, and is not intended to be, exhaustive in terms of all of the possible usage scenarios.

#### K.1 Use case 1—TPMR as User to Network Interface (UNI) demarcation device

Figure K-1 illustrates a use case where the TPMR performs the function of a UNI demarcation device between an customer network and a provider network. In this illustration, the user link between the customer Bridge and the TPMR, and the extension link between the TPMR and the provider Bridge, are both assumed to be IEEE 802.3 links, although, with the exception of the use of IEEE 802.3 EFM OAM on the extension link, these links could in principle be provided by use of any IEEE 802 LAN technology.

**Figure K-1—TPMR as UNI demarcation device**

The use of EFM OAM on the extension link allows the service provider to:

- a) Put the TPMR into an intrusive loopback for out-of-service testing.
- b) Query the IEEE 802.3 MIB in the TPMR.
- c) Be notified of critical events (Link Fault, Dying Gasp, Critical Event).
- d) Be notified of link performance events (Errored Symbol Period event, Errored Frame event, Errored Frame Period event, Errored Frame Seconds Summary event).

The potential exists with EFM OAM (on the extension link) to make use of extensions, via organization-specific OAMPDUs, to manage the Port of the TPMR that faces the user link.

Alternatively, the TPMR might be managed using SNMP over UDP/IP either in-band on the IEEE 802.3 extension link or out-of-band through separate management connector on the TPMR.

## 1 K.2 Use case 2—TPMRs with aggregated links

2 Figure K-2 illustrates a use case where two TPMRs are used within paired extension/user links that are  
3 aggregated at their endpoints (the Bridges). The TPMRs are transparent to the operation of the IEEE  
4 802.1AX Link Aggregation Control Protocol (LACP), because the Provider Bridge and Customer Bridge  
5 are configured to use the “Nearest non-TPMR Bridge group address” as the destination address for LACP;  
6 from the point of view of Link Aggregation, each paired extension link and user link, with the TPMR joining  
7 them together, appears to be a single IEEE 802.3 LAN.

**Figure K-2—TPMRs with aggregated links**

8 The TPMRs would be managed separately, via EFM OAM, as in use case 1 (K.1). It should be noted that the  
9 use of SNMP to manage the TPMRs in this scenario is problematic, as the aggregated link appears to the  
10 higher layers to be a single link, but individual conversations are allocated by the frame distributor in the  
11 aggregator to the links in the aggregation in a nondeterministic manner.

## 12 K.3 Use case 3—Multiple TPMRs

13 Figure K-3 shows a variant of use case 1 (K.1) where two extension links and a user link are used,  
14 interconnected using two TPMRs.

**Figure K-3—Multiple TPMRs**

15 Some commercial TPMRs used as demarcation devices power up in EFM OAM Passive mode, waiting to  
16 hear from the Active mode master device at the edge of the provider network. A passive-to-passive EFM  
17 OAM session, as would occur on extension link B, would never activate, making it impossible to manage  
18 the customer-facing TPMR by this means, unless significant changes were made to the capabilities of EFM  
19 OAM to allow some kind of relay capability. On the other hand, by using SNMP as the management  
20 protocol, this problem would be avoided.

## K.4 Special cases

Figure K-4 (new connectivity) and Figure K-6 (connectivity failure) represent the target cases for the MAC status propagation design.

Figure K-4 shows recovery of the individual LAN at one end of a TPMR chain. The result is to “blip” the MAC\_Operational status at the other end of the chain, delaying availability of the recovered link by slightly more than  $T_w + T_d$ . The figure also shows a possible effect of timing relationships between  $T_r$  and  $T_d$ , as the initiator of the change retries its Add message transmission just as the TPMR at the other end of the chain returns a confirm. The crossing of messages shown is unlikely, as the time sequence diagrams overemphasize the delay experienced by the Add and Confirm messages, but the effect is benign in any case.

**Figure K-4—Recovery at the end of a chain**

If the LAN between the end system and the first TPMR in the chain (TPMR 1) had failed instead of recovering, the rest of Figure K-4 would have looked the same, with the exception of the final state of that first LAN. The net effect of the status notification protocol is to transfer the change in MAC\_Operational to the other end of the chain so that both ends see the transition. For best effects the transfer should complete in a short enough time so that the end system protocols at the initiating end of the link are still executing their initial state.

Figure K-5 shows what happens if both ends of the link come up at the same time, the net effect is simply to delay the simultaneous start.

Figure K-6 shows simultaneous transitions of one LAN in the chain to OperUp and the other to OperDown, and illustrates a number of points about how the protocol or protocols do or should operate.

First, signaling of addition or loss can be somewhat arbitrary and depend on the relative timing of transitions on separate individual LANs. The same final connectivity can be represented by a loss followed by an

Figure K-5—Near simultaneous recoveries

Figure K-6—Near simultaneous failure and recovery

1 addition, or an addition followed by a loss. If the implied resulting state is to mean anything then the  
2 information “connected as far as,” or “connected to and beyond” also needs to be communicated. However,  
3 while this is a candidate for inclusion in any new protocol, support by existing protocols is unlikely.  
4 However, this clause persists with distinguishing Add and Loss messages, and their confirmations, because  
5 that ensures that closely spaced transitions, which might otherwise disguise unusual loss of higher layer

1 protocol messages, are not missed by the systems connected to the TPMR chain. Figure K-7 shows a loss  
2 followed by recovery of the same LAN.

**Figure K-7—Loss with quick recovery**

3 Second, no message is sent across the LAN between TPMRs 1 and 2 when the MAC is OperDown from the  
4 protocol client's point of view. That allows support of the protocol to be architected such that a message that  
5 signals “add(ition)” or “loss” is forwarded through the normal bridged path so its speed of propagation does  
6 not depend on scheduling or notifying a status propagation process in each TPMR. Also, users have a free  
7 choice about what additional functionality can reside between the entities responsible for status propagation  
8 and the “real” MAC.

9 One last common case of simultaneous transitions is what happens when the two ports of a TPMR power up  
10 or are enabled at the same time. Each tries to send a link notification through the other, and each link  
11 notification is discarded as the Port is not yet available (mssOperUp FALSE). The result is to “blip” each  
12 LAN. The ends of the TPMR chain see an Add Loss Add sequence, if they are protocol capable, and a blip  
13 in MAC\_Operational otherwise. If  $T_w$  is less than  $T_d$ , this will be a single blip.

## 1 Annex L

### 2 (informative)

## 3 Operation of the credit-based shaper algorithm

4 This annex contains a more detailed analysis of the way the credit-based shaper algorithm (8.6.8.2) operates,  
5 and how its operation affects the performance of the network, from the point of view of traffic that uses a  
6 credit-based shaped queue, and also from the point of view of other queues associated with the Port. The  
7 analysis and description in this annex does not take into account any interruption to bandwidth availability  
8 resulting from the operation of stream gates.

### 9 L.1 Overview of credit-based shaper operation

10 The credit-based shaper algorithm has a single externally determined parameter, *idleSlope* (see 8.6.8.2), that  
11 determines the maximum fraction of the *portTransmitRate* that is available to the queue associated with a  
12 traffic class (*bandwidthFraction*), as follows in Equation (L-1):

$$13 \quad \text{bandwidthFraction} = \text{idleSlope} / \text{portTransmitRate} \quad (\text{L-1})$$

14 where *portTransmitRate* is the maximum transmit data rate that the port supporting the outbound queue is  
15 able to deliver. The detailed derivation of Equation (L-1) can be seen in Equation (L-5) through  
16 Equation (L-8).

17 If a traffic class supported by the credit-based shaper algorithm uses less than the bandwidth allocated to it,  
18 then the unused bandwidth can be used by other traffic classes, in accordance with the relative priorities of  
19 the traffic classes and the transmission selection algorithms that are associated with them.

20 NOTE 1—It is a natural consequence of the way transmission selection operates that if a given traffic class does not  
21 have a frame available for transmission, then a lower priority traffic class that does have a frame available for  
22 transmission is able to transmit. Hence, if a given traffic class that uses the credit-based shaper algorithm has been  
23 allocated X% of the available bandwidth on a Port, but only uses (X-Y)%, then the unused portion of its allocation (Y%)  
24 is available for other traffic classes to use if they are in a position to do so. Whether this unused bandwidth can be used  
25 use by a traffic class depends upon the transmission selection algorithm that is associated with it. For example, a traffic  
26 class that has been allocated a specific bandwidth, such as one that uses the credit-based shaper algorithm, would be  
27 unable to use any bandwidth allocation not used by a higher priority traffic class, as that would result in it exceeding its  
28 bandwidth allocation; however, a traffic class that uses the strict priority algorithm, which is not associated with a  
29 bandwidth allocation, would be able to use bandwidth allocated to, but not used by, a higher priority traffic class.

30 The *idleSlope* parameter, in conjunction with the size of the frames that are being transmitted using the  
31 queue, and the maximum time delay that a queue can experience before it is able to transmit a queued frame,  
32 places an upper bound on the burst size that can be transmitted from queues that use the algorithm.

33 In order to describe the operation of the algorithm, it is useful to define the following values, in addition to  
34 the formal parameters of the algorithm described in 8.6.8.2:

- 35 a) **maxFrameSize.** The maximum sized frame that can be transmitted through the Port for the traffic  
36 class concerned. This value can be determined by admission control algorithms, or can be simply a  
37 function of the transmission behavior of the traffic source. Either way, the value can be smaller than  
38 would be allowed by the normal operation of the underlying MAC Service.
- 39 b) **hiCredit.** The maximum value that can be accumulated in the *credit* parameter. This parameter is a  
40 function of the operation of the algorithm, and cannot be controlled by management.

c) **loCredit**. The minimum value that can be accumulated in the *credit* parameter. The value of *loCredit* is a function of the values of *maxFrameSize*, *portTransmitRate*, and *sendSlope*, as follows in Equation (L-2).

$$loCredit = maxFrameSize \times (sendSlope/portTransmitRate) \quad (L-2)$$

d) **maxInterferenceSize**. The maximum size, in bits, of any burst of traffic that can delay the transmission of a frame that is available for transmission for this traffic class. For the numerically highest traffic class, *maxInterferenceSize* is exactly equal to the maximum sized frame that can be transmitted through the Port (the maximum frame size supported by the underlying MAC). For all other traffic classes, the derivation of *maxInterferenceSize* becomes more complex, owing to the possibility that any higher traffic classes that support the credit-based shaper algorithm can delay the transmission of a frame. *maxInterferenceSize* must also account for any media access delay, such as the recovery time in Energy Efficient Ethernet. A detailed analysis can be found in L.3.1.1.

NOTE 2—The definition of *maxInterferenceSize* assumes that any traffic classes that support the shaper algorithm are numerically higher than any traffic classes that support the default strict priority algorithm (8.6.8.1). If this is not true, then the value of *maxInterferenceSize* is infinite, and the operation of the credit-based shaper algorithm cannot provide the bandwidth that has been reserved for it. A detailed analysis of how *maxInterferenceSize* can be determined for a given traffic class is contained in L.3.

The value of *hiCredit* is determined by the worst-case interfering traffic, as follows in Equation (L-3).

$$hiCredit = maxInterferenceSize \times (idleSlope/portTransmitRate) \quad (L-3)$$

The value of *hiCredit* can therefore be considered as a “high water mark”; the operation of the algorithm is such that the value of the *credit* parameter will never exceed *hiCredit*.

The choice of value for *idleSlope*, and the calculated value of *hiCredit*, can be used to determine the maximum burst size that can be output from the queue, as follows in Equation (L-4).

$$maxBurstSize = (portTransmitRate \times ((hiCredit - loCredit)/(-sendSlope))) \quad (L-4)$$

NOTE 3—There is an interrelationship between the maximum burst size and the buffer size available to the traffic class. There is no point in accumulating more credit than the traffic class can handle in queued frames, as the limiting factor is the discarding of frames when the queue overflows. This means that the amount of bandwidth that can be reserved on a given Port for a given traffic class depends upon the amount of buffering available to that traffic class. This in turn, combined with the port’s transmission rate, will determine the maximum value of idle slope that can be supported for that traffic class on that Port.

The operation of the credit-based shaper algorithm is illustrated in the examples shown in Figure L-1 through Figure L-3. In Figure L-1, a frame is queued at a time when the *credit* value is zero, and there is no conflicting traffic (there is no higher priority traffic awaiting transmission, and there is no frame being transmitted on the Port). The frame is immediately selected for transmission, and *credit* decreases at the rate of *sendSlope* as the transmission proceeds. Once the frame transmission is complete, *credit* increases back to zero at the rate of *idleSlope*, at which point, a further frame can be selected for transmission.

If a continuous stream of frames is made available to the shaper algorithm, i.e., there is always one frame queued awaiting transmission when the *credit* value reaches zero, then the fraction of the *portTransmitRate* that is available to the queue (*bandwidthFraction*) is equal to the fraction of time that frames are being transmitted from the queue. Assuming that *credit* decreases to value *loCredit* at the end of each frame transmission, then the following shows the detailed derivation of Equation (L-1):

$$bandwidthFraction = (-loCredit/sendSlope)/[(-loCredit/sendSlope) + (loCredit/idleSlope)] \quad (L-5)$$

$$= (-1/sendSlope)/[(1/idleSlope) - (1/sendSlope)] \quad (L-6)$$

$$= (-idleSlope)/(sendSlope - idleSlope) \quad (L-7)$$

$$= idleSlope/portTransmitRate \quad (L-8)$$

This fraction of the bandwidth is available to the stream even in the presence of conflicting traffic, as illustrated in the following examples.

**Figure L-1—Credit-based shaper operation—no conflicting traffic**

1 In Figure L-2, a frame is queued at a time when the Port is transmitting conflicting traffic. The value of  
2 *credit* increases at the rate of *idleSlope* while the queued frame waits for the Port to become available.  
3 Transmission of the conflicting traffic completes before the value of *credit* is limited by *hiCredit*, and  
4 transmission of the queued frame starts. The value of *credit* starts to decrease at the rate of *sendSlope*;  
5 however, as the frame is not large enough to consume all of the available *credit*, and there are no further  
6 frames queued, *credit* is reduced to zero on completion of the transmission.

Figure L-2—Credit-based shaper operation—conflicting traffic

1 In Figure L-3, three frames are queued while the Port is transmitting conflicting traffic, and *credit*  
2 accumulates at the rate of *idleSlope*. Once the conflicting traffic has been transmitted, the first and second  
3 frames are transmitted back-to-back, because transmitting the first frame leaves  $credit \geq 0$ . However, as  
4 transmitting the second frame causes credit to become negative, transmission of the third frame is delayed  
5 until *credit* returns to zero.

Figure L-3—Credit-based shaper operation—burst traffic

## 1 L.2 “Class measurement intervals” in Bridges

2 The “class measurement interval” defines acceptable Talker behavior with respect to per-stream  
3 transmission (see 34.6.1.1); however, it does not directly impact the operation of the credit-based shaper  
4 algorithm in Bridges.

5 The maximum fraction of the available bandwidth that a queue operating the credit-based shaper algorithm  
6 consumes is determined by *idleSlope*, as discussed in L.1; if *idleSlope* is 75% of the link transmission rate,  
7 then the algorithm gets a maximum of 75% of the link, averaged over some time period (the class  
8 measurement interval) at the Talker. For a Bridge, where transmission becomes bursty due to interfering  
9 transmission from other traffic classes, the minimum measurement interval that is meaningful (i.e., the  
10 minimum period over which it is still possible to observe that the 75% maximum bandwidth is not exceeded)  
11 is the time taken for the traffic class concerned to transmit a maximum sized burst, multiplied by 100/75. In  
12 the case of the 125 μs class measurement interval for SR class A traffic, on 100 Mb/s Ethernet, and with  
13 75% reservation, the approximate calculation is (ignoring interframe gaps)

- 14 a) The maximum interference size (*maxInterferenceSize*) is one maximum sized Ethernet frame, which  
15 is 2000 octets, or 16 000 bits, so *hiCredit* would be 75% of that, or 12 000 bits.

16 NOTE 1—Media access delays, such as those imposed by Energy Efficient Ethernet, could be more significant than the  
17 interference created by a maximum sized frame.

18 NOTE 2—The figure of 2000 octets is a maximum for Ethernet and therefore a worst case for an interfering frame; in a  
19 specific implementation, the maximum frame size that is used could be smaller. In implementations where the maximum  
20 frame size is known to be less than 2000, the smaller value could be used.

- 21 b) The maximum frame size for this traffic class is 75% of the number of bits that can be transmitted in  
22 125 μs, so 75% of 12 500 bits in the case of a 100 Mb/s LAN, or 9375 bits (including up to 500 or so  
23 possible “overhead” octets—used for, e.g., Tag headers, physical layer overhead). As this is not an  
24 integral number of octets, this figure is rounded down to 9368. *loCredit* is 25% of that, or –2342.
- 25 c) The maximum burst size, for frames no greater than 9368 bits long, would occur if *credit* reached  
26 12 000, then a series of frames were transmitted that exactly took credit to 0, followed by a final  
27 9368 bit frame that would take credit down to –2342. This maximum burst is therefore calculated as  
28  $(12\,000 + 2342) \cdot (\text{portTransmitRate}/(-\text{sendSlope}))$  or 57 368 bits.
- 29 d) The minimum measurement interval over which one can expect to be able to measure the bandwidth  
30 utilization for SR class A, and observe that it does not exceed its 75% allocation, is therefore  
31 57 368 bit times multiplied by 100/75, which is 76 491 bit times, rounded up to the nearest integer,  
32 or 764.91 μs.

33 NOTE 3—The maximum sized burst will be preceded by a *maxInterferenceSize* event, and at the end of the burst, *credit*  
34 will have been reduced to –2342; it will therefore take  $2342/\text{idleSlope}$  seconds, or nearly 3123 bit times, for *credit* to  
35 return to zero, and for SR Class A to be allowed to transmit again. In addition, the actual utilization for SR Class A is  
36  $57368/(57368+16000+(2342/0.75)) = 75\%$ .

37 For the SR class B traffic, all that really changes is the potential size of any interference, which increases  
38 from the SR class A *maxInterferenceSize* to the maximum burst size for SR class A plus the class A  
39 *maxInterferenceSize*.

40 So, the smallest possible measurement interval over which the ratio  $\text{idleSlope}/\text{portTransmitRate}$  will be seen  
41 to hold good is dependent on the maximum interference size for the SR class, the maximum frame size for  
42 the SR class, and the value of *idleSlope*.

## 1 L.3 Determining worst-case latency contribution and buffering requirements

2 From the point of view of the operation of AV Bridges, it is important to be able to assess the contribution  
3 that each Bridge makes to the worst-case latency that stream data frames can be subject to during their  
4 transmission along the path from Talker to Listener. Closely related to the latency contribution that a Bridge  
5 makes is the buffering requirement that is required in the Bridge in order for the delay not to result in frame  
6 discard; if a Bridge can potentially delay a frame of a given SR class for a given period of time, then it must  
7 be capable of buffering the worst-case number of frames of that same SR class that could be received for  
8 onward transmission on each Port. The following discussion looks at the factors that contribute to the delay  
9 that could be experienced by a frame as it passes through a Bridge, and how the delay can be accurately  
10 determined.

11 NOTE 1—This discussion is also useful to guide designers of Talker stations in determining the delay added by the  
12 Talker's network interface.

13 The worst-case latency for a single hop from Bridge to Bridge, measured from arrival of the last bit at Port  $n$   
14 of Bridge A to the arrival of the last bit at Port  $m$  of Bridge B, can be broken out into the following  
15 components:

- 16 a) Input queuing delay. (There are no input queues in the IEEE 802.1 architecture, but if present, the  
17 implementation must account for them.)
- 18 b) Interference delay (L.3.1).
- 19 c) Frame transmission delay. (The time taken to transmit one maximum frame at *portTransmitRate*.)
- 20 d) LAN propagation delay. (A variable delay that depends on the length of the LAN connection to the  
21 next Bridge; this is measurable using the mechanisms defined in IEEE Std 802.1AS.)
- 22 e) Store-and-forward delay. This includes all other elements of forwarding delay that are a  
23 consequence of the internal processing of the Bridge, assuming that the input and output queues are  
24 empty, such as:
  - 25 1) The time needed to pass a frame from the input port to the output port, assuming empty queues.
  - 26 2) The time delay between a frame being available for transmission on a Port and the Port being  
27 ready to transmit the frame.

28 NOTE 2—For example, in the case where the MAC/PHY has entered a power saving mode, there may be a delay  
29 incurred in switching the Port back to normal operation.

- 30 3) The difference, if any, in the delay incurred by a frame that bypasses an empty queue, vs. that  
31 incurred by a frame that must be enqueued.
- 32 4) The time added (subtracted) by the lengthening (shortening) of the frame due to addition  
33 (removal) of frame headers such as Q-tags or MACSec-tags.
- 34 5) The time needed to encrypt a MACSec frame.

35 In the remainder of this clause, the following abbreviations are used:

- |    |                 |                                                                                                                                                                      |
|----|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 36 | $M_0$           | Maximum sized frame for non-SR classes                                                                                                                               |
| 37 | $M_x$           | Maximum sized frame for SR class $x$                                                                                                                                 |
| 38 | $R_0$           | <i>portTransmitRate</i>                                                                                                                                              |
| 39 | $R_x$           | <i>idleSlope</i> for SR class $x$                                                                                                                                    |
| 40 | $T_{xy}$        | Time interval between events $x$ and $y$                                                                                                                             |
| 41 | $W_x$           | <i>-sendSlope<sub>x</sub></i>                                                                                                                                        |
| 42 | $variable_{<x}$ | The sum of the values of the named <i>variable</i> for all SR classes with a higher priority<br>43 (and therefore earlier letter in the collating sequence) than $x$ |

### 1 L.3.1 Interference delay

2 The interference delay for frame X can be broken out into the following components:

- 3 a) **Queuing delay:** The delay caused by the frame that was selected for transmission an arbitrarily  
4 small time before frame X became eligible for transmission selection, plus the delay caused by  
5 queued-up frames from all stream frames with higher priority than frame X's class (i.e., the  
6 "*maxBurstSize*" for SR Classes with higher priority than X—see L.1). This is what is referred to as  
7 *maxInterferenceSize* in L.1. Queuing delay is analyzed in detail in L.3.1.1.
- 8 b) **Fan-in delay:** The delay caused by other frames in the same class as frame X that arrive at  
9 more-or-less the same time from different input Ports. Fan-in delay is analyzed in detail in L.3.1.2.
- 10 c) **Permanent delay:** The delay caused by frames that reside in a buffer for a long time, relative to the  
11 output queuing delay, because of the history of activity in the network. Permanent delay is analyzed  
12 in detail in L.3.1.3.

#### 13 L.3.1.1 Queuing delay

14 The queuing delay for frame X can be broken out into the following components:

- 15 a) The delay, *maxInterferenceTime*, before a frame X queued for an SR class, and that is eligible for  
16 transmission, can actually be transmitted. This delay is experienced when a frame, of any priority, is  
17 selected for transmission an arbitrarily small time before frame X became eligible for transmission;  
18 it is also experienced in LAN media, such as Ethernet, where there can be a low energy consumption  
19 mode that is entered under idle conditions, and where there is a significant delay,  
20 *mediumAccessDelay*, before the LAN returns to normal operation and is able to transmit. The value  
21 of *maxInterferenceTime* is therefore equal to whichever is the greater of the following:
  - 22 1) The time taken to transmit the maximum frame size supported by the medium, i.e.,  
23  $\text{maxFrameSize}_{(m)} / \text{portTransmitRate}$ .
  - 24 2) The *mediumAccessDelay* for the medium.
- 25 b) The delay caused by any queued-up frames associated with the next higher priority SR class than  
26 frame X's SR class (i.e., *maxBurstSize* for the next higher priority SR class), if frame X does not  
27 belong to the highest SR class.

28 For SR class A, only the first of these components applies, as there is no higher SR class.

29 Suppose that the queue for SR class A is full, and it has accumulated the maximum amount of *credit*  
30 (*hiCredit*). Because SR class A frames have priority over all other traffic (even BPDUs), *hiCredit* for SR  
31 class A is merely the credit accumulated during the *maxInterferenceTime* required to transmit a  
32 lower-priority frame. Until that accumulated credit is exhausted, SR class B (C, D,...) frames cannot be  
33 transmitted.

34 If SR class A were permitted to use 100% of the LAN bandwidth, then the SR class A queue would never  
35 catch up, because it would use credit as fast as it was gained, and there would never be a chance for any  
36 other traffic class to transmit a frame. If SR class A were permitted to use 99% of the LAN bandwidth, then  
37 SR class A can transmit back-to-back frames and the accumulated *credit* would be drained at 1% of the LAN  
38 bandwidth until it goes negative; at that point, SR class A cannot transmit further frames until its *credit*  
39 returns to a non-negative value, which ensures that at least 1% of the bandwidth is available to other traffic  
40 classes.

41 NOTE—In general, if SR Class A is permitted to use X% of the bandwidth, then only (100-X)% remains available for  
42 use by lower priority traffic classes. In practice, as 75% is the default value for the highest percentage of  
43 *portTransmitRate* that can be used by all SR classes, there is always at least 25% of *portTransmitRate* available for use  
44 by the non-SR traffic classes.

Figure L-4 illustrates this burst transmission behavior, and the effect of *maxInterferenceTime* on the latency of SR class frames. At point *a* on the time line, the queues for SR classes A and B are empty, and a maximum sized frame ( $M_0$  bits long) belonging to a non-SR traffic class starts transmission. An instant later, SR class A and B frames arrive that are all of the maximum size that the classes are currently experiencing ( $M_A$  and  $M_B$  bits long, respectively); however, as there is a frame already being transmitted, they are queued. At point *b*, transmission of the non-SR class frame completes, and the first of a burst of four SR class A frames are transmitted. By point *d*, SR class A's credit has been taken negative by the transmission of the last of its burst of frames, and therefore no further SR Class A frames can be transmitted until its credit is no longer negative; this allows SR Class B to transmit a frame. What happens at the end of the class B frame will depend on what frames are queued waiting for transmission, and whether the credit available to either of the SR classes is non-negative.

**Figure L-4—Interference and latency**

The queuing delay experienced by the first SR Class A frame is therefore the time interval between *a* and *b*,  $T_{ab}$ . If  $R_0$  is the transmission rate (*portTransmitRate*), then:

$$T_{ab} = M_0 / R_0 = \text{maxInterferenceTime} \quad (\text{L-9})$$

Figure L-5 shows how credit changes for SR Class A during this sequence.

**Figure L-5—Burst behavior and credit**

$R_A$  is the reserved data rate for SR Class A (which is the *idleSlope* for class A),  $R_B$  is the reserved data rate for SR Class B, and so on. The value of *credit*<sub>A</sub> accumulates up to *hiCredit*<sub>A</sub> during the transmission of the maximum sized non-SR frame so that:

$$\text{hiCredit}_A = R_A \times M_0 / R_0 = \text{idleSlope}_A \times \text{maxInterferenceTime} \quad (\text{L-10})$$

*credit* is drained during the transmission of the SR Class A frames, at the rate *sendSlope*<sub>A</sub>, as follows:

$$\text{sendSlope}_A = (R_A - R_0) \quad (\text{L-11})$$

1 *credit* reaches zero at point *c* in Figure L-5, which, for the purposes of this discussion, is assumed to happen  
2 exactly at the point where transmission of the third class A frame finishes. Since a frame can be transmitted  
3 when *credit* = 0, Class A's credits continue to drain to the following value:

$$4 \quad loCredit_A = (R_A - R_0) \times M_A / R_0 \quad (L-12)$$

5 during the transmission of the fourth class A frame ( $M_A$  bits long, transmitted in time  $M_A / R_0$ ). At point *d*,  
6 transmission of the fourth frame completes; as *credit*<sub>A</sub> is now negative, no more class A frames can be  
7 transmitted, and transmission of a class B frame starts.

8 So, for class A, the maximum burst size is equal to the transmission rate,  $R_0$ , multiplied by the time interval  
9 between points *b* and *d* in Figure L-5:

$$10 \quad \text{max Class A burst size} = R_0 \times (- (hiCredit_A - loCredit_A) / sendSlope_A) \quad (L-13)$$

11 Substituting  $hiCredit_A$ ,  $sendSlope_A$ , and  $loCredit_A$  from Equation (L-10), Equation (L-11), and  
12 Equation (L-12), respectively, results in the following:

$$13 \quad \text{max Class A burst size} = R_0 \times (- (R_A \times M_0 / R_0 - (R_A - R_0) \times M_A / R_0) / (R_A - R_0)) \quad (L-14)$$

$$14 \quad = R_0 \times (R_A \times M_0 / R_0) / (R_0 - R_A) + M_A / R_0 \quad (L-15)$$

$$15 \quad = (R_A \times M_0) / (R_0 - R_A) + M_A \quad (L-16)$$

16 The queuing delay experienced by SR class B is the time interval between *a* and *d* in Figure L-5,  $T_{ad}$ :

$$17 \quad T_{ad} = T_{ab} + T_{bc} + T_{cd} \quad (L-17)$$

$$18 \quad = M_0 / R_0 + hiCredit_A / (-sendSlope_A) + M_A / R_0 \quad (L-18)$$

$$19 \quad = M_0 / R_0 + (R_A \times M_0 / R_0) / (R_0 - R_A) + M_A / R_0 \quad (L-19)$$

$$20 \quad = M_0 / (R_0 - R_A) + M_A / R_0 \quad (L-20)$$

21 This can be generalized to calculate the queuing delay experienced by any SR class, *X*, by using the sum of  
22 the credits available to all higher priority SR classes. In the following, the subscript "<*X*" is used to indicate  
23 the sum of the values for all SR classes with higher priority (and therefore, earlier letters in the collating  
24 sequence) than *X*.

25 The credit acquisition rate  $idleSlope_{<X}$  for SR classes A through *X* – 1 is the sum of the data rates for all  
26 higher priority classes so that:

$$27 \quad idleSlope_{<X} = \sum_{K < X} R_K \quad (L-21)$$

28 This is just the sum of the  $idleSlope_K$  values for the higher classes. However, the combined classes  
29 accumulate credits only until the single interfering non-SR interfering frame stops transmitting, and then the  
30 credits start decreasing linearly. So, the upper limit for the combined credits is not the sum of the individual  
31 Class's credits; it is the number of bits divided by the slope, or:

$$32 \quad hiCredit_{<X} = (\sum_{K < X} R_K) \times M_0 / R_0 \quad (L-22)$$

33 Similarly, the combined  $sendSlope_{<X}$  is:

$$34 \quad sendSlope_{<X} = - (R_0 - \sum_{K < X} R_K) \quad (L-23)$$

35 These combined rates hold true until some class's buffer empties and its credits are forced to 0. In the  
36 worst-case scenarios examined here, this does not happen.

1 Defining:

$$2 \quad W_{<X} = -\text{sendSlope}_{<X} = R_0 - \sum_{K<X} R_K \quad (\text{L-24})$$

3 leads to:

$$4 \quad \text{sendSlope}_{<X} = -W_{<X} \quad (\text{L-25})$$

5 and:

$$6 \quad \text{hiCredit}_{<X} = (R_0 - W_{<X}) \times M_0 / R_0 \quad (\text{L-26})$$

7 For all combined classes,  $T_{ab}$  is the same as for SR class A, the time for the non-SR frame to transmit:

$$8 \quad T_{ab} = M_0 / R_0 \quad (\text{L-27})$$

9 The combined classes A through  $X - 1$  drain from  $\text{hiCredit}_{<X}$  to 0 in time  $\text{hiCredit}_{<X} / W_{<X}$  so that:

$$10 \quad T_{bc} = ((R_0 - W_{<X}) \times M_0 / R_0) / W_{<X} \quad (\text{L-28})$$

11 The worst-case value of  $\text{loCredit}_{<X}$  for the combined  $<X$  classes is not the sum  $\sum_{K<X} \text{loCredit}_K$  as this  
12 would overestimate the worst case. Only one of the  $<X$  classes can be transmitting a frame at a given time,  
13 so the end of the burst for the  $<X$  classes occurs when one of the  $<X$  classes, Q say, starts transmitting a  
14 frame at a point where all the other  $<X$  classes have negative credit, and their credit is therefore rising. If, by  
15 the time Q's frame transmission finishes, the other  $<X$  classes still have negative credit, then Q's frame is the  
16 last frame of the  $<X$  burst; but at that point, all the other  $<X$  classes must, by definition, have more credit  
17 than their respective  $\text{loCredit}$  values (i.e., for these other classes,  $\text{credit} > \text{loCredit}$ ) because even if they were  
18 at their respective  $\text{loCredit}$  values when Q started transmitting, they have been gaining credit during the  
19 transmission of Q's frame.

20 It is also not possible to decide that  $\text{loCredit}_{<X}$  is simply the time needed to transmit one copy of each  
21 Class's maximum-length frame; for some classes it could be possible transmit more than a single last frame  
22 after the total credits = 0, even if all Classes' credits reach 0 simultaneously. For example, classes A and B  
23 reach  $\text{credit} = 0$  at the same time; A transmits a frame, then B transmits a frame. By the end of the B frame,  
24 A's  $\text{credit}$  has returned to zero, and so A can transmit a further "last" frame.

25 Some class must transmit the last frame, and for it to be the worst case, that last frame is a maximum length  
26 frame. If it were not, then either:

- 27 c) Extending it to the maximum length still leaves the other classes at negative  $\text{credit}$ ; or
- 28 d) Extending it to the maximum length leaves one or more other class with 0 or positive  $\text{credit}$ , in  
29 which case they will transmit more frames.

30 So, for class Q to be the class that transmits the last frame of the  $<X$  burst, the following condition must be  
31 true for all other  $<X$  classes, P:

$$32 \quad M_q \times R_p > (R_0 - R_p) \times M_p \quad (\text{L-29})$$

33 Equation (L-29) follows from the fact that the increase in credits of class P during the transmission of  
34  $M_q$ , which is equal to  $(M_q/R_0) \times R_p$  is greater than the absolute value of the  $\text{loCredit}$  of P, which is equal to  
35  $(R_0 - R_p) \times M_p$ . So,

$$36 \quad (M_q/R_0) \times R_p > (R_0 - R_p) \times M_p / R_0 \quad (\text{L-30})$$

37 This statement is true because the other classes P must have low enough  $\text{credit}$  that their  $\text{credit}$  cannot climb  
38 above 0 during the transmission of  $M_q$ .

1 The very lowest that  $credit_{<X}$  might reach for three SR classes, Q, P, and S is shown in Equation (L-31).

$$2 \quad loCredit_{<X} \geq loCredit_Q + loCredit_P + loCredit_S + R_S \times M_q/R_0 + R_P \times M_q/R_0 \quad (L-31)$$

3 However, even this is pessimistic, as it assumes that more than one class can be at their  $loCredit$  at the same  
4 time, which is not the case. What this shows, however, is that if  $R_K$  is small for all  $K < X$  (i.e.,  $R_K \ll R_0$ ), then  
5 the  $R_K \times M_q/R_0$  terms all approach zero, and therefore  $loCredit_{<X}$  approaches the sum  $\sum_{K < X} loCredit_K$ . So,

$$6 \quad loCredit_{<X} = \sum_{K < X} loCredit_K \quad (L-32)$$

$$7 \quad = \sum_{K < X} (R_K - R_0) \times M_K / R_0 \quad (L-33)$$

8 But in this worst case,  $R_K \ll R_0$ ; therefore,

$$9 \quad loCredit_{<X} = \sum_{K < X} (-M_K) \quad (L-34)$$

10 Putting together these various components, the queuing delay for SR Class X,  $qDelay_X$ , is as follows:

$$11 \quad qDelay_X = M_0 / R_0 + (hiCredit_{<X} - loCredit_{<X}) / |sendSlope_{<X}| \quad (L-35)$$

$$12 \quad = M_0 / R_0 + ((R_0 - W_{<X}) \times M_0 / R_0 + \sum_{K < X} M_K) / W_{<X} \quad (L-36)$$

$$13 \quad qDelay_X = (M_0 + \sum_{K < X} M_K) / W_{<X} \quad (L-37)$$

14 For SR class A, this equation reduces to Equation (L-38):

$$15 \quad qDelay_A = M_0 / W_{<A} \quad (L-38)$$

16 As there is not a “<A” class, A being the highest priority class,  $W_{<A}$  is simply  $R_0$ , so this reduces to  
17 Equation (L-39):

$$18 \quad qDelay_A = M_0 / R_0 \quad (L-39)$$

19 This agrees with the earlier discussion in L.1.

20 For SR class B, the equation reduces to Equation (L-40):

$$21 \quad qDelay_B = (M_0 + M_A) / W_A \quad (L-40)$$

22 As  $W_A$  is  $-sendSlope_A$ , which is just  $R_0 - R_A$ , this can be rewritten as shown in Equation (L-41):

$$23 \quad qDelay_B = (M_0 + M_A) / (R_0 - R_A) \quad (L-41)$$

24 The maximum burst size for a given class, X, is the number of bits that can be transmitted in “back-to-back”  
25 frames by class X. The maximum burst occurs when that class has experienced the maximum queuing delay  
26 for that class,  $qDelay_X$ , and class X is then able to transmit frames, uninterrupted by any higher priority  
27 classes, until it reaches  $loCredit_X$ . The size of this burst,  $maxBurst_X$ , is equal to the number of bits that can  
28 be transmitted at line rate,  $R_0$ , in the time it takes for  $credit_X$  to reduce from  $hiCredit_X$  to  $-loCredit_X$ , as  
29 follows in Equation (L-42):

$$30 \quad maxBurst_X = (hiCredit_X - loCredit_X) \times R_0 / W_X \quad (L-42)$$

31 From the earlier results, the worst case for  $loCredit_X$  is just  $(-M_X)$  so that:

$$32 \quad = hiCredit_X \times R_0 / W_X + M_X \times R_0 / W_X \quad (L-43)$$

1 and  $hiCredit_X$  is the amount of credit that can be accumulated during  $qDelay_X$  seconds, which is  $qDelay_X$   
2 multiplied by the idle slope,  $R_X$ , so that:

$$3 \quad \maxBurst_X = (M_0 + \sum_{K < X} M_K) \times R_X \times R_0 / (W_{<X} \times W_X) + M_X \times R_0 / W_X \quad (L-44)$$

#### 4 L.3.1.2 Fan-in delay

5 The delay caused by other frames in the same class as frame X that arrive at more-or-less the same time from  
6 different input Ports. Consider the scenario in Figure L-6, where a Bridge has a number of Ports on which it  
7 receives frames for a given SR Class and the frames will be queued on a single outbound Port. Imagine that  
8 the “upstream” Bridge Ports feeding every reception Port of the Bridge all encounter a maximum  
9 interference event for Class X at the same time. The output Port will be starved of data. Then, once the  
10 interference events complete, the “upstream” Bridges start to transmit frames and the input Ports all receive  
11 a frame at the same moment; all received frames are delivered to the output queue.

Figure L-6—Fan-in scenario

12 Assuming that all of the Ports of the Bridge support the same data rate, and the outbound queues of the  
13 upstream Bridges are all configured the same as the outbound queue of this Bridge, then the outbound Port  
14 would not be able to transmit frames from its queue at the desired, combined data rate of the incoming  
15 traffic, as this would require the outbound Port (in this example) to transmit at 20 times its reserved data rate,  
16 which would not be permitted by the Stream Reservation Protocol (SRP). It follows that whatever the  
17 reserved data rate is on the outbound Port, this must be the same as the sum of the reserved data rates being  
18 fed into the inbound Ports.

19 By allocating the majority of the reserved bandwidth to one of the inbound Ports (shown in gray in  
20 Figure L-6) and a very small amount of bandwidth to all of the other inbound Ports, the amount of fan-in  
21 data that will be received can be maximized; the gray Port will receive  $\maxBurst_X$  bits of burst data, and all  
22 other Ports will receive a single frame of length  $M_X$ . Hence, the data that the outbound queue has to handle  
23 in this scenario is  $\maxBurst_X + 12 \times M_X$  bits of fan-in data.

24 NOTE 1—The reason that this choice maximizes the fan-in data burst size is that regardless of how little bandwidth is  
25 allocated to the black Ports, they still get to burst a complete frame.

1 The following is a procedure (not a formula) for determining the maximum amount of fan-in data for a given  
2 SR class and output port:

- 3 a) Determine  $B_O$ , the maximum possible bandwidth for class X on the output port.
- 4 b) For each possible input port  $i$ , determine the maximum possible bandwidth  $B_i$  for Class X—it is  
5 assumed that this information is obtained, by some means, from the transmitting Bridge that is the  
6 source of the frames received by  $i$ .
- 7 c) For input port  $i$ , calculate  $\max\text{Burst}_{X,i}$  using  $\max(B_O, B_i)$  for the bandwidth. (In the  $\max\text{Burst}$   
8 formula, use  $W_X = R_0 - \max(B_O, B_i)$ .)
- 9 d) Add  $\max(\max\text{Burst}_{X,i})$  to the total fan-in data.
- 10 e) Set  $B_O = B_O - B_i$  and repeat from step c) until  $B_O = 0$ .
- 11 f) For each remaining port, add  $M_{X,i}$  to the total fan-in data.

12 The fan-in delay is then equal to the time taken for the total fan-in burst data, computed as shown above, to  
13 be output at the line rate of the output port.

14 NOTE 2—The definition of a measurement interval for stream TSspecs implies a minimum frame transmission rate  
15 (8000 frames per second for class A's 125  $\mu\text{s}$  measurement interval). At this frame transmission rate, the frames are  
16 smaller and, due to the overhead in small frames, fewer streams are possible (no more than 13 through a 100 Mb port).  
17 These constraints should be given due consideration when determining the value to be used for  $M_X$  and for determining  
18 the maximum number of ports contributing to fan-in delay.

19 Example calculations of fan-in delay can be found in the paper “Calculating the Delay Added by Qav  
20 Stream Queue” [B3].

### 21 L.3.1.3 Permanent delay

22 Permanent delay reflects the fact that, if a path through the network is being used continuously at its full  
23 capacity for a particular SR class, interfering traffic can cause “permanent” buffer occupancy at the point of  
24 congestion. This is illustrated in Figure L-7 through Figure L-10 and the accompanying text.

25 In Figure L-7 a Talker station, T, has reserved the highest possible bandwidth,  $R_X$ , for an SR class X stream  
26 on the path through 3 Bridges to Listener L. For the purposes of the discussion,  $R_X$  is the maximum  
27 reservable data rate for class X on the outbound Ports of all three Bridges, and Talker T starts transmitting  
28 the stream, at the reserved data rate  $R_X$ . Assuming that the LANs are short and there is no interfering traffic  
29 (i.e., the only traffic being handled is this particular stream), the buffer occupancy in each Bridge will  
30 approach zero, as frames can be transmitted onwards as soon as they are received.

Figure L-7—Permanent delay scenario

31 In Figure L-8, a second transmission, Q, generates the maximum possible interference to class X (i.e., class  
32 X's next frame for transmission is delayed by  $q\text{Delay}_X$ ). Talker T's class X queue fills, and its *credit*  
33 increases to  $hi\text{Credit}_X$  (shown on the figure as  $C=C_X$ ). Because T is no longer transmitting class X frames,  
34 the downstream Bridges are starved of frames to transmit, their buffers are empty, and their credit is zero  
35 ( $C = 0$ ).

**Figure L-8—Building up buffer occupancy—1**

1 In Figure L-9, the interfering traffic goes away, and T is able to transmit a maximum sized class X burst of  
2 frames at line rate; once the burst has finished, T reverts to transmitting the stream at the reserved rate  $R_X$ .  
3 As Bridge 1 has no credit, it will have to buffer most of the burst of frames, and as T is sending frames as  
4 fast as Bridge 1 can get rid of them, its buffer occupancy will remain at that level unless something else  
5 affects that steady state. Bridge 1 ends up with a credit value that hovers around the *hiCredit* level; the credit  
6 in the other Bridges will have *credit* of 0 or some value between 0 and *loCredit* as the Bridges receive and  
7 transmit frames.

**Figure L-9—Building up buffer occupancy—2**

8 If the interfering traffic, Q, starts up again, Talker T's buffer occupancy will build up again; however, as  
9 Bridge 1 still has frames buffered, it can continue to transmit, and the downstream Bridges are not starved of  
10 frames, and Bridge 1's buffer occupancy and *credit* returns to around 0. When the interference stops, T  
11 transmits a burst at line rate, as before, which simply restores Bridge 1's queue to the state shown in  
12 Figure L-9.

13 If a new interfering frame source, S, starts up that affects class X in Bridge 1, then Bridges 2 and 3 could  
14 again be starved of traffic, and the buffer occupancy and credit in Bridge 1 could increase temporarily to  
15  $2C_X$  (see Figure L-10). When S stops transmitting, then Bridge 2 can create a line rate burst of traffic that  
16 will restore its buffer to the previous steady state (Figure L-9), but now Bridge 2 has a permanent buffer  
17 loading as shown in Figure L-10.

**Figure L-10—Building up buffer occupancy—3**

This can of course happen for other Bridges in the path, leading eventually to some level of permanent buffer occupancy in each Bridge (Table L-11). The problem does not get any worse from that point on, because no Bridge ever starves (i.e., no Bridge's credit is set to zero because it runs out of frames to send); starvation is a requirement in order for permanent partial occupancy to be created.

**Figure L-11—Building up buffer occupancy—4**

It may, therefore, be considered desirable for all Bridges to reserve a little bit more bandwidth than the actual total reserved by the Talkers, so that this “permanent” buffer build-up can drain away. However, this would not make the problem significantly better on the timescales of the output queuing delay, so it does not factor into those calculations, and, of course, this additional capacity would increase the queuing delay at each hop.

NOTE—Many applications have media clocks that are asynchronous to the free-running clock used to determine class measurement intervals. As the two clocks could be operating at the extremes of their permissible variation, it is necessary to reserve more bandwidth than is nominally needed in order to account for the potential difference in clock rate.

Since this kind of event could happen on multiple input ports at the same time, the “permanently buffered” data equals the worst-case fan-in data.

### L.3.2 Maximum interference delay and maximum buffer requirement

As discussed in L.3.1, the worst-case interference delay for SR class X on a given Port is the sum of the following three parts:

- a)  $qDelay_X$  [see Equation (L-35) in L.3.1.1]
- b) The fan-in delay (see L.3.1.2)
- c) The “permanent” buffer contents contribution (see L.3.1.3), which is equal to the worst-case fan-in delay

The buffering requirements for SR class X consist of the following three components:

- d) A contribution from the queuing delay, equal to  $maxBurst_X$
- e) The fan-in burst data size, computed as described in L.3.1.2
- f) The “permanent” buffer contents, which is equal to the fan-in burst data size

The fan-in burst size and the permanent buffer contents do not count twice; if a fan-in burst happens, then it becomes the permanent buffer contents. If it happens a second time, it can only happen after a pause that has allowed the permanent buffer loading to drain. So the worst-case buffering requirement for SR class X is simply the sum of the first two elements,  $maxBurst_X$  [Equation (L-42)] and fan-in burst data size; therefore,

$$maxBuffering_X = maxBurst_X + (fan-in burst data size)_X \quad (L-45)$$

1 The worst-case total buffering requirement for all of the SR classes on a given Port is the sum of the  
2 following two parts:

- 3 g) The worst-case buffering requirement for the lowest priority SR class on that Port
- 4 h) One max-size frame  $M_{i,Z}$  for each class Z of higher priority than Class X for each input port i

5 Since the worst-case buffer requirement for Class X is when it is taking almost all of the bandwidth from the  
6 higher-priority classes, the SR priority levels can share buffering space. The only additional requirement is  
7 for the fan-in from higher priorities on other Ports. Thus, the SR classes would do well to share their buffer  
8 space on each Port.

#### 9 **L.4 Operation of credit-based shaper in Coordinated Shared Network (CSN)**

10 A CSN is a contention-free, QoS-capable, time division multiplexed access network. One of the nodes of the  
11 network acts as the Network Coordinator (NC) node granting transmission opportunities to the other nodes  
12 of the network. The NC node also acts as the QoS manager of the network.

13 From the perspective of the specification of the credit-based shaper, a CSN is equivalent to a distributed  
14 Bridge. Rather than shaping the AV traffic in the egress nodes, which could lack the buffering resources to  
15 do so, the shaping could instead be performed by the CSN's NC per Class of Service when it schedules  
16 transmissions opportunities from the CSN's ingress to the CSN egress nodes. The behavior of CSN's egress  
17 to another MAC technology should be consistent with the behavior specified in this standard, regardless of  
18 how the shaper is implemented.

## 1 Annex M

2 (normative)

### 3 Support for PFC in link layers without MAC Control

#### 4 M.1 Overview

5 Priority-based Flow Control (PFC) is a function defined for only point-to-point full-duplex links in terms of  
6 the M\_CONTROL primitives (11.4 of IEEE Std 802.1AC-2016 [B10]). For IEEE 802.3 link layers the  
7 M\_CONTROL primitives are mapped into the MAC Control MA\_CONTROL primitives  
8 (IEEE Std 802.1AC), that use the PDU format defined in IEEE Std 802.3. Other link layers supporting  
9 point-to-point full-duplex operations need to define their mapping of the M\_CONTROL primitives. This  
10 annex describes a PDU format suitable to support PFC.

#### 11 M.2 PFC PDU format

12 Figure M-1 shows a PDU format suitable to support PFC.

**Figure M-1—PFC PDU format**

13 The Control opcode field contains a 2-octet operation code indicating the Control function.

14 The remaining fields contain the parameters defined in 36.1.2.

## Annex N

(informative)

### Buffer requirements for PFC

#### N.1 Overview

To ensure that data frames are not lost due to lack of receive buffer space, receivers must ensure that a PFC M\_CONTROL.request primitive is invoked while there is sufficient receive buffer to absorb the data that can continue to be received during the time needed by the remote system to react to the PFC operation. The precise calculation of this buffer requirement is highly implementation dependent. This annex provides an example of how it can be calculated based on a hypothetical delay model. Setting the PFCLinkDelayAllowance (see 12.22.6) to less than the round-trip delay value can result in frames loss.

Figure N-1 provides an high-level view of the various delays to consider:

- a) Processing and queuing delay of the PFC request
- b) Propagation delay of the PFC frame across the media
- c) Response time to the PFC indication at the far end
- d) Propagation delay across the media on the return path

Figure N-1—PFC delays

#### N.2 Delay model

Figure N-2 shows how to model the various delays between two stations connected by a point-to-point full-duplex IEEE 802.3 link.

The main delay components shown in Figure N-2 are as follows:

- a) **PFC transmission delay:** the time needed by a station to request transmission of a PFC frame after a PFC M\_CONTROL.request has been invoked (e.g., because a maximum length data frame can be transmitted).
- b) **Interface Delay (ID):** the sum of MAC Control, MAC/RS, PCS, PMA, and PMD delays. Interface Delay is dependent on the MAC and physical layer in use.

- 1 c) **Cable Delay:** the number of bits in flight stored in the transmission medium. This delay value is
- 2 dependent on the selected technology and on the medium length.
- 3 d) **Higher Layer Delay (HD):** the time needed for a queue to go into paused state after the reception of
- 4 a PFC M\_CONTROL.indication that paused its priority. A substantial portion of this delay
- 5 component is implementation specific.

**Figure N-2—Delay model**

6 Figure N-3 shows a possible worst-case delay example.

**Figure N-3—Worst-case delay**

1 The total Delay Value (DV) is the sum of all delays shown in Figure N-3:

$$2 \quad DV = 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + \text{TXd}_{s1} + \text{RXd}_{s2} + \text{HD}_{s2} + \text{TXd}_{s2} + \text{RXd}_{s1}$$

4 For any given station the Interface Delay includes both transmit and receive paths (i.e., ID = TXd + RXd).  
5 Therefore:

$$6 \quad DV = 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + \text{ID}_{s1} + \text{ID}_{s2} + \text{HD}_{s2}$$

7 Usually the peer stations connected by a point-to-point link use the same technology, therefore  $\text{ID}_{s1} = \text{ID}_{s2}$ :

$$8 \quad DV = 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + 2 \times \text{ID} + \text{HD}_{s2}$$

### 1 N.3 Interface Delay

2 The Interface Delay comprises all delay components below the MAC Control Client, excluding the cable  
3 delay. Table N-1 shows the Interface Delay constraints for some IEEE 802.3 interfaces.

**Table N-1—IEEE 802.3 Interface Delays**

| Sublayer                     | Maximum RTT<br>(bit times) | Maximum RTT<br>(pause quanta) | Reference<br>(subclause of IEEE<br>Std 802.3-2018 [B15]) |
|------------------------------|----------------------------|-------------------------------|----------------------------------------------------------|
| 10G MAC Control, MAC, and RS | 8192                       | 16                            | 46.1.4                                                   |
| XGXS and XAUI                | 2048                       | 4                             | 48.5                                                     |
| 10GBASE-X PCS                | 2048                       | 4                             | 49.2.15                                                  |
| 10GBASE-R PCS                | 3584                       | 7                             | 50.3.7                                                   |
| LX4 PMD                      | 512                        | 1                             | 53.2                                                     |
| CX4 PMD                      | 512                        | 1                             | 54.3                                                     |
| Serial PMA and PMD           | 512                        | 1                             | 52.2                                                     |
| 10GBASE-T                    | 25 600                     | 50                            | 55.11                                                    |

### 4 N.4 Cable Delay

5 The Cable Delay is the propagation delay over the transmission medium and can be approximated by the  
6 following equation:

$$7 \quad \text{Cable Delay} = \text{Medium Length} \times \frac{1}{BT \times v}$$

8 where  $v$  is the signal propagation speed in the medium and  $BT$  is the bit time of the medium.

### 9 N.5 Higher Layer Delay

10 The Higher Layer Delay comprises the delay components between the MAC Control Client and the port  
11 Transmission Selection. Example of these delays are MACsec and implementation specific delays.

12 For link speeds of up to 10Gb/s, MACsec constrains each of the transmit delay and the receive delay to a  
13 maximum of 19 360 bit times (see 36.1.3.3).

14 This standard constrains the implementation specific delays to be less than 614.4 ns (see 36.1.3.3). This  
15 delay is equivalent to 6144 bit times at the speed of 10Gb/s.

## 1 N.6 Computation example

2 A station needs to be capable of buffering DV bit times of data to ensure no frame loss due to congestion.  
3 The worst case is with a 10GBASE-T PHY. Assuming MACsec is not supported, this results in the  
4 following:

- 5 — Maximum envelope frame size: 2000 octets, 16 160 bit times;
- 6 — PFC frame size: 64 octets, 672 bit times;
- 7 — XGMII MAC/RS and XAUI interface:  $8192 + 2 \times 2048 = 12\,288$  bit times;
- 8 — 10GBASE-T Delay: 25 600 bit times;
- 9 — 100 meters Cat6 cable: 5556 bit times (computed assuming  $v = 0.6 \times c$ , where  $c$  is the speed of the  
10 light in meters per second);
- 11 — HD = 6144.

12 The total Delay Value in this scenario results as follows:

$$\begin{aligned} 13 \quad DV &= 2 \times (\text{Max Frame}) + (\text{PFC Frame}) + 2 \times (\text{Cable Delay}) + 2 \times \text{ID} + \text{HD}_{s2} \\ 14 \quad DV &= 2 \times (16\,160) + (672) + 2 \times (5556) + 2 \times (25\,600) + 2 \times (12\,288) + 6144 = 126\,024 \text{ bit times} \end{aligned}$$

15 For this case, the amount of buffering needed to ensure no frame loss due to congestion results to be  
16 126 024 bit times, roughly equivalent to 15.5 kB.

17 If MACsec is used, the High Layer Delay is incremented by 19 360 bit times; therefore, the total Delay  
18 Value results as follows:

$$19 \quad DV = 2 \times (16\,160) + (672) + 2 \times (5556) + 2 \times (25\,600) + 2 \times (12\,288) + 25\,504 = 145\,384 \text{ bit times}$$

20 For this case, the amount of buffering needed to ensure no frame loss due to congestion results to be  
21 145 384 bit times, roughly equivalent to 18 kB.

## 1 **Annex O**

2 (informative)

### 3 **Preserving the integrity of FCS fields in MAC Bridges**

#### 4 **O.1 Background**

5 When relaying frames between Ports of a MAC Bridge, one of the functions of the Bridge is to regenerate  
6 the FCS field in accordance with the MAC procedures that apply to the medium access method through  
7 which the frame will be relayed. One of the requirements of the MAC Bridge standard is that any such  
8 regeneration of the FCS shall not increase the level of undetected FCS errors that are experienced on the  
9 transmitting MAC over that which would be experienced by preserving the FCS. The point at issue here is  
10 only the *undetected* error rate; a conformant Bridge will discard frames that are received with an FCS error;  
11 however, there is a finite possibility of undetectable corruption taking place, i.e., the frame is corrupted, but  
12 the FCS algorithm does not reveal the error.

13 This annex looks at the various cases that apply to the operation of the MAC Bridge with respect to FCS  
14 regeneration and the alternative approaches that can be taken in order to address the cases. The following  
15 cases need to be considered:

16 a) The source and destination media access methods are identical from the point of view of the  
17 operation of the FCS algorithm.

18 NOTE—This is the case, for example, where the source and destination media access methods are identical. It could also  
19 happen with dissimilar media access methods if the FCS coverage, the FCS algorithm, the definitions of the fields  
20 covered by the FCS, and the bit/octet ordering are the same in both media access methods.

21 b) The source and destination media access methods differ from the point of view of the operation of  
22 the FCS algorithm.

23 c) The data covered by the FCS is not modified by the operation of the relay function of the Bridge.

24 d) The data covered by the FCS is modified by the operation of the relay function of the Bridge.

25 In each case, it is important to ensure that there is a low probability of additional undetected errors being  
26 generated by corruption of the data portion of the frame between removal of the old FCS and computation of  
27 the new one, which would result in the transmitted frame carrying invalid data and a valid FCS. Such  
28 corruption might occur, for example, as a result of the effect of environmental noise on the operation of the  
29 Bridge hardware.

30 If both item a) and item c) are true, then the FCS carried in the received frame is still valid, and the ideal  
31 approach would be to reuse this value as the FCS for the transmitted frame.

32 If either item b) or item d) are true, then it will be necessary for the Bridge to recalculate the FCS on  
33 transmission, and may therefore need to take additional precautions against in-memory corruption causing  
34 increased undetected FCS error levels.

## 1 O.2 Basic mathematical ideas behind CRC and FCS

2 The standard CRC algorithm is based on the following ideas:

- 3 a) An  $n$ -bit message is regarded as a polynomial,  $M(x)$ , of degree  $n - 1$ .
- 4 b) In order to generate a CRC value of length  $r$  bits, a generator polynomial,  $G(x)$ , is used, of degree  $r$
- 5 c) The value of the last  $r$  bits of  $M(x)$  are chosen such that  $M(x) \div G(x)$  has a remainder of 0 [i.e.,  $M(x) = 0 \bmod G(x)$ ].

7 Messages can be added, in which each coefficient is 0 or 1:

- 8 d)  $M3(x) = M1(x) + M2(x)$ . Messages are added together by bit-wise addition (XOR) of coefficients
- 9 with the same bit position (i.e., coefficients with the same exponent).

10 Subtraction of messages:

- 11 e) Addition and subtraction are equivalent operations (as  $A = A \text{ XOR } B \text{ XOR } B$ ); hence, using the
- 12 messages in item d) above,  $M1(x)$  can be regenerated from  $M3(x)$  by adding  $M2(x)$ .

13 Linearity:

- 14 f) If  $M(x) = 0 \bmod G(x)$ , then  $(M(x) + E(x)) = 0 \bmod G(x)$  IFF  $E(x) = 0 \bmod G(x)$ . In other words, if
- 15 an error pattern,  $E(x)$ , is added to a message,  $M(x)$ , then the resultant message will give no
- 16 remainder when divided by the generator polynomial if both  $M(x)$  and  $E(x)$  gave no remainder when
- 17 divided by the generator polynomial.
- 18 g)  $x^m M(x) = 0 \bmod G(x)$  IFF  $M(x) = 0 \bmod G(x)$ . A message can be shifted by adding zero padding
- 19 without affecting the integrity of the CRC.
- 20 h) Thus, the CRC algorithm has the property that it will detect any burst error, of length  $r$  bits or less,
- 21 applied to the message, as such an error must result in a nonzero remainder when the message is
- 22 divided by the generator polynomial. Alternatively, adding two messages together, both of which
- 23 have valid CRCs, results in a message with a valid CRC.

24 In Ethernet, the algorithm used differs from the standard CRC, and is known as an FCS. The FCS is based

25 on the CRC but with the following differences:

- 26 — The first 32 bits of  $M(x)$  are complemented before the FCS value is calculated.
- 27 — A CRC value is calculated, as described above, by dividing the first  $n - 32$  bits of  $M(x)$  by  $G(x)$  and
- 28 taking the remainder as the CRC value.
- 29 — The CRC value is complemented and inserted as the last 32 bits of  $M(x)$ .

30 By application of the addition and linearity rules, item d) and item f) above, the Ethernet frame with its FCS

31 can be viewed as consisting of the following component messages, added together:

- 32 — An  $n$ -bit message,  $M(x)$ , carrying a standard CRC as the last 32 bits.
- 33 — An  $n$ -bit “FCS adjustment factor,”  $A_n(x)$ , which adjusts the CRC to form an FCS.

34 Figure O-1 illustrates the conversion of a message with a CRC to the equivalent message with an FCS, by

35 the addition of the adjustment factor. The adjustment factor consists of the following two components:

- 36 — The first component, when added to  $M(x)$ , contributes an adjustment to the CRC, which is
- 37 equivalent to the effect of complementing the first 32 bits of  $M(x)$  before calculating the CRC bits,
- 38 and complements the first 32 bits of  $M(x)$ .
- 39 — The second component, when added to the partially adjusted  $M(x)$ , restores the first 32 bits of  $M(x)$
- 40 to their original value, and complements the (adjusted) CRC to form the final FCS.

Figure O-1—Converting a CRC to an FCS

1 O.3 Detection Lossless Circuit approach

2 This approach is illustrated in Figure O-2. The basis of this approach is that the FCS used in the modified  
3 message is always recomputed from scratch using the normal FCS generation algorithm (Check Generator  
4 B); however, the original message data and FCS are also used as an input to an FCS checker (Checker A) in  
5 order to check that the inputs to the FCS generator were correct. Hence, if errors are introduced into the  
6 message while it is in memory in the Bridge in the time period since the message was received and FCS-  
7 checked, then Checker A will detect the error at the same time as the new FCS for the modified message is  
8 being generated.

Figure O-2—Detection Lossless Circuit

9 Checker A is fed both with the original message in its unmodified form, and with the original message as  
10 used in the construction of the new message; this occurs after (or simultaneously with) the generation of the  
11 new FCS by Check Generator B. Any discrepancies detected by Checker A indicate that the information  
12 used to generate the new message and its FCS are suspect, and that the message should therefore be  
13 discarded.

## 1 O.4 Algorithmic modification of an FCS

2 In cases where the need to recalculate the FCS comes about as a result of changes to the data rather than by  
3 changes in the operation of the FCS algorithm, one option, rather than recalculating an FCS from scratch for  
4 a given message, is to examine the changes that have been made to the message and to calculate an FCS  
5 adjustment factor that reflects those changes. There are two cases, as follows:

- 6 a) The overall length of the message is unchanged, but the contents of one or more octets of data  
7 covered by the FCS have changed.
- 8 b) The overall length of the message has increased or decreased, as a result of the addition or removal  
9 of octets covered by the FCS, but the contents of the original octets is unchanged (although some  
10 may have been shifted in position as a result of the insertion/deletion).

### 11 O.4.1 Data changed, length unchanged

12 Adjustment of a message,  $MF_1(x)$ , in order to change the value of a field  $F$  from current value  $F_1$  to new  
13 value  $F_2$  consists of the following steps:

- 14 — Remove the FCS adjustment factor for a message of length  $n$ ,  $An(x)$ .
- 15 — Remove the contribution to the message and its FCS provided by the current value of the field,  
16  $F_1(x)$ .
- 17 — Add the contribution to the message and its FCS provided by the new value of the field,  $F_2(x)$ .
- 18 — Add the FCS adjustment factor for a message of length  $n$ ,  $An(x)$ .

19 In other words,

$$20 \quad MF_2(x) = MF_1(x) - An(x) - F_1(x) + F_2(x) + An(x)$$

21 The addition and subtraction of  $An(x)$  cancel each other out, so,

$$22 \quad MF_2(x) = MF_1(x) - F_1(x) + F_2(x)$$

23 Also, the correction factors  $F_1(x)$  and  $F_2(x)$  can be replaced by a single factor,  $F_3(x)$ , which is the  
24 contribution to  $M(x)$  and its FCS that would be provided by the value of Field  $F$  that would be produced by  
25  $F_1 \text{ XOR } F_2$ . So,

$$26 \quad MF_2(x) = MF_1(x) + F_3(x)$$

27 This is shown in Figure O-3.

28 Alternatively,

$$29 \quad \text{FCS of } MF_2(x) = (\text{FCS of } MF_1(x)) + \text{adjustment}$$

30 where

$$31 \quad \text{Adjustment} = (\text{FCS of } F_1(x)) + (\text{FCS of } F_2(x))$$

32 or equivalently,

$$33 \quad \text{FCS of } MF_2(x) = (\text{FCS of } MF_1(x)) + (\text{FCS of } F_3(x))$$

34 The adjustment factor (FCS of  $F_3(x)$ ) is incidentally the same factor that would be used if the value of  $F$   
35 were to be changed back from  $F_2$  to  $F_1$ .

|             |                |       |                |            |
|-------------|----------------|-------|----------------|------------|
| $MF_1(x)$   | x data octets  | $F_1$ | y data octets  | 32-bit FCS |
| $- F_1(x)$  | x octets of 00 | $F_1$ | y octets of 00 | 32-bit CRC |
| $+ F_2(x)$  | x octets of 00 | $F_2$ | y octets of 00 | 32-bit CRC |
| $= MF_2(x)$ | x data octets  | $F_2$ | y data octets  | 32-bit FCS |

Note also that

|            |                |                        |                |            |
|------------|----------------|------------------------|----------------|------------|
| $F_1(x)$   | x octets of 00 | $F_1$                  | y octets of 00 | 32-bit CRC |
| $+ F_2(x)$ | x octets of 00 | $F_2$                  | y octets of 00 | 32-bit CRC |
| $= F_3(x)$ | x octets of 00 | $F_1 \text{ XOR } F_2$ | y octets of 00 | 32-bit FCS |

**Figure O-3—Field change adjustment**

1 The relative simplicity of this case (relative to the case where the length changes) is a consequence of  
2 linearity and the fact that the FCS adjustment factor,  $An(x)$ , is constant for any given message length  $n$ , not a  
3 function of the data carried in the message.

#### 4 **O.4.2 Length changed, original data unchanged**

5 Adjustment of a message  $M(x)$  of length  $n$  to cater for an inserted field,  $I$ , of length  $i$  involves the following  
6 steps:

- 7 — Remove the FCS adjustment factor for a message of length  $n$ ,  $An(x)$ ;
- 8 — Remove the contribution to the message and FCS that is provided by the header portion of the  
9 message (the portion before the inserted field),  $H(x)$ ;
- 10 — Add the contribution to the message and FCS that is provided by the header plus the inserted field  $I$ ,  
11  $HI(x)$ ;
- 12 — Add the FCS adjustment factor for a message of length  $n+i$ ,  $An+i(x)$ .

13 So,

$$14 \quad MI(x) = M(x) - An(x) - H(x) + HI(x) + An+i(x)$$

15 This is shown in Figure O-4.

16 Alternatively,

$$17 \quad \text{FCS of } MI(x) = (\text{FCS of } M(x)) + \text{adjustment}$$

18 where

$$19 \quad \text{adjustment} = (\text{CRC of } An(x)) + (\text{CRC of } H(x)) + (\text{CRC of } HI(x)) + (\text{CRC of } (An+i(x)))$$

20 As with the field change example, the value of *adjustment* is the same adjustment factor that would be used  
21 to adjust the FCS of  $MI(x)$  if field  $I$  were to be removed from the message.

Figure O-4—Field insertion adjustment

1 O.4.3 Preservation of detectability

2 With either of the algorithmic adjustment methods described here, the important question is whether the  
3 ability of the FCS to detect errors in the message is preserved across these transformations; in other words, if  
4 a detectable error pattern, E(x), is added to the message M(x) before the modification, addition, or removal  
5 of a field, is that error still detectable after the message has been adjusted.

6 NOTE—The following analysis assumes that E(x) is a detectable error pattern, of length 32 bits or less. Analysis of the  
7 performance of this method with longer error patterns has not been attempted here.

8 In the cases where the error component is in those parts of the message that are not affected (changed or  
9 shifted) by the transformation, it is reasonably apparent that, as the transformation takes no account of the  
10 portion of the message that is in error, the detectability of that error is unchanged.

11 In the case of a field change, where field F<sub>1</sub> is to be replaced with F<sub>2</sub>, and E(x) had been applied in some part  
12 of the message before changing the field, the new FCS value would be calculated as follows:

13 
$$\text{FCS of } MF_2(x) = (\text{FCS of } MF_1(x)) + (\text{FCS of } F_1(x)) + (\text{FCS of } F_2(x))$$

14 However, the correction factor that is applied to the FCS contains components based only on F<sub>1</sub> and F<sub>2</sub>, and  
15 no contribution related to the error pattern E(x). Therefore, after the value of the field has been changed to  
16 F<sub>2</sub>, the new FCS value as calculated above will still be capable of detecting error pattern E(x), regardless of  
17 where the error pattern appears in the message.

18 In the case of a field insertion (or removal, as insertion and removal have already been shown to be  
19 equivalent), where E(x) has been applied to H(x), the correction factor that is applied to the FCS will contain  
20 two components related to E(x); the first based on E(x) in its original position, and the second based on E(x)  
21 shifted by i, the length of the inserted field, as follows:

22 
$$\text{FCS of } MI(x) = (\text{FCS of } M(x)) + \text{adjustment}$$

1 where

$$\begin{aligned} \text{adjustment} = & (\text{CRC of } A_n(x)) + (\text{CRC of } H(x)) + (\text{CRC of } H_i(x)) + (\text{CRC of } (A_{n+i}(x)) \\ & + (\text{CRC of } E(x)) + (\text{CRC of } (E(x) \text{ shifted by } i)) \end{aligned}$$

4 The presence of the (CRC of  $E(x)$ ) component ensures that the final message will still indicate an FCS error.  
5 (Note that, even if (CRC of  $E(x)$ ) and (CRC of  $(E(x)$  shifted by  $i$ )) turn out to be the same value, the final  
6 message will still indicate an FCS error, as its FCS is now correct for the value of  $M_i(x)$  without the error  
7 component.)

8 The above does not exhaustively analyze all the cases of field insertion and removal, and in particular, does  
9 not analyze the cases where the error pattern crosses the insertion/removal boundaries; however, it can be  
10 shown that the error detection characteristics of the FCS are preserved in these cases as well.

11 The conclusion from the above examples is that, as long as the field values used in the calculation of these  
12 FCS correction factors are the same as the field values present in the original and final messages (e.g., that  
13 the same value of  $H+E$  is used both in its original and shifted forms), then the properties of the FCS are  
14 preserved. However, if different values are used for calculation of the correction factor from those present in  
15 the messages (as could happen, for example, as a result of in-memory corruption), then the properties of the  
16 FCS are no longer preserved. Hence, if these algorithmic approaches are used, it is necessary to design the  
17 implementation in a manner that ensures that these conditions are met.

## 18 **O.5 Conclusions**

19 Where it is necessary to recalculate the FCS before transmission, then either the algorithmic FCS  
20 modification approaches or the Detection Lossless Circuit approach offer a basis for this to be achieved  
21 while still preserving the error detection coverage that was provided by the original FCS.

22 The Detection Lossless Circuit approach requires access to the entire contents of the original message, to  
23 compute the necessary FCS adjustments or to check the integrity of the data that is being used to create the  
24 new message and its FCS. In contrast, the algorithmic approach requires access only to the header, insert,  
25 and FCS of the original message.

26 With the algorithmic approach, care needs to be taken in the implementation in order to ensure that the  
27 inputs to the correction algorithms are consistent with the contents of the original and modified messages,  
28 whereas in the Detection Lossless Circuit, such consistency checking is inherent in the way that the original  
29 FCS is used to check the generation of the new FCS.

## **Annex P**

### **(informative)**

## **Frame duplication and misordering**

Although RSTP provides a single loop-free path between communicating stations at any instant, RSTP can reconfigure the active topology of the Bridged Network in less time than it can take a frame to transit from its source to its destination(s). This annex explains how this can result in user data frame duplication and misordering and examines the possible QoS impact.

NOTE—The ForceVersion parameter provided by RSTP allows network administrators to choose slower reconfiguration, thereby trading off service availability against the risk of duplication and misordering.

### **P.1 Background**

In a network of Bridges implementing STP, specified in the 1998 and earlier editions of IEEE Std 802.1D [B13], delays in transitioning Ports to Forwarding ensure that frames in transit prior to a network reconfiguration are delivered or discarded before being forwarded on the new active topology. In such a network, the only source of misordered or duplicated frames is a “magically healed” LAN between two Bridges, for example, as a result of accidental interconnections between shared media hubs.

RSTP, by design, can transition a Port to Forwarding very rapidly. A Root Port transition can occur as rapidly as the hardware can manage it, and a Designated Port transition in the time it takes to transmit two frames from separate stations on a single LAN. It is conceivable that a reconfiguration can take place, and a Port be made Forwarding as a result, while frames forwarded on the prior active topology are still in transit.

### **P.2 Frame duplication**

A unicast frame whose destination address has been learned by the Bridges that can forward it, can only be buffered for transmission on one Port of one Bridge at any one time, and cannot be duplicated.

A unicast frame whose destination address has not been learned, can be flooded by some Bridges, and therefore buffered on multiple outbound Ports at the same time, and can be duplicated during network reconfiguration. Figure P-1 provides an example. In this network fragment, the Root Bridge is assumed to be somewhere to the left of Bridge A’s Port A1, and the Port Path Costs of the three Bridges result in the active topology shown, with Port B3 Discarding and the remaining Ports all Forwarding.

If the configuration is stable, a unicast frame arriving at A1 and destined for an unlearned unicast destination reachable through B2 is flooded by Bridge A to its Ports A2 and A3, and by Bridge C to its Ports C2 and C3. As B3 is Discarding, only the frame reaching B1 is transmitted through B2, and the destination receives a single copy of the frame.

During reconfiguration the following sequence of events can occur:

- a) A receives the frame through A1 and transmits copies of it through A2 and A3.
- b) B and C each receive a copy and queue them for transmission through B2, C2, and C3.
- c) B2 transmits its copy of the frame to its destination.
- d) B detects that LAN A2-B1 has failed, and immediately makes B3 Forwarding as its new Root Port.
- e) C2 transmits its copy of the frame, B receives and transmits this second copy through B2.

1 The destination station, reachable through B2, receives the same frame twice. However, any subsequent  
2 response from the destination station would cause the address to be learned. While this reconfiguration will  
3 itself cause addresses to be flushed from the Bridge's FDBs of Bridges, the flushing commences after the  
4 Port becomes Forwarding, and will not increase frame duplication unless there are further changes in the  
5 active topology.

**Figure P-1—Frame duplication scenario**

6 Multicast frames are all potentially subject to duplication on reconfiguration events, as they can be buffered  
7 at multiple outbound Ports. Frame duplication does not cause problems in known multicast LAN protocols.

8 The risk of frame duplication depends upon network configuration, frequency of reconfiguration, equipment  
9 implementation details, and the characteristics of the network traffic that determine how long each frame is  
10 likely to be buffered in each Bridge, and therefore cannot be quantified without reference to the a particular  
11 network.

### 12 P.3 Frame misordering

13 A change in the active topology between two communicating end stations can result in frame misordering,  
14 as a frame sent after reconfiguration can experience a lower transit delay, being queued at fewer Bridge Ports  
15 or for less time. Figure P-2 provides an example. In this network fragment a station connected to A1 is  
16 communicating with a station connected to B2. Prior to reconfiguration, A2 is an Alternate Port and is  
17 Discarding; all traffic between the two stations is relayed by Bridge C. During reconfiguration the following  
18 sequence of events can occur:

- 19 a) Frame F1 is received through A1, buffered and transmitted through A3, received through C1 and  
20 buffered awaiting transmission through C2.
- 21 b) A detects that LAN A3-C1 has failed, and immediately makes A2 Forwarding as its new Root Port.
- 22 c) Frame F2 is received through A1, transmitted through A2 to B1, and then transmitted through B2.
- 23 d) F1 is transmitted through C2 to B3, and then transmitted through B2.

24 Clearly, the receiving station connected to B2 sees the frames in the reverse of the order in which the  
25 originating station transmitted them.

**Figure P-2—Frame misordering scenario**

1 As with frame duplication, the overall risk of frame misordering depends upon network configuration,  
2 frequency of reconfiguration, equipment implementation details, and the characteristics of the network  
3 traffic that determine how long each frame is likely to be buffered in each Bridge, and therefore cannot be  
4 quantified without reference to the a particular network.

5 Some LAN protocols, for example LAT, LLC2, and NETBEUI, are sensitive to misordering, so even a low  
6 incidence of misordering could result in perceived problems in networks that support these protocols.

## 7 **P.4 Other considerations**

8 The possibility that frames may be stored “in transit” on old routes after a reconfiguration has completed  
9 means that there is also a possibility that addresses will be mis-learned, leading to a risk of denial of service  
10 for the addresses concerned. Hence, it is necessary to run short aging timers for a period after a  
11 reconfiguration to allow such frames to be delivered or discarded.

12 The Bridge model described in this standard does not include the concept of queuing on input to a Port;  
13 however, practical Bridge designs generally include some input queuing. While this is not a solution to the  
14 effects described above, a Bridge should flush any input queue associated with a Port that becomes  
15 Disabled. This behavior is consistent with the Bridge model; if a frame is in an input queue, it has not been  
16 received as far as the Bridge Port is concerned, and therefore should not be received after the Port becomes  
17 Disabled.

## 1 **Annex Q**

### 2 (informative)

## 3 **Traffic scheduling**

4 This annex provides some background to the mechanisms provided in this standard for traffic scheduling,  
5 with the intent of providing some insight into the motivation for the provision of mechanisms for traffic  
6 scheduling and some of the ways that the mechanisms might be used.

### 7 **Q.1 Motivation**

8 Some applications have a need for frame delivery that is highly predictable in terms of the time at which  
9 frame transmission will occur, and the overall latency and jitter that will be experienced as the frame is  
10 propagated to its destination. Examples include industrial and automotive control applications, where data  
11 transmitted over the network is used to feed the parameters of control loops that are critical to the operation  
12 of the plant or machinery involved, and where frames carrying control data are transmitted on a repeating  
13 time schedule; late delivery of such frames can result in instability, inaccuracy, or failure of the operation of  
14 the control loops concerned. In some implementations, this need has been met by the provision of dedicated,  
15 highly engineered networks that are used solely for the transmission of time-critical control traffic; however,  
16 as the bandwidth occupied by such traffic is often low, and the cost of providing a dedicated control network  
17 can be high, it can be desirable to mix time-critical traffic with other classes of traffic in the same network,  
18 as long as such mixing can be achieved while still meeting the timing requirements of the time-critical  
19 traffic.

20 Prioritization alone is insufficient to address the needs of this kind of traffic; if a low priority frame is  
21 already being transmitted, then that transmission will complete before a higher priority frame can access the  
22 transmission medium, so there could be a delay of up to a maximum-sized frame before a high priority  
23 transmission can start. If such delays occur at every hop, then the accumulated latency could be  
24 unacceptably large.

25 Interfering traffic can itself be time-critical; for example, there could be multiple time-critical traffic streams  
26 related to different control systems. The ability to coordinate different time-critical traffic streams in such a  
27 way that they do not interfere with each other is also important.

28 One approach to meeting these objectives is to ensure that, at specific times, only one traffic class (or set of  
29 traffic classes) has access to the network; in effect to create a protected “channel” that is used by that traffic  
30 class alone. However, in order to ensure that the remaining unprotected traffic cannot affect the transmission  
31 of protected traffic, it is necessary to stop the transmission of unprotected traffic sufficiently far in advance  
32 of the protected time slot to be certain that the last unprotected transmission has completed before protected  
33 transmission starts. In the worst case, this would mean that the last unprotected transmission would start a  
34 maximum-sized frame transmission time before the start of the protected traffic “window.” In effect, a guard  
35 band is created before the time that the protected traffic transmission is due to start; transmission of  
36 unprotected traffic is not permitted between the start of the guard band and the start of the protected traffic  
37 window. The simplest approach is for the guard band to be as long as a maximum-sized frame transmission;  
38 however, the start of the guard band need not be fixed if the implementation is able to determine, from the  
39 size of the frames that it has queued, that there is sufficient time for a frame to be transmitted in its entirety  
40 before the start of the protected traffic window. This approach is illustrated in Figure Q-1. If the simple  
41 approach were taken, then the time difference between T0 and T1 would be equal to the transmission time of  
42 a maximum-sized frame on that port (Figure Q-1, part A); if the implementation is able to determine frame  
43 transmission times on the fly, then T0 could vary between a maximum frame transmission time before T1  
44 and a minimum frame transmission time before T1, depending upon what unprotected frames were available  
45 for transmission on the Port (Figure Q-1, part B).

**Figure Q-1—Establishing a guard band**

## 1 Q.2 Using gate operations to create protected windows

2 The enhancements for scheduled traffic described in 8.6.8.4 allow transmission to be switched on and off on  
3 a timed basis for each traffic class that is implemented on a port. This switching is achieved by means of  
4 individual on/off transmission gates associated with each traffic class and a list of gate operations that  
5 control the gates; an individual SetGateStates operation has a time delay parameter that indicates the delay  
6 after the gate operation is executed until the next operation is to occur, and a GateState parameter that  
7 defines a vector of up to eight state values (open or closed) that is to be applied to each gate when the  
8 operation is executed. The gate operations allow any combination of open/closed states to be defined, and  
9 the mechanism makes no assumptions about which traffic classes are being “protected” and which are  
10 “unprotected”; any such assumptions are left to the designer of the sequence of gate operations. The  
11 sequence of gate operations terminates at the end of the list, and restarts when OperCycleTime (8.6.9.4.19)  
12 nanoseconds have elapsed since the start of the sequence, thus providing a repeating cycle of gate state  
13 changes. If OperCycleTime is shorter than the total execution time of the sequence of operations, the  
14 sequence is truncated and restarted at OperCycleTime.

15 There is no necessity to explicitly define the start of a guard band, as the specification of how the gates  
16 operate states that a frame for a given traffic class can only be transmitted if the gate associated with that  
17 traffic class is open and there is sufficient time for the whole of the frame to be transmitted before the gate is  
18 due to close. Figure Q-2 illustrates how gate operations could be used to create a protected window for  
19 traffic class 3 in order to achieve the result illustrated in Figure Q-1. A SetGateStates operation at time T1  
20 sets the state of the gates for traffic classes 7, 6, 5, 4, 2, 1, and 0 to closed (C) and sets the state of the gate for  
21 traffic class 3 to open (o), so only traffic class 3 can transmit after T1. At time T2, the SetGateStates  
22 operation reverses the state for all eight traffic classes, so traffic class 3 can no longer transmit after T1, but  
23 all other traffic classes can.

24 There is no need to explicitly define the position of T0, because the “guard band” behavior is inherent in the  
25 defined behavior of the gates, as previously stated.

**Figure Q-2—Using gate operations**

### 1 Q.3 Availability of PTP

2 The timing of gate operations as specified in 8.6.8.4 assumes that PTP is operating and therefore PTP time is  
3 available to the Bridge or end station. However, that is clearly not the case on initial startup or when PTP  
4 communication is interrupted for some reason; particular implementations could also choose to use  
5 alternative (non-PTP) mechanisms for ensuring that a common view of time is available across a number of  
6 systems. The approach adopted in these circumstances will be heavily dependent on the application, and so  
7 is an implementation choice; the mechanisms described in 8.6.8.4 are not themselves affected by that choice.

### 8 Q.4 Scheduled traffic and end stations

9 It is possible for Bridges to support the enhancements for scheduled traffic while end stations connected to  
10 those Bridges do not. In general, the scheduling mechanism is not needed in end stations that are only  
11 recipients of scheduled traffic.

### 12 Q.5 CycleTimeExtension variables

13 The AdminCycleTimeExtension (8.6.9.4.4) and OperCycleTimeExtension (8.6.9.4.20) state machine  
14 variables provide a means for an operator to control how a new gating cycle is configured into a system that  
15 is already running an existing gating cycle.

16 If the choice of cycle time for the new gating cycle (AdminCycleTime) is unchanged from the cycle time for  
17 the old gating cycle (OperCycleTime), and if the base time chosen for the new gating cycle  
18 (AdminBaseTime) is an integer multiple of the OperCycleTime different to OperBaseTime, then the new  
19 gating cycle will exactly “line up” with the old gating cycle, i.e., the cycle start times for the new gating  
20 cycle will be the same as they would have been for the old configuration. This could be considered to be the  
21 ideal case and allows the new gating cycle to be installed and executed with no timing issues.

22 However, if AdminCycleTime differs from OperCycleTime, and/or AdminBaseTime is in the future and is  
23 not an integer multiple of OperCycleTime different to OperBaseTime, then the old and new cycles do not  
24 line up, and when AdminBaseTime is reached (i.e., when the new configuration is installed and starts to  
25 execute), the last old cycle would normally be truncated in order to start the first new cycle. This could be  
26 undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the  
27 penultimate old cycle by that small amount, rather than starting a very short cycle. The CycleTimeExtension  
28 variables allow this extension of the last old cycle to be done in a defined way; if the last complete old cycle  
29 would normally end less than OperCycleTimeExtension nanoseconds before the new base time, then the last  
30 complete cycle before AdminBaseTime is reached is extended so that it ends at AdminBaseTime.

## 1 **Annex R**

2 (informative)

### 3 **Preemption and IEEE 802.1AE MAC Security**

4 This annex answers questions about the use of MAC Security (MACsec) that arose in the development of  
5 the IEEE Std 802.1Qbu (Frame Preemption) amendment to this standard. It provides background for readers  
6 not familiar with MACsec. For the normative specification of MACsec and its supporting authentication and  
7 key management framework refer to IEEE Std 802.1AE and IEEE Std 802.1X.

8 NOTE—While these issues arose during development of preemption, they can also apply to other situations, such as a  
9 customer link running MACsec over a provider bridged network.

10 Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower  
11 priority (preemptible) frame, the preemptible frame transmission being resumed and completed once the  
12 express frame(s) have been transmitted. A preemptible frame can thus be broken into two or more  
13 fragments. A MACsec Cipher Suite implementation can protect each frame in its entirety before requesting  
14 its transmission, or can transmit the octets of the protected frame as soon as they are made available by the  
15 operation of the block by block symmetric cryptography. The latter is often preferred as it reduces the delay  
16 due to protection, and some implementations impose a constant delay in support of time-sensitive  
17 networking objectives. Similarly validation of a received frame can be delayed until its reception is  
18 complete, or can proceed as each block of octets becomes available. These implementation details lie  
19 outside the normative scope of IEEE Std 802.1AE, but naturally give rise to questions as to how frames  
20 should be protected when they are fragmented, particularly when the symmetric keys used to protect frames  
21 are being changed.

22 Each time a Cipher Suite's symmetric cryptography is used to protect a frame with a given key, a unique  
23 value, known as a 'nonce' or IV (initial value), has to be included in the computation. A PN (packet number)  
24 that is incremented for each frame transmitted forms part of the MACsec IV. A replayProtect control with a  
25 configurable replay window allows the receiver to use the PN to protect against misordered, replayed, and  
26 much delayed frames. A frame whose PN value is less than the highest received with a successfully  
27 validated frame (from the same source, protected by the same key) minus the replay window size is  
28 discarded. Setting the replay window size to zero and enabling replayProtect enforces strict replay  
29 protection, no out of order or replayed frames are accepted. The transmitter of each MACsec frame is  
30 identified by a Secure Channel Identifier (SCI), and the Secure Channel (SC) that allows it to communicate  
31 securely with its peers in a secure Connectivity Association (CA) is supported by a sequence of Secure  
32 Associations (SAs). Each SA is replaced by its successor when its associated secret Secure Association Key  
33 (SAK) can no longer be used, either because all or most of the PN space has been used with one of the SAs  
34 in the CA, or because the network administrator has a security policy that mandates regular key changes  
35 (often once a week). New SAs and SAKs are also required after reauthentication and reauthorization, when  
36 the (possibly changed) members of a CA acquire a fresh secure Connectivity Association Key (CAK), the  
37 shared secret key whose possession permits participation in the CA and that is used by the MAC Security  
38 Key Agreement protocol (MKA) to identify the CA members to each other and to distribute SAKs.

39 MACsec connectivity is not interrupted or delayed by SA and SAK changes. The SCI and the Association  
40 Number (AN), a two-bit circular sequence number that identifies the SA within the SC, are communicated  
41 by the MAC Security TAG (SecTAG) and form part of the IV. Their values thus have to be decided and  
42 encoded in the frame to be transmitted prior to encipherment. The MACsec operational and management  
43 models reflect the fact that, at any instant, the frame whose SecTAG is currently being encoded can be using  
44 a different SA and SAK than the frame currently being cryptographically processed. This accommodates  
45 implementations that buffer user transmit requests for performance or implementation reasons (e.g., to allow  
46 parallel processing). A transmit SA/SAK is not deleted until sometime after it has ceased to be used.  
47 Similarly an implementation that is enciphering a preemptible frame block by block can suspend its

1 cryptographic operation, encipher an express frame that has been assigned to a subsequent SA, and resume  
2 processing the preempted frame using the IV already encoded, the SAK identified by the SCI and AN for  
3 that IV, and the intermediate results produced by the Cipher Suite up to the point that the frame was  
4 preempted. The Integrity Check Value (ICV) generated, and appended to the MACsec protected frame,  
5 protects the entire frame. An attacker cannot omit a fragment or substitute one for another. The ICV also has  
6 exactly the same value that would be obtained by protecting the entire frame prior to transmitting any of its  
7 octets, which is important for reasons that go beyond facilitating interoperability between different styles of  
8 implementation. While MACsec protects communication between neighboring peer users of the MAC  
9 Service, those service instances can be supported by bridging at a lower layer. Communication between two  
10 C-VLAN Bridges can be supported by individual LANs connected by TPMRs, or by S-VLAN Bridges, for  
11 example. The receiving MAC Security Entity (SecY) that validates a preemptible frame can receive it in  
12 fragments that differ from those transmitted by the port and SecY that originally protected the frame, and is  
13 not necessarily aware that the received frame was fragmented en-route. The first of two TPMRs supporting  
14 a link between two C-VLAN Bridges (for example) might reassemble all received frames prior to  
15 forwarding, thus allowing express frames to overtake preemptible frames on the link connecting the TPMRs  
16 without fragmenting the latter.

17 Just as the use of an SA can be overlapped with the use of its successor on transmission, each receive SA and  
18 its successor are enabled for reception for 3 seconds after an MKA Key Server tells the other member(s) of  
19 the CA to start transmitting using a new SAK and SA(s). Thus the receipt of an express frame protected with  
20 a new SAK does not preclude the receipt and validation of a preempted frame, protected with the prior SAK,  
21 after its final fragment (including the protected frame's ICV) has been received.

22 IEEE Std 802.1AE describes the use of MACsec in a number of different systems, interface stacks, and  
23 interworking scenarios. When MACsec is used to secure connectivity across a provider network, the  
24 protected frame can be priority-tagged (6.13) so the provider can forward frames of different priorities  
25 appropriately, even if the contents of those frames is otherwise confidential, and they can be received and  
26 validated out of order just as they might be if some frames had been preempted en-route. The receiving  
27 SecY's replay window size can be managed to accommodate these frames, though it is not always easy to  
28 determine or predict an optimal value for the size of replay window that is needed. MACsec's strict replay  
29 protection can also be retained by assigning transmitted frames for different service access priorities (or for  
30 express and preemptible frames) to different SCs, each supported by its own sequence of SAs. From the  
31 point of view of a receiving SecY, the separate SCs behave just as if they had been transmitted by separate  
32 SecYs. IEEE Std 802.1AE allows the choice of SCI and access priority<sup>79</sup> to be determined by the frame's  
33 user priority.<sup>80</sup> (See Seaman [B62].)

<sup>79</sup> The priority value accompanying the service request made at the SecY's lower Common Port to transmit the protected frame.

<sup>80</sup> The priority value provided by the service request, to protect and transmit the frame, made at the SecY's upper Controlled Port.

## 1 **Annex S**

### 2 **(informative)**

### 3 **Preemption and scheduled traffic**

4 The enhancements for scheduled traffic specified in 8.6.8.4 and the support for frame preemption specified  
5 in 6.7.2 and 8.6.8 can be used individually or in combination in order to provide different degrees of  
6 protection to “time-sensitive traffic” from interference caused by traffic with less stringent timing  
7 requirements. The choice of which features to use, and in what combination, will depend upon the latency  
8 and jitter requirements of the application concerned. There are four permutations of interest. They are as  
9 follows:

- 10 a) Scheduling used in isolation (S.1)
- 11 b) Preemption used in isolation (S.2)
- 12 c) Scheduling and preemption used in combination, but without use of HOLD and RELEASE (S.3)
- 13 d) Scheduling and preemption used in combination, with use of HOLD and RELEASE (S.4)

14 NOTE—As the only MAC standard for preemption at the time this annex was developed was IEEE Std 802.3, it reflects  
15 constraints that exist in that particular approach to preemption.

#### 16 **S.1 Scheduling used in isolation**

17 This subject is dealt with in Annex Q.

#### 18 **S.2 Preemption used in isolation**

19 Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower  
20 priority (preemptable) frame, the preemptable frame transmission being resumed and completed once the  
21 express frame(s) have been transmitted.

22 The ability to designate one or more priority as express (and the remaining priorities as preemptable) means  
23 that, when an express frame is ready for transmission and a preemptable frame is already in the process of  
24 being transmitted, the delay before the express frame transmission starts is at worst 123 octet times and will  
25 often be 64 octet times or less. Preemption, used without scheduling, is therefore a useful tool for reducing  
26 the jitter experienced by time-sensitive frames. These frames could be transmitted using any of the available  
27 transmission selection algorithms (Table 8-6), but the likely choice would be an algorithm that is intended  
28 for use with time-sensitive data, such as the credit-based shaper (8.6.8.2). In common use cases, it would be  
29 expected that express traffic would have a higher priority than preemptable traffic.

30 NOTE 1—IEEE Std 802.3 defines a minimum final fragment size of 64 octets and allows the receiver to request that any  
31 non-final fragments are larger than this by 0, 64, 128, or 192 octets. Therefore, the minimum non-final fragment size is  
32 64, 128, 192, or 256 octets, depending upon the non-final fragment size stipulated by the receiving MAC. For the  
33 purposes of the discussion in this annex, it is assumed that the minimum non-final fragment size selected is 64 octets.

34 NOTE 2—The 123 octet times worst-case delay is because non-final fragments have to be 64 octets in length, including  
35 the mCRC that is added by the MAC Merge sublayer, so a fragment that is 124 (60 + 64) octets in length can be  
36 preempted, but a fragment that is 123 or fewer octets in length cannot be preempted. This occurs when transmission has  
37 just started for a fragment of a frame with less than 124 octets left to transmit, or for a preemptable frame of less than  
38 124 octets in total. The more likely case is that the delay would be between 0 and 64 octet times. The actual delay  
39 experienced also has to take account of the extra overheads imposed by the need for preamble, start of frame delimiter  
40 (SFD), inter-frame gap (IFG), and the latency of the MAC itself.

41 It should be noted that, other things being equal, designating a priority as “express” effectively increases its  
42 priority above that of any priority designated as “preemptable”. Also, in cases where the number of traffic

1 classes supported on a port is less than 8, all priority values that map to the same traffic class should have the  
2 same designation (all express or all preemptable).

3 If preemptable and express priorities are assigned to the same traffic class, an express frame might not be  
4 able to preempt a preemptable frame that is ahead of it in the queue.

### 5 **S.3 Scheduling and preemption used in combination, no HOLD/RELEASE**

6 The discussion of scheduling in Annex Q points out that there is no need for an explicitly scheduled “guard  
7 band” when using the scheduling mechanism in isolation, because the specification of the operation of the  
8 transmission gates is such that, in a conformant implementation, a frame cannot start transmission if the  
9 transmission gate for its traffic class is due to close before transmission of the frame would complete.  
10 However, the requirement not to transmit a frame if transmission cannot complete before the gate closes  
11 means that, depending upon the size of frames in the queue, there would be a significant length of time  
12 during which frames cannot be transmitted.

13 If the schedule that applies to the preemptable traffic classes was designed to allow preemptable traffic to be  
14 transmitted at any time (i.e., there is no “gate close” event for the preemptable traffic), then preemptable  
15 frame transmission can occur at any time up to the start of an express transmission, and depending upon the  
16 timings, can continue up to 123 octet times after the express traffic gate opens. This dramatically reduces the  
17 delay experienced by preemptable traffic, at the expense of increasing the delay experienced by express  
18 traffic. While that may be acceptable for some applications, it is clearly not acceptable for applications  
19 where it is desired to reduce or remove any delay experienced by express frames.

### 20 **S.4 Scheduling and preemption used in combination with HOLD/RELEASE**

21 The HOLD and RELEASE mechanism provided by preemption (6.7.2, 12.30.1) allows an explicit “guard  
22 band” to be implemented around a protected transmission window, but one that is rather smaller than would  
23 otherwise be needed. As with S.3, this scenario assumes that the preemptable traffic’s gate is scheduled to be  
24 open at all times. If an MM\_CTL.request(hold\_req) primitive is scheduled 124 octet times before the  
25 express traffic window opens, then preemptable frame transmission can start up to 124 octet times before the  
26 start of the protected window, and can potentially continue up to (but not beyond) the start of the window.

27 The result of using scheduling, HOLD/RELEASE and preemption in combination is that the express traffic’s  
28 protected window can be completely protected from interference from preemptable traffic, while at the same  
29 time reducing the impact of the protected window on the amount of bandwidth that is available to  
30 preemptable traffic.

31 A further reason to use HOLD and RELEASE is that a schedule will often be intended for a string of express  
32 frames to be sent within an open window. If HOLD/RELEASE is not used and there is a greater than IPG  
33 gap between transmitting express frames (e.g., because of minor jitter in their arrival time), a preemptable  
34 frame or fragment could be started between express frames and cause up to 124 octets of latency in the  
35 middle of the string of express frames. Using HOLD ensures that this will not happen.

### 36 **S.5 Bandwidth allocation and express traffic**

37 The implementation of preemption in an IEEE 802.3 MAC (see IEEE Std 802.3) does not enforce a limit on  
38 how long a preemptable frame can be preempted by express traffic. This is at odds with the following:

- 39 a) Transit delay requirements of a bridge, if there is any preempted traffic present.
- 40 b) The impossibility, as shown by queuing theory, of arranging express traffic to occupy exactly 100%  
41 of the available bandwidth in the absence of unbounded queues.

1 For effective use of preemption, system-wide mechanisms, such as bandwidth allocation, must operate so as  
2 to keep the bandwidth allocated to express traffic below 100% as judged on timescales comparable to the  
3 delays tolerated by time-sensitive traffic.

4 The fact that preemption can add delay that is invisible to transit delay protection could be addressed by  
5 schedules being set such that express traffic windows are short enough and gaps between them are short  
6 enough that the worst case time to send a preemptable frame is much less than transit delay requirements.  
7 For example, if transit delay is one second, the time between express windows is greater than the maximum  
8 transmission time for a single frame, and express window size is small compared to one second (e.g., <50  
9 ms), then preemption will not add significantly to worst-case transit delay.

10 For preemption without scheduling, there is no guarantee on the added latency, but that alternative should be  
11 used when the volume of express traffic is expected to be small. If the express traffic is using a shaper, such  
12 as the credit-based shaper, that could put a similar reasonable bound on transit delay.

# Annex T

## (informative)

### Cyclic queuing and forwarding<sup>81</sup>

#### T.1 Overview of CQF

Cyclic queuing and forwarding (CQF) is a method of traffic shaping that can deliver deterministic, and easily calculated, latency for time-sensitive traffic streams. As the name implies, the principle underlying CQF is that stream traffic is transmitted and queued for transmission along a network path in a cyclic manner. Time is divided into numbered time intervals  $i$ ,  $i+1$ ,  $i+2$ , ...  $i+N$ , each of duration  $d$ . Frames transmitted by a Bridge, *Alice*, during time interval  $i$  are received by a downstream Bridge, *Bob*, during time interval  $i$  and are transmitted onwards by *Bob* towards Bridge *Charlie* during time interval  $i+1$ , and so on. A starting assumption is that, for a given traffic class, all Bridges and all end stations connected to a given bridge have a common understanding (to a known accuracy) of the start time of cycle  $i$ , and the cycle duration,  $d$ .

Frames transmitted by *Alice* during interval  $i$  are transmitted by *Bob* in interval  $i+1$ ; the maximum possible delay experienced by a given frame is from the beginning of  $i$  to the end of  $i+1$ , or twice  $d$ . Similarly, the minimum possible delay experienced is from the end of  $i$  to the beginning of  $i+1$ , which is zero. More generally, the maximum delay experienced by a given frame is:

$$(h+1) \times d$$

and the minimum delay experienced by a given frame is:

$$(h-1) \times d$$

where  $h$  is the number of hops.

This illustrates the attraction of CQF as a technique for handling time-sensitive traffic; the latency introduced as a frame transits the network is completely described by the cycle time and the number of hops, and is unaffected by any other topology considerations, including interference from other non time-sensitive traffic. This only holds, however, if frames are kept to their allotted cycles; if, for example, some of the frames that were expected to be received by *Bob* during cycle  $i$  do not appear until cycle  $i+1$  has started, then the stated assumptions about maximum latency calculation no longer hold. Careful choice of cycle times, alignment of cycle times among the Bridges in the network, and the timing of first and last transmissions within a cycle are required in order to ensure that the desired latency bounds are achieved.

Any delays through a particular intermediate relay (for example, *Bob*) do not affect the end-to-end delay so long as *Bob*'s performance does not affect the correct assignment of frames to time intervals.

Since one of the goals for the handling of time-sensitive streams is zero frame loss (assuming that no unrecognizable non-conformant traffic is present), it is prudent to assume that reception is continuous—a frame received by a downstream system will always be assigned to one interval or another. This places most of the burden of correct interval assignment on the transmitting system; frames should not be transmitted if incorrect interval assignment is possible upon reception. It is therefore necessary to define the anticipated (and accommodated) errors in reception assignment with respect to the point in interval time,  $t$ , where interval  $i-1$  becomes interval  $i$ . A relay (such as *Bob*) can of course choose when to start reception assignment to  $i$  in relation to  $t$ ; it is assumed that *Bob*'s intent is that the earliest frame to be assigned to  $i$  is the first whose very last octet (or other frame transmission encoding symbol) is still on the transmission medium (or other definable external event to what is considered to be *Bob* reference point) at  $t$ , thus placing any accommodation of known implementation dependent delays within *Bob* under *Bob*'s control.

<sup>81</sup> In early discussions, CQF was known as the “Peristaltic Shaper” [B67].

1 While *Bob* attempts to start *i* reception with a frame coming off the medium at *i*, and may factor known and  
2 repeatable internal delays into the way he goes about that intent, his actual start time depends on:

- 3 a) The error in *Bob*'s time sync (i.e., the error in his determination as to when *t* actually occurs).
- 4 b) The maximum deviation (jitter) in *Bob*'s use of that time.
- 5 c) Additional delays that *Bob* does not account for, such as delays in selecting the output queue to be  
6 used for *i*.

7 *Alice* has to stop transmitting frames for *i*–1 before *t*, by a time that is the sum of *Bob*'s possible early start of  
8 *i* as a consequence of a) through c), and the following:

- 9 d) The error in *Alice*'s time sync (i.e., the error in her determination as to when *t* occurs).
- 10 e) The maximum deviation (jitter) in *Alice*'s use of that time.
- 11 f) The time between *Alice* deciding to commit a frame for transmission and the appearance of the last  
12 octet/symbol “on the medium” at *Alice*'s end.
- 13 g) The length of “the medium” in transmission time, i.e., the time for the last octet/symbol to leave  
14 *Alice* and reach *Bob*, including any consideration of the effect of interfering frames or fragments.

15 The description of CQF in terms of a number of consecutive intervals (as opposed to their support by “odd/  
16 even” queues, as discussed in T.2 onwards) gives easy answers to what to do with traffic still queued when  
17 its selected transmission interval has expired—discard it, or mark it down (discard eligible or priority  
18 change) and generate an alarm. In an environment where the stream bandwidth is allocated appropriately  
19 (i.e., the bandwidth allocated per time interval is less than can be received/transmitted in the chosen interval  
20 duration), this will be a rare occurrence, the traffic that follows will be conformant, and the overall system  
21 performance will be recoverable.

22 The discussion so far has assumed that all link speeds are the same; however, the situation becomes more  
23 complicated when links of different speeds are considered. One typical arrangement might comprise low  
24 speed links at the start and end of the path (network periphery to periphery), another with the high speed  
25 towards one end (periphery to core or vice versa). Taking the first of these, and placing *Alice* at the first  
26 transition from slow to fast, *Bob* as her fast neighbor, *Charlie* as his fast neighbor, and *Donald* at the  
27 transition from fast to slow, the important thing (treating the fast core of the network as a CQF black box) is  
28 that all conformant traffic received by *Alice* in interval *i* (say) is transmitted by *Donald* in a later interval  
29 *i*+*n*. A number of internal arrangements might be made between *Alice*, *Bob*, *Charlie*, and *Donald* to make  
30 this happen and would be valid from an external CQF perspective. It is also possible to consider fractional *n*,  
31 where *n* is still > 1, as *Alice* may need to collect the entirety of any slow cycle before transmitting that in a  
32 more compressed burst into the rest of the fast network. More complex possibilities are equivalent to  
33 redefining the slow cycle time. Some of the less elaborate possibilities for the use of links of different speeds  
34 are discussed in T.5.

## 35 T.2 An approach to CQF implementation

36 In essence, the approach involves the use of two transmission queues and a cycle timer. During even  
37 numbered cycles (intervals), queue 1 accumulates received frames from the Bridge's reception Ports (and  
38 does not transmit them), while queue 2 transmits any queued frames from the previous odd-numbered cycle  
39 (and does not receive any frames). During odd-numbered cycles, queue 2 accumulates received frames from  
40 the Bridge's reception Ports (and does not transmit them), while queue 1 transmits any queued frames  
41 from the previous even-numbered cycle (and does not receive any frames). With appropriate choice of  
42 receive and transmit cycle times (see T.5), such that, for any given stream, the cycle is at least long enough  
43 to accommodate all of the time-sensitive traffic that will need to be transmitted on the Bridge Port during the  
44 class measurement interval for that stream (see 34.6.1.1, also known as the observation interval in  
45 IEEE Std 802.1BA™ [B11]), plus a maximum-sized interfering frame (or frame fragment, if preemption is  
46 supported), then all of the stream's traffic will be accumulated during the cycle time in queues that are in  
47 receive mode, and it will all be transmitted during the cycle time when the queues switch to transmit mode.

1 CQF is implemented by configuring a combination of the stream gate control mechanisms defined in 8.6.5.4  
2 and the traffic scheduling mechanisms defined in 8.6.8.4 and 8.6.9. Per-stream filtering is used to direct  
3 received frames to one of a pair of outbound queues on a timed basis, determined by the cycle time of the  
4 per-stream filter, and traffic scheduling is used to ensure that frames are transmitted from the appropriate  
5 queue using the same cycle time, as described in the rest of this annex.

## 6 T.3 Use of Per-Stream Filtering and Policing for CQF

7 The first step in establishing the filtering and queuing structures needed for CQF is to set up one or more  
8 stream filters (8.6.5.3) and a stream gate instance (8.6.5.4) that will be receiving incoming time-sensitive  
9 frames. The stream filter(s) are configured so that all time-sensitive frames received on a given Port are  
10 directed to the same stream gate instance; in turn, the stream gate instance is configured so that the internal  
11 priority value (IPV) associated with the time-sensitive frames will direct them to one of two outbound  
12 queues on a timed basis. The use of the IPV allows this direction of frames to outbound queues to be  
13 independent of the received priority, and also does not affect the priority associated with the frame on  
14 transmission.

### 15 T.3.1 Stream filter configuration

16 The simplest stream filter configuration would be achieved where the same priority is used for all time-  
17 sensitive frames (and this priority is not used for any other frames); for example, the default priority  
18 assigned to SR class A (see Clause 34) could be used, in which case, the priority associated with the time-  
19 sensitive frames would be 3. The parameters that would define the stream filter for the time-sensitive frames  
20 would then be as follows:

- 21 a) The *stream handle specification* would take the wild-card value.
- 22 b) The *priority specification* would take the priority value 3.
- 23 c) The *stream gate instance identifier* would take the value of the instance identifier for the stream gate  
24 (T.3.2).
- 25 d) In the simplest case, there would be no further per-stream classification and metering operations  
26 (8.6.5.2); however, these could be added as appropriate, for example if the maximum SDU size  
27 (8.6.5.3.1) for the time-sensitive traffic is bounded at a value less than the maximum SDU size for  
28 the medium.

29 This stream filter configuration results in all frames that carry a priority value of 3 being submitted to the  
30 stream gate. As the operation of stream filters is such that received frames that do not match a stream filter  
31 are handled as if subsequent per-stream classification and metering operations were not implemented, there  
32 is no need for further stream filter configuration to handle frames that carry priorities other than 3 unless  
33 there are other filtering or gating decisions that need to be taken for such frames.

### 34 T.3.2 Stream gate configuration

35 The *stream gate instance* (8.6.5.4) needed to support the stream filter described in T.3.1 has a *stream gate*  
36 *control list* that contains two entries, each containing a SetGateAndIPV operation, with parameters as  
37 follows:

- 38 1) StreamGateState = *open*, IPV = 7, TimeInterval = T
- 39 2) StreamGateState = *open*, IPV = 6, TimeInterval = T

40 This control list has the effect of directing any traffic that passes the stream filter specified in T.3.1 to one of  
41 two different outbound queues (assuming that the outbound Ports support 8 queues, and that the default  
42 assignments for priorities to traffic classes follows the recommendation shown in Table 34-1); in the first  
43 time interval T, traffic is directed to queue 7, in the second time interval T, to queue 6, in the third time

interval to queue 7, in the fourth time interval, to queue 6, and so on. The choice of time interval  $T$  is discussed in T.5; the cycle time (OperCycleTime, see 8.6.9.4.19) for the stream gate state machines would need to be set to  $2T$  in order to accommodate the sum of the time intervals for the two gate operations. See Figure T-1.

**Figure T-1—Example Stream Filer and Stream Gate configuration for CQF**

## 5 T.4 Use of traffic scheduling for CQF

The traffic scheduling support needed on each outbound Port in order to support the PSFP configuration described in T.3 is to execute a gate control list that will set the GateState to *open* for queue 6 and *closed* for queue 7 for a TimeInterval of  $T$ , and then set the GateState to *open* for queue 7 and *closed* for queue 6 for a TimeInterval of  $T$ , repeating ad infinitum. If there are no other traffic scheduling considerations, this can be achieved with a gate control list that contains just two SetGateStates gate operations, with parameters as follows:

- 1) GateState: 0, 1, 2, 3, 4, 5, 6 *open*, 7 *closed*, TimeInterval =  $T$
- 2) GateState: 0, 1, 2, 3, 4, 5, 7 *open*, 6 *closed*, TimeInterval =  $T$

This sequence of gate operations has the effect that during the initial time period  $T$ , the GateState for queue 7 is closed while queue 7 is being filled, and queue 6 is open to allow any queued frames to be transmitted; during the second time period  $T$ , the GateState for queue 6 is closed while queue 6 is being filled, and queue 7 is open to allow any queued frames to be transmitted. The gates for all other queues are open. The choice of time interval  $T$  is discussed in T.5; the cycle time (OperCycleTime; see 8.6.9.4.19) for the scheduled traffic state machines would be set to  $2T$  in order to accommodate the sum of the time intervals for the two gate operations.

If there are traffic scheduling requirements for any of the other queues, then the gate control list could be extended to accommodate those requirements; however, the time interval between the changes of state of the gates for queues 6 and 7 has to be  $T$ , and consequently, OperCycleTime has to be a multiple of  $2T$ , in order for the CQF requirements to be met. Figure T-2 illustrates the simplest possible traffic scheduling configuration for the case that traffic scheduling is only needed to support CQF.

**Figure T-2—Traffic scheduling example for CQF**

## 1 T.5 Timing considerations

### 2 T.5.1 Choice of T

3 T should be chosen such that it is large enough to accommodate the stream data that can be received during  
 4 the class measurement interval for the stream(s) concerned, plus at least one maximal interfering frame or  
 5 frame fragment. This is important in order to ensure the key performance aspect associated with the class  
 6 measurement interval; namely, that if a stream or set of streams is observed over time, the reserved data rate  
 7 for that stream or set of streams will not be exceeded during any observed time period equal to the class  
 8 measurement interval associated with those streams. This effectively places a lower bound on the choice of  
 9 T, that it should not be smaller than the class measurement interval, and also places a restriction on larger  
 10 values of T, that they should be integer multiples of the class measurement interval.

11 If streams associated with two different observation intervals are being handled, for example if streams that  
 12 use SR classes A and B pass through the Bridge, then the OperCycleTime used for the transmit traffic  
 13 scheduling has to be a common multiple of the two class measurement intervals that are in use in order to  
 14 make it possible for the transmission cycles to properly match the two values of T that are chosen. Figure T-  
 15 3 and Figure T-4 illustrate how the Stream Filters, Stream Gates, and traffic scheduling could be configured  
 16 in the case where SR classes A and B are active; in Figure T-3, incoming frames that carry SR Class A  
 17 (priority 3) are handled using Gate 1, and the cycle time for the stream gate control list is twice the class  
 18 measurement interval for SR Class A, which is  $2 \times 125 \mu\text{s}$ . Gate 1 alternately tags these frames with an IPV  
 19 of 7 or 6. Incoming frames that carry SR Class B (priority 2) are handled using Gate 2, and the cycle time for  
 20 the stream gate control list is twice the class measurement interval for SR Class B, which is  $2 \times 250 \mu\text{s}$ . Gate  
 21 2 alternately tags these frames with an IPV of 5 or 4.

22 The traffic schedule is based on the smaller of the two class measurement intervals,  $125 \mu\text{s}$ , but now has four  
 23 entries in the gate control list (as opposed to 2 entries in Figure T-2), giving an overall cycle time of  $500 \mu\text{s}$ .  
 24 The gate control list switches the gate states for traffic classes 7 and 6 every  $125 \mu\text{s}$ , and switches the gate  
 25 states for traffic classes 5 and 4 every  $250 \mu\text{s}$ .

Figure T-3—Example Stream Filter and Stream Gate configuration with two values of T

1

## 2 T.5.2 Cycle interleaving

3 In some circumstances, particularly where the data rates differ between reception and transmission Ports, it  
4 can be desirable to interleave cycles on the faster Port so that the best use is made of the higher bandwidth  
5 available, and also to reduce the latency that is added as a stream passes through faster parts of the  
6 transmission path. Because there is a delay imposed on the transmission of received frames, caused by the  
7 cyclic switching of reception and transmission between a pair of queues, when a queue is allowed to  
8 transmit, all of its received frames will have been enqueued, and all of them will therefore be transmitted in  
9 a burst, assuming that priorities permit, and that the transmission queue uses the strict priority transmission  
10 selection algorithm (8.6.8.1). Hence, if the received traffic from a given Port was spread out over the time  
11 interval T, and it is all sent to the same queue, the transmitted traffic will be compressed into a burst. If

the transmission data rate is, say, ten times the reception data rate, then the maximum length of that burst is  $T/10$ , so there is the potential to fit 9 more such bursts into the bandwidth available on that transmission Port. With appropriate timing on reception Ports and transmission Ports, the reception and transmission cycles can be interleaved such that those additional transmission bursts can occur. In the example illustrated in Figure T-5, it is assumed that:

- a) There are two Ports on which stream data is being received, Rx1 and Rx2.
- b) There is a single Port on which stream data is being transmitted, Tx1.
- c) Rx1 and Rx2 operate at half of the data rate of Tx1 (or less).
- d) All stream traffic is SR Class A, and is received with priority 3.

**Figure T-5—Interleaving example—factor of 2**

On the reception side, traffic received on Rx1 with priority 3 is sent to traffic class queue 7 during the odd cycles and to traffic class queue 6 during the even cycles. Similarly, traffic received on Rx2 with priority 3 is sent to traffic class queue 5 during the odd cycles and to traffic class queue 4 during the even cycles; however, these cycles are offset with respect to the cycles for Rx1 by  $T/2$ .

On the transmission side, each queue is in the open (transmitting) state for  $T/2$ , and in the closed (receiving) state for  $3T/2$ . The timings of the gate open/gate closed events are arranged so that only one queue is transmitting at any one time.

It should be noted that with a scheme like this, although the transmit side appears to be operating on the basis of a value of  $T$  that is half that used on the Rx side, the effect from the point of view of the streams originating from a given reception Port is that the Rx and Tx timing is the same, as frames received on that Port are transmitted once in every time period  $T$ , and as assumed in the preceding point c), the transmit rate is twice the receive rate (or more), so the available transmit bandwidth is the same as or more than the receive bandwidth. The interleaving therefore meets the requirements stated in T.5.1. The reception Port of the Bridge downstream of Tx1 can operate using  $T/2$ , and if it is possible to carry this through to the transmission Ports as well, the contribution to the latency for streams passing through this Bridge will be  $T/2$ , rather than the  $T$  contributed by the first Bridge.

1 More complex schemes can be envisaged; for example, using more than two Rx Ports, and these can be  
2 made to work as long as the received bandwidth can be shared equally between the pairs of traffic classes  
3 that are used. Interleaving of this kind can also be defined for larger interleave factors; the only limitation is  
4 the number of available outbound queues. It is also possible to define interleaving schemes where the  
5 received bandwidth is not shared equally among the pairs of traffic classes, as long as the bandwidth  
6 allocated to a given pair of traffic classes does not exceed the bandwidth available during the time intervals  
7 when those traffic classes are able to transmit.

8 NOTE—Although the number of traffic classes described in this standard is limited to 8, the value of the IPV does not  
9 have such a limitation placed upon it. If a system supported more than 8 traffic classes, it would therefore be possible to  
10 define interleaving factors greater than 4.

### 11 T.5.3 Cycle alignment between adjacent Ports

12 The examples so far assume a perfect world where the transmission from transmission Port to reception Port  
13 is instantaneous and the internal timings of the transmitting and receiving systems are perfectly  
14 synchronized. In reality, transmission takes time, and synchronization is not perfect; therefore, it would be  
15 possible that a transmission Port launches the last frame(s) of one transmission burst just after the reception  
16 Port downstream has switched reception and transmission queues, which would mean that those last frames  
17 are placed in the wrong queue. Similarly, if the timing misalignment worked the other way, it would be  
18 possible for the transmission Port to finish transmitting its burst early, and switch to transmitting the next  
19 burst before the downstream Port had changed state.

20 In order to avoid this problem, the timings must be adjusted such that there is a very high degree of  
21 probability that when a reception Port changes the state of the stream filters to direct incoming frames to a  
22 different outbound queue, there are no frames still to be transmitted, or in flight, from the upstream  
23 transmission Port. This can be achieved by slightly delaying the start of the transmission window, and  
24 slightly advancing the end of the transmission window. The value of “slightly” depends on a number of  
25 factors, including the following:

- 26 a) Any error in the time synchronization between the adjacent systems.
- 27 b) Jitter in the propagation time of a frame from starting to leave the transmit queue in the upstream  
28 system to being presented to the downstream policing function.
- 29 c) Jitter in the propagation time of a frame between the downstream policing function and the  
30 appropriate transmission queue in the downstream system.
- 31 d) The size of any potential interfering frame or frame fragment.
- 32 e) Difference in the resolution of the clocks that are maintained by adjacent systems.

33 The effect of this adjustment factor,  $S$ , on the timings shown on the transmission Port in the earlier examples  
34 would be that the time slots where the gate is in the “open” state would be shorter by a factor of  $2S$ , and  
35 would start  $S$  later. Hence, the transmission phase for traffic class 7 in Figure T-5 would start at  $T+S$ , and  
36 would end at  $(3T/2)-S$ .  $S$  should be set to the sum of the errors or jitter values from all sources given in the  
37 preceding list.

## **Annex U**

(informative)

### **TSN configuration examples**

This annex provides implementation examples for Time-Sensitive Networking (TSN) configuration (Clause 46).

The examples in this annex are not intended to be comprehensive, but to serve as informative background to assist in understanding of Clause 46.

#### **U.1 Examples for time-aware talker**

One of the goals of TSN configuration is avoid forcing the user's application to be subservient to the network's configuration. The user describes what it does (e.g., `TrafficSpecification`) and what it needs from the network (e.g., `UserToNetworkRequirements`). The user also describes the configuration that it is willing to accept from the network (e.g., `InterfaceCapabilities`), but the goals are to keep that configuration to a minimum and to avoid topics that change aspects of the user's application, such as the timing of the application's execution and interaction with the physical world (e.g., sensors, actuators).

Aligned with these goals, it is possible for the Talker to transmit frames in a manner that is not aware of time synchronization protocols like IEEE Std 802.1AS. Using the time-aware features of `TrafficSpecification` and `InterfaceConfiguration`, it is also possible for a Talker to use awareness of time synchronization for transmission of frames. Nevertheless, TSN configuration avoids assumptions of a specific implementation of time-aware transmit, and TSN configuration avoids changes to application timing.

In order to demonstrate these concepts, consider an example in which Talkers and Listeners use IEEE Std 802.1AS to execute synchronized application loops at an interval of 500  $\mu$ s. The code for the application consists of two stages: a 250  $\mu$ s computation stage that generates data and a 250  $\mu$ s stage to transmit that data in TSN frames. The `MaxLatency` requirements can span one or more iterations of the application loop.

This example uses IEEE Std 802.1AS for time synchronization. The application begins execution on September 13, 2020, at 12:26:40 pm TAI, which corresponds to 1 600 000 000 000 000  $\mu$ s in IEEE 802.1AS time.

The application loops begin in alignment with IEEE 802.1AS time; in other words, the 250  $\mu$ s transmit stage begins at a base offset of 250  $\mu$ s in IEEE 802.1AS time. For example, after the application has been running for 6 s, a sequence of transmit stages can execute at 1 600 000 006 000 750  $\mu$ s, 1 600 000 006 001 250  $\mu$ s, 1 600 000 006 001 750  $\mu$ s, and so on.

This example focuses on a single Talker that transmits two Streams, J and K. The application generates a single frame of data for J and/or K at arbitrary times in the computation. In other words, during a single iteration data for K can follow J, and in the next iteration data for J can follow K, and in the next iteration data can be J only.

The frame for Stream J uses 120  $\mu$ s in time. The frame for Stream K uses 80  $\mu$ s in time. This implies a 100 Mb/s LAN technology.

## 1 U.1.1 Using enhancements for scheduled traffic

2 One option for implementation of this time-aware Talker is the enhancements for scheduled traffic (8.6.8.4).  
3 The Talker has two queues for transmit: one for TSN frames and another for non-TSN frames (e.g., best  
4 effort). The scheduled traffic enhancements use IEEE 802.1AS time to open and close gates for each queue  
5 (traffic class).

6 The enhancements of 8.6.8.4 schedule traffic per queue, and not per stream. Given the preceding application  
7 assumptions, therefore, the frame for Stream J can precede the frame for Stream K, and in the next cycle K  
8 can precede J.

9 For a time-aware Talker, the Jitter of TrafficSpecification (46.2.3.5) represents the variance in time for the  
10 single Stream. Since the enhancements of 8.6.8.4 are per queue, the Jitter must include the variance that is  
11 introduced by other Streams from this Talker.

12 Using the scheduled traffic enhancements of 8.6.8.4, the time-aware Talker needs an open TSN window of  
13  $120+80=200\text{ }\mu\text{s}$  for both J and K. The network (CNC) can locate that TSN window from  $250\text{ }\mu\text{s}$  to  $450\text{ }\mu\text{s}$   
14 through  $300\text{ }\mu\text{s}$  to  $500\text{ }\mu\text{s}$ . The Talker uses the TimeAwareOffset returned in InterfaceConfiguration  
15 (46.2.5.3) to determine where to locate the TSN window.

16 For this implementation, the TrafficSpecifications are as follows:

- 17 — Stream J
  - 18 — MaxFrameSize = (120  $\mu\text{s}$  in time)
  - 19 — MaxFramesPerInterval = 1
  - 20 — Interval = 500  $\mu\text{s}$
  - 21 — Jitter = 40  $\mu\text{s}$  (Stream K can occur before J, such that J is 80  $\mu\text{s}$  in window.  
22 Stream K can occur after J, such that J is 0  $\mu\text{s}$  in window.  
23 Jitter represents the midpoint of this variance.  
24 Use the returned TimeAwareOffset-Jitter as the start of  
25 the TSN window.)
  - 26 — EarliestTransmitOffset =  $250\text{ }\mu\text{s} + \text{Jitter} = 290\text{ }\mu\text{s}$
  - 27 — LatestTransmitOffset =  $500\text{ }\mu\text{s} - \langle \text{MaxFrameSize in time} \rangle - \text{Jitter} = 340\text{ }\mu\text{s}$
- 28 — Stream K
  - 29 — MaxFrameSize = (80  $\mu\text{s}$  in time)
  - 30 — MaxFramesPerInterval = 1
  - 31 — Interval = 500  $\mu\text{s}$
  - 32 — Jitter = 60  $\mu\text{s}$  (Stream J can occur before or after K)
  - 33 EarliestTransmitOffset =  $250\text{ }\mu\text{s} + \text{Jitter} = 310\text{ }\mu\text{s}$
  - 34 — LatestTransmitOffset =  $500\text{ }\mu\text{s} - \langle \text{MaxFrameSize in time} \rangle - \text{Jitter} = 360\text{ }\mu\text{s}$

35 Assume that the CNC decides to use EarliestTransmitOffset, presumably because that can be aligned with  
36 the schedules in Bridges. This results in InterfaceConfigurations of:

- 37 — Stream J
  - 38 — TimeAwareOffset = 290  $\mu\text{s}$
- 39 — Stream K
  - 40 — TimeAwareOffset = 310  $\mu\text{s}$

41 The Talker subtracts the Jitter from these TimeAwareOffset values and uses the lower of the results to  
42 configure AdminBaseTime and OperBaseTime of 8.6.8.4. The resulting configuration of the scheduled  
43 traffic enhancements of 8.6.8.4 is shown in Figure U-1 along with example traffic.

**Figure U-1—Example of enhancements for scheduled traffic**

NOTE—For this example, the Talker could also decide to use OperBaseTime of 0  $\mu$ s and swap OperControlList elements 0 and 1 (i.e., 250  $\mu$ s TSN closed followed by 250  $\mu$ s TSN open). That configuration is equivalent from the network perspective.

## 1 U.1.2 Using strict priority

2 If the Talker has no hardware to assist in scheduling of traffic, it can take advantage of its application timing  
3 for TSN configuration of its Streams. This implementation assumes that the Talker has two queues for  
4 transmit, but each queue uses strict priority alone for transmission selection (8.6.8.1). The TSN queue uses a  
5 higher priority traffic class than the non-TSN queue.

6 For this implementation, assume that the Talker disables the TSN queue during its computation stage, but  
7 continues to place frames for J and K into the TSN queue. When the Talker transitions to its transmit stage  
8 (i.e., 250  $\mu$ s base offset in IEEE 802.1AS time), it enables the TSN queue for transmit.

9 When the TSN queue is enabled, a non-TSN frame (e.g., best effort) can interfere such that it has just begun  
10 its transmit. For 100 Mb/s full-duplex IEEE Std 802.3 and a maximum frame size of 1522, this interference  
11 is 123.36  $\mu$ s. This interference must be incorporated into the Jitter of TrafficSpecification, much like the  
12 Jitter of Streams J and K in U.1.1.

13 This implementation has no flexibility in the location of its TSN window, which always starts at a 250  $\mu$ s  
14 offset.

15 For this implementation, the TrafficSpecifications are as follows:

- 16 — Stream J
- 17 — MaxFrameSize = (120  $\mu$ s in time)
- 18 — MaxFramesPerInterval = 1
- 19 — Interval = 500  $\mu$ s
- 20 — Jitter = (80  $\mu$ s + 123.36  $\mu$ s) / 2 = 101.68  $\mu$ s
- 21 (Stream K and max non-TSN can occur before J. )
- 22 — EarliestTransmitOffset = 250  $\mu$ s + Jitter = 351.68  $\mu$ s
- 23 — LatestTransmitOffset = 250  $\mu$ s + Jitter = 351.68  $\mu$ s
- 24 (No flexibility. TSN window always starts at 250  $\mu$ s. )

- 1 — Stream K
- 2 — MaxFrameSize = (80  $\mu$ s in time)
- 3 — MaxFramesPerInterval = 1
- 4 — Interval = 500  $\mu$ s
- 5 — Jitter = (120  $\mu$ s + 123.36  $\mu$ s) / 2 = 121.68  $\mu$ s
- 6 — EarliestTransmitOffset = 250  $\mu$ s + Jitter = 371.68  $\mu$ s
- 7 — LatestTransmitOffset = 250  $\mu$ s + Jitter = 371.68  $\mu$ s

8 This results in the following InterfaceConfigurations (or a failure):

- 9 — Stream J
- 10 — TimeAwareOffset = 351.68  $\mu$ s
- 11 — Stream K
- 12 — TimeAwareOffset = 371.68  $\mu$ s

13 Due to the high Jitter and inflexibility of the scheduling window, this implementation has the potential for  
14 more Stream configuration failures as compared to the implementation described in U.1.1.

### 15 U.1.3 Using per-stream scheduling

16 Some Talker implementations provide additional hardware assistance for time-aware transmission, such that  
17 each individual Stream has its own scheduled gating (i.e., per stream).

18 One such implementation is similar to the scheduled traffic enhancements of 8.6.8.4, but each Stream has a  
19 dedicated transmit queue and gate control list. An alternative implementation has a single transmit queue for  
20 TSN traffic, but each frame has an associated timestamp to specify its time for transmit. A variety of  
21 implementations are possible. For this example, assume that scheduled transmit is per stream, but do not  
22 assume a specific hardware implementation.

23 Assume that the per-stream scheduling hardware uses IEEE 802.1AS time directly. Therefore, the time-  
24 aware transmit has no additional variance beyond what IEEE Std 802.1AS provides, and the Jitter of  
25 TrafficSpecification is zero.

26 Given the application requirements, the CNC can locate Stream J anywhere in the window from 250  $\mu$ s to  
27 500  $\mu$ s. The CNC can also locate Stream K anywhere in the window from 250  $\mu$ s to 500  $\mu$ s, but it cannot  
28 overlap with Stream J.

29 For this implementation, the TrafficSpecifications are as follows:

- 30 — Stream J
  - 31 — MaxFrameSize = (120  $\mu$ s in time)
  - 32 — MaxFramesPerInterval = 1
  - 33 — Interval = 500  $\mu$ s
  - 34 — Jitter = 0  $\mu$ s
  - 35 — EarliestTransmitOffset = 250  $\mu$ s + Jitter = 250  $\mu$ s
  - 36 — LatestTransmitOffset = 500  $\mu$ s – <MaxFrameSize in time> – Jitter = 380  $\mu$ s
- 37 — Stream K
  - 38 — MaxFrameSize = (80  $\mu$ s in time)
  - 39 — MaxFramesPerInterval = 1
  - 40 — Interval = 500  $\mu$ s
  - 41 — Jitter = 0  $\mu$ s
  - 42 — EarliestTransmitOffset = 250  $\mu$ s + Jitter = 250  $\mu$ s
  - 43 — LatestTransmitOffset = 500  $\mu$ s – <MaxFrameSize in time> – Jitter = 420  $\mu$ s

1 Assuming that the CNC can locate Stream J at 250  $\mu$ s and Stream K immediately after, this results in the  
2 following InterfaceConfigurations:

- 3     — Stream J
- 4         — TimeAwareOffset = 250  $\mu$ s
- 5     — Stream K
- 6         — TimeAwareOffset = 370  $\mu$ s

7 Due to the zero Jitter and improved flexibility of the scheduling window, this implementation has the  
8 potential for more Stream configuration success as compared to the implementation described in U.1.1. In  
9 addition, given that each Stream has a distinct offset in time, this implementation enables the CNC to  
10 configure the scheduled traffic enhancements of 8.6.8.4 in Bridges such that multiple Streams do not overlap  
11 upon ingress from multiple Ports. In turn, the overall variance in latency is reduced.

## 12 U.2 Example of workflow for fully centralized models

13 This subclause provides an example workflow for the centralized TSN configuration models of Clause 46.  
14 The example is not intended to be comprehensive, but to help the reader understand how aspects of the  
15 configuration can be addressed (e.g., TSN domain detection and enforcement).

16 The example assumes the fully centralized model (46.1.3.3) with a single Centralized User Configuration  
17 (CUC) entity and a single Centralized Network Configuration (CNC) entity.

18 Many user-level protocol standards exist for the purpose of discovering and configuring end stations in order  
19 to design a distributed application. The application is usually specific to a particular market segment (e.g.,  
20 industrial automation, professional audio/video). A centralized software entity is used for the application's  
21 design, possibly including programming of software in end stations (e.g., industrial Programmable Logic  
22 Controller). The centralized entity uses the user-level protocol to communicate with the relevant end stations  
23 for its application. When TSN configuration is applied to these existing standards, the goal is to integrate  
24 TSN functionality without significant changes. The existing application design software is represented by  
25 the CUC concept, and the end stations are represented by the Talker and Listener concepts. This example  
26 does not designate a specific user-level protocol, but it does assume the existence of a single CUC.

27 The CNC discovers capabilities of network infrastructure (e.g., Bridges) and configures those features.

28 The example provides a workflow as a framework for describing each step in the TSN configuration  
29 procedure. The steps do not necessarily need to occur sequentially. Although the example assumes a single  
30 CUC, its CNC workflow (i.e., step 4 through step 8 below) can be applied to other examples that assume  
31 multiple CUCs, such as the following:

- 32     a) Multiple application design tools are used (i.e., multiple user-level protocols), and therefore multiple  
33         CUCs are used with a single CNC.
- 34     b) No application design tool is used, and instead each CUC represents a single Talker or Listener that  
35         communicates directly with the CNC.
- 36     c) Each CUC represents a single Talker or Listener that uses the Nearest Bridge as a proxy to the CNC  
37         (i.e., centralized network/distributed user model).

38 The workflow for this example consists of the following steps:

### 39 1) CUC discovers Talker and Listener end stations.

40     The protocol used by the CUC is outside the scope of this standard. When the communication  
41     between CUC and end stations uses IP, protocols such as mDNS (IETF RFC 6762 [B42]) are  
42     sometimes used.

2) **CUC reads the capabilities of each end station.**

This step includes TSN capabilities, but also many other capabilities that are not related to network technology. For example, if the end station is a sensor, the CUC reads the capabilities of the sensor as it applies to the physical world. The CUC also reads the frame size that is needed to transfer the sensor's measured value and associated diagnostics.

Although the communication between CUC and end station is not directly related to Clause 46, the CUC needs to obtain the following information:

- Number of Ports and MAC address of each Port
- InterfaceCapabilities: IEEE 802.1 capabilities of each Port
- TrafficSpecification.MaxFrameSize and MaxFramesPerInterval: Size of end station's data

The user-level protocol used by the CUC is outside the scope of this standard.

3) **End-user designs the distributed application using the CUC.**

The end user of the CUC decides which end stations communicate with one another as part of the distributed application. In other words, in terms of this standard, the CUC is used to design the Streams, including selection of the Talker and Listeners for each Stream. The CUC is also used to design the application's timing requirements.

The CUC creates the following information for each Stream, and its end stations are not directly aware of this information:

- StreamID: This identifier is primarily used between CUC and CNC.
- StreamRank: The importance of each Stream is related to its use in the application.
- UserToNetworkRequirements: MaxLatency is tied to application timing requirements.

The periodic execution of application code is designed using the CUC. This translates to the interval (i.e., period, rate) at which a Talker transmits its data. The CUC sends this interval to its end stations using the user-level protocol.

4) **CNC discovers the physical network topology.**

To discover the physical links between end stations and Bridges, the CNC uses IEEE Std 802.1AB (LLDP) along with a remote management protocol.

5) **CNC reads the TSN capabilities of each Bridge.**

The CNC uses a remote management protocol to read the TSN capabilities of each Bridge.

Whereas the previous step used the MIB/YANG of IEEE Std 802.1AB, this step uses the MIB/YANG of standards for TSN, such as IEEE Std 802.1Q, IEEE Std 802.1AS, and IEEE Std 802.1CB. The CNC uses the Chassis (Bridge) and Port identifications from the IEEE 802.1AB MIB/YANG to find the corresponding Port capabilities in the MIB/YANG of other IEEE 802.1 standards.

For example, the CNC will read the Bridge Delay (12.32.1) and Propagation Delay (12.32.2) from each Bridge in order to compute AccumulatedLatency (for step 9).

The CNC of this fully centralized model coexists with the fully distributed model (46.1.3.1). If the CNC finds a Bridge with msrpEnabledStatus TRUE (12.22.1) and MRP externalControl FALSE (12.32.4.1), the CNC avoids use of MSRP's VLAN ID (12.22.2, 12.22.4) for Streams configured by the CNC. The CNC also avoids use of MSRP's Priority (12.20.4) and associated traffic class. Although there might be methodologies for sharing the same resources (VLANs and traffic classes) between both models, this CNC takes the simpler approach of keeping the resources separate.

6) **CUC sends Talker/Listener groups to the CNC.**

The CUC requests configuration of Streams by sending Join requests (46.2.2) that specify the Talker group and Listener groups for each Stream.

The EndStationInterfaces group of each Talker and Listener identifies the associated end station in the physical topology, using the end station's MAC address. The MAC address is persistent (i.e., does not change due to software or protocols) and is assumed to be unique within the network, which serves as excellent identification in the physical topology. For this example, assume that end

stations use MAC address as their LLDP Chassis ID, such that the CNC can associate each Talker/Listener group to its neighboring Bridge Port.

**7) CNC configures TSN domain(s).**

Using the information learned in step 4 through step 6, the CNC knows the Bridges in the path(s) between each Talker and its Listeners. The CNC also knows the Bridge Ports that do not transmit frames for a Stream. This effectively defines the TSN domain for the collection of Streams.

The CNC uses destination MAC address and VLAN ID as tools to configure TSN features within the TSN domain. The InterfaceConfiguration group provides a mechanism for the CNC to allocate destination MAC addresses and VLAN IDs from its own pool and to provide the allocated values to the CUC (and the end stations). If end stations do not support InterfaceConfiguration, the CNC learns the destination MAC addresses and VLAN IDs from the DataFrameSpecification of each Stream.

**i) Inside the TSN domain**

When Bridges in the TSN domain are using spanning tree protocols (e.g., MSTP, ISIS-SPB) to forward Streams, the CNC uses management of the Static Filtering Entries (12.7) in order to avoid spanning tree protocols updating the active topology of the VLAN used by Streams.

When the CNC uses IEEE Std 802.1CB for redundant paths for Streams, the CNC uses management of Static Trees (12.32.3) and the associated TE-MSTID in order to avoid spanning tree operation on the VLAN ID used by Streams. The CNC uses management of IEEE Std 802.1CB to configure the redundant paths in Bridges between each Talker and its Listeners.

**ii) Outside the TSN domain**

The CNC uses management of Static Filtering Entries (12.7) to prevent transmit of TSN frames to Bridge Ports outside the TSN domain.

The CNC uses management of the Priority Regeneration Table (12.6) to prevent interference by non-TSN frames received on Bridge Ports outside the TSN domain, in that the priority of the non-TSN frame can be downgraded to zero. This is similar to the use of the Priority Regeneration Override Table (12.20.3) by SRP (6.9.4).

The accuracy/precision of IEEE Std 802.1AS degrades slightly for each Bridge that transfers time, so it makes sense for the CNC to limit the size of the IEEE 802.1AS domain as much as possible. As its default mode of operation, the CNC of this example uses management of IEEE Std 802.1AS to disable operation on Ports outside of the TSN domain. For example, assume that the CNC detects two distinct TSN domains G and H with respect to Talkers and Listeners (i.e., no Stream from G to H or vice versa). There is a Bridge between TSN domains G and H, and that Bridge supports IEEE Std 802.1AS. Rather than use a single IEEE 802.1AS domain that spans G and H, the CNC disables IEEE Std 802.1AS on the Ports between G and H; this action effectively creates two distinct IEEE 802.1AS domains, one for each TSN domain.

**8) CNC configures TSN features for Streams.**

The CNC uses the management of IEEE Std 802.1Q to configure TSN features in the path(s) from Talker to Listeners. Examples include enhancements for scheduled traffic (8.6.8.4), frame preemption (6.7.2), and the credit-based shaper (8.6.8.2).

**9) CNC returns the Status of each Stream to the CUC.**

This step includes the success/failure of each Stream's configuration, the AccumulatedLatency, and the InterfaceConfiguration for each end station.

1   **10) CUC configures each end station.**

2       If one or more Streams fail configuration, the CUC might decide to adjust its requirements and try  
3       again (i.e., return to step 3).

4       Assuming that the Stream status is sufficient to proceed, the CUC configures each end station to  
5       prepare it for application execution. Although the communication between CUC and end station is  
6       not directly related to Clause 46, the CUC provides the following information for each Stream:

7       — InterfaceConfiguration: Provides the destination MAC address and/or VLAN ID (if needed).

8   **11) CUC executes the distributed application.**

9       If there are other CUCs for other applications, the CNC can continue to configure Bridge resources  
10      for those while this application runs.

11   **12) CUC stops the distributed application.**

12      The CUC can send Leave requests (46.2.2) for Streams that are no longer needed.

13      If the application is changed, this workflow can return to step 1, step 2, or step 3.

## 1 **Annex V**

2 (informative)

### 3 **Asynchronous Traffic Shaping delay analysis framework**

4 The framework in this annex provides methods for worst-case delay analysis in static networks with static  
5 configurations. General assumptions of this framework are listed in V.1. The end-to-end delay modeling  
6 approach is described in V.2. An upper bound on buffering delays is described in V.3. Subsequent clauses  
7 (V.4 through V.8) cover additional sources of delays. The combined delay bounds are shown in V.9.

#### 8 **V.1 General assumptions**

9 The following assumptions are made throughout the remainder of this framework:

- 10 a) The Transmission Selection Table (8.6.8) of all transmission Ports under consideration assigns the  
11 ATS Transmission Selection Algorithm (Table 8-6, 8.6.8.5) to one or more numerically highest  
12 traffic classes (i.e., no other algorithm than the ATS Transmission Selection Algorithm is assigned to  
13 a numerically higher traffic class than the traffic classes to which the ATS Transmission Selection  
14 Algorithm is assigned).
- 15 b) The transmission gates (8.6.8.4) associated with all traffic classes using the ATS Transmission  
16 Selection Algorithm of all transmission Ports under consideration reside permanently in state Open.
- 17 c) All streams are associated with ATS traffic classes in all transmission Ports.
- 18 d) If frame preemption (6.7.2) is supported by a transmission Port under consideration, it is assumed  
19 that the frame preemption status in the frame preemption status table associated with the  
20 transmission Port in the network is either express, or preemptable for all traffic classes using the  
21 ATS Transmission Selection Algorithm.
- 22 e) The underlying MAC Service of all transmission Ports under consideration transmits at a constant  
23 data rate.
- 24 f) The committed information rate parameters in Bridges under consideration are set consistently with  
25 the constraints in V.8.
- 26 g) The data rate of a Port under consideration is greater than the sum of associated committed  
27 information rates.
- 28 h) Frames at all transmission Ports have the same media-dependent overhead (12.4.2.2). Likewise,  
29 there is no variation in frame lengths (i.e., tag addition or removal along a path is not considered).

#### 30 **V.2 End-to-end delay modeling approach**

31 The path from the Talker station to a single Listener station is subdivided into the contained  $n$  hops, where  
32 the 1st hop is the hop from the Talker to the first Bridge on the path, and the  $n$ th hop is the hop from the last  
33 Bridge on the path to the Listener.

34 The end-to-end delay bound  $d_{\max}(f)$  of a stream of interest is given by per hop delay bounds  $d_{\max}(k, f)$  of  
35 the  $n$  subsequent hops along the path of stream  $f$  as shown in Equation (V-1).

$$36 \quad d_{\max}(f) = \sum_{k=1}^n d_{\max}(k, f) \quad (\text{V-1})$$

1 where

- 2  $f$  is the stream of interest  
 3  $k$  is the hop index at the path from the Talker to the Listener ( $1 \leq k \leq n$ )  
 4  $d_{\max}(k, f)$  is the per hop delay bound of stream  $f$  at the  $k$ th hop

5 Figure V-1 illustrates the path of stream  $f$  across the relevant mechanisms and interfaces of two subsequent  
 6 bridges along the path, and the associated delay bounds [e.g.,  $d_{AT, \max}(k)$ , introduced in V.5] described in  
 7 the following subclauses.

**Figure V-1—Path of frames along a single hop with index  $k$  with two Bridges**

### 8 V.3 Buffering delays

9 The buffering delays comprise all delays on frames of a stream  $f$  resulting from their residence in queues of  
 10 associated traffic classes in the transmission Ports along the path. For a transmission Port on the path, these  
 11 delays are caused by:

- 12 a) Competing frames in queues of traffic classes different than the traffic class of stream  $f$ .
- 13 b) Competing frames in the queue of the traffic class of stream  $f$  competing for transmission.
- 14 c) The enforcement of traffic envelopes by the operation of the ATS scheduler state machines (8.6.11).
- 15 d) Store and forward operation in reception Ports.

A delay bound  $d_{BU, \max}(k, f)$  on the buffering delay for a single hop in absence of the effects covered in subsequent clauses is known (see Specht and Samii [B66]). For  $k < n$  (i.e., all but the last hop to the Listener), the delay bound  $d_{BU, \max}(k, f)$  is given by Equation (V-2).

$$d_{BU, \max}(k, f) = \max_{h \in F_S(k, f)} \left\{ \frac{\sum_{g \in F_H(k, h) \cup F_S(k, h)} b_{\max}(k, g) - l_{\min}(h) + l_{LP, \max}(k, h)}{R(k) - \sum_{g \in F_H(k, h)} r_{\max}(k, g)} + \frac{l_{\min}(h)}{R(k)} \right\} \quad (V-2)$$

For  $k = n$  (i.e., the last hop to the Listener), this bound is given by Equation (V-3).

$$d_{BU, \max}(n, f) = \frac{\sum_{g \in F_H(n, f) \cup F_S(n, f)} b_{\max}(n, g) - l_{\min}(f) + l_{LP, \max}(n, f)}{R(n) - \sum_{g \in F_H(n, f)} r_{\max}(n, g)} + \frac{l_{\min}(f)}{R(n)} \quad (V-3)$$

where

|                                               |                                                                                                                                                                                                           |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $F_H(k, f)$ and $F_H(k, h)$                   | denote the set of streams transmitted in a numerically higher traffic class (8.6.8) than stream $f$ and a stream $h$ , respectively, at the upstream transmission Port of the $k$ th hop                  |
| $F_S(k, f)$ and $F_S(k, h)$                   | denote the set of streams transmitted in the same traffic class as stream $f$ , including stream $f$ and stream $h$ , respectively, at the upstream transmission Port of the $k$ th hop                   |
| $l_{LP, \max}(k, f)$ and $l_{LP, \max}(k, h)$ | denote the maximum interference length, in bits, by any numerically lower traffic class than the class of stream $f$ and a stream $h$ , respectively, at the upstream transmission Port of the $k$ th hop |
| $l_{\min}(f)$ and $l_{\min}(h)$               | denote the minimum frame length of stream $f$ and a stream $h$ , respectively, in bits, including all media-dependent overhead (8.6.11.3.11, 12.4.2.2)                                                    |
| $b_{\max}(k, g)$                              | is the maximum burst size associated with a stream $g$ at the $k$ th hop, in bits                                                                                                                         |
| $r_{\max}(k, g)$                              | is the committed information rate of stream $g$ at the upstream device of the $k$ th hop, in bits per second                                                                                              |
| $R(k)$                                        | is the transmission rate, in bits per second, that the underlying MAC Service that supports transmission through the upstream transmission Port of the $k$ th hop provides                                |

NOTE 1—The relationship between  $b_{\max}(k, g)$  and the committed burst size at the Talker station is further discussed in V.7.

NOTE 2—The relationship between  $r_{\max}(k, g)$  and the committed information rate at the Talker station (47.2) is further discussed in V.8.

NOTE 3—If frame preemption is not supported,  $l_{LP, \max}(k, f)$  is at most one maximum frame length, including all media-dependent overhead, supported by the upstream transmission Port of the  $k$ th hop. If frame preemption is supported, and all classes with the ATS transmission selection algorithm can preempt all numerically lower traffic classes,  $l_{LP, \max}(k, f)$  is at most a maximum fragment length (S.2), including all media-dependent overhead.

## 1 V.4 Media-dependent delays

2 Frames of stream  $f$  experience a media-dependent delay between the upstream transmission Port of this hop  
3 and the downstream reception Port of a hop. This delay is measured between:

- 4 a) The time at which a particular octet of a frame passed the boundary from the upstream transmission  
5 Port to the network physical medium and
- 6 b) The time at which this particular octet passed the boundary from the network physical medium to  
7 the downstream Port.

8 The maximum media-dependent delay of the  $k$ th hop is denoted as  $d_{MD, \max}(k)$  and assumed to be known  
9 for analysis.

10 Variations in media-dependent delays do not affect the combined delay bounds in V.9. Such variations  
11 happen before the arrival time recognition by the associated ATS scheduler clock and the processing by the  
12 associated ATS scheduler instance. A frame that experiences a lower media-dependent delay than an earlier  
13 frame processed by the same scheduler instance would be delayed by scheduler, if required by envelope  
14 enforcement.

## 15 V.5 Bridge—Internal arrival time recognition delays

16 The maximum arrival time recognition delay in the upstream Bridge of the  $k$ th hop ( $k > 1$ ) for any frame of  
17 a stream is given by the associated ArrivalRecognitionDelayMax parameter (8.6.11.3.1, 12.31.8.5). For  
18 compact representation and notational consistency, ArrivalRecognitionDelayMax is subsequently denoted  
19 as  $d_{AT, \max}(k)$ .

20 Variations in arrival time recognition delays do not affect the combined delay bounds in V.9, similar to  
21 variations in media-dependent delays (V.4).

## 22 V.6 Bridge—Internal processing delays

23 The bounds on the processing delays in the upstream Bridge of the  $k$ th hop ( $k > 1$ ) for any frame of a stream  
24 are given by the associated ProcessingDelayMin and ProcessingDelayMax parameters (8.6.11.3.2,  
25 12.31.8.6, 12.31.8.7). The associated ProcessingDelayMin and ProcessingDelayMax parameters are  
26 subsequently denoted as  $d_{PR, \min}(k)$  and  $d_{PR, \max}(k)$ , respectively.

27 Variations in Bridge-internal processing delays can increase the burst sizes in buffering delays (V.3). Based  
28 on the specified computation of the assigned eligibility time (8.6.11.3.2), these variations reside within the  
29 associated clock offset variations (V.7).

30 NOTE—The total of the maximum arrival time recognition delay and the maximum processing delay is different from  
31 the associated maximum independent delay found in the Bridge Delay attributes (12.32.1.1). This total can be larger.

## 1 V.7 Bridge—Internal clock offset variations

2 The maximum clock offset variation in the upstream Bridge of the  $k$ th hop ( $k > 1$ ) for any frame of a stream  
3 is given by the associated ClockOffsetVariationMax parameter (8.6.11.2, 12.31.8.3). The associated  
4 ClockOffsetVariationMax is subsequently denoted as  $\Delta_{CO,max}(k, g)$ .

5 Clock offset variations of up to  $d_{AT,max}(k)$  between ATS scheduler clock and transmission selection clock  
6 instances (8.6.11.2) associated with a stream  $g$  can increase the burst size of streams subsequently competing  
7 in the transmission Port.

8 This impact can be taken into account by definition of  $b_{max}(k, g)$  for  $k > 1$ , as shown in Equation (V-4).

$$9 \quad b_{max}(k, g) = r_{max}(k, g)\Delta_{CO,max}(k, g) + b_{max}(1, g) \quad (V-4)$$

10 where  $b_{max}(1, g)$  is the committed burst size of stream  $g$  at the Talker station (47.2).

## 11 V.8 Inter-device clock rate deviations

12 The clock constraints in 8.6.11 limit ATS scheduler clock instances and transmission selection clock  
13 instances in a Bridge to effectively operate at the same rate, although differences within  
14 [ClockOffsetMin,ClockOffsetMax] are permitted (8.6.11.2). As a basic property of asynchronous  
15 mechanisms such as ATS, no such limitation exists between different devices (i.e., clocks in different  
16 devices are not synchronized).

17 Deviations of clocks from their nominal rates (e.g., within oscillator tolerances) affect the spacing between  
18 successive frames according to the assigned eligibility times (8.6.11.3.2, 8.6.8.5). If the upstream device at a  
19 hop runs faster than nominal (e.g., +100 ppm), and a connected downstream Bridge at this hop runs slower  
20 than nominal (e.g., –100 ppm), the backlog as well as the per hop delay in the downstream Bridge could  
21 grow under peak load conditions.

22 The situation can be prevented by management constraints (12.31.5) on  $r_{max}(k, g)$  for  $1 < k < n$ , such that  
23 Equation (V-5) holds for any stream  $g$ .

$$24 \quad r_{max}(k, g) \geq \frac{1 + 10^{-6}\Delta_{CR,max}(k-1)}{1 - 10^{-6}\Delta_{CR,max}(k)} r_{max}(k-1, g) \quad (V-5)$$

25 where

26  $\Delta_{CR,max}(k)$  is the upper bound over all absolute rate deviations of all ATS scheduler clocks and  
27 transmission selection clocks from their nominal rate in the upstream device of the  $k$ th hop  
28 available via the associated ClockRateDeviationMax parameter (12.31.8.4), in ppm (e.g.,  
29  $\Delta_{CR,max}(k) = 100$ )  
30  $r_{max}(1, g)$  is the committed information rate of stream  $g$  at the Talker station (47.2)

## V.9 Combined delay bounds

For a path from a Talker station to a Listener station with at least one Bridge ( $n > 1$ ), a combined end-to-end delay bound  $d_{\max}(f)$  of a stream of interest  $f$  can be summarized by Equation (V-6)

$$d_{\max}(f) = \sum_{k=1}^n d_{BU, \max}(k, f) + \sum_{k=1}^n d_{MD, \max}(k) + \sum_{k=2}^n d_{AT, \max}(k) + \sum_{k=2}^n d_{PR, \max}(k) \quad (V-6)$$

with Equation (V-7), Equation (V-8), and Equation (V-9) for  $1 < k < n$ .

$$d_{BU, \max}(1, f) = \max_{h \in F_S(1, f)} \left\{ \frac{\sum_{g \in F_H(1, h) \cup F_S(1, h)} b_{\max}(1, g) - l_{\min}(h) + l_{LP, \max}(1, h)}{R(1) - \sum_{g \in F_H(1, h)} r_{\max}(1, g)} + \frac{l_{\min}(h)}{R(1)} \right\} \quad (V-7)$$

$$d_{BU, \max}(n, f) = \frac{\sum_{g \in F_H(n, f) \cup F_S(n, f)} (r_{\max}(n, g) \Delta_{CO, \max}(n, g) + b_{\max}(1, g)) - l_{\min}(f) + l_{LP, \max}(n, f)}{R(n) - \sum_{g \in F_H(n, f)} r_{\max}(n, g)} + \frac{l_{\min}(f)}{R(n)} \quad (V-8)$$

$$d_{BU, \max}(k, f) = \max_{h \in F_S(k, f)} \left\{ \frac{\sum_{g \in F_H(k, h) \cup F_S(k, h)} (r_{\max}(k, g) \Delta_{CO, \max}(k, g) + b_{\max}(1, g)) - l_{\min}(h) + l_{LP, \max}(k, h)}{R(k) - \sum_{g \in F_H(k, h)} r_{\max}(k, g)} + \frac{l_{\min}(h)}{R(k)} \right\} \quad (V-9)$$

In absence of Bridges on the path from the Talker station to the Listener station (i.e.,  $n = 1$ ), the end-to-end delay bound can be summarized by Equation (V-10).

$$d_{\max}(1, f) = \frac{\sum_{g \in F_H(1, f) \cup F_S(1, f)} b_{\max}(1, g) - l_{\min}(f) + l_{LP, \max}(1, f)}{R(1) - \sum_{g \in F_H(1, f)} r_{\max}(1, g)} + \frac{l_{\min}(f)}{R(1)} + d_{MD, \max}(1) \quad (V-10)$$

## 1 Annex W

### 2 (informative)

### 3 Maintaining frame order with Congestion Isolation

4 The process of congestion isolation involves identifying the frames of a congesting flow and subsequently  
5 modifying the egress traffic class of those frames based on the level of congestion in the monitored and  
6 congesting queues. During this process, it is possible that frames for the same flow can exist in multiple  
7 queues at the same time, resulting in the possibility of an out-of-order frame delivery. As an illustration,  
8 consider the following example depicted in Figure W-1.

**Figure W-1—Isolation out-of-order frame example**

9 In the example in Figure W-1, the frames of two flows, red and blue, are intermixed while traversing a  
10 common monitored queue. As the monitored queue fills, the red flow is determined to be a congesting flow  
11 and subsequent frames of that flow will be reclassified and queued in the congesting queue. Previously  
12 received frames for that flow, numbered 1 through 4, may reside in the monitored queue. Since the  
13 congesting queue is empty, the subsequent frames, numbered 5 and 6, are placed at the head of the  
14 congesting queue. Depending upon the traffic selection algorithm, it may be possible for frames 5 and 6 to  
15 be selected for transmission before some of frames 1 through 4.

16 The priority of the congesting queue is lower than the priority of the monitored queue. The strict priority  
17 transmission selection algorithm (8.6.8.1) will ensure that no out-of-order frame delivery occurs, however  
18 there is a risk of starvation for congesting flows and alternative traffic selection algorithms may be desired.  
19 The enhanced transmission selection algorithm (8.6.8.3) or other vendor specific algorithms may not ensure  
20 no out-of-order delivery without special consideration.

While the strict priority transmission selection algorithm can ensure in-order delivery when congesting flows are isolated to the congesting queue, it does not ensure in-order delivery when those flows are returned to non-congesting status except in the case where both the congesting and monitored queues themselves become empty. Implementations may want to free resources and reduce flow completion time by returning flows to non-congesting status as soon as possible. This, however, may create another situation where frames from the same flow exist in both the congesting and monitored queue at the same time. Figure W-2 shows an example of possible out-of-order frame delivery when de-isolating a flow (i.e., returning the flow to non-congesting status).

**Figure W-2—De-isolation out-of-order frame example**

In the example in Figure W-2, a red flow has been isolated to the congesting queue and the blue flow is traversing the monitored queue. Since the queue occupancy is low in both queues, the implementation may decide to de-isolate the red flow. Subsequent frames 7 and 8 will now be placed in the monitored queue resulting in frames from the red flow existing in both queues at the same time. The monitored queue is scheduled at a higher priority or with a greater frequency than the congesting queue and it may become possible for frames 7 and 8 to exit the system ahead of frames 5 and 6. Waiting for the congesting queue to completely empty before de-isolating any congesting flows can ensure in-order delivery during de-isolation, but it may leave flows in a congesting state longer than necessary and makes the transition of one congesting flow dependent upon all other congesting flows.

Congestion isolation defines a transmission gate (8.6.8.6) for the monitored and congesting queues that make those queues available to the transmission selection algorithm. When the transmission selection algorithm is strict priority, the transmission gate is permanently *open*. The transmission gate is controlled by the `cipGateControl` variable for other transmission selection algorithms that can not ensure in-order delivery at all times. The management of `cipGateControl` is implementation dependent, but must be asserted in a way to ensure the externally visible behavior of the Bridge supporting congestion isolation is to maintain frame order.

The following informative description provides example mechanisms to preserve frame order when isolating and de-isolating flows.

## 1 W.1 Queue markers for order preservation

2 The mechanism below provides control of the cipGateControl variable for a congesting queue in order to  
3 preserve the order of frames for a contested flow. It involves a queue position marker and marker counter for  
4 both the monitored and congesting queues. The mechanism is described using the example shown in  
5 Figure W-3.

**Figure W-3—Using queue markers and counters to preserve order when isolating**

7 The example in Figure W-3 shows the state of the position markers and marker counters during four  
8 different phases of congestion isolation operation; before a flow is isolated, position marking during the  
9 isolation of a flow, the closing of the congesting queue transmission gate, and the opening of the congesting  
10 queue transmission gate. When a queue transmission gate is open, that queue is available to the traffic  
11 selection algorithm. When it is closed, the queue is not available to the traffic selection algorithm.

12 In the example, the frames of two flows are intermixed in the monitored queue as they traverse the Bridge.  
13 Since no flows have been isolated yet, the position marker counters of both the congesting queue and the  
14 monitored queue are set to 0. Once a flow has been isolated and subsequent frames of that flow are placed in  
15 the congesting queue, a marker is placed in both the congesting queue and the monitored queue. The marker  
16 counter is incremented for both queues once the position is marked. The congesting queue is empty at the  
17 time the first flow is isolated, so the marker will be at the head of the queue. When a marker is at the head of  
18 the congesting queue and the marker counters are equal, the cipGateControl variable for the congesting  
19 queue is set to closed. The monitored queue continues to drain and eventually the position marker will reach  
20 the head of the monitored queue. The marker counter for the monitored queue will be decremented when the  
21 frame associated with the position marker is scheduled for transmission and exits the queue. When the value  
22 of the congesting queue marker counter is greater than the monitored queue position counter, it is possible to  
23 set the cipGateControl variable to open and begin to schedule the congesting queue. Whenever a frame that  
24 aligns with a position marker is scheduled for transmission, the associated marker counter is decremented.

25 A variation of the mechanism above can be used to ensure in-order delivery when de-isolating a flow  
26 (i.e., returning a flow to non-congesting status). A separate set of counters and markers can be used to  
27 identify the positions in the queues when a congesting flow is allowed to begin to use the monitored queue  
28 again.

1

**Figure W-4—Using queue markers and counters to preserve order when de-isolating**

2 The example in Figure W-4 shows the state of a separate set of position markers and marker counters during  
3 four different phases of the congestion de-isolation process; during isolation, during initial de-isolation,  
4 closing the monitored queue, and opening the monitored queue once order has been ensured. In the example,  
5 the red flow is currently isolated to the congesting queue and the blue flow is traversing the monitored  
6 queue. Since there are no flow ordering issues the counters are initialized to 0. When the implementation  
7 decides to de-isolate the red flow, it places a marker after the last frame of the red flow in the congesting  
8 queue and with the next frame of the congesting flow in the monitored queue. The counters are incremented  
9 each time a marker is placed in the queue. The queue scheduling continues when the counters are equal and  
10 no markers are at the head of the monitored queue. Once the marker of the monitored queue reaches the head  
11 of the queue, the transmission gate for the monitored queue is closed by setting the `cipGateControl` variable  
12 to *closed*. The lower priority congesting queue is scheduled, allowing the previously isolated frames to be  
13 transmitted. Once the marker in the congesting queue is removed and the counter is decremented, the  
14 monitored queue gate is opened by setting `cipGateControl` to *open* and the normal scheduling continues.

15 The marker and counter mechanism described in these examples is fairly simple, but care must be taken  
16 when combining the mechanisms for isolation and de-isolation to ensure no deadlocks exist. Implementation  
17 details depend on queue and memory architectures and are beyond the scope of this standard.

## 18 W.2 Congestion Isolation queuing and Priority-based Flow Control

19 Priority-based Flow Control (PFC) (Clause 36) is used to create a lossless network on the traffic classes for  
20 which it is enabled. PFC, as defined by this standard, is intentionally ambiguous about when the PFC  
21 Initiator entity (36.2.1) generates `M_CONTROL` PFC requests using the `M_CONTROL.request` primitive.  
22 This allows implementation flexibility, as there are many possible buffering and queuing approaches used in  
23 practice. Some Bridges may be input buffered, others may be primarily output buffered with small ingress  
24 buffers, some may have shared memory and others may use combinations of different memory architectures.  
25 In each implementation, the events that cause the PFC Initiator entity to generate an `M_CONTROL` PFC  
26 request may be different. In all cases, however, the purpose of PFC is to avoid dropping frames, not only  
27 within a single Bridge but across the entire network. The PFC Initiator is expected to generate an  
28 `M_CONTROL` PFC request when internally Bridge buffering is not able to absorb the reception of  
29 additional frames. The `M_CONTROL` PFC request is expected to eliminate the chance of frame loss.

PFC is known to cause congestion spreading and has recommended use within the data center because of its limited extent (36.1.1). One of the key objectives for congestion isolation is to reduce the frequency of PFC requests and avoid head-of-line blocking in lossless data center networks. By reducing the frequency of PFC requests the impact of congestion spreading can be reduced. Congestion isolation does this by isolating congesting flows to a separate congesting queue, reducing the need to invoke PFC requests caused by congesting flows. During the isolation process, however, it is possible for frames of the same flow to be in multiple queues at the same time, both within the local system and the upstream peer. This scenario can require special consideration for the design of the PFC Initiator.

Consider the Bridge architecture shown in Figure W-5. In the figure, the 4-port Bridge has small ingress buffers, shown on port 1, designed to absorb received frames while forwarding decisions are made. There are two priorities represented in the figure. In this example, priority 3 is the congesting queue and priority 4 is the monitored queue. In the example, frames are being forwarded from port 1 to the egress buffers of port 3. The shaded buffers are assumed to be occupied.

**Figure W-5—Example Bridge buffering supporting PFC and CI**

When congestion isolation occurs, as seen in Figure W-6, frames received by the downstream Bridge will begin to be placed in the congesting queue (priority 3). A CIM is sent upstream to inform the peer to isolate the same flow. The upstream peer has several frames queued in the monitored queue and will continue transmission while the CIM is in flight.

**Figure W-6—Example CI initiation by downstream peer**

During the isolation process, as seen in Figure W-7, frames will continue to drain from the monitored queue of the upstream peer and will begin to accumulate in the congesting queue. Since the monitored queue has higher priority than the congesting queue, and to avoid delivering out-of-order frames, the scheduling of the congesting queue in the upstream peer is blocked. Frames from the congesting flow accumulate in the congesting queue of the downstream Bridge while previous frames begin to drain from the monitored queue.

1 When multiple flows are sharing the monitored queue the number of frames accumulating in the congesting  
2 queue can increase. Since frames for the congesting flow are still in the monitored queue upstream, they will  
3 egress the upstream peer at priority 4.

**Figure W-7—Example CI in process**

4 If the congesting queue is not allowed to drain at a rate faster than it is being filled, the congesting queue can  
5 become exhausted, as seen in Figure W-8. Since the congesting queue is at priority 3, the natural response to  
6 an exhausted queue in a lossless environment would be to issue a PFC request on priority 3. However, in the  
7 example, there are still frames for the congesting flow egressing the upstream peer at priority 4. A pause on  
8 priority 3 will have no effect. Additional frames received at priority 4 on the downstream Bridge may be  
9 dropped unless a PFC request is issued at priority 4.

**Figure W-8—Example PFC request for congesting queue**

10 The problem with the example in Figure W-8 is that the PFC Initiator is considering the occupancy of the  
11 egress queue as the stimulus for issuing the PFC without considering the frame's priority at ingress. The  
12 PFC design in this example is not taking into account that a frame's priority may be changed by congestion  
13 isolation after reception.

14 One solution to the problem is for the Bridge to hold the frame at ingress until there is space at egress to  
15 queue it. The PFC Initiator can be solely based on the occupancy of the ingress buffers in this case. A PFC  
16 request would only be issued for the priority of received frames that have no space in their ultimate egress  
17 queue. Obviously it is critical that the downstream Bridge can determine the traffic class used by the  
18 upstream peer to transmit the frame.

**Figure W-9—Example PFC request to avoid packet loss with CI enabled**

2 Figure W-9 shows the scenario where the PFC request is issued on priority 4 to prevent frame loss within the  
3 downstream Bridge even though those frames will egress the downstream Bridge at priority 3. This scenario  
4 avoids internal packet loss, but has the unfortunate consequence of blocking the monitored queue and  
5 potentially creating head-of-line blocking for other non-isolated flows. While this unfortunate scenario only  
6 exists in a lossless environment, it defeats the purpose of congestion isolation. The scenario does not create  
7 an erroneous situation and is expected to be rare.
