## 1 17.2.1 Structure of the IEEE8021-TC-MIB

2 The IEEE8021-TC-MIB defines textual conventions used throughout the IEEE 802.1Q MIB modules and  
3 summarized in Table 17-2. Textual conventions (TCs) originally appeared in each of the MIB modules for  
4 IEEE Std 802.1Q produced by the IETF. Many of the original IETF TCs are still used in the various MIB  
5 modules for VLAN-Bridge management and have not been imported into this module.

**Table 17-2—IEEE8021-TC-MIB structure**

| IEEE8021-TC-MIB object                     | Reference                                                                 |
|--------------------------------------------|---------------------------------------------------------------------------|
| IEEE8021PbbComponentIdentifier             | 12.3 l)                                                                   |

The IEEE8021-FQTSS-MIB module in 17.7.12 defines additional TEXTUAL-CONVENTIONS that are utilized by the managed objects that support use of the Credit-based shaper algorithm (8.6.8.2, Clause 34).

The textual conventions used by IEEE 802.1Q MIB modules not contained in this TC module, but contained in IETF RFC 4318 and IETF RFC 4363 are as follows:

BridgeId  
Timeout  
PortList  
VlanIdOrAny  
VlanIdOrNone  
VlanIdOrAnyOrNone

## 17.2.2 Structure of the IEEE8021-BRIDGE-MIB

This MIB module is based upon the BRIDGE MIB version in IETF RFC 4188 and the P-BRIDGE MIB originally in IETF RFC 4363. While many tables and objects are similar, the IEEE8021-BRIDGE-MIB has been reindexed and rerooted.

Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects. The overall structure and assignment of objects to their subtrees is shown below. Where appropriate, the corresponding IETF RFC 4188 object name, IEEE 802.1D™-2004 [B14] management object name, and reference are also included. If the IETF RFC mapping is missing, it means there is no equivalent in the original IETF MIB modules. If the Managed Object is missing, it means that no managed object is specified in the referenced clause.

Table 17-3 indicates the structure of the IEEE8021-BRIDGE-MIB module as well as showing its relationship to the IETF MIB that is being obsoleted.

**Table 17-3—IEEE8021-BRIDGE-MIB structure**

| IEEE8021-BRIDGE-MIB table/object        | IETF MIB table/object      | Reference      |

\*This object is an INDEX of the table in which it resides.

1 The IEEE8021-BRIDGE-MIB contains the following object subtrees:

- 2 a) The ieee8021BridgeBase Subtree  
3 This subtree contains the objects that are applicable to all types of Bridges.
- 4 b) The ieee8021BridgeTp Subtree  
5 This subtree contains objects that describe the entity's state with respect to transparent bridging. If  
6 transparent bridging is not supported, this subtree will not be implemented. This subtree is  
7 applicable to transparent-only Bridges.
- 8 c) The ieee8021BridgePriority Subtree  
9 This subtree contains the objects for configuring and reporting status of Priority-based queuing  
10 mechanisms in a Bridge. This includes per Bridge Port user\_priority treatment, mapping of  
11 user\_priority in frames into internal traffic classes, and outbound user\_priority and access\_priority.
- 12 d) The ieee8021BridgeMrp Subtree  
13 This subtree contains the objects for configuring and reporting on operation of the Multiple  
14 Registration Protocol (MRP).
- 15 e) The ieee8021BridgeMmrp Subtree  
16 This subtree contains the objects for configuring and reporting on operation of the Multiple MAC  
17 Registration Protocol (MMRP).
- 18 f) The ieee8021BridgeInternal LAN Subtree  
19 This subtree contains the objects for configuring and reporting on operation of the Internal LAN  
20 interface. An I-LAN Interface is used to create internal connections between Bridge Ports in an  
21 IEEE 802.1 device.

22 The IEEE 802.1D-2004 [B14] management objects in Table 17-4 have not been included in the  
23 IEEE8021-BRIDGE-MIB module for the indicated reasons. Note that there is a conformance requirement  
24 that the base modules SNMPv2-MIB [RFC3418] and IF-MIB [RFC2863] will be implemented as a default  
25 on all Bridges.

**Table 17-4—IEEE 802.1D objects not in the IEEE8021-BRIDGE-MIB**

| IEEE 802.1D object   | Disposition                    |
|----------------------|--------------------------------|
| Bridge.BridgeName    | Same as sysDescr (SNMPv2-MIB)  |
| Bridge.BridgeUpTime  | Same as sysUpTime (SNMPv2-MIB) |
| Bridge.PortAddresses | Same as ifPhysAddress (IF-MIB) |

### 26 17.2.3 Structure of the IEEE8021-SPANNING-TREE MIB

27 A RSTP MIB originally appeared in IETF RFC 4318. While many tables and objects are similar, the  
28 IEEE8021-SPANNING-TREE-MIB has been merged with spanning tree objects from the BRIDGE MIB in  
29 IETF RFC 4188 and also reindexed and rerooted with its inclusion in this subclause.

30 This subclause defines an SMIV2 MIB module for managing RSTP capability originally defined by the  
31 IEEE Std 802.1t™ and IEEE Std 802.1w™ amendments to IEEE Std 802.1D, 1998 Edition [B13], for

- 1 bridging between LANs. The objects in this MIB are defined to apply both to transparent bridging and to  
2 Bridges connected by subnetworks other than LANs.
- 3 The MIB module in this clause is based on IEEE Std 802.1D-2004 [B14], though the references are to this  
4 standard.
- 5 Table 17-5 indicates the structure of the IEEE8021-SPANNING\_TREE-MIB module as well as showing its  
6 relationship to the IETF MIB that is being obsoleted.

**Table 17-5—IEEE8021-SPANNING-TREE MIB structure**

\*This object is an INDEX of the table in which it resides.

1 The IEEE8021-SPANNING-TREE MIB contains the following object subtrees:

- 2 a) The ieee8021SpanningTree Subtree
- 3 This subtree contains the objects that denote the Bridge's state with respect to the spanning tree
- 4 protocol.
- 5 b) The ieee8021SpanningTreePort Subtree
- 6 This subtree contains the objects that denote the Bridge Port's state with respect to the spanning tree
- 7 protocol.

8 For compatibility with the original MIB defined in IETF RFC 4318, the IEEE8021-SPANNING-TREE-MIB  
9 continues to use disabled, blocking, listening, learning, forwarding, and broken  
10 ieee8021SpanningTreePortStates. The learning and forwarding states correspond exactly to the Learning  
11 and Forwarding Port States specified in Clause 12 of this standard. Disabled, blocking, listening, and broken  
12 all correspond to the Discarding Port State—while those ieee8021SpanningTreePortStates serve to  
13 distinguish reasons for discarding frames, the operation of the Forwarding and Learning processes is the  
14 same for all of them. The ieee8021SpanningTreePortState broken represents the failure or unavailability of  
15 the Port's MAC as indicated by MAC\_Operational FALSE; disabled represents exclusion of the Port from  
16 the active topology by management setting of the Administrative Port State to Disabled; blocking represents  
17 exclusion of the Port from the active topology by the spanning tree algorithm [computing an Alternate or  
18 Backup Port Role (17.7 of IEEE Std 802.1D-2004 [B14])]; listening represents a Port that the spanning tree  
19 algorithm has selected to be part of the active topology (computing a Root Port or Designated Port role) but  
20 is temporarily discarding frames to guard against loops or incorrect learning.

1 The IEEE 802.1D management objects in Table 17-6 have not been included for the indicated reasons.

**Table 17-6—Clause 12 objects not in the IEEE8021-SPANNING-TREE MIB**

## 2 17.2.4 Structure of the IEEE8021-Q-BRIDGE-MIB

3 A Q-BRIDGE MIB originally appeared in IETF RFC 4363. While many tables and objects are similar, it has  
4 been reindexed and rerooted with its inclusion in this subclause.

5 Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects.  
6 Where appropriate, the corresponding IETF RFC 4363 object name and IEEE Std 802.1Q management  
7 reference is also included.

8 Unlike IEEE Std 802.1D, 1998 Edition [B13], this standard does not define exact syntax for a set of  
9 managed objects. The following cross-references indicate only the subclause numbering of the descriptions  
10 of management operations from Clause 12.

11 Table 17-7 indicates the structure of the IEEE8021-Q-BRIDGE-MIB module as well as showing its  
12 relationship to the IETF MIB that is being obsoleted.

**Table 17-7—IEEE8021-Q-BRIDGE MIB structure**

\*This object is an INDEX of the table in which it resides.

1 The IEEE8021-Q-BRIDGE-MIB contains the following object subtrees:

- 2 a) The ieee8021QBridgeBase Subtree  
3 This subtree contains the objects that are applicable to all Bridges implementing IEEE Std 802.1Q  
4 VLANs.
- 5 b) The ieee8021QBridgeTp Subtree  
6 This subtree contains objects that control the operation and report the status of transparent bridging.  
7 This includes management of the dynamic FDBs for both unicast and multicast forwarding. This  
8 subtree will be implemented by all Bridges that perform destination-address filtering.
- 9 c) The ieee8021QBridgeStatic Subtree  
10 This subtree contains objects that control static configuration information for transparent bridging.  
11 This includes management of the static entries in the FDBs for both unicast and multicast  
12 forwarding.
- 13 d) The ieee8021QBridgeVlan Subtree  
14 This subtree contains objects that control configuration and report status of the VLANs known to a  
15 Bridge. This includes management of the statically configured VIDs as well as reporting VIDs  
16 discovered by other means [e.g., Multiple VLAN Registration Protocol (MVRP)]. It also controls  
17 configuration and reports status of per-Port objects relating to VIDs and reports traffic statistics. It  
18 also provides for management of the VID to FID allocation.
- 19 e) The ieee8021QBridgeProtocol Subtree  
20 This subtree contains objects that control configuration and report status of the mappings from  
21 Protocol Templates to Protocol Group Identifiers used for Port-and-Protocol-based VLAN  
22 classification.
- 23 f) The ieee8021QBridgeVIDX Subtree  
24 This subtree contains objects that control configuration of VID translation for VLAN ports. A single

1 symmetric translation value or an individual ingress and egress translation is allowed depending on  
2 the management table supported.

3 The Clause 12 management objects in Table 17-8 have not been included in the  
4 IEEE8021-Q-BRIDGE-MIB for the indicated reasons. Note that the assumption is made the base modules  
5 SNMPv2-MIB and IF-MIB will be implemented as a default on all Bridges.

**Table 17-8—Clause 12 management not in IEEE8021-Q-BRIDGE-MIB**

| Clause 12 operation                        | Disposition                                                                              |

## 6 17.2.5 Structure of the IEEE8021-PB-MIB

7 The IEEE8021-PB-MIB provides objects to configure and manage Provider Bridges.

8 Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects.

9 Where appropriate, the corresponding Clause 12 management reference is also included.

<sup>1</sup> Table 17-9 indicates the structure of the IEEE8021-PB-MIB module.

**Table 17-9—IEEE8021-PB-MIB structure**

## **1 17.2.6 Structure of the IEEE8021-MSTP-MIB**

<sup>2</sup> The IEEE8021-MSTP-MIB provides objects to configure and manage multiple spanning trees.

<sup>3</sup> Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects.

<sup>4</sup> Where appropriate, the corresponding Clause 12 management reference is also included.

<sup>1</sup> Table 17-10 indicates the structure of the IEEE8021-MSTP-MIB module.

**Table 17-10—IEEE8021-MSTP-MIB structure**

## 1 17.2.7 Structure of the IEEE8021-CFM-MIB

2 Subclause 12.14 of this document defines the information model associated with this standard in a  
3 protocol-independent manner. Table 17-11 and Table 17-12 describe the relationship between the SMIV2  
4 objects defined in the MIB module in 17.4.9, the variables defined in Clause 20, and the  
5 protocol-independent objects defined in 12.14.

6 Note that there are actually two MIB modules—IEEE8021-CFM-MIB and IEEE8021-CFM-V2-MIB. The  
7 former contains all original and current tables as well as deprecated tables. The latter contains reindexed  
8 tables (to support PBB per Clause 26) and a complete conformance clause that lists all the current tables.

<sup>1</sup> Table 17-11 lists only the current tables (i.e., the deprecated tables are not listed) in the  
<sup>2</sup> IEEE8021-CFM-MIB module, and Table 17-12 lists the reindexed tables in the IEEE8021-CFM-V2-MIB  
<sup>3</sup> module (that replace the deprecated tables of IEEE8021-CFM-MIB).

## 17.2.8 Structure of the IEEE8021-PBB-MIB

The IEEE8021-PBB-MIB provides objects to configure and manage PBBs.

Objects in this MIB module are arranged based on their description in Clause 12. Where appropriate in the table, the corresponding Clause 12 management reference is included.

Table 17-13 indicates the structure of the IEEE8021-PBB-MIB module.

## 1 17.2.9 Structure of the IEEE8021-DDCFM-MIBs

2 The IEEE8021-DDCFM-MIB provides objects to configure and manage the DDCFm capabilities.

1 Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects  
2 as follows:

- 3 a) RR subtree: this subtree contains the objects that are applicable to Bridges that support DDCFM's  
4 RR function.
- 5 b) RFM Receiver subtree: this subtree contains the objects that are applicable to Bridges or end stations  
6 that support DDCFM's RFM Receiver function.
- 7 c) DR subtree: this subtree contains the objects that are applicable to Bridges that support DDCFM's  
8 DR function.
- 9 d) SFM Originator subtree: this subtree contains the objects that are applicable to Bridges or end  
10 stations that support DDCFM's SFM Originator function.

11 Table 17-14 indicates the structure of the IEEE8021-DDCFM-MIB module.

#### 1 17.2.10 Structure of the IEEE8021-PBBTE-MIB

2 The IEEE8021-PBBTE-MIB provides objects to configure and manage PBBs that support Traffic  
3 Engineering.

4 Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects.  
5 Where appropriate, the corresponding Clause 12 management reference is also included.

6 Table 17-15 shows the mapping of the PBB-TE Clause 12 managed objects to the tables and columns of the  
7 PBB-TE MIB that model those managed objects.

**Table 17-15—IEEE8021-PBBTE-MIB structure**

| Variable | IEEE8021- PBBTE-MIB table/object             | Reference      |

1 This standard defines a TE-SID as an implementation-dependent identifier used to refer to a TESI. However,  
2 TE-SIDs are used externally by management to refer to these TESIs; in particular they are used to create  
3 MAs that monitor the health of a TESI. Thus, while the identifier itself is implementation dependent, a  
4 canonical external representation of the identifiers is needed for the purpose of MIB definition. The textual  
5 convention `IEEE8021PbbTeTSidId` is used to represent TE-SID values externally. This convention  
6 defines TE-SIDs to be a simple integer of local significance to a particular Bridge component for the  
7 purpose of MIB management.

8 A TESI consists of a set of ESPs. Each ESP is identified by a 3 tuple consisting of an  
9 `<ESP-DA,ESP-SA,ESP-VID>`. These tuples are represented by the textual convention  
10 `IEEE8021PbbTeEsp`, which is a fixed length octet string containing the two MAC addresses along with  
11 the VID value.

12 TESIs themselves are represented by the `ieee8021PbbTeTeSiEspTable`. This table has five columns.  
13 Two are indices and consist of the TE-SID and an index into the list of ESPs. The remaining columns consist  
14 of the ESP itself along with a storage type and row status. The storage type indicates if the value defined by  
15 this row of the MIB persists across system restarts. The row status column is used by the management  
16 station to add, delete, activate, and deactivate rows from this table. Consider Figure 26-7 of this standard.

The `ieee8021PbbTeTeSiEspTable` for that switch would have the information shown in Table 17-16, assuming no other TESIs were configured. In the example shown in Table 17-16, two TESIs are present in the system. The first has a single ESP, while the second has two ESPs.

**Table 17-16—Example of `ieee8021PbbTeTeSiEspTable`**

| ID | EspIndex | Esp               | StorageType | RowStatus |
|----|----------|-------------------|-------------|-----------|
| 1  | 1        | <DA3, SA1, VID-1> | nonVolatile | Active    |
| 2  | 1        | <DA3, SA2, VID-1> | nonVolatile | Active    |
| 2  | 2        | <DA3, SA3, VID-2> | nonVolatile | Active    |

#### 17.2.10.1 Using the MIB to create MAs associated with TESIs

In order to support protection switching, PBB-TE defines a mechanism to allow redundant TESIs to carry the same traffic. The implementation of protection switching requires a mechanism to monitor the health of this TESI. The CFM MA is used as this mechanism.

Configuring an MA requires adding a row to the CFM MIB's `StackTable`. Two columns are used in the `StackTable` to define the data stream upon which the MA operates. These are the `IEEE8021ServiceSelectorType` column and the `IEEE8021ServiceSelectorValue` column. The first column defines how the value in the second column is to be interpreted. If the value of the first column is set to `tesid(3)`, then the second column is interpreted as the external representation of a TE-SID.

Thus, TESIs, and their corresponding identifiers, configured in the `ieee8021PbbTeTeSiEspTable` provide the TE-SID values that are used as parameters to rowcreate operations for the `CFMStackTable` to create MAs that monitor the health of TESIs in a PBB-TE network. Creating entries in the `CFMStackTable`, in turn, defines MAID values, represented as unsigned integers, that are used subsequently to configure the protected service.

#### 17.2.10.2 Using the MIB to create protection groups

A TE protection group is a group of two TESIs referred to as WORKING and PROTECTION between a pair of CBPs. The TE protection group carries a set of backbone service instances between these CBPs and in the event of failure of one of the TESIs, the other TESI is used to transport the backbone service instances.

The TE protection groups are created by adding rows to the `ieee8021PbbTeProtectionGroupListTable`. Each entry in the table contains two columns indicating the MAs associated with the TESIs used to carry the traffic and a `RowStatus` column used to managed the creation and deletion of the TE protection group. The MAs are referred to by MAID and can be found in the `StackTable` of the CFM MIB managed objects.

#### 17.2.10.3 Using the MIB to query and configure protection groups

Each configuration group has status and configuration information that can be managed. This information is located in the `ieee8021PbbTeProtectionGroupConfigTable`. This table allows management stations to determine which TESI is being used to transmit traffic and it also allows for management commands to switch the traffic between the two TESIs. There are also optional parameters that configure the time to trigger a switchover and the time to restore after a failure condition has cleared.

#### 17.2.10.4 Using the MIB to prevent erroneous forwarding in the PBB-TE network

Normally in a bridged network, a frame with an unknown unicast destination address is flooded to an appropriate set of ports determined by the frame's VID. PBB-TE networks do not operate this way. A frame with an unknown unicast destination MAC address whose VID is an ESP-VID is discarded. Item a) 3) of 8.8.1 takes care of this. This clause allows for a new kind of filtering entry. This filtering entry applies to all frames with individual, as opposed to group or broadcast, destination addresses to which no other filtering entry applies. By associating a drop action with this filtering action, the relay function will cause all frames that arrive with a VID belonging to the set of PBB-TE VIDs with an unknown DA to be dropped. The table that sets up these filtering entries is called the `ieee8021PbbTeBridgeStaticForwardAnyUnicastTable`.

#### 17.2.11 Structure of the TPMR MIB

The TPMR MIB is organized into the following MIB groups:

- TPMR Configuration
- TPMR Port Configuration
- TPMR Port Counters
- TPMR Port Discard Details
- TPMR MSP Configuration
- TPMR MSP Statistics

Clause 12 defines the information model associated with this standard in a protocol-independent manner. Table 17-17 describes the relationship between the SMIV2 objects defined in this MIB module and the protocol-independent objects defined in Clause 12.

**Table 17-17—IEEE8021-TPMR-MIB structure**

| Managed object definition                                                                           | IEEE8021-TPMR-MIB table/object                                                                                               | Reference                                                                      |

## 1 17.2.12 Structure of the IEEE8021-FQTSS-MIB

2 The IEEE8021-FQTSS-MIB provides objects to configure and manage those aspects of a VLAN Bridge that  
3 are related to Forwarding and Queuing Enhancements for time-sensitive streams (FQTSS) (see Clause 34).

4 Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects.  
5 Where appropriate, the corresponding Clause 12 management reference is also included.

6 Table 17-18 indicates the structure of the IEEE8021-FQTSS-MIB module.

**Table 17-18—IEEE8021-FQTSS-MIB structure**

<sup>a</sup> This table is an artifact of SNMP, required to find an entry in the ieee8021CnCpTable, given a CPID (32.8.2, 33.4.4).

## 17.2.14 Structure of the IEEE8021-SRP-MIB

The IEEE8021-SRP-MIB provides objects to configure and manage those aspects of a VLAN Bridge that are related to the Stream Reservation Protocol (SRP).

Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects. Where appropriate, the corresponding Clause 12 management reference is also included.

Table 17-20 indicates the structure of the IEEE8021-SRP-MIB module.

**Table 17-20—IEEE8021-SRP-MIB structure**

| ieee8021SrpReservationAccumulatedLatency  | Latency at ingress port for Talker registrations, or latency at end of egress media for Listener Declarations, 12.22.5, 35.2.2.8.6. |
| ieee8021SrpReservationFailureSystemId     | system ID of system that changed Talker Advertise to Talker Failed, 12.22.5, 35.2.2.8.7 a).                                         |
| ieee8021SrpReservationFailureCode         | Failure Code associated with system that changed Talker Advertise to Talker Failed, 12.22.5, 35.2.2.8.7 b).                         |
| ieee8021SrpReservationDroppedStreamFrames | Number of stream data frames (not MSRPDU) that have been dropped for this stream on this port, 12.22.5, 35.2.5.1.                   |
| ieee8021SrpReservationStreamAge           | Number of seconds since reservation was established, 12.22.5, 35.2.1.4 c).                                                          |

## 17.2.15 Structure of the IEEE8021-MVRPX-MIB

The IEEE8021-MVRPX-MIB extends the Bridge Port VLAN table to add three variables to control whether the MVRP Participant on each Port operates as a Full Participant or a New-Only Participant (10.6), how New messages are treated, and whether to transmit the 0 VID. Table 17-21 describes the relationship between the SMIV2 objects defined in the MIB module in 17.7.15 and the variables and managed objects defined in Clause 12.

**Table 17-21—IEEE8021-MVRPX-MIB structure**

| IEEE8021-MVRPX-MIB table/object        | Reference                    |
|----------------------------------------|------------------------------|
| <b>ieee8021MvrpxPortTable</b>          | 12.9.2                       |

## 4 17.2.18 Structure of the IEEE8021-TEIPS-MIB

5 The IEEE8021-TEIPS-MIB provides objects to configure and manage IPS in PBB-TE Region (26.11).

6 Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of related objects.  
7 Where appropriate, the corresponding Clause 12 management reference is also included.

8 Table 17-24 shows the mapping of the IPS Clause 12 managed objects to the tables and columns of the  
9 TEIPS MIB that model those managed objects.

**Table 17-24—IEEE8021-TEIPS MIB structure**

| Variable | IEEE8021-TEIPS-MIB table/object        | Reference      |
|----------|----------------------------------------|----------------|
|          | <b>ieee8021TeipsV2IpgTable</b>         |                |
|          | ieee8021TeipsV2Ipgid                   | 12.24.1.1.3 a) |

1 An IPG can be referenced externally. For this reason, a canonical external IPG identifier is provided via the  
2 textual convention `IEEE8021TeipsIpgid`. The convention defines a simple integer of local significance  
3 to a particular Bridge component for the purpose of MIB management.

4 An Infrastructure Segment can be referenced externally. For this reason, a canonical external Infrastructure  
5 Segment Identifier (SEG-ID) is provided via the textual convention `IEEE8021TeipsSegid`. The  
6 convention defines a simple integer of local significance to a particular Bridge component for the purpose of  
7 MIB management.

8 In the case of 1:1 IPS, an IPG specifies a Working Segment and a Protection Segment. In the case of M:1  
9 IPS, the IPG specifies a Working Segment and a list of candidate Protection Segments from which the  
10 Protection Segment is selected. Each Infrastructure Segment is associated with a pair of Segment  
11 Monitoring Paths (SMPs). Each SMP is identified by a 3-tuple consisting of a  
12 <SMP-DA,SMP-SA,SMP-VID> tuple. Each such tuple is represented by the textual convention  
13 `IEEE8021TeipsSmpid`, which is a fixed-length octet string containing the two MAC addresses and the  
14 VID value.

#### 15 17.2.18.1 Using the TEIPS MIB to create MAs for Infrastructure Segments

16 IPS requires a mechanism to monitor the health of each Infrastructure Segment associated with an IPG. The  
17 CFM MA provides this mechanism.

18 Configuring an MA requires adding a row to the CFM MIB's `StackTable`. Two columns are used in the  
19 `StackTable` to define the Infrastructure Segment upon which the MA operates. These are the  
20 `IEEE8021ServiceSelectorType` column and the `IEEE8021ServiceSelectorValue`  
21 column. The first column defines how the value in the second column is to be interpreted. If the value of the  
22 first column is set to `segid(4)`, then the second column is interpreted as the external representation of a  
23 SEG-ID.

24 Thus, Infrastructure Segments, and their corresponding identifiers, configured in the  
25 `ieee8021TeipsV2SegTable` provide the SEG-ID values that are used as parameters to rowcreate  
26 operations for the `CFMStackTable` to create MAs that monitor the health of Infrastructure Segments.  
27 Creating entries in the `CFMStackTable`, in turn, defines MAID values, represented as unsigned integers,  
28 that are used subsequently to configure the protected services.

## 17.2.18.2 Using the TEIPS MIB to create IPGs

IPGs are created by adding rows to the `ieee8021TeipsV2IpgTable`. Each entry in the table contains columns representing the Working and Protection Segment MAs associated with the IPG, the Port Number associated with each Infrastructure Segment MA, and a RowStatus column used to manage the creation and deletion of the IPG. The MAs are referred to by MAID and can be found in the `StackTable` of the CFM MIB managed objects. The value of the Port Number column is derived from the corresponding Infrastructure Segment MA.

## 17.2.18.3 Using the TEIPS MIB to query and configure IPGs

Each IPG has status and configuration information that can be managed. This information is located in the `ieee8021TeipsV2IpgConfigTable`. This table allows management stations to determine whether the Working Segment or Protection Segment is active, and it allows traffic to be switched by management command. It provides optional parameters for configuration of the waiting time before triggering a switchover and the time to restore after a failure condition has cleared.

## 17.2.19 Structure of the IEEE8021-SPB-MIB

The IEEE8021-SPB-MIB provides objects to configure both SPBV and SPBM as defined in Clause 27 and Clause 28. Table 17-25 describes the relationship between the SMIV2 objects defined in the MIB module in (17.7.19) and the variables and managed objects defined in Clause 12.

**Table 17-25—IEEE8021-SPB-MIB structure**

| IEEE8021-SPB-MIB table/object          | Reference                       |

#### 1 17.2.20 Structure of the IEEE8021-EVB-MIB

2 The IEEE8021-EVB-MIB provides objects to configure and manage an EVB station system or EVB Bridge  
3 system. Objects in this MIB module are arranged into subtrees. Each subtree is organized as a set of  
4 related objects. Where appropriate, the corresponding Clause 12 management reference is also included.  
5 Table 17-26 indicates the structure of the IEEE8021-EVB-MIB module.

## 1 17.2.21 Structure of the IEEE8021-ECMP-MIB

2 The IEEE8021-ECMP-MIB provides for configuration of flow filtering (44.2) on ports (CBPs and PNPs)  
3 and the configuration of ISIS-SPB advertisements specific to the ECMP ECT Algorithm (44.1.2). It also  
4 allows reading of FDB state and statistics related to ECMP and flow filtering. Table 17-27 indicates the  
5 relationship between the SMIV2 objects defined in the MIB module (17.7.21) and managed objects defined  
6 in Clause 12.

\*This object is an INDEX of the table in which it resides.

## 17.3 MIB module relationships

In order to facilitate interoperable management of VLAN Bridges by remote means, 17.7 contains a complete set of SMIPv2 MIB modules.

Some of these MIB modules have been derived from, and now replace, previous IETF MIB modules, as noted in Table 17-1. This was necessary because significant changes had to be made in these MIB modules, in particular the table indexing schemes, to support the evolution of VLAN Bridges. For example, Provider Backbone Bridging, described in Clause 26, supports multiple Bridge instances within a BEB. To avoid duplication of the base Bridge MIB modules within a PBB MIB module, the base Bridge modules have been reindexed to allow their use within a BEB. A BEB may have multiple I-components and zero or one B-components. A component identifier index, unique within a particular BEB, is used in the various MIB tables of these modules to distinguish between instances. In Bridges supporting multiple component or Bridge instances, the component identifier index is still present but is set to a default value of 1.

### 17.3.1 Relationship of the IEEE8021-TC-MIB to other MIB modules

Textual conventions (TCs) originally appeared in each of the MIB modules for IEEE Std 802.1Q produced by the IETF. However, with the transition of all modules for IEEE Std 802.1Q to this clause, it made sense to have a single module with all the TCs contained within it. Note that many of the original IETF TCs are still used in the various MIB modules for VLAN-Bridge management since they can be used unchanged.

These TCs in the IEEE8021-TC-MIB module, as well as many TCs from IETF MIB modules, are used by all of the MIB modules presented in this clause.

The component identifier (IEEE8021PbbComponentIdentifierTC) is defined in this module and is used as the syntax for component ID table indices in subsequent MIB modules.

### 17.3.2 Relationship of the IEEE8021-BRIDGE-MIB to other MIB modules

As described in Table 17-4 of 17.2.2, some IEEE 802.1D management objects have not been included in this MIB module because they overlap with objects in other MIB modules that are applicable to a Bridge implementing this MIB module.

#### 17.3.2.1 Relationship to the SNMPv2-MIB

The SNMPv2-MIB [RFC3418] defines objects that are generally applicable to managed devices. These objects apply to the device as a whole, irrespective of whether the device's sole functionality is bridging, or whether bridging is only a subset of the device's functionality.

As explained in Table 17-4 of 17.2.2, full support for the IEEE 802.1D management objects requires that the SNMPv2-MIB objects sysDescr and sysUpTime be implemented. Note that compliance with the current SNMPv2-MIB module requires additional objects and notifications to be implemented, as specified in IETF RFC 3418.

#### 17.3.2.2 Relationship to the IF-MIB

The IF-MIB [RFC2863], requires that any MIB that is an adjunct of the IF-MIB clarify specific areas within the IF-MIB. These areas were intentionally left vague in the IF-MIB in order to avoid over-constraining the MIB, thereby precluding management of certain media types.

The IF-MIB enumerates several areas that a media-specific MIB must clarify. Each of these areas is addressed in a following subclause. The implementor is referred to the IF-MIB in order to understand the general intent of these areas.

1 The IF-MIB [RFC2863] defines managed objects for managing network interfaces. A network interface is  
2 thought of as being attached to a *subnetwork*. Note that this term is not to be confused with *subnet*, which  
3 refers to an addressing partitioning scheme used in the Internet suite of protocols. The term *segment* is used  
4 in this clause to refer to such a subnetwork, whether it be an Ethernet LAN, a *ring*, a WAN link, or even an  
5 SDH virtual circuit.

6 As explained in 17.2.2, full support for the IEEE 802.1D management objects requires that the IF-MIB  
7 objects ifIndex, ifType, ifDescr, ifPhysAddress, and ifLastChange are implemented. Note that compliance to  
8 the current IF-MIB module requires additional objects and notifications to be implemented as specified in  
9 IETF RFC 2863.

10 Implicit in this BRIDGE-MIB is the notion of Bridge Ports (3.30). Each Bridge Port is associated with one  
11 interface of the *interfaces* subtree (one row in ifTable), and in most situations, each Bridge Port is associated  
12 with a different interface. However, there are situations in which multiple Bridge Ports are associated with  
13 the same interface. That is, for a given IF-MIB, interface refers to one of the interface points in the bridging  
14 architecture (in Figure 8-1), and that zero or more multiple interface table entries can thus be instantiated for  
15 a given Bridge Port. An example of such a situation would be several Bridge Ports each corresponding  
16 one-to-one with several Ethernet private lines (or SDH virtual circuits) but all on the same interface.  
17 Alternatively, there is the Link Aggregation (IEEE Std 802.1AX) case where there are many physical Ports  
18 for one Bridge Port.

19 Each Bridge Port is uniquely identified by a Port Number. A Port Number has no mandatory relationship to  
20 an interface number, but in the simple case, a Port Number will have the same value as the corresponding  
21 interface's interface number. As a result of limitations in the BPDU for STP, this standard [see item i) in  
22 12.3] limits the maximum number of Bridge Ports to 4095. However, in the absence of spanning tree there is  
23 no restriction. As a result, Port Numbers are in the range (1..65 535) to allow correspondence to interface  
24 numbers—but the STP restriction must be adhered to if it is supported on a Bridge.

25 Discontinuities in the value of the counter on the Bridge Port can occur at reinitialization of the management  
26 system, and at other times as indicated by the value of ifCounterDiscontinuityTime object of the associated  
27 interface (if any).

28 Some entities perform other functionalities as well as bridging through the sending and receiving of data on  
29 their interfaces. In such situations, only a subset of the data sent/received on an interface is within the  
30 domain of the entity's bridging functionality. This subset is considered to be delineated according to a set of  
31 protocols, with some protocols being bridged, and other protocols not being bridged. For example, in an  
32 entity that exclusively performs bridging, all protocols would be considered as bridged, whereas in an entity  
33 that performs IP routing on IP datagrams and only Bridges other protocols, only the non-IP data would be  
34 considered as having been bridged.

35 Thus, this BRIDGE-MIB (and in particular, its counters) are applicable only to that subset of the data on an  
36 entity's interfaces that is sent/received for a protocol being bridged. All such data is sent/received via the  
37 Ports of the Bridge.

38 The BRIDGE MIB also defines a new interface type called an internal LAN (I-LAN). This interface is  
39 identified by an ifIndex and is intended to help manage internal associations between bridging components.  
40 The BRIDGE-MIB provides the ability to create and destroy I-LAN interfaces. When an I-LAN interface is  
41 created, a corresponding row is created in the ifTable. The ifType of this interface is 247.<sup>29</sup>

<sup>29</sup> IANA ifType registry is <https://www.iana.org/assignments/ianaiftype-mib/ianaiftype-mib>.

I-LAN interfaces support stacking through the ifStackTable. Through this mechanism, the I-LAN interface can create internal connections between components. For example, an I-LAN interface can connect two C-VLAN components in a system. To complete this process, the following steps are required:

- a) Create C-VLAN component 1.
- b) Create C-VLAN Port 1 on component 1.
- c) Create a Bridge Port interface (ifType 209) identified by ifIndex 1 using a external mechanism.
- d) Associate C-VLAN Port 1 on component 1 to Bridge Port interface 1.
- e) Create an I-LAN interface identified with ifIndex 2.
- f) Stack Bridge Port interface 1 on the I-LAN interface 2.
- g) Create C-VLAN component 2.
- h) Create C-VLAN Port 1 on component 2.
- i) Create a Bridge Port interface (ifType 209) identified by ifIndex 3 using a external mechanism.
- j) Associate C-VLAN Port 1 on component 2 to Bridge Port interface 3.
- k) Stack Bridge Port interface 3 on the I-LAN interface 2.

The result of the previous configuration steps are displayed in the Figure 17-1.

**Figure 17-1—C-VLAN component internal LAN managed system**

As a result, traffic can now be forwarded between C-VLAN component 1 and C-VLAN component 2 through the internal LAN.

### 17.3.2.3 FDB for IEEE 802.1D Bridges

The tables needed to explicitly manage the FDB for IEEE 802.1D Bridges have been removed from the IEEE8021-BRIDGE-MIB. There were separate tables for this function in the original IETF MIBs, but these duplicate tables in the IEEE8021-QBRIDGE MIB and are not needed.

As a result, single FDB implementations, like IEEE Std 802.1D, should just implement the ieee8021QBridgeTpFdbTable with an ieee8021QBridgeFdbId of 1, and setting any VID indices to 0.

### 17.3.3 Relationship of the IEEE8021-RSTP MIB to other MIB modules

The objects in the RSTP MIB supplement those defined in the BRIDGE MIB.

The original IETF BRIDGE-MIB [RFC1493] and its SMIPv2-compliant version [RFC4188] have been replaced by 17.7.2. Besides using different prefix names for modules, an additional index was added to allow use of the RSTP MIB module in PBB.

### 17.3.4 Relationship of the IEEE8021-Q-BRIDGE-MIB to other MIB modules

#### 17.3.4.1 Relationship to the IF-MIB

This standard assumes the interpretation of the Interfaces Subtree to be in accordance with the IF-MIB [RFC2863], which states that the interfaces table (ifTable) contains information on the managed resource's interfaces and that each sublayer below the internetwork layer of a network interface is considered an interface.

This standard does not make any assumption that within an entity, VIDs that are instantiated as an entry in dot1qVlanCurrentTable—either by management configuration through dot1qVlanStaticTable or by dynamic means (e.g., through MVRP)—are also represented by an entry in ifTable.

Where an entity contains higher-layer protocol entities (e.g., IP-layer interfaces that transmit and receive traffic to/from a VLAN), these should be represented by an interface that represents the protocol entity and an interface of ifType l2vlan (135) with the ifStackTable indicating the stacking relationship between the two entities.

#### 17.3.4.1.1 ifStackTable

In addition, the IF-MIB [RFC2863] defines a table 'ifStackTable' for describing the relationship between logical interfaces within an entity. It is anticipated that implementors will use this table to describe the binding of (for example) Link Aggregation Group (LAG) interfaces to physical Ports, although the presence of VLANs makes the representation less than perfect for showing connectivity. The ifStackTable cannot represent the full capability of this standard, since this standard makes a distinction between VLAN bindings on *ingress* to and *egress* from a Port. These relationships may or may not be symmetrical; whereas, Interface MIB Evolution assumes a symmetrical binding for transmit and receive. This makes it necessary to define other manageable objects for configuring which Ports are in the member set for which VIDs.

#### 17.3.4.1.2 ifRcvAddressTable

This table contains all MAC addresses, unicast, multicast, and broadcast, for which an interface will receive frames and forward them up to a higher-layer entity for local consumption. Note that this does not include addresses for data-link layer control protocols such as STP, RSTP, MSTP, MMRP, or MVRP. The format of the address, contained in ifRcvAddressAddress, is the same as for ifPhysAddress.

This table does not include unicast or multicast addresses that are accepted for possible forwarding out some other Port. This table is explicitly not intended to provide a Bridge address filtering mechanism.

#### 17.3.4.2 Relationship to IEEE8021-BRIDGE-MIB

This subclause defines how objects in the IEEE8021-BRIDGE-MIB module should be represented for devices that implement the extensions. Some of the old objects are less useful in such devices, but must still be implemented for reasons of backwards compatibility.

#### 1 17.3.4.2.1 ieee8021BridgeBase subtree

2 This subtree contains objects that are applicable to all types of Bridges. Interpretation of this subtree is  
3 unchanged.

#### 4 17.3.4.2.2 ieee8021BridgeTp subtree

5 This subtree contains objects that describe the entity's state with respect to transparent bridging.

6 In a device operating with a single FDB, interpretation of this subtree is unchanged.

7 In a device supporting multiple FDBs, this subtree is interpreted as follows:

- 8 a) ieee8021BridgeTpLearnedEntryDiscards  
9 The number of times that any of the FDBs became full.
- 10 b) ieee8021BridgeTpAgingTime  
11 This applies to all FDBs.
- 12 c) ieee8021BridgeTpFdbTable  
13 Report MAC addresses learned on each Port, regardless of which FDB they have been learned in. If  
14 an address has been learned in multiple databases on a single Port, report it only once. If an address  
15 has been learned in multiple databases on more than one Port, report the entry on any one of the  
16 valid Ports.
- 17 d) ieee8021BridgeTpPortTable  
18 This table is Port-based and is not affected by multiple FDBs or multiple VIDs. The counters should  
19 include frames received or transmitted for all VIDs.

#### 20 17.3.4.2.3 ieee8021BridgeStatic subtree

21 This optional subtree contains objects that describe the configuration of destination-address filtering.

22 In a device operating with a single FDB, interpretation of this subtree is unchanged.

23 In a device supporting multiple FDBs, this subtree is interpreted as follows:

- 24 a) ieee8021BridgeStaticTable  
25 Entries read from this table include all static entries from all of the FDBs. Entries for the same MAC  
26 address and receive Port in more than one FDB must appear only once, since these are the indices of  
27 this table. This table should be implemented as read-only in devices that support multiple FDBs.  
28 Instead, write access should be provided through dot1qStaticUnicastTable and  
29 dot1qStaticMulticastTable, as defined in this standard.

#### 30 17.3.4.2.4 Additions to the IEEE8021-BRIDGE-MIB

31 To supplement the BRIDGE-MIB, this module contains the following:

- 32 a) Support for multiple traffic classes and dynamic multicast filtering as per IEEE Std 802.1D.
- 33 b) Support for bridged VLANs as per IEEE Std 802.1Q.
- 34 c) Support for 64-bit versions of BRIDGE-MIB Port counters.

#### 35 17.3.5 Relationship of the IEEE8021-PB-BRIDGE MIB to other MIB modules

36 To supplement the Q-BRIDGE-MIB, this module contains the following:

- 37 a) The Q-Bridge MIB directly supports VID translation. The original bidirectional VID translation of  
38 PB MIB is supported by the Q-Bridge MIB as well as separate ingress and egress VID translation.
- 39 b) Support for Provider Edge Bridges.

### 1 17.3.6 Relationship of the IEEE8021-MSTP-MIB to other MIB modules

2 The objects in the IEEE8021-MSTP-MIB supplement those defined in the IEEE8021-RSTP MIB.

### 3 17.3.7 Relationship of the IEEE8021-CFM-MIB to other MIB modules

#### 4 17.3.7.1 Relationship to Interface MIB

5 Subclause 17.7.7 defines a CFM MIB module that supports 12.14 with the textual conventions imported  
6 from the TC MIB in 17.7.1. A system implementing the CFM MIB module in 17.7.7 shall also implement at  
7 least the System Group of the SNMPv2-MIB defined in IETF RFC 3418 and the Interfaces Group (the  
8 Interfaces MIB module, or IF-MIB) defined in IETF RFC 2863. The Interfaces Group has one conceptual  
9 row in a table for every interface in a system. 3.3 of IETF RFC 2863 defines hierarchical relationships  
10 among interfaces.

11 IETF RFC 2863 also requires that any MIB module that is an adjunct of the Interface Group clarify specific  
12 areas within the Interface MIB module. These areas were intentionally left vague in IETF RFC 2863 to  
13 avoid over-constraining the MIB, thereby precluding management of certain media types. These areas are  
14 clarified in other clauses that define the Bridge MIB modules. Even if a Bridge supports none of these, if it  
15 supports the CFM MIB module, and hence, the Interfaces Group, the clarifications from the other clauses  
16 shall be applied to the Interfaces Group. The relationship between IETF RFC 2863 and IETF RFC 3418  
17 interfaces and Bridge Ports is also described in previous subclauses of 17.3. In addition, if both the CFM  
18 MIB module (17.7.7) and IEEE Std 802.1AX are supported, a Bridge shall

- 19 a) Assign each IEEE 802.1AX Port in the aggregation its own conceptual row in the IETF RFC 2863  
20 IF-MIB.
- 21 b) Assign one conceptual row in the IETF RFC 2863 IF-MIB that references the aggregated Port. This  
22 may be the same as the interface identifying the Bridge Port. It shall not be the same as any of the  
23 IEEE 802.1AX Ports being aggregated.

#### 24 17.3.7.2 IEEE8021-CFM-MIB and IEEE8021-CFM-V2-MIB

25 The inclusion of PBB (Clause 26) required the addition of additional indices to numerous tables in the CFM  
26 MIB. As a result, these tables are deprecated in the existing IEEE8021-CFM-MIB module and new  
27 reindexed tables are created in a second IEEE8021-CFM-V2-MIB module. Unchanged tables remain in the  
28 IEEE8021-CFM-MIB module. Specifically, groups with tables left unchanged are imported in the  
29 IEEE8021-CFM-V2-MIB module to appear in the compliance statement and new groups containing the new  
30 reindexed tables are added to the compliance statement.

31 The following tables are renamed:

32 dot1agPbbCfmStackTable  
33 dot1agPbbCfmVlanTable  
34 dot1agPbbCfmDefaultMdTable  
35 dot1agPbbCfmConfigErrorListTable  
36 dot1agPbbCfmMaCompTable

37 The new names are as follows:

38 ieee8021CfmStackTable  
39 ieee8021CfmVlanTable  
40 ieee8021CfmDefaultMdTable  
41 ieee8021CfmConfigErrorListTable  
42 ieee8021CfmMaCompTable

### 17.3.8 Relationship of the IEEE8021-PBB-MIB to other MIB modules

The IF-MIB, [RFC2863], requires that any MIB that is an adjunct of the IF-MIB clarify specific areas within the IF-MIB. These areas were intentionally left vague in the IF-MIB in order to avoid over-constraining the MIB, thereby precluding management of certain media types. The IF-MIB enumerates several areas that a media-specific MIB must clarify. Each of these areas is addressed in a following subclause. The implementor is referred to the IF-MIB in order to understand the general intent of these areas. The IF-MIB [RFC2863] defines managed objects for managing network interfaces.

A network interface is considered attached to a *subnetwork*. The term *segment* is used to refer to such a subnetwork, whether it be an Ethernet LAN, a *ring*, a WAN link, or even an SDH virtual circuit. Full support for PBB managed objects requires that the IF-MIB objects `ifIndex`, `ifType`, `ifDescr`, `ifPhysAddress`, and `ifLastChange` be implemented. Note that compliance to the current IF-MIB module requires additional objects and notifications to be implemented as specified in IETF RFC 2863.

The interpretation of the Interfaces Subtree is assumed to be in accordance with the IF-MIB, which states that the interfaces table (`ifTable`) contains information on the managed resource's interfaces and that each sublayer below the internetwork layer of a network interface is considered an interface. Specifically, in the PBB MIB module, the PIP index has been equated to an interface index (`ifIndex`). Therefore, when a PIP is created, a row is also created in the `ifTable` identified by the PIP's `ifIndex`. The `ifType` of this interface is 248.<sup>30</sup>

In addition, the IF-MIB defines a table 'ifStackTable' for describing the relationship between logical interfaces within an entity. The `ifStackTable` cannot represent the full capability of this standard, since this standard makes a distinction between VLAN bindings on *ingress* to and *egress* from a Port. These relationships may or may not be symmetrical; whereas, Interface MIB Evolution assumes a symmetrical binding for transmit and receive. This makes it necessary to define other manageable objects for configuring which Ports are in the member set for which VIDs.

A PIP supports stacking through the `ifStackTable`. For external PIP interfaces, a PIP can be stacked on an Ethernet interface (`ifType` 6). If the PIP is internal, it can be stacked on an I-LAN interface to create a connection between an I-component and a B-component. The following is an example of how this process is completed:

- a) Create I-component 1.
- b) Create VIP 1 on component 1.
- c) Create a PIP identified by `ifIndex` 1.
- d) Associate VIP 1 on component 1 to the PIP.
- e) Create an I-LAN interface identified with `ifIndex` 2.
- f) Stack PIP 1 on the I-LAN interface 2.
- g) Create B-component 2.
- h) Create CBP 1 on component 2.
- i) Associate CBP 1 on component 2 to I-LAN interface 2.

The result of the previous configuration steps are displayed in Figure 17-2.

As a result, traffic can now be forwarded between I-component 1 and B-component 2 once a service is provisioned.

<sup>30</sup> IANA `ifType` registry is <https://www.iana.org/assignments/ianaiftype-mib/ianaiftype-mib>.

Figure 17-2—I/B-component internal LAN managed system

### 17.3.9 Relationship of the IEEE8021-DDCFM to other MIB modules

Subclause 17.7.9 defines the DDCFM MIB module that supports 12.17. A system implementing the DDCFM MIB module in 17.7.9 shall also implement at least the System Group of the SNMPv2-MIB defined in IETF RFC 3418 and Interfaces Group (the Interfaces MIB module, or IF-MIB) defined in IETF RFC 2863.

### 17.3.10 Relationship of the IEEE8021-PBBTE-MIB to other MIB modules

The IEEE8021-PBBTE-MIB is used to manage IB-BEBs that support additional PBB-TE functionality for the configuration of TESIs across provider backbone networks. The IEEE8021-PBBTE-MIB uses textual conventions and objects from the following MIB modules:

- IEEE8021-TC-MIB
- IEEE8021-BRIDGE-MIB
- Q-BRIDGE-MIB
- IEEE8021-Q-BRIDGE-MIB

The IEEE8021-PBBTE-MIB has the purpose of managing PBB-TE-specific functionality. As a PBB-TE IB-BEB is a specialized PBB IB-BEB with additional functionality, management of the system will also require that the system support the following Clause 17 MIB modules:

- IEEE8021-BRIDGE-MIB
- IEEE8021-CFM-MIB
- IEEE8021-CFM-V2-MIB
- IEEE8021-Q-BRIDGE-MIB
- IEEE8021-MSTP-MIB
- IEEE8021-PB-MIB
- IEEE8021-PBB-MIB

Specifically, support of the IEEE-PBBTE-MIB requires that the system support the MIB and compliances in Table 17-1.

**Table 17-1—PBB-TE required MIB compliances**

| MIB                 | Compliance                     |
|---------------------|--------------------------------|
| IEEE8021-PBB-MIB    | ieee8021PbbWithPbbTeCompliance |
| IEEE8021-CFM-MIB    | dot1agCfmWithPbbTeCompliance   |
| IEEE8021-CFM-V2-MIB |                                |

### 17.3.11 Relationship of the IEEE8021-TPMR MIB to other MIB modules

Subclause 17.7.11 defines a TPMR MIB module that supports the managed objects defined in 12.19. A system implementing the TPMR MIB module in 17.7.11 shall also implement at least the System Group of the SNMPv2-MIB defined in IETF RFC 3418 and the Interfaces Group (the Interfaces MIB module, or IF-MIB) defined in IETF RFC 2863. The Interfaces Group has one conceptual row in a table for every interface in a system. See Table 17-17 for the key objects from the System and Interfaces groups.

### 17.3.12 Relationship of the IEEE8021-FQTSS-MIB to other MIB modules

The IEEE8021-FQTSS-MIB provides objects that extend the core management functionality of a Bridge, as defined by the IEEE8021-BRIDGE-MIB (17.7.2), in order to support the additional management functionality needed when the FQTSS, as defined in Clause 34, is supported by the Bridge. As support of the objects defined in the IEEE8021-FQTSS-MIB also requires support of the IEEE8021-BRIDGE-MIB, the provisions of 17.3.2 apply to implementations claiming support of the IEEE8021-FQTSS-MIB.

### 17.3.13 Relationship of the IEEE802-CN-MIB to other MIB modules

#### 17.3.13.1 Interface MIB

Subclause 17.7.13 defines a Congestion Notification MIB (IEEE802-CN-MIB) module that supports congestion notification with the textual conventions imported from the TC MIB in 17.7.13. A system implementing the IEEE802-CN-MIB module in 17.7.13 shall also implement at least the System Group of the SNMPv2-MIB defined in IETF RFC 3418 and the Interfaces Group (the Interfaces MIB module, or IF-MIB) defined in IETF RFC 2863. The Interfaces Group has one conceptual row in a table for every interface in a system. 3.3 of IETF RFC 2863 defines hierarchical relationships among interfaces. IETF RFC 2863 also requires that any MIB module that is an adjunct of the Interface Group clarify specific areas within the Interface MIB module. These areas were intentionally left vague in IETF RFC 2863 to avoid over-constraining the MIB, thereby precluding management of certain media types. These areas are clarified in other clauses that define the MIB modules in this standard. Even if a system supports none of these, if it supports the IEEE802-CN-MIB module, and hence, the Interfaces Group, the clarifications from the other clauses shall be applied to the Interfaces Group. The relationship between IETF RFC 2863 and IETF RFC 3418 interfaces and ports is also described in previous subclauses of 17.3. In addition, if both the IEEE802-CN-MIB module (17.7.13) and IEEE Std 802.1AX are supported, a Bridge component or end station may

- a) Assign each port in the aggregation its own conceptual row in the IETF RFC 2863 IF-MIB.
- b) Assign one conceptual row in the IETF RFC 2863 IF-MIB that references the aggregated port. This can be the same as the interface identifying the port. It shall not be the same as any of the ports being aggregated.

### 17.3.13.2 IEEE8021-CFM-MIB and IEEE8021-CFM-V2-MIBs

Subclause 31.1 allows a system that supports either the dot1agCfmVlanTable from the IEEE8021-CFM-MIB module or the ieee8021CfmVlanTable from the IEEE8021-CFM-V2-MIB module to use those tables to select the vlan\_identifier for a transmitted CNM.

### 17.3.14 Relationship of the IEEE8021-SRP-MIB to other MIB modules

The IEEE8021-SRP-MIB provides objects that extend the core management functionality of a Bridge, as defined by the IEEE8021-BRIDGE-MIB (17.7.2), in order to support the management functionality needed when the SRP extensions, as defined in Clause 35, are supported by the Bridge. As support of these objects defined in the IEEE8021-SRP-MIB also requires support of the IEEE8021-TC-MIB, IEEE8021-BRIDGE-MIB, and IEEE8021-FQTSS-MIB, the provisions of 17.3.2 apply to implementations claiming support of the IEEE8021-SRP-MIB.

### 17.3.15 Relationship of the IEEE8021-MVRPX-MIB to other MIB modules

The IEEE8021-MVRPX-MIB, because it adds variables to the ieee8021BridgeBasePortEntry in the IEEE8021-BRIDGE-MIB, depends upon that MIB. It also imports items from the SNMPv2-SMI, SNMPv2-TC, and SNMPv2-CONF MIBs, and requires the systemGroup of the SNMPv2-MIB for conformance.

### 17.3.16 Relationship of the IEEE8021-MIRP-MIB to other MIB modules

The IEEE8021-MIRP-MIB, because it extends the variables in the IEEE8021-PBB-MIB (17.7.8), depends upon that MIB. Because it adds a variable to the ieee8021BridgeBasePortEntry in the IEEE8021-BRIDGE-MIB, it also depends upon that MIB. It also imports items from the SNMPv2-SMI, SNMPv2-TC, SNMPv2-CONF, and Q-BRIDGE-MIB MIBs, and requires the systemGroup of the SNMPv2-MIB for conformance.

### 17.3.17 Relationship of the IEEE8021-PFC-MIB to other MIB modules

A system implementing the IEEE8021-PFC-MIB module (17.7.17) shall also implement at least the System Group of the SNMPv2-MIB defined in IETF RFC 3418 and the Interfaces Group (the Interfaces MIB module, or IF-MIB) defined in IETF RFC 2863. The Interfaces Group has one conceptual row in a table for every interface in a system. 3.3 of IETF RFC 2863 defines hierarchical relationships among interfaces. IETF RFC 2863 also requires that any MIB module that is an adjunct of the Interface Group clarify specific areas within the Interface MIB module. These areas were intentionally left vague in IETF RFC 2863 to avoid over constraining the MIB, thereby precluding management of certain media types. These areas are clarified in other clauses which define the MIB modules in this standard. Even if a system supports none of these, if it supports the PFC MIB module, and hence, the Interfaces Group, the clarifications from the other clauses shall be applied to the Interfaces Group. The relationship between IETF RFC 2863 and IETF RFC 3418 interfaces and ports is also described in previous subclauses of 17.3.

### 17.3.18 Relationship of the IEEE8021-TEIPS-MIB to other MIB modules

The IEEE8021-TEIPS-MIB is used to manage IB-BEBs and BCBs that support IPS functionality. The IEEE8021-TEIPS-MIB uses textual conventions and objects from the following MIB modules:

- IEEE8021-TC-MIB
- IEEE8021-BRIDGE-MIB

The IEEE8021-TEIPS-MIB has the purpose of managing IPS in PBB-TE Region (26.11). Thus, use of the IEEE8021-TEIPS-MIB requires that the system support the same set of MIB modules specified within 17.3.10 and requires the compliances described by Table 17-21.

### 17.3.19 Relationship of the IEEE8021-SPB-MIB to other MIB modules

The IEEE8021-SPB-MIB, because it provides mainly control plane functions and reuses VLANs in the Q-BRIDGE-MIB depends on that MIB. It also imports items from the SNMPv2-SMI, SNMPv2-TC, IF-MIB, and IEEE8021-TC-MIB, and requires SNMPv2-CONF for conformance.

PCR operations are based on ISIS-SPB sub-TLVs, with additional objects that support MRT operations.

### 17.3.20 Relationship of the IEEE8021-EVB-MIB to other MIB modules

The IEEE8021-EVB-MIB provides objects that extend the core management functionality of a Bridge, as defined by the IEEE8021-BRIDGE-MIB (17.7.2), in order to support the management functionality needed for EVB (5.23, 5.24), as defined in Clause 40, Clause 41, Clause 42, and Clause 43. As support of the objects defined in the IEEE8021-EVB-MIB also requires support of the IEEE8021-TC-MIB and IEEE8021-BRIDGE-MIB, the provisions of 17.3.2 apply to implementations claiming support of the IEEE8021-EVB-MIB.

### 17.3.21 Relationship of the IEEE8021-ECMP-MIB to other MIB modules

The IEEE8021-ECMP-MIB extends SPBM functionality and therefore is closely related to the IEEE8021-SPB-MIB and IEEE8021-PBB-MIB. For example, it includes configuration for an optional ISIS-SPB sub-TLV for the ECMP ECT Algorithm (28.12.6.1) and configuration for flow filtering on PNPs and CBPs (44.2.2).

Because it provides control functions related to VIDs, it depends on the Q-BRIDGE-MIB. It also augments tables defined in the IEEE8021-Q-BRIDGE-MIB (adding the ability to read the FDB Port Map for an individual address and adding TTL discard statistics). It also imports items from the SNMPv2-SMI, SNMPv2-TC, and IEEE8021-TC-MIB and requires SNMPv2-CONF for conformance.

### 17.3.22 Relationship of the IEEE8021-ST-MIB to other MIB modules

The IEEE8021-ST-MIB provides objects that extend the core management functionality of a Bridge, as defined by the IEEE8021-BRIDGE-MIB (17.7.2), in order to support the additional management functionality needed when the scheduled traffic extensions, as defined in 8.6.8.4, are supported by the Bridge. As support of the objects defined in the IEEE8021-ST-MIB also requires support of the IEEE8021-BRIDGE-MIB, the provisions of 17.3.2 apply to implementations claiming support of the IEEE8021-ST-MIB.

### 17.3.23 Relationship of the IEEE8021-Preemption-MIB to other MIB modules

The IEEE8021-Preemption-MIB provides objects that extend the core management functionality of a Bridge, as defined by the IEEE8021-BRIDGE-MIB (17.7.2), in order to support the additional management functionality needed when the frame preemption extensions are supported by the Bridge. As support of the objects defined in the IEEE8021-Preemption-MIB also requires support of the IEEE8021-BRIDGE-MIB, the provisions of 17.3.2 apply to implementations claiming support of the IEEE8021-Preemption-MIB.

### 17.3.24 Relationship of the IEEE8021-PSFP-MIB to other MIB modules

The IEEE8021-PSFP-MIB provides objects that extend the core management functionality of a Bridge, as defined by the IEEE8021-BRIDGE-MIB (17.7.2), in order to support the additional management functionality needed when the PSFP extensions, as defined in 8.6.5.2.1 and 8.6.10, are supported by the Bridge. As support of the objects defined in the IEEE8021-PSFP-MIB also requires support of the IEEE8021-BRIDGE-MIB, the provisions of 17.3.2 apply to implementations claiming support of the IEEE8021-PSFP-MIB.

### **1 17.3.25 Relationship of the IEEE8021-TSN-REMOTE-MANAGEMENT-MIB to other MIB 2 modules**

3 The IEEE8021-TSN-REMOTE-MANAGEMENT-MIB provides objects that support management of TSN  
4 stream reservations by providing Bridge transit delay and Bridge Port propagation delay information, by  
5 allowing a remote manager to determine whether static trees are supported (12.32.3), and provides  
6 additional control over MSRP attribute propagation. As support of the objects defined in the  
7 IEEE8021-TSN-REMOTE-MANAGEMENT-MIB also requires support of the IEEE8021-BRIDGE-MIB,  
8 the provisions of 17.3.2 apply to implementations claiming support of the  
9 IEEE8021-TSN-REMOTE-MANAGEMENT-MIB.

### **10 17.3.26 Relationship of the IEEE8021-PBBN-AA-MIB to other MIB modules**

11 The IEEE8021-PBBN-AA-MIB provides objects that extend the functionality of IEEE802.1AB LLDP.

## **12 17.4 Security considerations**

13 SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for  
14 example, by using IPsec), there is no control about who on the secure network is allowed to access and  
15 GET/SET (read/change/create/delete) the objects in these MIB modules.

16 It is recommended that implementers consider the security features as provided by the SNMPv3 framework  
17 (see IETF RFC 3410 (2002), section 8), including full support for the SNMPv3 cryptographic mechanisms  
18 (for authentication and privacy).

19 Further, deployment of SNMP versions prior to SNMPv3 is not recommended. Instead, it is recommended  
20 to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to  
21 ensure that the SNMP entity giving access to an instance of these MIB modules is properly configured to  
22 give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET  
23 (change/create/delete) them.

### **24 17.4.1 Security considerations of the IEEE8021-TC-MIB**

25 This module does not define any management objects. Instead, it defines a set of textual conventions that  
26 may be used by other MIB modules to define management objects. Meaningful security considerations are  
27 contained in the following subclauses that describe security considerations for other MIB modules that  
28 define management objects with a SYNTAX of any of these textual conventions.

### **29 17.4.2 Security considerations of the IEEE8021-BRIDGE-MIB**

30 There are a number of management objects defined in the IEEE8021-BRIDGE-MIB module that have a  
31 MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or  
32 vulnerable in some network environments. The support for SET operations in a nonsecure environment  
33 without proper protection can have a negative effect on network operations.

34 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
35 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
36 important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to  
37 even encrypt the values of these objects when sending them over the network via SNMP.

1 The following tables and objects in the IEEE8021-BRIDGE-MIB can be manipulated to interfere with the  
2 operation of priority classes. This could, for example, be used to force a reinitialization of state machines,  
3 thus causing network instability. Another possibility would be for an attacker to override established policy  
4 on Port priorities, thus giving a user (or an attacker) unauthorized preferential treatment.

5       ieee8021TrafficClassesEnabled  
6       ieee8021GmrpStatus  
7       ieee8021PortPriorityTable  
8       ieee8021UserPriorityRegenTable  
9       ieee8021TrafficClassTable  
10       ieee8021PortGarpTable  
11       ieee8021PortGmrpTable

- 12 a) The writable object ieee8021BridgeTpAgingTime controls how fast dynamically-learned  
13 forwarding information is aged out. Setting this object to a large value may simplify FDB overflow  
14 attacks. Setting this object to too small a value may compromise the throughput of the network by  
15 causing excessive flooding.
- 16 b) The writable ieee8021BridgeStaticTable provides a filtering mechanism controlling to which Ports  
17 frames originating from a specific source may be forwarded. Write access to this table can be used to  
18 turn provisioned filtering off or to add filters to prevent rightful use of the network.

19 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
20 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
21 important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to  
22 even encrypt the values of these objects when sending them over the network via SNMP. These tables and  
23 objects and their sensitivity/vulnerability are described as follows:

- 24 — The objects ieee8021DeviceCapabilities and ieee8021PortCapabilitiesTable in the  
25 IEEE8021-P-BRIDGE-MIB could be used by an attacker to determine which attacks might be  
26 useful to attempt against a given device.
- 27 — The readable objects defined in the IEEE8021-BRIDGE-MIB module provide information about the  
28 topology of a bridged network and the attached active stations. The addresses listed in the  
29 ieee8021BridgeTpFdbTable usually reveal information about the manufacturer of the MAC  
30 hardware, which can be useful information for mounting other specific attacks.
- 31 — The two notifications, newRoot and topologyChange, are emitted during spanning tree computation  
32 and may trigger management systems to inspect the status of Bridges and to recompute internal  
33 topology information. Hence, forged notifications may cause management systems to perform  
34 unnecessary computations and to generate additional SNMP traffic directed to the Bridges in a  
35 network. Therefore, forged notifications may be part of a denial of service attack.

#### 36 17.4.3 Security considerations of the IEEE8021-SPANNING-TREE MIB

37 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
38 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
39 environments. The support for SET operations in a nonsecure environment without proper protection can  
40 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
41 described below.

42 The following writable objects could be misused to cause network delays and spanning tree instabilities:

43       ieee8021SpanningTreeVersion  
44       ieee8021SpanningTreeRstpTxHoldCount  
45       ieee8021SpanningTreeRstpPortProtocolMigration  
46       ieee8021SpanningTreeRstpPortAdminEdgePort

1 ieee8021SpanningTreeRstpPortAdminPathCost  
2 ieee8021SpanningTreeRstpPortAdminPointToPoint

3 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
4 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
5 important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to  
6 even encrypt the values of these objects when sending them over the network via SNMP. These tables and  
7 objects and their sensitivity/vulnerability are described below:

8 ieee8021SpanningTreeVersion could be read by an attacker to identify environments containing applications  
9 or protocols that are potentially sensitive to RSTP mode.

10 The writable objects:

11 ieee8021SpanningTreePriority  
12 ieee8021SpanningTreeBridgeMaxAge  
13 ieee8021SpanningTreeBridgeHelloTime  
14 ieee8021SpanningTreeBridgeForwardDelay  
15 ieee8021SpanningTreePortPriority  
16 ieee8021SpanningTreePortEnable  
17 ieee8021SpanningTreePortPathCost

18 influence the spanning tree protocol. Unauthorized write access to these objects can cause the spanning tree  
19 protocol to compute other default topologies or it can change the speed in which the spanning tree protocol  
20 reacts to failures.

#### 21 17.4.4 Security considerations of the IEEE8021-Q-BRIDGE-MIB

22 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
23 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
24 environments. The support for SET operations in a nonsecure environment without proper protection can  
25 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
26 described below.

27 The following tables and objects in the IEEE8021-Q-BRIDGE-MIB could be manipulated to interfere with  
28 the operation of VLANs. This could, for example, be used to force a reinitialization of state machines to  
29 cause network instability, or to change the forwarding and filtering policies.

30 ieee8021GvrpStatus  
31 ieee8021ForwardAllTable  
32 ieee8021StaticUnicastTable  
33 ieee8021StaticMulticastTable  
34 ieee8021VlanStaticTable  
35 ieee8021PortVlanTable  
36 ieee8021LearningConstraintsTable  
37 ieee8021ProtocolGroupTable  
38 ieee8021ProtocolPortTable

39 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
40 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
41 important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to  
42 even encrypt the values of these objects when sending them over the network via SNMP. These tables and  
43 objects and their sensitivity/vulnerability are described below.

1 The following read-only tables and objects in the IEEE8021-Q-BRIDGE-MIB could be used by an attacker  
2 to determine which attacks might be useful to attempt against a given device, could be used by an attacker to  
3 detect whether their attacks are being blocked or filtered, or could be used to understand the logical topology  
4 of the network.

5       ieee8021MaxVlanID

7       ieee8021NumVlans  
8       ieee8021FdbTable  
9       ieee8021TpFdbTable  
10       ieee8021TpPortGroupTable  
11       ieee8021VlanCurrentTable  
12       ieee8021PortVlanStatisticsTable

#### 13 **17.4.5 Security considerations of the IEEE8021-PB-MIB**

14 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
15 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
16 environments. The support for SET operations in a non-secure environment without proper protection can  
17 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
18 described below.

19 The following tables and objects in the PB-MIB could be manipulated to interfere with the operation of  
20 VLANs. This could, for example, be used to force a reinitialization of state machines to cause network  
21 instability, or to change the forwarding and filtering policies.

22       ieee8021PbProviderBridgePortTable  
23       ieee8021PbVidTranslationTable  
24       ieee8021PbCVidRegistrationTable  
25       ieee8021PbEdgePortTable  
26       ieee8021PbInternalInterfaceTable

#### 27 **17.4.6 Security considerations of the IEEE8021-MSTP-MIB**

28 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
29 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
30 environments. The support for SET operations in a nonsecure environment without proper protection can  
31 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
32 described below.

33 Writable objects that could be misused to cause network delays and spanning tree instabilities include the  
34 following:

35       ieee8021CistEnableBPDURx  
36       ieee8021CistEnableBPDUTx  
37       ieee8021CistPortAdminEdgePort  
38       ieee8021CistPortMacEnabled  
39       ieee8021MstpPortPriority  
40       ieee8021MstpPortPathCost

1 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
2 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
3 important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to  
4 even encrypt the values of these objects when sending them over the network via SNMP. These tables and  
5 objects and their sensitivity/vulnerability are described below:

6 ieee8021SpanningTreeVersion could be read by an attacker to identify environments containing applications  
7 or protocols that are potentially sensitive to RSTP mode.

#### 8 **17.4.7 Security considerations of the IEEE8021-CFM-MIB**

9 It is expected that, in some provider networks, management access to a Bridge can be granted, by an  
10 organization that owns and is responsible for the normal operations of the Bridge, to another organization  
11 that needs to configure and manage CFM entities in that Bridge. For example, a Provider could sell a service  
12 to a customer that connects sites in cities thousands of kilometers apart. That Provider might not have a  
13 physical presence in all of those cities (or any of them, for that matter) and therefore would need to contract  
14 with other Providers to supply a number of interconnected PBNs that together are able to offer the service to  
15 the customer. The relationship between the Provider and Owner is not necessarily cordial; there can be  
16 personal or financial incentives for misbehavior.

17 To support this scenario, the MIB module in 17.7.7 defines the Maintenance Domain table—  
18 dot1agCfmMdTable. Each row (dot1agCfmMdEntry) in this table corresponds to one Maintenance Domain  
19 managed object (12.14.5). A Maintenance Domain managed object can be created, read, and written by the  
20 Bridge's Owner. More limited access to that object can be granted to another Provider, who thereby becomes  
21 that Maintenance Domain's administrator. Associated with each row in the Maintenance Domain table are  
22 any number of rows (dot1agCfmMaNetEntry and dot1agCfmMaCompEntry) in the MA  
23 tables—dot1agCfmMaNetTable and dot1agCfmMaCompTable. Each of the paired rows in these two tables  
24 corresponds to a Maintenance Association managed object (12.14.6). A Maintenance Domain administrator  
25 has the ability to create and alter these rows. Additional MIB tables are defined in 17.7.7 that correspond to  
26 the Maintenance Domain list managed object (12.14.1), the CFM Stack managed object (12.14.2), and the  
27 Default MD Level managed object (12.14.3), all of which can be used by an Owner of the Bridge, but not by  
28 a Maintenance Domain administrator.

29 The SNMPv3 framework (IETF STD 62) defines a securityName, which provides for secure identification  
30 of a user (or group of users) via an SNMPv3 Security Model. For ease of reference in this present standard,  
31 the "Owner" of a system (in particular, a Bridge) is defined as a user whose "MIB view" includes  
32 READ-WRITE access to the System Group of the SNMPv2-MIB (IETF RFC 3418). A Management  
33 Domain administrator is then a user whose MIB view includes more limited access to the Maintenance  
34 Domain managed object, and full READ-WRITE access to its subordinate Maintenance Association  
35 managed objects (12.14.6), each of which is a pair of rows (dot1agCfmMaNetEntry and  
36 dot1agCfmMaCompEntry) in the two tables—dot1agCfmMaNetTable and dot1agCfmMaCompTable.

37 A Bridge can support IETF STD 62 (SNMPv3) in order to provide a secure means for confining access by  
38 Management Domain administrators to their corresponding Maintenance Association managed objects, and  
39 to prevent inappropriate access to the rest of the Bridge's management objects. If the SNMPv3 framework is  
40 not implemented in a Bridge, an Owner is defined, imprecisely, as an administrator of the Bridge, and a  
41 Management Domain administrator (even less precisely) as an administrator of one Management Domain.

42 Therefore, it is recommended that the implementors consider the security features as provided by the  
43 SNMPv3 framework, including full support for the SNMPv3 cryptographic mechanisms (for authentication  
44 and privacy). Specifically, a Bridge can use the User-Based Security Model, IETF RFC 3414, and/or the  
45 View-Based Access Control Model, IETF RFC 3415, for controlling access to the CFM managed objects. It

1 is then a customer/user responsibility to ensure that the SNMP agent giving access to an instance of this MIB  
2 is properly configured to give access to the objects only to those principals (users) that have legitimate rights  
3 to GET or SET (change/create/delete) them.

4 The control of access by Providers to other MIB modules, for example, the Interface Group, is not specified  
5 by this standard.

6 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
7 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
8 environments. The support for SET operations in a nonsecure environment without proper protection can  
9 have a negative effect on network operations. Table 17-2 lists the MIB tables and objects and their  
10 sensitivity/vulnerability.

**Table 17-2—Sensitive managed objects: tables and notifications**

| Table or object                                                                                                                                                                                          | Reason for sensitivity to security considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dot1agCfmDefaultMdTable<br>dot1agCfmVlanTable                                                                                                                                                            | The integrity of the spanning tree(s) running in a network is dependent on certain configuration parameters, especially Static VLAN Registration Entries (8.8.2). The assignment of VIDs to particular service instances, and hence to MAs, is controlled by the administrator responsible for the integrity of the spanning tree, namely the Owner of the Bridge.                                                                                                                                                                                                                      |
| dot1agCfmMdTable<br>dot1agCfmMaNetTable<br>dot1agCfmMaCompTable<br>dot1agCfmVlanTable<br>dot1agCfmMaMepListTable<br>dot1agCfmMepTable<br>dot1agCfmMepDbTable<br>dot1agCfmLtrTable<br>dot1agCfmFaultAlarm | The business relationships among the various Maintenance Domain administrators, and between them and the Owner of the Bridge, are not defined by this standard. The ability of one Maintenance Domain administrator to identify another, or even detect the presence of another Maintenance Domain administrator, in the same Bridge, may jeopardize those business relationships. The CFM MIB module separates objects by Maintenance Domain so that the Bridge Owner can ensure that management by one Maintenance Domain administrator does not conflict with management by another. |

11 There is no detailed list in this standard of all vulnerable objects with a MAX-ACCESS clause of read-write  
12 or read-create and of the security threats associated to their intentional or unintentional manipulation by  
13 write actions. The reason is that this standard takes the approach that objects within a maintenance domain  
14 are protected as if in a “walled garden,” accessible only by administrators authorized for the respective  
15 Maintenance Domains. See Figure 12-1 for an illustration of this concept.

16 The only exceptions to this approach are the read-create MIB objects that define the maintenance  
17 domains themselves and their capabilities. The vulnerabilities associated with these objects are shown in  
18 Table 17-3.

#### 19 **17.4.8 Security considerations of the IEEE8021-PBB-MIB**

20 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
21 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
22 environments. The support for SET operations in a nonsecure environment without proper protection can  
23 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
24 described next.

25 The following tables and objects in the PBB MIB could be manipulated to interfere with the operation of  
26 PBBs. This could, for example, be used to force a reinitialization of state machines to cause network  
27 instability, or changing the forwarding and filtering policies. The following are vulnerable writable objects  
28 from the IEEE8021-PBB-MIB:

**Table 17-3—Sensitive managed objects: variables in dot1agCfmMdTable**

| Object                               | Reason for sensitivity to security considerations                                                                                                                                                                                                                       |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dot1agCfmMdFormat<br>dot1agCfmMdName | An intentional or accidental write operation on these objects may lead to the modification of the identifiers of the Maintenance Domains and would impact the capacity of existing administrators to identify and manage the entities within those Maintenance Domains. |
| dot1agCfmMdMdLevel                   | An intentional or accidental write operation on this object may impact the CFM operations on the Maintenance Domain by altering the MD Level associated with the Maintenance Domain.                                                                                    |
| dot1agCfmMdMhfCreation               | An intentional or accidental write operation on this object may impact the capabilities for creating MIP Half Functions (MHFs) in the Maintenance Domain.                                                                                                               |

1 ieee8021PbbVipISid

2 ieee8021PbbPipVipMap

3 In addition, the following are vulnerable tables from the IEEE8021-PBB-MIB:

4 ieee8021PbbCBPServiceMappingTable

5 ieee8021PbbPipPriorityTable

6 ieee8021PbbVipToPipMappingTable

7 ieee8021PbbCbpTable

8 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
9 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
10 important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to  
11 even encrypt the values of these objects when sending them over the network via SNMP.

12 The following read-only tables and objects in this MIB could be used by an attacker to determine which  
13 attacks might be useful to attempt against a given device, or could be used to understand the logical topology  
14 of the network:

15 ieee8021PbbBackboneEdgeBridgeAddress

16 ieee8021PbbVipPipIfIndex

17 ieee8021PbbISidToVipComponentId

18 ieee8021PbbISidToVipPort

#### 19 17.4.9 Security considerations of the IEEE8021-DDCFM-MIB

20 There are a number of management objects defined in DDCFM MIB module with a MAX-ACCESS clause  
21 of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
22 environments. The support for SET operations in a nonsecure environment without proper protection can  
23 have a negative effect on network operations. Table 17-4 lists the MIB tables and objects and their  
24 sensitivity/vulnerability.

25 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
26 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
27 important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the  
28 values of these objects when sending them over the network via SNMP. Table 17-5 lists the MIB tables and  
29 objects that are sensitive to read.

**Table 17-4—Sensitive managed objects (of DDCFM): tables and notifications**

| Table or object             | Reason for sensitivity to security considerations                                                                                                                                                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ieee8021DdcfmRr             | Once created and activated, ieee8021DdcfmRr can intercept selected data frames traversing through a Bridge interface, and send its copy encapsulated in RFM header to a specific destination within the maintenance domain. The action can create extra traffic within the maintenance domain.    |
| ieee8021DdcfmDr             | Once created and activated, ieee8021DdcfmDr will decapsulate received SFM and send the decapsulated data frame to location specified by the data frame's destination_address. This action practically injects specific traffic into the network.                                                  |
| ieee8021DdcfmSFMSOriginator | Once created and activated, ieee8021DdcfmSFMSOriginator injects SFMs into the maintenance domain. However, if the corresponding ieee8021DdcfmDr is not activated, the received SFMs are dropped. Therefore, ieee8021DdcfmSFMSOriginator is less sensitive than the corresponding ieee8021DdcfmDr. |

1

**Table 17-5—Sensitive managed objects (of DDCFM) for read**

| Table or object          | Reason for sensitivity to security considerations                                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ieee8021DdcfmRFMReceiver | Once created, ieee8021DdcfmRFMReceiver can receive the RFM, which encapsulate actual data frame that could be sensitive and need to be protected. It is very important to control the GET operation on this object. |

## 2 17.4.10 Security considerations of the IEEE8021-PBBTE-MIB

3 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
4 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
5 environments. The support for SET operations in a nonsecure environment without proper protection can  
6 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
7 described below.

8 The following tables and objects in the PBB MIB could be manipulated to interfere with the operation of  
9 IB PBBs. This could, for example, be used to force a reinitialization of state machines to cause network  
10 instability, or changing the forwarding and filtering policies. The following are all the writable objects from  
11 the IEEE8021-PBB-MIB:

- 12 ieee8021PbbTeProtectionGroupListWorkingMA
- 13 ieee8021PbbTeProtectionGroupListProtectionMA
- 14 ieee8021PbbTeProtectionGroupListRowStatus
- 15 ieee8021PbbTeTesiComponent
- 16 ieee8021PbbTeTesiBridgePort
- 17 ieee8021PbbTeProtectionGroupConfigCommandAdmin
- 18 ieee8021PbbTeProtectionGroupConfigWTR
- 19 ieee8021PbbTeProtectionGroupConfigHoldOff
- 20 ieee8021PbbTeProtetcionGroupConfigNotifyEnable
- 21 ieee8021PbbTeProtectionGroupISidGroupId
- 22 ieee8021PbbTeProtectionGroupISidRowStatus
- 23 ieee8021PbbTeBridgeStaticForwardAnyUnicastTable
- 24 ieee8021PbbTeBridgeStaticForwardAnyUnicastEgressPorts
- 25 ieee8021PbbTeBridgeStaticForwardAnyUnicastForbiddenPorts

#### 17.4.11 Security considerations of the IEEE8021-TPMR-MIB

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a nonsecure environment without proper protection can have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are described below.

The following object in the SNMPv2-MIB could be manipulated to interfere with the operation of a management system and its ability to recognize and manage a TPMR device.

sysName

The following object in the SNMPv2-MIB could be manipulated to interfere with the operation of a management system and its ability to recognize and manage a TPMR Port.

ifName

The following objects in the TPMR-MIB could be manipulated to interfere with the operation of MSP on a TPMR Port and, for example, be used to cause network instability.

ieee8021TpmrMspLinkNotify  
ieee8021TpmrMspLinkNotifyWait  
ieee8021TpmrMspLinkNotifyRetry  
ieee8021TpmrMspMacNotify  
ieee8021TpmrMspMacNotifyTime  
ieee8021TpmrMspMacRecoverTime

#### 17.4.12 Security considerations of the IEEE8021-FQTSS-MIB

There are a number of management objects defined in the IEEE8021-FQTSS-MIB module that have a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a nonsecure environment without proper protection can have a negative effect on network operations.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than notaccessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP.

The following tables and objects in the IEEE8021-FQTSS-MIB can be manipulated to interfere with the operation of the forwarding and queuing mechanisms in a manner that would be detrimental to the transmission of time-sensitive streams:

ieee8021FqtssDeltaBandwidth  
ieee8021FqtssAdminIdleSlopeMs  
ieee8021FqtssAdminIdleSlopeLs  
ieee8021FqtssClassMeasurementInterval  
ieee8021FqtssSrClassId  
ieee8021FqtssTxSelectionAlgorithmID  
ieee8021FqtssPriorityRegenOverride

- a) ieee8021FqtssDeltaBandwidth can be manipulated to reduce the amount of bandwidth available to a given SR class.
- b) ieee8021FqtssAdminIdleSlopeMs and ieee8021FqtssAdminIdleSlopeLs can be manipulated to change the overall amount of bandwidth available to stream traffic on a Port, in a network where SRP is not used for stream reservations.

- 1 c) ieee8021FqtssClassMeasurementInterval can be manipulated to change the measurement interval  
2 that is used, together with TSpec, to calculate reserved bandwidth.
- 3 d) ieee8021FqtssSrClassId can be manipulated to change the priority mapping of a SRclassID to a  
4 priority. This can impact the behavior of Streams.
- 5 e) ieee8021FqtssTxSelectionAlgorithmID can be manipulated in order to apply the wrong  
6 transmission selection algorithm to a traffic class that was being used by stream traffic.
- 7 f) ieee8021FqtssPriorityRegenOverride can be manipulated to disrupt stream traffic within an SRP  
8 domain with non-stream traffic entering from outside the SRP domain boundary.

#### 9 **17.4.13 Security considerations of the IEEE8021-CN-MIB**

10 There are a number of management objects defined in the IEEE8021-MIRP-MIB module with a  
11 MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or  
12 vulnerable in some network environments. The support for SET operations in a nonsecure environment  
13 without proper protection can have a negative effect on network operations. These tables and objects and  
14 their sensitivity/vulnerability are described in the paragraphs that follow.

15 Improper manipulation of certain tables and objects can result in the misidentification of the boundaries of  
16 CNDs (30.6). Any such errors can result in the following problems:

- 17 a) Frames not originated through an RP (31.2.2.2) can pass through CPs (31.1.1). The inability to  
18 throttle these frames via CNMs (33.3) can cause legitimate, RP-originated frames to experience  
19 unacceptably high loss rates.
- 20 b) Frames not originating through an RP (31.2.2.2) can pass through queues in the bridged network that  
21 are not CPs (31.1.1), where they can encounter uncontrolled congestion. This can cause those  
22 frames to experience unacceptably high loss rates.
- 23 c) The CN-TAG (30.5) in a data frame or CNM can be improperly discarded. This can cause that  
24 CNM, or a CNM resulting from the data frame, to be discarded by the end station that sourced the  
25 frame. As a result, that flow, and all flows passing through the same CPs, can experience  
26 unacceptably high loss rates.
- 27 d) The CN-TAG in a data frame or CNM can be improperly retained. This can result in a failure of two  
28 end stations to communicate, because the receiving end station is unable to process frames with  
29 CN-TAGs.

30 The following tables and objects in the IEEE8021-MIRP-MIB can cause such CND boundary identification  
31 errors:

- 32 ieee8021CnGlobalMasterEnable
- 33 ieee8021CnComPriDefModeChoice
- 34 ieee8021CnComPriAdminDefenseMode
- 35 ieee8021CnComPriCreation
- 36 ieee8021CnComPriLldpInstanceChoice
- 37 ieee8021CnComPriLldpInstanceSelector
- 38 ieee8021CnComPriRowStatus
- 39 ieee8021CnPortPriDefModeChoice
- 40 ieee8021CnPortPriAdminDefenseMode
- 41 ieee8021CnPortPriLldpInstanceChoice
- 42 ieee8021CnPortPriLldpInstanceSelector

43 Improper manipulation of certain other objects can result in assigning a data frame or CNM to the incorrect  
44 priority. This can result in the affected data streams experiencing loss rates that are either higher or lower  
45 than expected by the network administrator. Lower than expected loss rates for one data stream can cause

1 higher than expected loss rates for other streams. These affects are typically, but not universally, less severe  
2 than the loss rate anomalies caused by CND boundary misidentification. The following variables can cause  
3 improper priority assignment:

4       ieee8021CnGlobalCnmTransmitPriority  
5       ieee8021CnComPriAlternatePriority  
6       ieee8021CnPortPriAlternatePriority

7 Improper manipulation of the remainder of the read-write and read-create objects can cause the congestion  
8 notification algorithm to operate in ways not intended by the network administrator. This can result in  
9 excessively high data frame loss rates and/or low link utilization rates. These variables are the following:

10       ieee8021CnCpQueueSizeSetPoint  
11       ieee8021CnCpFeedbackWeight  
12       ieee8021CnCpMinSampleBase  
13       ieee8021CnCpMinHeaderOctets  
14       ieee8021CnRpPortPriMaxRps  
15       ieee8021CnRpgEnable  
16       ieee8021CnRpgTimeReset  
17       ieee8021CnRpgByteReset  
18       ieee8021CnRpgThreshold  
19       ieee8021CnRpgMaxRate  
20       ieee8021CnRpgAiRate  
21       ieee8021CnRpgHaiRate  
22       ieee8021CnRpgGd  
23       ieee8021CnRpgMinDecFac  
24       ieee8021CnRpgMinRate

25 Unintended access to any of the readable tables or variables in the IEEE8021-MIRP-MIB alerts the reader  
26 that congestion notification is configured, and (for all tables and variables except those in the  
27 ieee8021CnGlobalTable and ieee8021CnCpidToInterfaceTable) on which priority value or values  
28 congestion notification is configured. This information can suggest to an attacker what applications are  
29 being run, and thus suggest application-specific attacks, or to enable the attacker to detect whether their  
30 attacks are successful. It is thus important to control even GET and/or NOTIFY access to these objects and  
31 possibly to even encrypt the values of these objects when sending them over the network via SNMP.

#### 32 **17.4.14 Security considerations of the IEEE8021-SRP-MIB**

33 The purpose of MSRP is to create reservations for various types of data streams, including audio/video (AV)  
34 content. Access to the objects within the IEEE8021-SRP-MIB module, whether they have MAX-ACCESS  
35 of read-write, read-create, or read-only, may reveal sensitive information in some network environments.  
36 Very serious health and safety situations could arise if MSRP was involved in configuring network resources  
37 for an emergency public safety announcement and the MSRP behavior of the bridged network was allowed  
38 to be modified unexpectedly.

39 With these considerations in mind it is thus important to control all types of access (including GET and/or  
40 NOTIFY) to these objects and possibly even encrypt their values when sending them over the network via  
41 SNMP.

42 The following tables and objects in the IEEE8021-SRP-MIB can be manipulated to interfere with the  
43 operation of the stream reservation mechanisms in a manner that would be detrimental to the transmission of  
44 the associated stream data:

45       ieee8021SrpBridgeBaseMsrpEnabledStatus  
46       ieee8021SrpBridgeBaseMsrpTalkerPruning

- 1 ieee8021SrpBridgeBaseMsrpMaxFanInPorts  
2 ieee8021SrpBridgeBaseMsrpLatencyMaxFrameSize  
3 ieee8021SrpBridgeBaseMsrpTalkerVlanPruning  
4 ieee8021SrpBridgePortMsrpEnabledStatus  
5 ieee8021SrpBridgePortSrPvid  
6 ieee8021SrpBridgeBaseMsrpTalkerPruningPerPort
- 7 a) ieee8021SrpBridgeBaseMsrpEnabledStatus can be manipulated to enable or disable MSRP  
8 operations for the entire Bridge.  
9 b) ieee8021SrpBridgeBaseMsrpTalkerPruning can be manipulated to stop the propagation of Talker  
10 attributes if Listeners are not configured to support Talker Pruning.  
11 c) ieee8021SrpBridgeBaseMsrpMaxFanInPorts can be manipulated to set the number of ingress Ports  
12 supporting streaming down to one, which would stop Talkers streams from coming in on any other  
13 Port.  
14 d) ieee8021SrpBridgeBaseMsrpLatencyMaxFrameSize can be manipulated to set a frame size that is  
15 so large or so small that it causes the Bridge to calculate unreasonable maximum latency.  
16 e) ieee8021SrpBridgeBaseMsrpTalkerVlanPruning can be manipulated to change the behavior of a  
17 Bridge regarding Talker declarations. This can either restrict Talker declarations in an unintended  
18 way or cause Talker declarations to be forwarded on unintended Ports.  
19 f) ieee8021SrpBridgePortMsrpEnabledStatus can be manipulated to enable or disable MSRP on a  
20 particular Port, perhaps allowing sensitive stream data to be sent to unacceptable devices.  
21 g) ieee8021SrpBridgePortSrPvid can be manipulated to move Streams to a VLAN that has been  
22 blocked by management, thus disabling reception of the Stream by one or more Listeners.  
23 h) ieee8021SrpBridgeBaseMsrpTalkerPruningPerPort can be manipulated to disable MAC address  
24 pruning per Port, causing Talker declarations to be forwarded on unintended Ports.
- 25 ieee8021SrpBridgePortSrPvid can be manipulated to move Streams to a VLAN that has been blocked by  
26 management, thus disabling reception of the Stream by one or more Listeners.

#### 27 **17.4.15 Security considerations of the IEEE8021-MVRPX-MIB**

28 The objects in IEEE8021-MVRPX-MIB could be manipulated to interfere with the  
29 operation of PBBs. Setting ieee8021MvrpxPortNewOnly, ieee8021MvrpxPortMvrpNewPropagated, or  
30 ieee8021MvrpxPortXmitZero to the wrong value could cause New messages to be transmitted when they  
31 should not be or suppressed when they should be transmitted. This can result in the FDB being flushed either  
32 too often or not at all, or in lost or spurious VLAN registrations. Extra New messages waste resources in the  
33 Bridge's supervisory processor and can cause unnecessary flooding of data frames to unknown destinations,  
34 and lost New messages can prevent connectivity until the entries in the FDB time out. Lost or spurious  
35 VLAN registrations can cause the loss of connectivity for particular VLANs, or waste system resources  
36 transporting data frames to parts of the network where they are not needed.

#### 37 **17.4.16 Security considerations of the IEEE8021-MIRP-MIB**

38 The following tables and objects in the IEEE8021-MIRP-MIB could be manipulated to interfere with the  
39 operation of PBBs. They could, for example, prevent Multiple I-SID Registration Protocol Data Units  
40 (MIRPDUs) from reaching their intended destinations, or cause them to reach unintended destinations. The  
41 former could result in temporary loss of service due to MAC address entries being timed out, instead of  
42 being flushed. The latter could result in excessive computation time taken by the PIPs or I-components  
43 unnecessarily receiving the MIRPDUs. The following are vulnerable writable objects from the  
44 IEEE8021-MIRP-MIB:

- 45 ieee8021MirpV2PortTable  
46 ieee8021MirpV2PortEnabledStatus

1       ieee8021PbbMirpEnableStatus  
2       ieee8021PbbMirpBvid  
3       ieee8021PbbMirpDestSelector  
4       ieee8021PbbMirpPnpEnable  
5       ieee8021PbbMirpPnpPortNumber

#### 6 **17.4.17 Security considerations of the IEEE8021-PFC-MIB**

7 One management object defined in the IEEE8021-PFC-MIB module has a MAXACCESS clause of  
8 read-write. Such object can be considered sensitive or vulnerable in some network environments. The  
9 support for SET operations in a nonsecure environment without proper protection can have a negative effect  
10 on network operations. The management object is:

11       PFCLinkDelayAllowance

12 Improper setting of this management object can result in improper network operations. If the value of this  
13 management object is too high, then PFC can be invoked excessively, negatively impacting the link  
14 bandwidth. If the value of this management object is too low, then PFC can be invoked too late and frame  
15 loss can occur.

#### 16 **17.4.18 Security considerations of the IEEE8021-TEIPS-MIB**

17 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
18 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
19 environments. The support for SET operations in a nonsecure environment without proper protection can  
20 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
21 described below.

22 The following tables and objects in the TEIPS-MIB could be manipulated to interfere with the operation of  
23 PBBs. This could, for example, be used to force a reinitialization of state machines to cause network  
24 instability or to change the forwarding and filtering policies. The following are all the writable objects from  
25 the IEEE8021-TEIPS-MIB:

26       ieee8021TeipsV2Ipgid  
27       ieee8021TeipsV2IpgWorkingMA  
28       ieee8021TeipsV2IpgProtectionMA  
29       ieee8021TeipsV2TesiId  
30       ieee8021TeipsV2CandidatePsMA  
31       ieee8021TeipsV2IpgConfigWTR  
32       ieee8021TeipsV2IpgConfigHoldOff  
33       ieee8021TeipsV2IpgConfigMWTR

#### 34 **17.4.19 Security considerations of the IEEE8021-SPB-MIB**

35 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
36 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
37 environments. The support for SET operations in a non-secure environment without proper protection can  
38 have a negative effect on network operations. These tables and objects and their sensitivity/vulnerability are  
39 described next.

40       ieee8021SpbMtidStaticEntryMtid

1 The following tables and objects in the SPB-MIB could be manipulated to interfere with the operation of  
2 Shortest Path Bridges. This could, for example, be used to misconfigure the network to cause loss of  
3 connectivity, or misconnect traffic. The following are vulnerable writable objects from the  
4 IEEE8021-SPB-MIB:

5       ieee8021SpbSys  
6       ieee8021SpbSysAreaAddress  
7       ieee8021SpbSysId  
8       ieee8021SpbSysControlAddr  
9       ieee8021SpbSysName  
10       ieee8021SpbSysBridgePriority  
11       ieee8021SpbMtidStaticTable  
12       ieee8021SpbMtidStaticTableEntry  
13       ieee8021SpbMTidStaticEntryMtidOverload  
14       ieee8021SpbmBsiStaticTable  
15       dot1agCfmMepSpbmEspTable  
16       ieee8021PcrEctStaticTable

17 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not  
18 accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to  
19 control all types of access (including GET and/or NOTIFY) to these objects and possibly to even encrypt the  
20 values of these objects when sending them over the network via SNMP. The following read-only tables with  
21 their respective objects in this MIB could be used by an attacker to understand the logical topology of the  
22 network:

23       ieee8021SpbEctDynamicTable  
24       ieee8021SpbAdjDynamicTable  
25       ieee8021SpbTopNodeTable  
26       ieee8021SpbTopEctTable  
27       ieee8021SpbTopEdgeTable  
28       ieee8021PcrTopEctTable

#### 29 **17.4.20 Security considerations of the IEEE8021-EVB-MIB**

30 The purpose of EVB is to coordinate VSIs within an EVB station with a data center network (DCN). In this  
31 environment the EVB station and the EVB Bridge may be under different management authorities. Access  
32 to the objects within the IEEE8021-EVB-MIB module of the EVB Bridge by the EVB station and access to  
33 objects within the IEEE8021-EVB-MIB module of the EVB station by the EVB Bridge may therefore need  
34 to be restricted.

35 Access to the objects within the IEEE8021-EVB-MIB module, whether they have MAX-ACCESS of  
36 read-write, read-create, or read-only, can reveal sensitive information in some network environments. Very  
37 serious health and safety situations could arise if EVB systems were involved in configuring network  
38 resources for an emergency public safety announcement and the EVB Bridge system behavior of the bridged  
39 network was allowed to be modified unexpectedly.

40 With these considerations in mind, it is thus important to control all types of access (including GET and/or  
41 NOTIFY) to these objects. SNMP versions prior to SNMPv3 did not include adequate security. Even if the  
42 network itself is secure (for example, by using IPsec), there is no control about who on the secure network is  
43 allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

1 It is recommended that implementers consider the security features as provided by the SNMPv3 framework  
2 (see IETF RFC 3410 (2002), section 8), including full support for the SNMPv3 cryptographic mechanisms  
3 (for authentication and privacy).

4 Further, deployment of SNMP versions prior to SNMPv3 is not recommended. Instead, it is recommended  
5 to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to  
6 ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give  
7 access to the objects only to the principals (users) that have legitimate rights to indeed GET or SET  
8 (change/create/delete) them.

9 There are a number of management objects defined in IEEE8021-EVB-MIB module with a MAX-ACCESS  
10 clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some  
11 network environments. The support for SET operations in a non-secure environment without proper  
12 protection can have a negative effect on network operations. Table 17-6 describes the tables and objects and  
13 their sensitivities/vulnerabilities.

**Table 17-6—Sensitive managed objects (of EVB): tables and notifications**

| Table or object                                                                                                                  | Reason for sensitivity to security considerations                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| evbSysEvbLldpTxEnable<br>evbSysEvbLldpManual<br>evbSysEvbLldpGidCapable                                                          | The EVB TLV exchange controls how the VDP, ECP, and reflective relay parameters are set. These parameters allow manual configurations of the EVB parameters, which can be used to disable the operation of these protocols. |
| ieee8021BridgeEvbSysEcpAckTimer<br>ieee8021BridgeEvbSysEcpMaxRetires                                                             | The ECP timer and retry count are set to provide reliable delivery of control frames. Incorrect settings can cause failures of the control protocols.                                                                       |
| ieee8021BridgeEvbSysVdpDfltRsrcWaitDelay                                                                                         | The VDP resource timer determines the time required by the system to locate a profile. Setting this time too short may make VDP requests always fail.                                                                       |
| ieee8021BridgeEvbSbpRowStatus<br>ieee8021BridgeEvbUapRowStatus<br>ieee8021BridgeEvbCapRowStatus<br>ieee8021BridgeEvbUrpRowStatus | These variables allow creations of new ports on an EVB Bridge or EVB station. Inappropriate use of these may allow unauthorized interception of data.                                                                       |

14 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
15 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
16 important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the  
17 values of these objects when sending them over the network via SNMP. Table 17-7 provides the identity of  
18 VSIs and the addresses used to access them that could be used to identify the user application and what  
19 addresses can be used to interfere with or intercept their traffic.

**Table 17-7—Sensitive managed objects (of EVB) for read**

| Table                          | Reason for sensitivity to security considerations                                                                                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ieee8021BridgeEvbVsiDbTable    | The VSI database provides a list of all operating VSIs along with their primary system keys. This information may be used to spy on the operating applications and the activity associated with each application. |
| ieee8021BridgeEvbVsiDbMacTable | The VSI MAC table provides the network addresses associated with operating applications. This information may be used in system attacks.                                                                          |

#### 1 17.4.21 Security considerations of the IEEE8021-ECMP-MIB

2 There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of  
3 read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network  
4 environments. The support for SET operations in a non-secure environment without proper protection can  
5 have a negative effect on network operations. These objects and their sensitivity/vulnerability are described  
6 next.

7 The following objects in the IEEE8021-ECMP-MIB could be manipulated to interfere with the operation of  
8 ECMP networks. These could, for example, be used to misconfigure the network to cause loss of  
9 connectivity or undesirable path selection. The following are vulnerable writable objects from the  
10 IEEE8021-ECMP-MIB:

11       ieee8021EcmpFlowFilterCtlTtl  
12       ieee8021EcmpEctStaticEntryBridgePriority  
13       ieee8021EcmpEctStaticEntryRowStatus

#### 14 17.4.22 Security considerations of the IEEE8021-ST-MIB

15 There are a number of management objects defined in the IEEE8021-ST-MIB module that have a  
16 MAX-ACCESS clause of read-write. Such objects may be considered sensitive or vulnerable in some  
17 network environments. The support for SET operations in a nonsecure environment without proper  
18 protection can have a negative effect on network operations.

19 The following tables and objects in the IEEE8021-ST-MIB can be misconfigured to interfere with the  
20 operation of the forwarding and queuing mechanisms in a manner that would be detrimental to the  
21 transmission of scheduled traffic:

22       ieee8021STMaxSDU  
23       ieee8021STGateEnabled  
24       ieee8021STAdminGateStates  
25       ieee8021STAdminControlListLength  
26       ieee8021STAdminControlList  
27       ieee8021STAdminCycleTimeNumerator  
28       ieee8021STAdminCycleTimeDenominator  
29       ieee8021STAdminCycleTimeExtension  
30       ieee8021STAdminBaseTime  
31       ieee8021STConfigChange  
32       ieee8021STConfigChangeTime

- 33 a) ieee8021STMaxSDU can be misconfigured to affect the ability of a Port to transmit frames of  
34 greater than a given SDU size.
- 35 b) ieee8021STGateEnabled can be misconfigured to enable/disable scheduled traffic processing.
- 36 c) ieee8021STAdminGateStates can be misconfigured to affect the gate states of a Port on startup.
- 37 d) ieee8021STAdminControlListLength, ieee8021STAdminControlList,  
38 ieee8021STAdminCycleTimeNumerator, ieee8021STAdminCycleTimeDenominator,  
39 ieee8021STAdminCycleTimeExtension, ieee8021STAdminBaseTime, ieee8021STConfigChange,  
40 and ieee8021STConfigChangeTime can be misconfigured to affect the traffic schedule for the Port.

41 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not  
42 accessible) can be considered sensitive or vulnerable in some network environments. Thus it is important to  
43 control all types of access (including GET and/or NOTIFY) to these objects and possibly to encrypt the  
44 values of these objects when sending them over the network via SNMP.

#### 1 17.4.23 Security considerations of the IEEE8021-Preemption-MIB

2 There is one management object defined in the IEEE8021-Preemption-MIB module that has a  
3 MAX-ACCESS clause of read-write. Such objects may be considered sensitive or vulnerable in some  
4 network environments. The support for SET operations in a nonsecure environment without proper  
5 protection can have a negative effect on network operations.

6 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than  
7 not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus  
8 important to control all types of access (including GET and/or NOTIFY) to these objects and possibly to  
9 even encrypt the values of these objects when sending them over the network via SNMP.

10 The following tables and objects in the IEEE8021-Preemption-MIB can be manipulated to interfere with the  
11 operation of the forwarding and queuing mechanisms in a manner that would be detrimental to the  
12 transmission of frames:

13 ieee8021FramePreemptionAdminStatus

- 14 a) Misconfiguration of the ieee8021FramePreemptionAdminStatus object can lead to the degradation  
15 of the quality of service for the application on the port at the respective traffic class that is wrongly  
16 preempted, or to the saturation of the priority queues on the port because of preemptable traffic  
17 classes receiving express processing.

#### 18 17.4.24 Security considerations of the IEEE8021-PSFP-MIB

19 There are a number of management objects defined in the IEEE8021-PSFP-MIB module that have a  
20 MAX-ACCESS clause of read-write or read-create. Such objects may be considered sensitive or vulnerable  
21 in some network environments. The support for SET operations in a nonsecure environment without proper  
22 protection can have a negative effect on network operations.

23 The following tables and objects in the IEEE8021-PSFP-MIB can be misconfigured to interfere with the  
24 operation of the forwarding and queuing mechanisms in a manner that would be detrimental to the operation  
25 of PSFP:

26 ieee8021PSFPStreamHandleSpec  
27 ieee8021PSFPPrioritySpec  
28 ieee8021PSFPStreamGateInstanceID  
29 ieee8021PSFPFilterSpecificationList  
30 ieee8021PSFPStreamBlockedDueToOversizeFrameEnable  
31 ieee8021PSFPStreamBlockedDueToOversizeFrame  
32 ieee8021PSFPGateEnabled  
33 ieee8021PSFPAdminGateStates  
34 ieee8021PSFPAdminControlListLength  
35 ieee8021PSFPAdminControlList  
36 ieee8021PSFPAdminCycleTimeNumerator  
37 ieee8021PSFPAdminCycleTimeDenominator  
38 ieee8021PSFPAdminCycleTimeExtension  
39 ieee8021PSFPAdminBaseTime  
40 ieee8021PSFPConfigChange  
41 ieee8021PSFPConfigChangeTime  
42 ieee8021PSFPAdminIPV  
43 ieee8021PSFPOperIPV  
44 ieee8021PSFPGateClosedDueToInvalidRxEnable

1 ieee8021PSFPGateClosedDueToInvalidRx  
2 ieee8021PSFPGateClosedDueToOctetsExceededEnable  
3 ieee8021PSFPGateClosedDueToOctetsExceeded  
4 ieee8021PSFPFlowMeterInstance  
5 ieee8021PSFPFlowMeterCIR  
6 ieee8021PSFPFlowMeterCBS  
7 ieee8021PSFPFlowMeterEIR  
8 ieee8021PSFPFlowMeterCF  
9 ieee8021PSFPFlowMeterCM  
10 ieee8021PSFPFlowMeterDropOnYellow  
11 ieee8021PSFPFlowMeterMarkAllFramesRedEnable  
12 ieee8021PSFPFlowMeterMarkAllFramesRed  
13 a) ieee8021PSFPStreamHandleSpec, ieee8021PSFPPrioritySpec,  
14 ieee8021PSFPStreamGateInstanceID, and ieee8021PSFPFilterSpecificationList can be  
15 misconfigured to adversely affect the policing functions that are applied to received frames.  
16 b) ieee8021PSFPGateEnabled can be misconfigured to enable/disable scheduled traffic processing.  
17 c) ieee8021PSFPAdminGateStates can be misconfigured to affect the gate state of a stream filter on  
18 startup.  
19 d) ieee8021PSFPAdminControlListLength, ieee8021PSFPAdminControlList,  
20 ieee8021PSFPAdminCycleTimeNumerator, ieee8021PSFPAdminCycleTimeDenominator,  
21 ieee8021PSFPAdminCycleTimeExtension, ieee8021PSFPAdminBaseTime,  
22 ieee8021PSFPConfigChange, and ieee8021PSFPConfigChangeTime can be misconfigured to affect  
23 the filter schedule for the Port.  
24 ieee8021PSFPFlowMeterInstance, ieee8021PSFPFlowMeterCIR, ieee8021PSFPFlowMeterCBS,  
25 ieee8021PSFPFlowMeterEIR, ieee8021PSFPFlowMeterCF, ieee8021PSFPFlowMeterCM,  
26 ieee8021PSFPFlowMeterDropOnYellow, ieee8021PSFPFlowMeterMarkAllFramesRedEnable,  
27 ieee8021PSFPFlowMeterMarkAllFramesRed, ieee8021PSFPGateClosedDueToInvalidRxEnable,  
28 ieee8021PSFPGateClosedDueToInvalidRx,  
29 ieee8021PSFPGateClosedDueToOctetsExceededEnable,  
30 ieee8021PSFPGateClosedDueToOctetsExceeded,  
31 ieee8021PSFPStreamBlockedDueToOversizeFrameEnable, and  
32 ieee8021PSFPStreamBlockedDueToOversizeFrame can be misconfigured to adversely affect the  
33 way that flow metering operates.

34 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not  
35 accessible) can be considered sensitive or vulnerable in some network environments. It is thus important to  
36 control all types of access (including GET and/or NOTIFY) to these objects and possibly to encrypt the  
37 values of these objects when sending them over the network via SNMP.

#### 38 17.4.25 Security considerations of the 39 IEEE8021-TSN-REMOTE-MANAGEMENT-MIB

40 There are a number of management objects defined in the  
41 IEEE8021-TSN-REMOTE-MANAGEMENT-MIB module that have a MAX-ACCESS clause of read-write  
42 or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The  
43 support for SET operations in a nonsecure environment without proper protection can have a negative effect  
44 on network operations.

45 The following tables and objects in the IEEE8021-TSN-REMOTE-MANAGEMENT-MIB can be  
46 misconfigured to interfere with the operation of the forwarding and queuing mechanisms in a manner that  
47 would be detrimental to the connectivity, delay, and jitter provided to TSN streams and other network traffic:

1        ieee8021TsnRemoteMgmtMsrpMrpExternalControl

## 2 **17.4.26 Security considerations of the IEEE8021-PBBN-AA-MIB**

3 There are a number of management objects defined in the IEEE8021-PBBN-AA-MIB module that have a  
4 MAX-ACCESS clause of read-write. Such objects can be considered sensitive or vulnerable in some  
5 network environments. The support for SET operations in a non-secure environment without proper  
6 protection can have a negative effect on network operations.

7 The following tables and objects in the IEEE8021-PBBN-AA-MIB can be misconfigured to interfere with  
8 the operation of the forwarding and queuing mechanisms in a manner that would be detrimental to the  
9 transmission of scheduled traffic:

|    |                                 |
|----|---------------------------------|
| 10 | ieee8021AaSystemEnable          |
| 11 | ieee8021AaPortRowStatus         |
| 12 | ieee8021AaPortEnable            |
| 13 | ieee8021AaIsidVidAsgnsRowStatus |
| 14 | ieee8021AaIsidVidAsgnsIsid      |
| 15 | ieee8021AaIsidVidAsgnsVlan      |

16 Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not  
17 accessible) can be considered sensitive or vulnerable in some network environments. It is thus important to  
18 control all types of access (including GET and/or NOTIFY) to these objects and possibly to encrypt the  
19 values of these objects when sending them over the network via SNMP.

20

## 1 17.5 Dynamic component and Port creation

### 2 17.5.1 Overview of the dynamically created Bridge entities

3 The IEEE Bridge MIBs allow for the possibility of Bridge components and Bridge Ports to be created under  
4 the control of management operations. This functionality is optional. Compliant Bridges need not support  
5 this functionality or may tie the creation of components and Ports to the insertion or extraction of system  
6 hardware. This subclause outlines the rules and table interactions used by management stations to create soft  
7 configurable dynamic components and Ports on those systems that support this functionality.

8 A Bridge component contains, at a minimum, a collection of Bridge Ports, a relay unit that forwards and  
9 filters frames that travel between Ports, and managed objects to control the operation of the component.  
10 Certain types of components may contain other objects. These will be addressed later in this subclause in  
11 component-specific text.

12 Bridge components are the Owners of Bridge Ports, so components must be created before components can  
13 be populated with Ports.

14 The tables that are indexed by a single component ID index are as follows:

|    |                                               |
|----|-----------------------------------------------|
| 15 | ieee8021BridgeBaseTable                       |
| 16 | ieee8021QBridgeTable                          |
| 17 | ieee8021QBridgeNextFreeLocalVlanTable         |
| 18 | ieee8021QBridgeLearningConstraintDefaultTable |
| 19 | ieee8021CistTable                             |
| 20 | ieee8021MstConfigIdTable                      |
| 21 | ieee8021CfmVlanTable                          |

#### 22 17.5.1.1 Components

23 A component contains a relay function whose purpose is to move frames between interfaces to the relay  
24 called a Bridge Port or an Edge Relay Port. Different types of components are provided in this standard that  
25 are used to construct different types of Bridges.

#### 26 17.5.1.2 Bridge Ports

27 A Bridge Port or Edge Relay Port is a frame source or sink directly attached to the relay function of a Bridge  
28 component.

#### 29 17.5.1.3 Internal LAN connections

30 A BEB is composed of zero or one B-component and zero or more I-components. When the BEB has both a  
31 B-component and some I-components, the PIPs and CBPs of these I-components are connected by internal  
32 LAN connections. There needs to be a way to specify the interconnections between the PIPs on the  
33 I-component and the CBP on the B-component. This is done via the ieee8021BridgeILanIfTable defined in  
34 the IEEE8021-BRIDGE-MIB.

35 Essentially, this table allows for the creation of a new “interface” to represent the connection and then the  
36 ifStackTable is used to specify the interconnection.

1 These interconnections are used in multi-component Bridges, such as:

- 2       Provider Edge Bridges
- 3       BEBs
- 4       EVB stations
- 5       EVB Bridges

6 to specify the relationship between two interfaces in the following manner:

7 Two Port interfaces are interconnected if the invocation of a request operation at one of the interfaces causes  
8 an indication operation with the same parameters to happen at the other interface.

#### 9 **17.5.1.4 Provider Instance Ports (PIPs)**

10 Even though it is not a Bridge Port, the creation of PIPs on I-components are discussed as part of the Bridge  
11 Port creation logic for I-components.

### 12 **17.5.2 Component creation**

13 A component is created by making an entry in the `ieee8021BridgeBaseTable` with the  
14 `ieee8021BridgeBaseComponentType` set to the proper value. Components can also be created indirectly by  
15 making entries in other system-specific tables, which then automatically create entries in the  
16 `ieee8021BridgeBaseTable`.

17 A Bridge component consists of a relay function and related Bridge Ports or Edge Relay Ports. The  
18 component type determines if the relay operates on untagged, C-tagged, or S-tagged frames. It also  
19 determines which specific type(s) of Bridge Ports or Edge Relay Ports may be created on the component.

#### 20 **17.5.2.1 MAC Bridge component creation**

21 The MAC Bridge component has no specific component creation rules.

#### 22 **17.5.2.2 C-VLAN component creation**

23 C-VLAN components are used in the following different types of Bridges:

- 24   a)   C-VLAN Bridges
- 25   b)   Provider Edge Bridges
- 26   c)   EVB Bridges

27 Provider Edge Bridge C-VLAN components are created implicitly by the creation of a CEP on the S-VLAN  
28 component of the Provider Edge Bridge. C-VLAN components that belong to customer Bridges or to EVB  
29 Bridges are created by a management station performing a row-create on the component table or by implicit  
30 action such as the insertion of blades into a system.

#### 31 **17.5.2.3 S-VLAN component creation**

32 S-VLAN components are used in three different ways in Bridges. The first is as the S-VLAN component of  
33 an S-VLAN Bridge or Provider Edge Bridge or the foundation for an I-component or B-component. The  
34 second is as a Port-mapping S-VLAN component in a Provider Edge Bridge. The third is as a Port-mapping  
35 S-VLAN component in an EVB station or an EVB Bridge.

36 Provider Edge Bridge Port-mapping S-VLAN components are created implicitly by the creation of a RCAP  
37 on the primary S-VLAN component of the Provider Edge Bridge.

1 EVB Bridge and EVB station Port-mapping S-VLAN components are created implicitly by the creation of  
2 an Uplink Access Port (UAP) on an ISS of an EVB Bridge or an EVB station. For an EVB Bridge the ISS is  
3 allocated to a Bridge Port of the primary C-VLAN component. On an EVB station the ISS has no permanent  
4 Bridge Port or Edge Relay Port assignment.

#### 5 **17.5.2.4 B-component creation**

6 The B-component has no specific component creation rules.

#### 7 **17.5.2.5 I-component creation**

8 The I-component has no specific component creation rules.

#### 9 **17.5.2.6 ER creation**

10 ERs of an EVB station are created implicitly by the creation of a URP, or actions such as the insertion of  
11 blades into a system or the installation of a software driver on the EVB station.

#### 12 **17.5.2.7 T-component creation**

13 The T-component has no specific component creation rules.

### 14 **17.5.3 Port creation**

15 This subclause discusses how Ports of each relevant Port type are created on each relevant component type.

16 The general procedure is for the network administrator to perform an SNMP row-create operation on a table  
17 specific to the type of Port being created. If the operation succeeds, an entry will be implicitly created in the  
18 ieee8021BridgeBasePortTable by the agent.

19 The specific details are outlined in the 17.5.3.1 through 17.5.3.7.

#### 20 **17.5.3.1 Port creation on MAC Bridge components**

21 MAC Bridge components are used in MAC Bridges. Creation of a Port on a MAC Bridge component  
22 requires specifying the component and Port index in the ieee8021BridgeCreatableBaseBridgeGroup table.

23 The type of the component referred to by the component ID parameter must be dBridgeComponent.

24 The implicitly constructed ieee8021BridgeBasePortTable entry will have the following fields filled in:

|    |                                             |                                     |
|----|---------------------------------------------|-------------------------------------|
| 25 | ieee8021BridgeBaseComponentId               | - Implementation Specific           |
| 26 | ieee8021BridgeBasePort                      | - Implementation Specific           |
| 27 | ieee8021BridgeBasePortIfIndex               | - Implementation Specific Action    |
| 28 | ieee8021BridgeBasePortDelayExceededDiscards | - Statistic, reset to 0 by creation |
| 29 | ieee8021BridgeBasePortMtuExceededDiscards   | - Statistic, reset to 0 by creation |
| 30 | ieee8021BridgeBasePortCapabilities          | - Implementation Specific           |
| 31 | ieee8021BridgeBasePortTypeCapabilities      | - Implementation Specific           |
| 32 |                                             | bit customerVlanPort(0) must be set |
| 33 | ieee8021BridgeBasePortType                  | - dBridgePort(8)                    |
| 34 | ieee8021BridgeBasePortExternal              | - Implementation Specific           |

### 17.5.3.2 Port creation on C-VLAN components

C-VLAN components support several different types of Bridge Ports. These are C-VLAN Ports, CEPs, PEPs, and SBPs.

A C-VLAN component that is not part of a Provider Edge Bridge may have C-VLAN Ports. A C-VLAN component that is part of a Provider Edge Bridge must have exactly 1 CEP and any number of PEPs.

The only type of Ports that may be created by operating on the C-VLAN component that is not part of an EVB Bridge are the C-VLAN Ports. On an EVB Bridge it is possible to create both C-VLAN Bridge Ports and SBPs.

CEPs are created by a management action on the S-VLAN component of a Provider Edge Bridge. From a management perspective, these entities are managed through the S-VLAN component or via management operations specific to the Provider Edge Bridge.

PEPs, together with the associated CNP and the internal connection between them, are created by performing row-create operations for a C-VID in the `ieee8021PbCvidRegistrationTable` and the corresponding S-VID in the `ieee8021PbEdgePortTable`.

#### 17.5.3.2.1 Creating C-VLAN Ports

C-VLAN Ports are created by performing a row-create operation on the `ieee8021QBridgeCVlanPortTable` for a C-VLAN component that is configured to act as a VLAN Bridge. The required columns are the component ID and the Port Number to use for the newly created Port.

The type of the component referred to by the component ID parameter must be `cVlanComponent` configured for Q-Bridge operation.

The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|                                                          |                                                  |
|----------------------------------------------------------|--------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>QBridgeCVlanPortTable</code>      |
| <code>ieee8021BridgeBasePort</code>                      | - As per <code>QBridgeCVlanPortTable</code>      |
| <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                 |
| <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation              |
| <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation              |
| <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                        |
| <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                        |
|                                                          | bit <code>customerVlanPort(0)</code> must be set |
| <code>ieee8021BridgeBasePortType</code>                  | - <code>customerVlanPort(2)</code>               |
| <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                        |

#### 17.5.3.2.2 Creating SBPs

SBPs are created by performing a row-create operation on the `ieee8021BridgeEvbSbpConfigTable` for a C-VLAN component that is configured to act as an EVB Bridge. The required columns are the component ID and the Port Number to use for the newly created Port.

The type of the component referred to by the component ID parameter is a `cVlanComponent` configured for Q-Bridge operation.

1 The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|    |                                                          |                                                       |
|----|----------------------------------------------------------|-------------------------------------------------------|
| 2  | <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>ieee8021BridgeEvbSbpConfigTable</code> |
| 3  | <code>ieee8021BridgeBasePort</code>                      | - As per <code>ieee8021BridgeEvbSbpConfigTable</code> |
| 4  | <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                      |
| 5  | <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset at creation                        |
| 6  | <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset at creation                        |
| 7  | <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                             |
| 8  | <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific:                            |
| 9  |                                                          | bit <i>Station-facing Bridge Port</i> (8) is set      |
| 10 | <code>ieee8021BridgeBasePortType</code>                  | - Station-facing Bridge Port (8)                      |
| 11 | <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                             |

### 12 17.5.3.2.3 Creating CEPs

13 CEPs are created by doing a RowStatus create operation on the CEP table belonging to the PEB.

### 14 17.5.3.2.4 Creating PEPs

15 PEPs, together with the associated CNP and the internal connection between them, are created by  
16 performing row-create operations for a C-VID in the `ieee8021PbCvidRegistrationTable` and the  
17 corresponding S-VID in the `ieee8021PbEdgePortTable`. See the discussion on provisioning a C-tagged  
18 service interface in 17.6.1.2.

### 19 17.5.3.3 Port creation on S-VLAN components

20 S-VLAN components are the S-VLAN component of an S-VLAN Bridge or Provider Bridges. There are  
21 several different types of Ports that may be created on S-VLAN components. These are PNPs, CNPs, CEPs,  
22 RCAPs, and UAPs.

### 23 17.5.3.3.1 Creating PNPs

24 A PNP on an S-VLAN component works pretty much the same way as a `customerVlanPort` on a C-VLAN  
25 component except that the VID value used for forwarding and filtering decisions must come from an S-TAG  
26 and not a C-TAG.

27 Creating a PNP on a Provider Bridge is done by adding an entry to the `ieee8021PbPnpTable` specifying the  
28 `componentId` and Port Number.

|    |                                                |                                           |
|----|------------------------------------------------|-------------------------------------------|
| 29 | <code>ieee8021BridgeBasePortComponentId</code> | - Component to which the new Port belongs |
| 30 | <code>ieee8021BrdigeBasePort</code>            | - Port Number for the new Port            |

31 The type of the component referred to by the component ID parameter must be `sVlanComponent`.

32 This will cause an implicit entry in the `ieee8021QBridgePortVlan` table associated with the S-VLAN  
33 component.

34 The Component ID must refer to the S-VLAN component of a Provider Edge Bridge and the Port Number  
35 must refer to the Port Number of the PNP associated with that S-VLAN component.

1 The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|    |                                                          |                                                     |
|----|----------------------------------------------------------|-----------------------------------------------------|
| 2  | <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>PbPnpTable</code>                    |
| 3  | <code>ieee8021BridgeBasePort</code>                      | - As per <code>PbPnpTable</code>                    |
| 4  | <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                    |
| 5  | <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation                 |
| 6  | <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation                 |
| 7  | <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                           |
| 8  | <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                           |
| 9  |                                                          | bit <code>providerNetworkPort(1)</code> must be set |
| 10 | <code>ieee8021BridgeBasePortType</code>                  | - <code>providerNetworkPort(3)</code>               |
| 11 | <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                           |

### 12 17.5.3.3.2 Creating CNPs

13 There are two variants on the creation of CNPs. CNPs are either internal or external. Internal CNPs are  
14 directly connected to either a PEP on a C-VLAN component or a PAP on a Port-mapping S-VLAN  
15 component of a PEB and provide a C-tagged or Port-based service interface, respectively. External CNPs are  
16 connected to an external customer system and provide either a Port-based or S-tagged service interface.

#### 17 a) Creating an external CNP.

18 The external CNP is used to provide a Port-based or S-tagged service interface to customer of the  
19 PBN. Creating an external CNP requires specifying the component ID and Bridge Port Number of  
20 the Port to be created. This is done by creating an entry in the `ieee8021PbCnpTable`. This creates a  
21 new entry in the `ieee8021QBridgePortVlanTable` for the provider Bridge's S-VLAN  
22 component. This operation also created a new entry in the `ieee8021BridgeBasePortTable`.

23 The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled  
24 in:

|    |                                                          |                                                     |
|----|----------------------------------------------------------|-----------------------------------------------------|
| 25 | <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>PbCnpTable</code>                    |
| 26 | <code>ieee8021BridgeBasePort</code>                      | - As per <code>PbCnpTable</code>                    |
| 27 | <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                    |
| 28 | <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation                 |
| 29 | <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation                 |
| 30 | <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                           |
| 31 | <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                           |
| 32 |                                                          | bit <code>customerNetworkPort(2)</code> must be set |
| 33 | <code>ieee8021BridgeBasePortType</code>                  | - <code>customerNetworkPort(4)</code>               |
| 34 | <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                           |

#### 35 b) Creating an internal CNP.

36 The internal CNP is used to provide a C-tagged service interface or a Port-based RCSI to the  
37 customer of a PBN.

38 An internal CNP, together with the associated PEP and the internal connection between them, is  
39 created by performing row-create operations for an S-VID in the `ieee8021PbEdgePortTable` and the  
40 corresponding C-VID in the `ieee8021PbCvidRegistrationTable`. See the discussion on  
41 provisioning a C-tagged service interface in 17.6.1.2. An internal CNP together with the associated  
42 PAP and the internal connection between them are created by configuring a Port-based RCSI,  
43 that is, performing a row-create operation on the `ieee8021PbInternalInterfaceTable` with an  
44 `ieee8021PbIInternalPortType` of `customerNetworkPort`.

45 Internal CNPs are not directly manageable.

### 17.5.3.3.3 Creating a CEP

CEPs are created either by doing a row-create operation on the Provider Edge Bridge's CEP table or as a side effect of mapping an external S-VID on a RCAP to a C-tagged RCSI. The `ieee8021PbCepTable` contains the following columns:

|                                                |                                                                  |
|------------------------------------------------|------------------------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code> | - S-VLAN component ID that "owns" the CEP                        |
| <code>ieee8021BridgeBasePort</code>            | - The Port Number of the CEP on the S-VLAN component.            |
| <code>ieee8021PbCepCComponentId</code>         | - C-VLAN component read only index cross-ref for entity MIB      |
| <code>ieee8021PbCepCepPortNumber</code>        | - C-VLAN component Port read-only index cross-ref for entity MIB |
| <code>ieee8021PbCepRowStatus</code>            | - Controls the creation and deletion of the Port                 |

Note that the C-VLAN component containing the newly created CEP does not appear in the IEEE 802.1 Bridge MIB's list of components. So `ieee8021PbCepCComponentId` and the `ieee8021PbCepCepPortNumber`, are index values that are not further interpreted by any IEEE 802.1 MIB. These index values, if present, can be used in an implementation-dependent manner to allow management stations to cross reference entries in other MIBs, such as the IETF's entity MIB, back to the information managed by the IEEE MIBs.

The newly created Port will be added to the Port list of the S-VLAN component of the Provider Edge Bridge.

The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|                                                          |                                                  |
|----------------------------------------------------------|--------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>CustomerEdgePortTable</code>      |
| <code>ieee8021BridgeBasePort</code>                      | - As per <code>CustomerEdgePortTable</code>      |
| <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                 |
| <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation              |
| <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation              |
| <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                        |
| <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                        |
|                                                          | bit <code>customerEdgePort(3)</code> must be set |
| <code>ieee8021BridgeBasePortType</code>                  | - <code>customerEdgePort(5)</code>               |
| <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                        |

### 17.5.3.3.4 Creating an RCAP

RCAPs are created by doing a row-create operation on the Provider Edge Bridge's RCAP table. The `ieee8021PbRcapTable` contains the following columns:

|                                                |                                                                               |
|------------------------------------------------|-------------------------------------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code> | - primary S-VLAN component ID that "owns" the RCAP                            |
| <code>ieee8021BridgeBasePort</code>            | - The Port Number of the RCAP on the primary S-VLAN component.                |
| <code>ieee8021PbRcapSComponentId</code>        | - Port-mapping S-VLAN component read only index cross-ref for entity MIB      |
| <code>ieee8021PbRcapRcapPortNumber</code>      | - Port-mapping S-VLAN component Port read-only index cross-ref for entity MIB |
| <code>ieee8021PbRcapRowStatus</code>           | - Controls the creation and deletion of the Port                              |

Note that the Port-mapping S-VLAN component containing the newly created RCAP does not appear in the IEEE 802.1 Bridge MIB's list of components. So `ieee8021PbRcapSComponentId` and the `ieee8021PbRcapRcapPortNumber`, are index values that are not further interpreted by any IEEE 802.1 MIB.

1 These index values, if present, can be used in an implementation-dependent manner to allow management  
2 stations to cross reference entries in other MIBs, such as the IETF's entity MIB, back to the information  
3 managed by the IEEE MIBs.

4 The newly created Port will be added to the Port list of the primary S-VLAN component of the Provider  
5 Edge Bridge.

6 The implicitly constructed ieee8021BridgeBasePortTable entry will have the following fields filled in:

|    |                                             |                                             |
|----|---------------------------------------------|---------------------------------------------|
| 7  | ieee8021BridgeBasePortComponentId           | - As per RcapTable                          |
| 8  | ieee8021BridgeBasePort                      | - As per RcapTable                          |
| 9  | ieee8021BridgeBasePortIfIndex               | - Implementation Specific Action            |
| 10 | ieee8021BridgeBasePortDelayExceededDiscards | - Statistic, reset to 0 by creation         |
| 11 | ieee8021BridgeBasePortMtuExceededDiscards   | - Statistic, reset to 0 by creation         |
| 12 | ieee8021BridgeBasePortCapabilities          | - Implementation Specific                   |
| 13 | ieee8021BridgeBasePortTypeCapabilities      | - Implementation Specific                   |
| 14 |                                             | bit remoteCustomerAccessPort(7) must be set |
| 15 | ieee8021BridgeBasePortType                  | - remoteCustomerAccessPort(9)               |
| 16 | ieee8021BridgeBasePortExternal              | - Implementation Specific                   |

### 17 17.5.3.3.5 Creating an Uplink Access Port (UAP)

18 UAPs are created by doing a row-create operation on the EVB Bridge's or EVB station's  
19 ieee8021BridgeEvpUapConfigTable. The required column is the ISS Port Number to use for the newly  
20 created Port. The ComponentID and PortNumber are specified if the system chooses to build an implicit  
21 ieee8021BridgeBasePortTable entry. The ieee8021BridgeEvpUapConfigTable contains the following  
22 columns:

|    |                                           |
|----|-------------------------------------------|
| 23 | ieee8021BridgeEvpUapIssPortNumber         |
| 24 | ieee8021BridgeEvpUapComponentId           |
| 25 | ieee8021BridgeEvpUapPortNumber            |
| 26 | ieee8021BridgeEvpUapCdcAdminEnable        |
| 27 | ieee8021BridgeEvpUapAdminCDCPRole         |
| 28 | ieee8021BridgeEvpUapAdminCDCPChanCap      |
| 29 | ieee8021BridgeEvpUapOperCDCPChanCap       |
| 30 | ieee8021BridgeEvpUapAdminCDCPSVIDPoolLow  |
| 31 | ieee8021BridgeEvpUapAdminCDCPSVIDPoolHigh |
| 32 | ieee8021BridgeEvpUapOperState             |
| 33 | ieee8021BridgeEvpUapCdcRemoteEnabled      |
| 34 | ieee8021BridgeEvpUapCdcRemoteRole         |
| 35 | ieee8021BridgeEvpUapConfigRowStatus       |

36 The optional implicitly constructed ieee8021BridgeBasePortTable entry will have the following fields filled  
37 in:

|    |                                             |                                          |
|----|---------------------------------------------|------------------------------------------|
| 38 | ieee8021BridgeBasePortComponentId           | - As per ieee8021BridgeEvpUapConfigTable |
| 39 | ieee8021BridgeBasePort                      | - As per ieee8021BridgeEvpUapConfigTable |
| 40 |                                             | UapPortNumber                            |
| 41 | ieee8021BridgeBasePortIfIndex               | - Implementation Specific Action         |
| 42 | ieee8021BridgeBasePortDelayExceededDiscards | - Statistic, reset to 0 by creation      |
| 43 | ieee8021BridgeBasePortMtuExceededDiscards   | - Statistic, reset to 0 by creation      |
| 44 | ieee8021BridgeBasePortCapabilities          | - Implementation Specific                |
| 45 | ieee8021BridgeBasePortTypeCapabilities      | - Implementation Specific:               |
| 46 |                                             | bit <i>Uplink Access Port</i> (9) is set |
| 47 | ieee8021BridgeBasePortType                  | - Uplink Access Port                     |
| 48 | ieee8021BridgeBasePortExternal              | - Implementation Specific                |

#### 17.5.3.4 Port creation on B-components

B- and I-components are the two components that constitute a BEB (see Clause 26). These components provide what is generally known as “MAC in MAC” transport of Ethernet frames.

Ports on these BEB components are created using 12.16 managed objects.

##### 17.5.3.4.1 Creating PNPs

A B-component is an S-VLAN component with one or more CBPs. A B-component may be a component of a BEB. PNP creation on a B-component follows the same logic used to create a PNP on an S-VLAN component.

Creating a PNP on a BEB is done by adding an entry to the `ieee8021PbPnpTable` specifying the `componentId` and Port Number.

|                                                |                                           |
|------------------------------------------------|-------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code> | - Component to which the new Port belongs |
| <code>ieee8021BridgeBasePort</code>            | - Port Number for the new Port            |

The type of the component referred to by the component ID parameter must be `sVlanComponent`.

As a PNP is a Port on a B-component, which is a type of S-VLAN component, the act of creating a PNP causes entries to be made in the `ieee8021QBridgePortVlanTable` and the `ieee8021BridgeBasePortTable`.

The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|                                                          |                                                     |
|----------------------------------------------------------|-----------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>PbPnpTable</code>                    |
| <code>ieee8021BridgeBasePort</code>                      | - As per <code>PbPnpTable</code>                    |
| <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                    |
| <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation                 |
| <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation                 |
| <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                           |
| <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                           |
|                                                          | bit <code>providerNetworkPort(1)</code> must be set |
| <code>ieee8021BridgeBasePortType</code>                  | - <code>providerNetworkPort(3)</code>               |
| <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                           |

#### 17.5.3.4.2 Creating CBPs

Creating a CBP on a B-component is done by creating an entry in the `ieee8021PbbCbpTable` with the following column values:

|                                                |                                          |
|------------------------------------------------|------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code> | - Component number of the B-component    |
| <code>ieee8021BridgeBasePort</code>            | - Port Number for the newly created Port |

As a CBP is a Port on a B-component, which is a type of S-VLAN component, the act of creating a PNP causes entries to be made in the `ieee8021QBridgePortVlanTable` and the `ieee8021BridgeBasePortTable`.

The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|                                                          |                                                      |
|----------------------------------------------------------|------------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>PbbCbpTable</code>                    |
| <code>ieee8021BridgeBasePort</code>                      | - As per <code>PbbCbpTable</code>                    |
| <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                     |
| <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation                  |
| <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation                  |
| <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                            |
| <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                            |
|                                                          | bit <code>customerBackbonePort(4)</code> must be set |
| <code>ieee8021BridgeBasePortType</code>                  | - <code>customerBackbonePort(6)</code>               |
| <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                            |

#### 17.5.3.5 Port creation on I-components

Creating a Bridge Port on an I-component works the same way as creating a Port on a B-component with the exception that the rules for determining the legality of the Port type are different.

Creating PIPs works in a manner analogous to the creation of a Bridge Port, but as PIPs are not Bridge Ports the details are somewhat different.

#### 17.5.3.5.1 Creating CNPs

The CNP is used to provide a Port-based or S-tagged service interface to customer of the PBBN.

Creating a CNP requires specifying the I-component ID and Bridge Port Number of the Port to be created. This is done by creating an entry in the `ieee8021PbCnpTable`. This creates a new entry in the `ieee8021QBridgePortVlanTable` for the provider Bridge's I-component. This operation also created a new entry in the `ieee8021BridgeBasePortTable`.

The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|                                                          |                                            |
|----------------------------------------------------------|--------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>QBridgePortVlanTable</code> |
| <code>ieee8021BridgeBasePort</code>                      | - As per <code>QBridgePortVlanTable</code> |
| <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action           |
| <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation        |
| <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation        |
| <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                  |
| <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                  |
|                                                          | bit (2) must be set                        |
| <code>ieee8021BridgeBasePortType</code>                  | - <code>customerNetworkPort(4)</code>      |
| <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                  |

### 17.5.3.5.2 Creating VIPs

The creation of VIP starts with the creation of an entry in the `ieee8021PbbVipTable` with the following columns set:

|                                                |                                                                          |
|------------------------------------------------|--------------------------------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code> | - Component Number of I-component                                        |
| <code>ieee8021BridgeBasePort</code>            | - As appropriate                                                         |
| <code>ieee8021PbbVipRowStatus</code>           | - Probably either <code>createAndGo</code> or <code>createAndWait</code> |

An entry will be created in the `ieee8021PbbVipTable` with the following columns set:

|                                           |                     |
|-------------------------------------------|---------------------|
| <code>ieee8021PbbVipPipIfIndex</code>     | - 0                 |
| <code>ieee8021PbbVipISid</code>           | - 1                 |
| <code>ieee8021PbbVipDefaultDstBMAC</code> | - 00-1E-83-00-00-01 |
| <code>ieee8021PbbVipRowStatus</code>      | - “Active”          |

As a VIP is a Port on a I-component, which is a type of S-VLAN component, the act of creating a VIP causes entries to be made in the `ieee8021QBridgePortVlanTable` and the `ieee8021BridgeBasePortTable`.

The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|                                                          |                                                  |
|----------------------------------------------------------|--------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>QBridgePortVlanTable</code>       |
| <code>ieee8021BridgeBasePort</code>                      | - As per <code>QBridgePortVlanTable</code>       |
| <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                 |
| <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation              |
| <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation              |
| <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                        |
| <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific                        |
|                                                          | bit <code>virtualInstancePort</code> must be set |
| <code>ieee8021BridgeBasePortType</code>                  | - <code>virtualInstancePort</code>               |
| <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                        |

Note that before becoming operational, the VIP must be assigned to a PIP and must be assigned to a service by setting an I-SID value. Furthermore, the mapping tables must be set up in a consistent basis.

### 17.5.3.5.3 Creating PIPs

PIPs are not Bridge Ports, but they are necessary parts of the internal operation of a BEB. They share many characteristics of Bridge Ports, simply because both PIPs and Bridge Ports are interfaces that transfer MAC frames, but are not connected to a MAC relay function.

PIPs are created using a BEB managed object. This object maps to the `ieee8021PbbPipTable` in the PBB MIB module. An entry needs to be created in the table with the following attributes:

|                                         |                                                       |
|-----------------------------------------|-------------------------------------------------------|
| <code>ieee8021PbbPipIfIndex</code>      | - A previously unallocated <code>ifIndex</code> value |
| <code>ieee8021PbbPipBMACAddress</code>  | - Implementation Default or specified value           |
| <code>ieee8021PbbPipName</code>         | - Implementation Default or specified value           |
| <code>ieee8021PbbPipIComponentId</code> | - I-component index to which this PIP belongs         |
| <code>ieee8021PbbPipVipMap</code>       | - Empty Mapping                                       |

Note that before the operation can occur on this PIP, it may be necessary to modify the B-MAC address value of the PIP, especially in the case where local MAC addresses are used in the PBBN.

### 17.5.3.6 Required post creation operations

Before a Bridge Port is ready for operational use, the Bridge Port must be associated with an entity that acts as a frame source and frame sink. For a Bridge with or without the dynamic Port creation capability, this will likely be an ISS. For a Bridge with dynamic Port creation, it will be an ISS.

Most Bridge Ports manage this association by using the `ieee8021BridgeBasePortIfIndex` column in the `ieee8021BridgeBasePort` table. It is system dependent if the `ieee8021BridgeBasePortIfIndex` column in the `ieee8021BridgeBasePort` table needs to be filled in with the appropriate `ifIndex` for the newly created Bridge Port. Systems that enforce a specific mapping between Bridge Port Numbers and physical interfaces may have the agent automatically fill in this field and the association may not be modifiable.

The association for CEPs is managed by the `ieee8021PbCepTable`.

The association between PEPs and CNPs for PEBs is managed implicitly by the creation of the PEP/CNP pair by adding a CEP to the member set of an S-VID.

The association between PAPs and CNPs for PEBs is managed implicitly by the creation of a PAP/CNP pair by mapping an external S-VID on a RCAP to a Port-based RCSI. The association between PAPs and CEPs for PEBs is managed implicitly by the creation of a PAP/CEP pair by mapping an external S-VID on a RCAP to a C-tagged RCSI.

The association between PIPs and CBPs is managed by the internal LAN table (`ieee8021BridgeILanIfTable`).

Additionally, for Ports on elements of Provider Bridges and PBBs, instances in service tables must be created before the Ports are capable of passing frames according to the relevant clauses of this standard and subsequent amendments.

### 17.5.3.7 Port creation on ERs

Creating a URP implicitly creates the ER itself. When a URP is created it is not necessarily bound to an ISS. The operating environment of the EVB system may choose to bind the URP to either an S-channel or to an ISS when it chooses. The ER may be created with a DRP or it may dynamically create them on demand from the operating environment.

Creating a DRP on an ER works the same way as creating a Port on a C-VLAN-aware component (17.5.3.2) with the exception that the rules for determining the legality of the Port type are different.

#### 17.5.3.7.1 Creating DRPs

DRPs are created by performing a row-create operation on the `ieee8021EvbPortTable` for an ER. The required columns are the component ID and the Port Number to use for the newly created DRP.

### 17.5.3.7.2 Creating URPs

URPs are created by performing a row-create operation on the `ieee8021BridgeEvpUrpConfigTable` of an EVB station. The required columns are the component ID and the Port Number to use for the newly created Port.

The implicitly constructed `ieee8021BridgeBaseTable` entry will have the following fields filled in:

|                                                      |                                                       |
|------------------------------------------------------|-------------------------------------------------------|
| <code>ieee8021BridgeBaseComponentId</code>           | - As per <code>ieee8021BridgeEvpUrpConfigTable</code> |
| <code>ieee8021BridgeBaseBridgeAddress</code>         | - As per <code>ieee8021BridgeEvpUrpConfigTable</code> |
| <code>ieee8021BridgeBaseNumPorts</code>              | - Implementation Specific Action                      |
| <code>ieee8021BridgeBaseComponentType</code>         | - Type edge relay                                     |
| <code>ieee8021BridgeBaseDeviceCapabilities</code> -  | - Implementation Specific                             |
| <code>ieee8021BridgeBaseTrafficClassesEnabled</code> | - Implementation Specific                             |
| <code>ieee8021BridgeBaseMmrpEnabledStatus</code>     | - Implementation Specific                             |
| <code>ieee8021BridgeBaseRowStatus</code>             |                                                       |

The implicitly constructed `ieee8021BridgeBasePortTable` entry will have the following fields filled in:

|                                                          |                                                                |
|----------------------------------------------------------|----------------------------------------------------------------|
| <code>ieee8021BridgeBasePortComponentId</code>           | - As per <code>ieee8021BridgeEvpUrpConfigTable</code>          |
| <code>ieee8021BridgeBasePort</code>                      | - As per <code>ieee8021BridgeEvpUrpConfigTable</code>          |
| <code>ieee8021BridgeBasePortIfIndex</code>               | - Implementation Specific Action                               |
| <code>ieee8021BridgeBasePortDelayExceededDiscards</code> | - Statistic, reset to 0 by creation                            |
| <code>ieee8021BridgeBasePortMtuExceededDiscards</code>   | - Statistic, reset to 0 by creation                            |
| <code>ieee8021BridgeBasePortCapabilities</code>          | - Implementation Specific                                      |
| <code>ieee8021BridgeBasePortTypeCapabilities</code>      | - Implementation Specific:<br>bit Uplink Relay Port(10) is set |
| <code>ieee8021BridgeBasePortType</code>                  | - Uplink Relay Port (10)                                       |
| <code>ieee8021BridgeBasePortExternal</code>              | - Implementation Specific                                      |

## 17.6 MIB operations for service interface configuration

This subclause outlines, on a per-service interface basis, the MIB operations that a Provider must perform to configure each type of service interface. The clause is organized into two broad subclauses. The first subclause explains how service interfaces for Provider networks (Clause 15, Clause 16, etc.), are configured. The second subclause explains how service interfaces for Provider Backbone Networks (Clause 25, Clause 26, etc.), are configured. Both of these subclauses have the same substructure. First, a description of the MIB operations that are service interface type independent, and secondly a description of the service type MIB operations organized in a per-service type manner.

### 17.6.1 Provisioning PBN service interfaces

This clause assumes that the components and Ports, if dynamic, have been created, although there may be some notes on the parameters used for Port creation on a per-service basis, if there are restrictions. This subclause describes the MIB operations needed to configure service interfaces for PBN equipment.

Table 17-1 lists the parameters required for each of the service interface types that can be used to interface to a provider network. These parameter names are used in subsequent clauses as values to be entered in the appropriate MIB tables.

**Table 17-1—Provider Bridge service interface parameters**

| Parameter              | Description                                                                            | Customer service interface type |                 |                                                         |
|------------------------|----------------------------------------------------------------------------------------|---------------------------------|-----------------|---------------------------------------------------------|
|                        |                                                                                        | Port-based                      | C-tagged        | S-tagged                                                |
| ComponentID            | ID of the S-VLAN component                                                             | Mandatory                       | Mandatory       | Mandatory                                               |
| Port Number            | Bridge Port Number that Receives Customer Frames                                       | CNP Port Number                 | CEP Port Number | CNP Port Number                                         |
| RelaySVid              | S-VID value used within the provider network                                           | Mandatory                       | Mandatory       | Mandatory                                               |
| CVid                   | C-VID value used to identify frames to be transported by the specified service         | Not needed                      | Mandatory       | Not needed                                              |
| LocalSVid              | S-VID value used to identify the frames to be transported by the service               | Not needed                      | Not Needed      | Optional: if not specified, the RelaySVid value is used |
| Default CVID value     | C-VID value to be used for frames received from the Provider Network without C-TAGs    | Not needed                      | Mandatory       | Not needed                                              |
| Default Priority Value | Priority value to be used for frames received from the Provider Network without C-TAGs | Not needed                      | Mandatory       | Not needed                                              |

### 17.6.1.1 Provisioning a Port-based service interface

This subclause describes the MIB operations needed to provision a Port-based service interface.

Creating a Port-based service on a CNP requires manipulation of the Port member sets of the `ieee8021QBridgeVlanStaticTable`. One must manipulate the Port member sets for the row with the following index values:

|                                                   |               |
|---------------------------------------------------|---------------|
| <code>ieee8021QBridgeVlanStaticComponentId</code> | - ComponentId |
| <code>ieee8021QBridgeVlanStaticVlanIndex</code>   | - RelaySVid   |

The CNP must be added to the PortList specified by the `ieee8021QBridgeVlanStaticEgressPorts` column of this row and must be added to the PortList specified by the `ieee8021QBridgeVlanStaticUntaggedPorts` column of this row.

One may, or may not, wish to allow the customer to specify priorities for the arriving customer traffic. In either case one must set the `ieee8021QBridgePortAcceptableFrameTypes` column of the entry in the `ieee8021QBridgePortVlanTable` indexed by:

|                                                |               |
|------------------------------------------------|---------------|
| <code>ieee8021BridgeBasePortComponentId</code> | - ComponentId |
| <code>ieee8021BridgeBasePort</code>            | - PortNumber  |

to `admitUntaggedAndPriority` and set the `ieee8021QBridgePortIngressFiltering` column to TRUE to ensure that customers may not “spoof” the provider network by sending S-tagged frames to the CNP.

### 17.6.1.2 Provisioning a C-tagged service interface

This subclause describes the MIB operations needed to provision a C-tagged service interface.

The CEP must be added to the Port member set of each S-VID on the S-VLAN component of the Provider Edge Bridge that is to provide service for the CEP. This is done by modifying the `ieee8021QBridgeVlanStaticTable` `ieee8021QBridgeStaticEgressPorts` PortList whose matching index column values are as follows:

|                                                   |               |
|---------------------------------------------------|---------------|
| <code>ieee8021QBridgeVlanStaticComponentId</code> | - ComponentId |
| <code>ieee8021QBridgeVlanStaticVlanIndex</code>   | - RelaySVid   |

Adding the CEP to the member set of an S-VID implies the existence of a CNP on the S-VLAN component that is internally connected to a PEP on the C-VLAN component. Enabling the CEP to send and receive frames from the service instance identified by the RelaySVid requires creating a linkage between the S-VID, the CNP, the PEP, and a C-VID. This is accomplished by configuring the `ieee8021PbEdgePortTable` and `ieee8021PbCVidRegistrationTable`.

Each S-VID value that is associated with a provider service instance accessed through the CEP requires that an entry be made in the `ieee8021PbEdgePortTable`. An entry in this table maps an S-VID to a CNP and associates that CNP with a specific PEP. The CNP is identified by the CEP port number and the S-VID that form the index values for the table. The contents of the table entry identify the PEP by specifying the C-VID value used as the PVID for that PEP (as well as providing other configuration parameters for that PEP). A CNP is implicitly created by the first entry identifying a given PEP (i.e., the first entry that contains a given C-VID value). In some cases it is useful to create multiple entries to map multiple S-VIDs to the same CNP. Two or more entries map to the same CNP if the C-VID value identifying the PVID of the PEP is the same (the other values of the entry should be the same as well). This many-to-one mapping of S-VIDs to CNP/PEP pairs can be used to configure asymmetric VLANs for supporting rooted-multipoint connectivity (F.1.3.2).

1 The table entry with the following index values:

|   |                                   |               |
|---|-----------------------------------|---------------|
| 2 | ieee8021BridgeBasePortComponentId | - ComponentId |
| 3 | ieee8021BridgeBasePort            | - PortNumber  |
| 4 | ieee8021PAbEdgePortSVid           | - RelaySVid   |

5 needs to have the following columns set:

|   |                                          |                   |
|---|------------------------------------------|-------------------|
| 6 | ieee8021PbEdgePortPVID                   | - DefaultCVid     |
| 7 | ieee8021PbEdgePortDefaultUserPriority    | - DefaultPriority |
| 8 | ieee8021PbEdgePortAcceptableFrameType    | - As Desired      |
| 9 | ieee8021PbEdgePortEnableIngressFiltering | - As Desired      |

10 Each C-VID value that is to be mapped to a provider service instance requires that an entry be made in the  
11 ieee8021PbCVidRegistrationTable. An entry in this table maps a C-VID to a PEP and associates that PEP  
12 with a specific CNP. The PEP is identified by the CEP port number and the C-VID that form the index  
13 values for the table. The contents of the table entry identify the CNP by specifying the S-VID value used as  
14 the PVID for that CNP (as well as providing member set and untagged set information for the C-VID). A  
15 PEP is implicitly created by the first entry identifying a given CNP (i.e., the first entry that contains a given  
16 S-VID value). In some cases it is useful to create multiple entries to map multiple C-VIDs to the same PEP.  
17 Two or more entries map to the same PEP if the S-VID value identifying the PVID of the CNP is the same.  
18 This many-to-one mapping of C-VIDs to PEP/CNP pairs can be used to support bundling multiple  
19 C-VLANs into a single service instance. The table entry with the following index values:

|    |                                   |               |
|----|-----------------------------------|---------------|
| 20 | ieee8021BridgeBasePortComponentId | - ComponentId |
| 21 | ieee8021BridgeBasePort            | - PortNumber  |
| 22 | ieee8021PbCVidRegistrationCVid    | - CVid        |

23 needs to have the following columns set:

|    |                                       |              |
|----|---------------------------------------|--------------|
| 24 | ieee8021PbCVidRegistrationSVid        | - RelaySVid  |
| 25 | ieee8021PbCVidRegistrationUntaggedPep | - As Desired |
| 26 | ieee8021PbCVidRegistrationUntaggedCep | - As Desired |

### 27 17.6.1.3 Provisioning an S-tagged service interface

28 This subclause describes the MIB operations needed to provision an S-tagged service interface.

29 Creating an S-tagged-based service interface requires manipulation of the Port member sets of the CNP  
30 entry in the ieee8021QBridgeVlanStaticTable. One must manipulate the Port member sets for the row with  
31 the following index values:

|    |                                      |               |
|----|--------------------------------------|---------------|
| 32 | ieee8021QBridgeVlanStaticComponentId | - ComponentId |
| 33 | ieee8021QBridgeVlanStaticVlanIndex   | - RelaySVid   |

34 The CNP must be added to the PortList specified by the ieee8021QBridgeVlanStaticEgressPorts column of  
35 this row. The CNP must not be in the PortList specified by the ieee8021QBridgeVlanStaticUntaggedPorts  
36 column of this row as this service requires S-TAGS in all frames.

37 If the Provider wishes to use separate S-TAG values for the customer and provider S-VLAN spaces, then the  
38 entry in the ieee8021PbVidTranslationTable indexed by the following:

|    |                                   |               |
|----|-----------------------------------|---------------|
| 39 | ieee8021BridgeBasePortComponentId | - ComponentId |
| 40 | ieee8021BridgeBasePort            | - PortNumber  |
| 41 | ieee8021PbVidTranslationLocalVid  | - LocalSVid   |

42 must be created or changed so that the ieee8021PbVidTranslationRelayVid column is set to the RelaySVid.

## 17.6.2 Provisioning Backbone Bridged Network service interfaces

This subclause describes the MIB operations needed to provision service interfaces on PBBNs. In particular, this subclause assumes that the provider backbone network service instance exists and that the following information is available:

The I-SID value that identifies the correct backbone service instance is known.

At any BEB that is to have a service interface map customer data to a backbone service instance, given the I-SID, the following information can be determined:

- The Component ID of the B-component that contains the appropriate PNP used to access the service instance.
- The Port number of the PNP.
- The B-VID value used to transport that service over the Backbone Core.
- The DA used to transport the frame over the Backbone Core. Either a default MAC address, or the service MAC address.

Furthermore, the core of the network is assumed to be operationally correct. That is, if a frame is presented to the Backbone Core by a BEB with the proper B-VID value and proper Backbone Destination MAC address (B-DA) at the proper PNP, then the frame will arrive at the appropriate VIP(s). This can be achieved by statically configuring the member sets of the BCBs or by configuring the network such that dynamic address and VLAN registration protocols ensure that the Core Bridges Port member sets and FDBs are set appropriately.

Provisioning a service interface in a BEB to access a backbone service interface requires configuring two components. The first is the I-component. The I-component determines the backbone service instance to which customer data is mapped. The second component is the B-component. The B-component determines how the backbone service instance is forwarded over the PBBN core. Thus, the I-component determines the I-SID value, and thus the backbone service instance, to which the customer data belongs and the B-component determines the B-VID and B-DA values that will be used by the relay functions of the BCBs to determine the forwarding path through the core network used by the customer's data.

In the case of an I-tagged service interface, the service interface used by the customer is configured on the CBP of a BEB and the physical interconnection between the backbone network and the customer network is between the CBP of a provider managed B-component and the PIP of a customer managed I-component.

To simplify the discussion of service interface provisioning, this subclause first discusses interface type-independent provisioning of the B-component, and then service interface-independent provisioning of the I-component. Following that discussion, interface type-specific configuration is discussed. This type-specific configuration consists of instructions on how to determine the parameters needed by the service independent configuration of both the I- and B-components along with the provisioning of service-specific tables in the I- and B-components.

Table 17-2 lists the parameters required to provision each type of service interface per Clause 25. The parameters are used in the descriptions of the MIB table operations needed to configure each service in the following subclauses.

**Table 17-2—PBB service interface parameters**

| Parameter           | Description                                                                      | Service interface type                                                           |                                                                                  |                                                                                  |                                                                 |
|---------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------|-----------------------------------------------------------------|
|                     |                                                                                  | Port-based                                                                       | Unbundled one-to-one S-tagged                                                    | Bundled many-to-one or all-to-one S-tagged                                       | I-tagged service interface                                      |
| IComponentID        | Component ID of the I-component of a BEB                                         | Mandatory                                                                        | Mandatory                                                                        | Mandatory                                                                        | Not needed                                                      |
| BComponentID        | Component ID of the B-component of a BEB                                         | Mandatory                                                                        | Mandatory                                                                        | Mandatory                                                                        | Mandatory                                                       |
| CBPPortNumber       | Port number of a Customer Backbone Port                                          | Mandatory                                                                        | Mandatory                                                                        | Mandatory                                                                        | Mandatory                                                       |
| BackboneSid         | I-SID value used between the PIP and CBP                                         | Mandatory                                                                        | Mandatory                                                                        | Mandatory                                                                        | Mandatory                                                       |
| MappingType         | Used for point-to-multipoint services where ingress or egress limiting is needed | Optional                                                                         | Optional                                                                         | Optional                                                                         | Optional                                                        |
| DefaultDest Address | MAC address to use as the backbone DA                                            | Optional: if not specified, the service default address is used                  | Optional: if not specified, the service default address is used                  | Optional: if not specified, the service default address is used                  | Optional: if not specified, the service default address is used |
| B-Vid               | Backbone VID that identifies the VLAN to transport the service over the backbone | Optional: if not specified, the default B-VLAN is used                           | Optional: if not specified, the default B-VLAN is used                           | Optional: if not specified, the default B-VLAN is used                           | Optional: if not specified, the default B-VLAN is used          |
| LocalSID            | I-SID value to be used in the backbone network.                                  | Optional: if not specified, the BackboneSID value is used                        | Optional: if not specified, the BackboneSID value is used                        | Optional: if not specified, the BackboneSID value is used                        | Optional: if not specified, the BackboneSID value is used       |
| PCPSpec             | Priority Code Point encoding and decoding specifications                         | Optional: note that separate values may be required for the I- and B-component s | Optional: note that separate values may be required for the I- and B-component s | Optional: note that separate values may be required for the I- and B-component s | Not needed                                                      |
| LocalSVid           | S-TAG value that designates traffic at the CNP, if different from the RelaySVid  | Not needed                                                                       | Optional: RelaySVid used if not specified                                        | Optional: RelaySVid used if not specified                                        | Not needed                                                      |

**Table 17-2—PBB service interface parameters (continued)**

| Parameter            | Description                                                                                            | Service interface type |                               |                                            |                            |
|----------------------|--------------------------------------------------------------------------------------------------------|------------------------|-------------------------------|--------------------------------------------|----------------------------|
|                      |                                                                                                        | Port-based             | Unbundled one-to-one S-tagged | Bundled many-to-one or all-to-one S-tagged | I-tagged service interface |
| RelaySVid            | S-TAG value used within the I-component to identify traffic belonging to a particular service instance | Mandatory              | Mandatory                     | Mandatory                                  | Not needed                 |
| VIPPortNumber        | Port number of the VIP                                                                                 | Mandatory              | Mandatory                     | Mandatory                                  | Not needed                 |
| PIPIIndex            | Identifier of the PIP to which the VIP belongs                                                         | Mandatory              | Mandatory                     | Mandatory                                  | Not needed                 |
| VIP-SID              | ISID value used by a VIP                                                                               | Mandatory              | Mandatory                     | Mandatory                                  | Not needed                 |
| adminPointToPointMAC | Indicates if the service is a point-to-point service                                                   | Optional               | Optional                      | Optional                                   | Optional                   |
| CNPPortNumber        | The Bridge Port number of a CNP on an I-component                                                      | Mandatory              | Mandatory                     | Mandatory                                  | Not needed                 |

### 17.6.2.1 Service type-independent provisioning of the B-component

All frames that are transmitted over a PBBN service instance ultimately start at a CBP. Thus part of provisioning any service interface requires configuration of the CBP. This is done with the `ieee8021PbbCBPServiceMappingTable`.

Provisioning this portion of the service interface is straightforward. One needs to add a row to the `ieee8021PbbCBPServiceMappingTable` whose columns are set to the values specified in the required parameters. Furthermore, one may need to ensure that both the CBP and PNP belong to the member set of the B-VID if dynamic configuration of VIDs is not supported.

### 17.6.2.2 Service type-independent provisioning of the I-component

The I-component needs to be configured when either Port-based or S-tagged service interfaces are configured. Traffic belonging to an I-tagged service interface does not transit the I-component; hence there is no configuration of the I-component for that service. The I-component's provisioning is more service interface dependent than the provisioning of the B-component. However, some of the logic needed to provision the I-component does not depend upon the service being provisioned. In particular the configuration of the `ieee8021PbbVIPTable` and the `ieee8021PbbPipTable` is provisioned almost identically for both Port-based and S-tagged service instances.

### 1 17.6.2.2.1 Configuring the ieee8021PbbVipTable

2 Traffic for both Port-based and S-tagged services interfaces transitions a VIP on the I-component. The  
3 particular VIP over which the traffic transits determines the backbone service instance, and thus the I-SID  
4 value for the traffic. A VIP must be created for each service instance for which the I-component forwards  
5 traffic. Bundled services interfaces map multiple customer S-VIDs to a single service instance. Generally,  
6 when creating a service the first step is to create the VIP that will carry this service. This is done by creating  
7 a row in the ieee8021PbbVipTable. The following columns must be set in the table:

|    |                                   |                                                |
|----|-----------------------------------|------------------------------------------------|
| 8  | ieee8021BridgeBasePortComponentId | - set to IComponentId                          |
| 9  | ieee8021BridgeBasePort            | - set to VIPPortNum                            |
| 10 | ieee8021PbbVipISid                | - set to the VIP-SID (which may be localSID or |
| 11 |                                   | backboneSID depending on the use of I-SID      |
| 12 |                                   | translation at the B-component)                |

13 As a side effect of this row creation, a row will be created in the ieee8021PbbISidToVipTable. Essentially,  
14 this table implements the inverse mapping, taking an I-SID value to the VIP that is the local endpoint of the  
15 service instance.

### 16 17.6.2.2.2 Configuring the ieee8021PbbPipTable

17 For Port-based, unbundled service interfaces, and for the first S-VID allocated to a bundled service, then the  
18 VIP used for the service must be configured to use the appropriate PIP. Use the IComponentID and PIPIndex  
19 to select a row in this table. Set the bit corresponding to the VIPPortNum in the appropriate MAP column of  
20 that row to 1. This adds the VIP to the PIP and, as a side effect, sets the ieee8021PbbVipPipIndex column  
21 in the ieee8021PbbVipTable.

### 22 17.6.2.3 Service-dependent provisioning for an I-tagged service interface

23 The I-tagged service interface of a PBBN allows a customer to attach directly to a CBP of a B-component of  
24 a BEB allowing the customer to transport frames that already possess an I-TAG. A scenario for this is when  
25 the customer is also a backbone provider and is purchasing transport across another Provider's network.  
26 Another scenario is when an access network provides an I-tagged interface. The I-tagged service interface is  
27 defined in 25.5.

28 The provisioning is accomplished by using the parameter values of Table 17-7 and applying the procedures  
29 outlined in 17.6.2.1 to provision the B-component.

### 30 17.6.2.4 Service-dependent provisioning a Port-based service interface

31 The Port-based service interface of a PBBN causes all of the traffic arriving at the CNP of the I-component  
32 of a BEB to be mapped to a single backbone service instance. The Port-based interface of a PBBN provides the  
33 same customer service as a Port-based service interface of a PBN. The implementation of this service  
34 interface in a PBBN is defined in 25.3.

### 35 17.6.2.4.1 Configuring the B-component

36 Given the PIP, one uses the I-LAN table to find the B-component and CBP that the traffic for this service  
37 will transit. This gives us the following two parameters:

|    |                                                          |
|----|----------------------------------------------------------|
| 38 | BComponentId—B-component ID for the CBP                  |
| 39 | CBPPortNumber—Port number of the CBP on this B-component |

40 These two service parameters found from the I-LAN table along with the remainder of the parameters  
41 defined in Table 17-5 are used to configure the B-component as outlined in 17.6.2.1. As a side effect of  
42 configuring the CBP via the ServiceMapping table, the ieee8021PbbVipDefaultDstBMAC column is set in  
43 the ieee8021PbbVipTable.

#### 17.6.2.4.2 Configuring the Port operating modes and I-component VID

The first step is to configure the I-component VID used to interconnect the VIP with the CNP. This is done by creating an entry in the `ieee8021QBridgeVlanStaticTable` with the columns set to the following values:

|                                                     |                                                 |
|-----------------------------------------------------|-------------------------------------------------|
| <code>ieee8021QBridgeVlanStaticComponentId</code>   | - IcomponentId                                  |
| <code>ieee8021QBridgeVlanStaticVlanIndex</code>     | - IcompPVid                                     |
| <code>ieee8021QBridgeVlanStaticName</code>          | - Something administratively convenient         |
| <code>ieee8021QBridgeVlanStaticEgressPorts</code>   | - Port List containing just the VIP and the CNP |
| <code>ieee8021QBridgeVlanStaticUntaggedPorts</code> | - PortList containing just the VIP and the CNP  |

This sets the VIP and the CNP to be the only Ports present on the new I-component PVID. Furthermore, they are both set for untagged traffic. Thus, traffic arriving at one Port will be relayed to the other Port without any S-TAGs.

The final step is to configure the ingress filtering on both the VIP and CNP. This is done by modifying their entries in the `ieee8021QBridgePortVlanTable`. For both of these Ports, the following columns in the table must be set:

|                                                      |                             |
|------------------------------------------------------|-----------------------------|
| <code>ieee8021QBridgePortAcceptableFrameTypes</code> | - acceptUntaggedAndPriority |
| <code>ieee8021QBridgePortIngressFiltering</code>     | - TRUE                      |

#### 17.6.2.5 Service-dependent provisioning for an S-tagged service interfaces

This subclause describes the MIB operations specific to S-tagged service interface provisioning. Configuration is done in a manner similar to Port-based services. The configuration differences are largely confined to different configurations of the CNP and VIP Port member sets, tagging, and ingress filtering.

The parameters for an S-tagged service interface are similar to those for a Port-based service interface.

##### 17.6.2.5.1 Configuring the B-component

If the service interface to be created is unbundled, or if the service interface is bundled and the newly configured service interface is the first S-VID value to be transported on this Backbone I-SID, then the B-component will need to be configured.

The first step is to find the B-component ID and CBP for the traffic. Given the PIP, one uses the I-LAN table to find the B-component and CBP that the traffic for this service interface will transit. This gives us the following two parameters:

|                            |                                             |
|----------------------------|---------------------------------------------|
| <code>BComponentId</code>  | —B-component ID for the CBP                 |
| <code>CBPPortNumber</code> | —Port number of the CBP on this B-component |

These, together with the `BackboneSid`, `DefaultDestAddress`, and `BVid` value can be used to configure the B-component as per the previous instructions. As a side effect of configuring the CBP via the `ServiceMapping` table, the `ieee8021PbbVipDefaultDstBMAC` column is set in the `ieee8021PbbVipTable`.

#### 1 17.6.2.5.2 Configuring the I-component for S-tagged service interfaces

2 These service interfaces are configured by creating one or more static VLANs on the I-component whose  
3 S-VIDs are the values specified as the S-VID parameters to the service. For a one-to-one service, exactly  
4 one S-VID value is specified. For a many-to-one or all-to-one service, multiple S-VID values are specified.  
5 This is done by creating an entry in the ieee8021QBridgeVlanStaticTable with the columns set to the  
6 following values:

|    |                                      |                                                 |
|----|--------------------------------------|-------------------------------------------------|
| 7  | ieee8021QBridgeVlanStaticComponentId | - IcomponentId                                  |
| 8  | ieee8021QBridgeVlanStaticVlanIndex   | - S-VID                                         |
| 9  | ieee8021QBridgeVlanStaticName        | - Something administratively convenient         |
| 10 | ieee8021QBridgeVlanStaticEgressPorts | - Port List containing just the VIP and the CNP |

11 For the one-to-one service set:

|    |                                        |                                    |
|----|----------------------------------------|------------------------------------|
| 12 | ieee8021QBridgeVlanStaticUntaggedPorts | - PortList containing just the VIP |
|----|----------------------------------------|------------------------------------|

13 For the many-to-one or all-to-one service:

|    |                                        |            |
|----|----------------------------------------|------------|
| 14 | ieee8021QBridgeVlanStaticUntaggedPorts | - Null set |
|----|----------------------------------------|------------|

15 For the unbundled one-to-one service, the VIP and CNP are set to be the only Ports that are members of the  
16 I-component's VLAN identified by S-VID. Adding the VIP to the set of untagged Ports means that the data  
17 will be sent to the CBP on the B-component untagged.

18 For the bundled many-to-one or all-to-one service interfaces, the VIP may be in the member set of more than  
19 one S-VID. This is the mechanism by which multiple CNP services, identified by S-VID, are mapped to the  
20 same I-SID value. Furthermore, unlike the unbundled service, the VIP is not a member of the untagged  
21 egress set of the S-VID.

## 1 17.7 MIB modules<sup>31 32</sup>

2 In this subclause, certain terms (e.g., “SHOULD” and “MUST”) denote requirements terminology according  
3 to the usage specified in IETF RFC 2119, as is customary for IETF MIB module definitions. In the MIB  
4 modules definitions below, if any discrepancy between the DESCRIPTION text and the corresponding  
5 definition in any other part of this standard occur, the definitions outside this subclause take precedence.

16  STATUS      current
17  DESCRIPTION
18      "A port type. The possible port types are:
19
20      customerVlanPort(2) - Indicates a port is a
21      C-tag-aware port of an enterprise VLAN-aware Bridge.
22
23      providerNetworkPort(3) - Indicates a port is an S-tag-
24      aware port of a Provider Bridge or Backbone Edge
25      Bridge used for connections within a PBN or PBBN.
26
27      customerNetworkPort(4) - Indicates a port is an S-tag-
28      aware port of a Provider Bridge or Backbone Edge
29      Bridge used for connections to the exterior of a
30      PBN or PBBN.
31
32      customerEdgePort(5) - Indicates a port is a C-tag-
33      aware port of a Provider Bridge used for connections
34      to the exterior of a PBN or PBBN.
35
36      customerBackbonePort(6) - Indicates a port is a I-tag-
37      aware port of a Backbone Edge Bridge's B-component.
38
39      virtualInstancePort(7) - Indicates a port is a virtual
40      S-tag-aware port within a Backbone Edge Bridge's
41      I-component that is responsible for handling
42      S-tagged traffic for a specific backbone service
43      instance.
44
45      dBridgePort(8) - Indicates a port is a VLAN-unaware
46      member of an IEEE 802.1D Bridge.
47
48      remoteCustomerAccessPort (9) - Indicates a port is an
49      S-tag-aware port of a Provider Bridge used for
50      connections to remote customer interface LANs
51      through another PBN.
52
53      stationFacingBridgePort (10) - Indicates a port of a
54      Bridge that supports the EVB status parameters
55      (40.4) with an EVBMode parameter value of
56      EVB Bridge.
57
58      uplinkAccessPort (11) - Indicates a port on a
59      Port-mapping S-VLAN component that connects an EVB
60      Bridge with an EVB station.
61
62      uplinkRelayPort (12) - Indicates a port of an edge relay
63      that supports the EVB status parameters (40.4)
64      with an EVBMode parameter value of EVB station."

59     DESCRIPTION
60         "A value that represents a type (and thereby the format)
61         of a IEEE8021ServiceSelectorValue. The value can be one of
62         the following:
63
64         ieeeReserved(0)    Reserved for definition by IEEE 802.1
65                           recommend to not use zero unless
66                           absolutely needed.
67         vlanId(1)          12-Bit identifier as described in IEEE Std 802.1Q.
68         isid(2)            24-Bit identifier as described in IEEE Std 802.1ah.
69         tesid(3)           32 Bit identifier as described below.
70         segid(4)           32 Bit identifier as described below.
71         path-tesid(5)      32 Bit identifier as described below.
72         group-isid(6)      24 Bit identifier as described below.

```

1       ieeeReserved(7)   Reserved for definition by IEEE Std 802.1

2

3       To support future extensions, the IEEE8021ServiceSelectorType

4       textual convention SHOULD NOT be subtyped in object type

5       definitions. It MAY be subtyped in compliance statements in

6       order to require only a subset of these address types for a

7       compliant implementation.

8

9       The tesid is used as a service selector for MAs that are present

10      in Bridges that implement PBB-TE functionality. A selector of

11      this type is interpreted as a 32 bit unsigned value of type

12      IEEE8021PbbTeTSidId. This type is used to index the

13      ieee8021PbbTeTeSiEspTable to find the ESPs that comprise the TE

14      Service Instance named by this TE-SID value.

15

16      The segid is used as a service selector for MAs that are present

17      in Bridges that implement IPS functionality. A selector of

18      this type is interpreted as a 32 bit unsigned value of type

19      IEEE8021TeipsSegid. This type is used to index the

20      Ieee8021TeipsSegTable to find the SMPs that comprise the

21      Infrastructure Segment named by this segid value.

22

23      The path-tesid is used as a service selector for SPBM path MAs.

24      A selector of this type is interpreted as a 32 bit unsigned value

25      corresponding to the MA index dotlagCfmMaIndex. This type is used

26      to index the dotlagCfmMepSpbmEspTable to find the ESPs that

27      comprise the SPBM path associated with an SPBM path MA.

28

29      The group-isid is used as a service selector for SPBM group MAs.

30      A selector of this type is interpreted as a 24 bit unsigned value

31      corresponding to the I-SID associated with an SPBM group MA.

32

33      Implementations MUST ensure that IEEE8021ServiceSelectorType

34      objects and any dependent objects (e.g.,

35      IEEE8021ServiceSelectorValue objects) are consistent. An

36      inconsistentValue error MUST be generated if an attempt to

37      change an IEEE8021ServiceSelectorType object would, for

38      example, lead to an undefined IEEE8021ServiceSelectorValue value."

39      SYNTAX        INTEGER {

40                    vlanId(1),

41                    isid(2),

42                    tesid(3),

43                    segid(4),

44                    path-tesid(5),

45                    group-isid(6),

46                    ieeeReserved(7)

47                    }

48

49      IEEE8021ServiceSelectorValueOrNone ::= TEXTUAL-CONVENTION

50        DISPLAY-HINT "d"

51        STATUS        current

52        DESCRIPTION

53        "An integer that uniquely identifies a generic MAC Service,

54        or none. Examples of service selectors are a VLAN-ID

55        (IEEE 802.1Q) and an I-SID (IEEE Std 802.1ah).

56

57        An IEEE8021ServiceSelectorValueOrNone value is always

58        interpreted within the context of an

59        IEEE8021ServiceSelectorType value. Every usage of the

60        IEEE8021ServiceSelectorValueOrNone textual convention is

61        required to specify the IEEE8021ServiceSelectorType object

62        that provides the context. It is suggested that the

63        IEEE8021ServiceSelectorType object be logically registered

64        before the object(s) that use the

65        IEEE8021ServiceSelectorValueOrNone textual convention, if

66        they appear in the same logical row.

67

68        The value of an IEEE8021ServiceSelectorValueOrNone object

69        must always be consistent with the value of the associated

70        IEEE8021ServiceSelectorType object. Attempts to set an

71        IEEE8021ServiceSelectorValueOrNone object to a value

72        inconsistent with the associated

```

1      IEEE8021ServiceSelectorType must fail with an
2      inconsistentValue error.
3
4      The special value of zero is used to indicate that no
5      service selector is present or used. This can be used in
6      any situation where an object or a table entry MUST either
7      refer to a specific service, or not make a selection.
8
9      Note that a MIB object that is defined using this
10     TEXTUAL-CONVENTION SHOULD clarify the meaning of
11     'no service' (i.e., the special value 0), as well as the
12     maximum value (i.e., 4094, for a VLAN ID)."
13     SYNTAX      Unsigned32 (0 | 1..4294967295)
14
15 IEEE8021ServiceSelectorValue ::= TEXTUAL-CONVENTION
16     DISPLAY-HINT "d"
17     STATUS      current
18     DESCRIPTION
19         "An integer that uniquely identifies a generic MAC Service.
20         Examples of service selectors are a VLAN-ID (IEEE 802.1Q)
21         and an I-SID (IEEE Std 802.1ah).
22
23         An IEEE8021ServiceSelectorValue value is always interpreted
24         within the context of an IEEE8021ServiceSelectorType value.
25         Every usage of the IEEE8021ServiceSelectorValue textual
26         convention is required to specify the
27         IEEE8021ServiceSelectorType object that provides the context.
28         It is suggested that the IEEE8021ServiceSelectorType object
29         be logically registered before the object(s) that use the
30         IEEE8021ServiceSelectorValue textual convention, if they
31         appear in the same logical row.
32
33         The value of an IEEE8021ServiceSelectorValue object must
34         always be consistent with the value of the associated
35         IEEE8021ServiceSelectorType object. Attempts to set an
36         IEEE8021ServiceSelectorValue object to a value inconsistent
37         with the associated IEEE8021ServiceSelectorType must fail
38         with an inconsistentValue error.
39
40         Note that a MIB object that is defined using this
41         TEXTUAL-CONVENTION SHOULD clarify the

57 DESCRIPTION

58 "Indicates the capabilities of this port. The corresponding

59 instance of ieee8021BridgeBasePortType can potentially take

60 any of the values for which the corresponding bit in this

61 object is 1. The possible port types are as follows:

62

63 customerVlanPort(0) - Indicates the port can be a C-TAG-

64 aware port of an enterprise VLAN-aware Bridge.

65

66 providerNetworkPort(1) - Indicates the port can be an

67 S-TAG-aware port of a Provider Bridge or Backbone

68 Edge Bridge used for connections within a PBN or

69 PBBN.

70

71 customerNetworkPort(2) - Indicates the port can be an

72 S-TAG-aware port of a Provider Bridge or Backbone

```

1         Edge Bridge used for connections to the exterior of
2         a PBN or PBBN.
3
4         customerEdgePort(3) - Indicates the port can be a C-TAG-
5         aware port of a Provider Bridge used for connections
6         to the exterior of a PBN or PBBN.
7
8         customerBackbonePort(4) - Indicates the port can be a
9         I-TAG-aware port of a Backbone Edge Bridge's
10        B-component.
11
12        virtualInstancePort(5) - Indicates the port can be a
13        virtual S-TAG-aware port within a Backbone Edge
14        Bridge's I-component that is responsible for
15        handling S-tagged traffic for a specific backbone
16        service instance.
17
18        dBridgePort(6) - Indicates the port can be a VLAN-unaware
19        member of an IEEE 802.1Q Bridge.
20
21        remoteCustomerAccessPort(7) - Indicates the port can be an
22        S-TAG-aware port of a Provider Bridge capable of providing
23        Remote Customer Service Interfaces.
24
25        stationFacingBridgePort(8) - Indicates the station-facing
26        Bridge Port in a EVB Bridge.
27
28        uplinkAccessPort(9) - Indicates the uplink access port
29        in an EVB Bridge or EVB station.
30
31        uplinkRelayPort(10) - Indicates the uplink relay port
32        in an EVB station."

66        MAX-ACCESS   read-write
67        STATUS       current
68        DESCRIPTION
69            "For a port running spanning tree, this object represents the
70            administrative point-to-point status of the LAN segment
71            attached to this port, using the enumeration values of
72            IEEE Std 802.1AC. A value of forceTrue(1) indicates

```

that this port should always be treated as if it is connected to a point-to-point link. A value of forceFalse(2) indicates that this port should be treated as having a shared media connection. A value of auto(3) indicates that this port is considered to have a point-to-point link if it is an Aggregator and all of its members are aggregatable, or if the MAC entity is configured for full duplex operation, either through auto-negotiation or by management means. Manipulating this object changes the underlying adminPointToPointMAC.

For a VIP, the adminPointToPointMAC parameter controls the mechanism by which the Default Backbone Destination parameter for the VIP is determined. For a backbone service instance that includes only 2 VIPs, the value may be set to forceTrue(1) which permits dynamic learning of the Default Backbone Destination parameter. For a backbone service instance that includes more than 2 VIPs, the value MUST be set to ForceFalse(2) or auto(3).

When this object is set to forceTrue(1) for a VIP, the Default Backbone Destination parameter is modified by the subsequent M\_UNITDATA.indications as specified in 6.10.1 (and described in 26.4.1). Whenever the parameter is set to forceFalse(2) or auto(3), the value for the Default Backbone Destination parameter is set to the Backbone Service Instance Group Address for the VIP-ISID.

The value of this object MUST be retained across reinitializations of the management system."

STATUS current

DESCRIPTION

"For a port running spanning tree, this object represents the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection. If adminPointToPointMAC is set to auto(2), then the value of operPointToPointMAC is determined in accordance with the specific procedures defined for the MAC entity concerned, as defined in IEEE Std 802.1AC. The value is determined dynamically; that is, it is re-evaluated whenever the value of adminPointToPointMAC changes, and whenever the specific procedures defined for the MAC entity evaluate a change in its point-to-point status.

For a VIP, this object simply reflects the value of the corresponding instance of ieee8021BridgeBasePortAdminPointToPoint. The value will be true(1) if that object is forceTrue(1), and the value will be false(2) if the value of that object is either forceFalse(2) or auto(3)."

18
19 ieee8021BridgeILanIfTable OBJECT-TYPE
20     SYNTAX      SEQUENCE OF Ieee8021BridgeILanIfEntry
21     MAX-ACCESS  not-accessible
22     STATUS      current
23     DESCRIPTION
24         "This table is a sparse augmentation of ifTable and controls
25         the creation of the I-LAN Interface. An I-LAN Interface is
26         used to create internal connections between Bridge Ports in a
27         802.1 device. An I-LAN Interfaces can be directly associated
28         with a set of Bridge Ports. An I-LAN Interfaces can also be
29         used as a stacking interface to relate other interfaces before
30         association to Bridge Ports.
31
32         For example, an I-LAN interface can be created to link traffic
33         between a PIP and a CBP. In this case a CBP is created on the
34         B-Component and the CBP's related IfEntry is stacked upon the
35         IfEntry of the I-LAN. The PIP is stacked upon the I-LAN using
36         the IfStackTable. Finally, a VIP is created on the I-Component
37         and is associated with the PIP, thus completing the path from
38         the I-Component's MAC relay to the CBP on the B-Component.
39
40         Entries in this table MUST be persistent over power up
41         restart/reboot."

48 SYNTAX      Unsigned32 (0|4096..4294967295)
49 MAX-ACCESS  read-only
50 STATUS      current
51 DESCRIPTION
52     "The next available value for ieee8021QBridgeVlanIndex of a local
53     VLAN entry in ieee8021QBridgeVlanStaticTable. This will report
54     values >=4096 if a new Local VLAN may be created or else
55     the value 0 if this is not possible."
56
57     A row creation operation in this table for an entry with a local
58     VlanIndex value may fail if the current value of this object
59     is not used as the index. Even if the value read is used,
60     there is no guarantee that it will still be the valid index
61     when the create operation is attempted; another manager may
62     have already got in during the intervening time interval.
63     In this case, ieee8021QBridgeNextFreeLocalVlanIndex should be re-read
64     and the creation re-tried with the new value.
65
66     This value will automatically change when the current value is
67     used to create a new row."

56   MAX-ACCESS  read-write
57   STATUS      current
58   DESCRIPTION
59       "When this is admitTagged(3), the device will
60       discard untagged frames or Priority-tagged frames
61       received on this port. When admitAll(1), untagged
62       frames or Priority-tagged frames received on this port
63       will be accepted and assigned to a VID based on the
64       PVID and VID Set for this port.
65
66       This control does not affect VLAN-independent Bridge
67       Protocol Data Unit (BPDU) frames, such as MVRP and
68       Spanning Tree Protocol (STP). It does affect VLAN-
69       dependent BPDU frames, such as MMRP.
70
71       The value of this object MUST be retained across
72       reinitializations of the management system."

30     SYNTAX      SEQUENCE OF Ieee8021PbVidTranslationEntry
31     MAX-ACCESS   not-accessible
32     STATUS       deprecated
33     DESCRIPTION
34         "This table is used to configure the VID Translation Table
35         defined in 12.10.1.8. The VID
36         Translation Table is used to implement a bidirectional
37         mapping between a local S-VID, used in data and protocol
38         frames transmitted and received through a CNP or PNP,
39         and a relay S-VID, used by the filtering and forwarding
40         process. Each row in this table is indexed by component,
41         port, and local S-VID value and indicates the relay S-VID
42         value to be used for the specified S-VID. If no entry for
43         a component, port, and local-svid is present in this table
44         is present then the relay S-VID used for a frame received
45         on that port with the local S-VID value will be the S-VID
46         that has the same numeric value as the local S-VID of the
47         received frame.
48
49         Entries in this table must be persistent over power up
50         restart/reboot."

38 DESCRIPTION  
39 "The Common and Internal Spanning Tree (CIST) Table. Each row in  
40 the table represents information regarding a Bridge's Bridge  
41 Protocol Entity for the CIST.  
42  
43 Note that entries will exist in this table only for Bridge  
44 components for which the corresponding instance of  
45 ieee8021SpanningTreeVersion (from the IEEE8021-SPANNING-TREE-MIB)  
46 has a value of mstp(3).  
47  
48 This table contains objects corresponding to the following items  
49 from 12.8.1.1 and 12.8.1.3. Some of those items are provided  
50 in the IEEE8021-SPANNING-TREE-MIB as noted below.  
51  
52 From 12.8.1.1:  
53 Items a), c), o), p), and q) are defined in this table  
54 The remaining items are covered in the  
55 IEEE8021-SPANNING-TREE-MIB:  
56 b) ieee8021SpanningTreeTimeSinceTopologyChange  
57 c) ieee8021SpanningTreeTopChanges  
58 e) ieee8021SpanningTreeDesignatedRoot  
59 f) ieee8021SpanningTreeRootCost  
60 g) ieee8021SpanningTreeRootPort  
61 h) ieee8021SpanningTreeMaxAge  
62 i) ieee8021SpanningTreeForwardDelay  
63 j) ieee8021SpanningTreeBridgeMaxAge  
64 k) ieee8021SpanningTreeBridgeHelloTime  
65 l) ieee8021SpanningTreeBridgeForwardDelay  
66 m) ieee8021SpanningTreeHoldTime  
67 n) ieee8021SpanningTreeVersion  
68 From 12.8.1.3:  
69 Item g) is defined in this table  
70 The remaining items are covered in the  
71 IEEE8021-SPANNING-TREE-MIB:  
72 a) ieee8021SpanningTreeBridgeMaxAge

```

1          b) ieee8021SpanningTreeBridgeHelloTime
2          c) ieee8021SpanningTreeBridgeForwardDelay

## 1 17.7.7 Definitions for the CFM MIB modules

2 There are two modules for CFM as a result of the reindexing required with the addition of PBB (see 17.3.2).  
3 Since the IEEE8021-CFM-MIB module contains deprecated tables replaced by reindexed tables in  
4 IEEE8021-CFM-V2 MIB module, both modules are needed for CFM implementations.

### 5 17.7.7.1 Definitions for the IEEE8021-CFM-MIB module

62                                absolutely needed.
63             none(1)           No format specified, usually because
64                                there is not (yet) a Maintenance
65                                Domain Name. In this case, a zero
66                                length OCTET STRING for the Domain
67                                Name field is acceptable.
68             dnsLikeName(2)     Domain Name like string, globally unique
69                                text string derived from a DNS name.
70             macAddrAndUint(3)  MAC address + 2-octet (unsigned) integer.
71             charString(4)      RFC2579 DisplayString, except that the
72                                character codes 0-31 (decimal) are not

```

1                                   used.  
2       ieeeReserved(xx)   Reserved for definition by IEEE 802.1  
3                                   xx values can be [5..31] and [96..255]  
4       ituReserved(xx)    Reserved for definition by ITU-T G.8013/Y.1731  
5                                   xx values range from [32..63]  
6       ietfReserved(xx)   Reserved for definition by IETF.   xx values range  
7                                   from [64..95].  
8  
9       To support future extensions, the DotlagCfmMaintDomainNameType  
10       textual convention SHOULD NOT be subtyped in object type  
11       definitions. It MAY be subtyped in compliance statements in  
12       order to require only a subset of these address types for a  
13       compliant implementation.  
14  
15       Implementations MUST ensure that DotlagCfmMaintDomainNameType  
16       objects and any dependent objects (e.g.,  
17       DotlagCfmMaintDomainName objects) are consistent. An  
18       inconsistentValue error MUST be generated if an attempt to  
19       change an DotlagCfmMaintDomainNameType object would, for  
20       example, lead to an undefined DotlagCfmMaintDomainName value.  
21       In particular,  
22       DotlagCfmMaintDomainNameType/DotlagCfmMaintDomainName pairs  
23       MUST be changed together if the nameType changes.  
24       "  
25       REFERENCE  
26        "21.6.5, Table 21-18"  
27       SYNTAX            INTEGER {  
28                          none                    (1),  
29                          dnsLikeName            (2),  
30                          macAddressAndUint      (3),  
31                          charString            (4)  
32                          }  
33  
34       DotlagCfmMaintDomainName ::= TEXTUAL-CONVENTION  
35        STATUS           current  
36        DESCRIPTION  
37        "Denotes a generic Maintenance Domain Name."  
38  
39       A DotlagCfmMaintDomainName value is always interpreted within  
40       the context of a DotlagCfmMaintDomainNameType value. Every  
41       usage of the DotlagCfmMaintDomainName textual convention is  
42       required to specify the DotlagCfmMaintDomainNameType object  
43       that provides the context. It is suggested that the  
44       DotlagCfmMaintDomainNameType object be logically registered  
45       before the object(s) that use the DotlagCfmMaintDomainName  
46       textual convention, if they appear in the same logical row.  
47  
48       The value of a DotlagCfmMaintDomainName object MUST always  
49       be consistent with the value of the associated  
50       DotlagCfmMaintDomainNameType object. Attempts to set  
51       an DotlagCfmMaintDomainName object to a value inconsistent  
52       with the associated DotlagCfmMaintDomainNameType MUST fail  
53       with an inconsistentValue error.  
54  
55       When this textual convention is used as the syntax of an  
56       index object, there may be issues with the limit of 128  
57       sub-identifiers specified in SMIV2, IETF STD 58. In this  
58       case, the object definition MUST include a 'SIZE' clause  
59       to limit the number of potential instance sub-identifiers;  
60       otherwise the applicable constraints MUST be stated in  
61       the appropriate conceptual row DESCRIPTION clauses, or  
62       in the surrounding documentation if there is no single  
63       DESCRIPTION clause that is appropriate.  
64  
65       A value of none(1) in the associated  
66       DotlagCfmMaintDomainNameType object means that no Maintenance  
67       Domain name is present, and the contents of the  
68       DotlagCfmMaintDomainName object are meaningless.  
69  
70       See the DESCRIPTION of the DotlagCfmMaintAssocNameType  
71       TEXTUAL-CONVENTION for a discussion of the length limits on  
72       the Maintenance Domain name and Maintenance Association name.

61             ituReserved(xx)   Reserved for definition by ITU-T G.8013/Y.1731
62                                xx values range from [33..63]
63             ietfReserved(xx)  Reserved for definition by IETF
64                                xx values range from [64..95]
65
66             To support future extensions, the DotlagCfmMaintAssocNameType
67             textual convention SHOULD NOT be subtyped in object type
68             definitions. It MAY be subtyped in compliance statements in
69             order to require only a subset of these address types for a
70             compliant implementation.
71
72             Implementations MUST ensure that DotlagCfmMaintAssocNameType

```

objects and any dependent objects (e.g., DotlagCfmMaintAssocName objects) are consistent. An inconsistentValue error MUST be generated if an attempt to change an DotlagCfmMaintAssocNameType object would, for example, lead to an undefined DotlagCfmMaintAssocName value. In particular, DotlagCfmMaintAssocNameType/DotlagCfmMaintAssocName pairs MUST be changed together if the nameType changes.

The Maintenance Domain name and Maintenance Association name, when put together into the CCM PDU, MUST total 48 octets or less. If the DotlagCfmMaintDomainNameType object contains none(1), then the DotlagCfmMaintAssocName object MUST be 45 octets or less in length. Otherwise, the length of the DotlagCfmMaintDomainName object plus the length of the DotlagCfmMaintAssocName object, added together, MUST total less than or equal to 44 octets.

DotlagCfmMaintAssocName ::= TEXTUAL-CONVENTION

    STATUS          current

    DESCRIPTION

        "Denotes a generic Maintenance Association Name. It is the part of the Maintenance Association Identifier that is unique within the Maintenance Domain Name and is appended to the Maintenance Domain Name to form the Maintenance Association Identifier (MAID)."

        A DotlagCfmMaintAssocName value is always interpreted within the context of a DotlagCfmMaintAssocNameType value. Every usage of the DotlagCfmMaintAssocName textual convention is required to specify the DotlagCfmMaintAssocNameType object that provides the context. It is suggested that the DotlagCfmMaintAssocNameType object be logically registered before the object(s) that use the DotlagCfmMaintAssocName textual convention, if they appear in the same logical row.

        The value of a DotlagCfmMaintAssocName object MUST always be consistent with the value of the associated DotlagCfmMaintAssocNameType object. Attempts to set an DotlagCfmMaintAssocName object to a value inconsistent with the associated DotlagCfmMaintAssocNameType MUST fail with an inconsistentValue error.

        When this textual convention is used as the syntax of an index object, there may be issues with the limit of 128 sub-identifiers specified in SMIV2, IETF STD 58. In this case, the object definition MUST include a 'SIZE' clause to limit the number of potential instance sub-identifiers; otherwise the applicable constraints MUST be stated in the appropriate conceptual row DESCRIPTION clauses, or in the surrounding documentation if there is no single DESCRIPTION clause that is appropriate.

65 DotlafCfmIndexIntegerNextFree ::= TEXTUAL-CONVENTION
66     DISPLAY-HINT "d"
67     STATUS      current
68     DESCRIPTION
69         "An integer that may be used as a new Index in a table.
70
71         The special value of 0 indicates that no more new entries can
72         be created in the relevant table.

```

```

1
2   When a MIB is used for configuration, an object with this
3   SYNTAX always contains a legal value (if non-zero) for an
4   index that is not currently used in the relevant table. The
5   Command Generator (Network Management Application) reads this
6   variable and uses the (non-zero) value read when creating a
7   new row with an SNMP SET. When the SET is performed, the
8   Command Responder (agent) MUST determine whether the value is
9   indeed still unused; Two Network Management Applications may
10  attempt to create a row (configuration entry) simultaneously
11  and use the same value. If it is currently unused, the SET
12  succeeds and the Command Responder (agent) changes the value
13  of this object, according to an implementation-specific
14  algorithm. If the value is in use, however, the SET fails.
15  The Network Management Application MUST then re-read this
16  variable to obtain a new usable value.
17
18  An OBJECT-TYPE definition using this SYNTAX MUST specify the
19  relevant table for which the object is providing this
20  functionality.

28     DESCRIPTION
29         "A Provider Backbone Bridge (PBB) can comprise a number of
30         components, each of which can be managed in a manner
31         essentially equivalent to an IEEE 802.1Q Bridge. In order to
32         access these components easily, an index is used in a number of
33         tables. If any two tables are indexed by
34         DotlagCfmPbbComponentIdentifier, then entries in those tables
35         indexed by the same value of DotlagCfmPbbComponentIdentifier
36         correspond to the same component.

28 -- *****
29 -- The Default MD Level Table
30 -- *****
31
32 dotlagCfmDefaultMdTable OBJECT-TYPE
33     SYNTAX      SEQUENCE OF DotlagCfmDefaultMdEntry
34     MAX-ACCESS  not-accessible
35     STATUS      deprecated
36     DESCRIPTION
37         "For each Bridge component, the Default MD Level Managed Object
38         controls MHF creation for VIDs that are not attached to a
39         specific Maintenance Association Managed Object, and Sender ID
40         TLV transmission by those MHFs.
41
42         For each Bridge Port, and for each VLAN ID whose data can
43         pass through that Bridge Port, an entry in this table is
44         used by the algorithm in 22.2.3 only if there is no
45         entry in the Maintenance Association table defining an MA
46         for the same VLAN ID and MD Level as this table's entry, and
47         on which MA an Up MEP is defined. If there exists such an
48         MA, that MA's objects are used by the algorithm in
49         22.2.3 in place of this table entry's objects. The
50         agent maintains the value of dotlagCfmDefaultMdStatus to
51         indicate whether this entry is overridden by an MA.
52
53         When first initialized, the agent creates this table
54         automatically with entries for all VLAN IDs,
55         with the default values specified for each object.
56
57         After this initialization, the writable objects in this
58         table need to be persistent upon reboot or restart of a
59         device.

58  MAX-ACCESS  not-accessible
59  STATUS      current
60  DESCRIPTION
61     "The Maintenance Association table. Each row in the table
62     represents an MA. An MA is a set of MEPs, each configured
63     with a single service instance.
64
65     This is the part of the complete MA table that is constant
66     across all Bridges in a Maintenance Domain, and across all
67     components of a single Bridge. That part of the MA table that
68     can vary from Bridge component to Bridge component is contained
69     in the dotlagCfmMaCompTable.
70
71     Creation of a Service Instance establishes a connectionless
72     association among the selected DSAPs. Configuring a

```

1 Maintenance association Endpoint (MEP) at each of the  
2 DSAPs creates a Maintenance Association (MA) to monitor  
3 that connectionless connectivity. The MA is identified by a  
4 Short MA Name that is unique within the Maintenance Domain  
5 and chosen to facilitate easy identification of the Service  
6 Instance. Together, the Maintenance Domain Name and the  
7 Short MA Name form the Maintenance Association Identifier  
8 (MAID) that is carried in CFM Messages to identify  
9 incorrect connectivity among Service Instances. A small  
10 integer, the Maintenance association Endpoint Identifier  
11 (MEPID), identifies each MEP among those configured on a  
12 single MA (3.142, 18.2).  
13  
14 This table uses two indices, first index is the index of the  
15 Maintenance Domain table. The second index is the same as the  
16 index of the dotlagCfmMaCompEntry for the same MA.  
17  
18 The writable objects in this table need to be persistent  
19 upon reboot or restart of a device.

46
47        This is the part of the complete MA table that is variable
48        across the Bridges in a Maintenance Domain, or across the
49        components of a single Bridge. That part of the MA table that
50        is constant across the Bridges and their components in a
51        Maintenance Domain is contained in the dotlagCfmMaNetTable.
52
53        This table uses three indices, first index is the
54        DotlagCfmPbbComponentIdentifier that identifies the component
55        within the Bridge for which the information in the
56        dotlagCfmMaCompEntry applies. The second is the index of the
57        Maintenance Domain table. The third index is the same as the
58        index of the dotlagCfmMaNetEntry for the same MA.
59
60        The writable objects in this table need to be persistent
61        upon reboot or restart of a device.

43 dotlagCfmMaMepListTable OBJECT-TYPE
44     SYNTAX      SEQUENCE OF DotlagCfmMaMepListEntry
45     MAX-ACCESS   not-accessible
46     STATUS       current
47     DESCRIPTION
48         "List of MEPIDs that belong to this MA.
49
50         12.14.6.1.3 specifies that a list of MEPIDs in all
51         Bridges in that MA, but since SNMP SMI does not allow to
52         state in a MIB that an object in a table is an array, the
53         information has to be stored in another table with two
54         indices, being the first index, the index of the table that
55         contains the list or array.
56
57         For all Bridges in which the same MAID {dotlagCfmMdFormat,
58         dotlagCfmMdName, dotlagCfmMaNetFormat, and dotlagCfmMaNetName}
59         is configured, the same set of dotlagCfmMaMepListIdentifiers
60         MUST be configured in the Bridges' dotlagCfmMaMepListTables.
61         This allows each MEP to determine whether or not it is
62         receiving CCMs from all of the other MEPs in the MA.
63
64         For example, if one were creating a new MA whose MAID were
65         {charString, 'Dom1', charString, 'MA1'}, that had 2 MEPs, whose
66         MEPIDs were 1 and 3, one could, in Bridge A:
67         1. Get a new MD index d from dotlagCfmMdTableNextIndex.
68         2. Create the Maintenance Domain {charString, 'Dom1'}.
69         3. Get a new MA index a from dotlagCfmMdMaNextIndex [d].
70         4. Create the Maintenance Association {charString, 'MA1'}.
71         5. Create a new dotlagCfmMaMepListEntry for each of the MEPs
72         in the MA: [d, a, 1] and [d, a, 3].

```

```

1      6. Create one of the new MEPS, say [d, a, 1].
2      Then, in Bridge B:
3      7. Do all of these steps 1-6, except for using the other MEPID
4         for the new MEP in Step 6, in this example, MEPID 3.
5      Note that, when creating the MA, MEP List Table, and MEP
6      entries in the second Bridge, the indices 'd' and 'a'
7      identifying the MAID {charString, 'Dom1', charString, 'MA1'}
8      may have different values than those in the first Bridge.

62     MAX-ACCESS  not-accessible
63     STATUS      current
64     DESCRIPTION
65         "The Maintenance Association Endpoint (MEP) table.
66
67         Each row in the table represents a different MEP. A MEP is
68         an actively managed CFM entity, associated with a specific
69         DSAP of a Service Instance, which can generate and receive
70         CFM PDUs and track any responses. It is an endpoint of a
71         single Maintenance Association, and is an endpoint of a
72         separate Maintenance Entity for each of the other MEPS in

```

the same Maintenance Association (3.142).

This table uses three indices. The first two indices are the indices of the Maintenance Domain and MA tables, the reason being that a MEP is always related to an MA and Maintenance Domain.

The MEP table also stores all the managed objects for sending LBM and LTM.

#### \*LBM Managed objects

LBM Managed objects in the MEP table enables the management entity to initiate transmission of Loopback messages. It will signal the MEP that it SHOULD transmit some number of Loopback messages and detect the detection (or lack thereof) of the corresponding Loopback messages.

Steps to use entries in this table:

- 1) Wait for dotlagCfmMepTransmitLbmStatus value to be false. To do this do this sequence:
  - a. an SNMP GET for both SnmpSetSerialNo and dotlagCfmMepTransmitLbmStatus objects (in same SNMP PDU).
  - b. Check if value for dotlagCfmMepTransmitLbmStatus is false.
    - if not, wait x seconds, go to step a above.
    - if yes, save the value of SnmpSetSerialNo and go to step 2) below
- 2) Change dotlagCfmMepTransmitLbmStatus value from false to true to ensure no other management entity will use the service. In order to not disturb a possible other NMS do this by sending an SNMP SET for both SnmpSetSerialNo and dotlagCfmMepTransmitLbmStatus objects (in same SNMP PDU, and make sure SnmpSetSerialNo is the first varBind). For the SnmpSetSerialNo varBind, use the value that you obtained in step 1)a.. This ensures that two cooperating NMSes will not step on each others toes. Setting this MIB object does not set the corresponding LBIActive state machine variable.
- 3) Setup the different data to be sent (number of messages, optional TLVs,...), except do not set dotlagCfmMepTransmitLbmMessages.
- 4) Record the current values of dotlagCfmMepLbrIn, dotlagCfmMepLbrInOutOfOrder, and dotlagCfmMepLbrBadMsdu.
- 6) Set dotlagCfmMepTransmitLbmMessages to a non-zero value to initiate transmission of Loopback messages. The dotlagCfmMepTransmitLbmMessages indicates the number of LBMs to be sent and is not decremented as loopbacks are actually sent. dotlagCfmMepTransmitLbmMessages is not equivalent to the LBMTToSend state machine variable.
- 7) Check the value of dotlagCfmMepTransmitLbmResultOK to find out if the operation was successfully initiated or not.
- 8) Monitor the value of dotlagCfmMepTransmitLbmStatus. When it is reset to false, the last LBM has been transmitted. Wait an additional 5 seconds to ensure that all LBRs have been returned.
- 9) Compare dotlagCfmMepLbrIn, dotlagCfmMepLbrInOutOfOrder, and dotlagCfmMepLbrBadMsdu to their old values from step 4, above, to get the results of the test.

#### \*LTM Managed objects

The LTM Managed objects in the MEP table are used in a manner similar to that described for LBM transmission, above. A SET operation to the variable dotlagCfmMepTransmitLtmFlags triggers the transmission of an LTM. Then, the variables dotlagCfmMepTransmitLtmSeqNumber and dotlagCfmMepTransmitLtmEgressIdentifier return the information required to recover the results of the LTM from the dotlagCfmLtrTable.

1 dotlagCfmMepTransmitLtmEgressIdentifier OBJECT-TYPE
2     SYNTAX      OCTET STRING (SIZE(8))
3     MAX-ACCESS  read-create
4     STATUS      current
5     DESCRIPTION
6         "Identifies the MEP Linktrace Initiator that is originating,
7         or the Linktrace Responder that is forwarding, this LTM.
8         The low-order six octets contain a 48-bit IEEE MAC address
9         unique to the system in which the MEP Linktrace Initiator
10        or Linktrace Responder resides. The high-order two octets
11        contain a value sufficient to uniquely identify the MEP
12        Linktrace Initiator or Linktrace Responder within that system.
13
14        For most Bridges, the address of any MAC attached to the
15        Bridge will suffice for the low-order six octets, and 0 for
16        the high-order octets. In some situations, e.g., if multiple
17        virtual Bridges utilizing emulated LANs are implemented in a
18        single physical system, the high-order two octets can be used
19        to differentiate among the transmitting entities.
20
21        The value returned is undefined if
22        dotlagCfmMepTransmitLtmResult is false.

25 -- whenever a MEP loses/restores contact with one or more other MEPs.
26 -- *****
27
28 dotlagCfmFaultAlarm NOTIFICATION-TYPE
29     OBJECTS      { dotlagCfmMepHighestPrDefect
30                     }
31     STATUS      current
32     DESCRIPTION
33         "A MEP has a persistent defect condition. A notification
34         (fault alarm) is sent to the management entity with the OID
35         of the MEP that has detected the fault.
36
37         Whenever a MEP has a persistent defect,
38         it may or may not generate a Fault Alarm to warn the system
39         administrator of the problem, as controlled by the MEP
40         Fault Notification Generator State Machine and associated
41         Managed Objects. Only the highest-priority defect, as shown
42         in Table 20-1, is reported in the Fault Alarm.
43
44         If a defect with a higher priority is raised after a Fault
45         Alarm has been issued, another Fault Alarm is issued.
46
47         The management entity receiving the notification can identify
48         the system from the network source address of the
49         notification, and can identify the MEP reporting the defect
50         by the indices in the OID of the dotlagCfmMepHighestPrDefect
51         variable in the notification:
52
53         dotlagCfmMdIndex - Also the index of the MEP's
54                           Maintenance Domain table entry
55                           (dotlagCfmMdTable).
56         dotlagCfmMaIndex - Also an index (with the MD table index)
57                           of the MEP's Maintenance Association
58                           network table entry
59                           (dotlagCfmMaNetTable), and (with the MD
60                           table index and component ID) of the
61                           MEP's MA component table entry
62                           (dotlagCfmMaCompTable).
63         dotlagCfmMepIdentifier - MEP Identifier and final index
64                               into the MEP table (dotlagCfmMepTable).

17 -- The CFM Default MD Level Table
18 -- *****
19
20 ieee8021CfmDefaultMdTable OBJECT-TYPE
21     SYNTAX      SEQUENCE OF Ieee8021CfmDefaultMdEntry
22     MAX-ACCESS  not-accessible
23     STATUS      current
24     DESCRIPTION
25         "For each Bridge component, the Default MD Level Managed Object
26         controls MHF creation for VIDs that are not attached to a
27         specific Maintenance Association Managed Object, and Sender ID
28         TLV transmission by those MHFs.
29
30         For each Bridge Port, and for each VLAN ID whose data can
31         pass through that Bridge Port, an entry in this table is
32         used by the algorithm in 22.2.3 only if there is no
33         entry in the Maintenance Association table defining an MA
34         for the same VLAN ID and MD Level as this table's entry, and
35         on which MA an Up MEP is defined. If there exists such an
36         MA, that MA's objects are used by the algorithm in
37         22.2.3 in place of this table entry's objects. The
38         agent maintains the value of ieee8021CfmDefaultMdStatus to
39         indicate whether this entry is overridden by an MA.
40
41         When first initialized, the agent creates this table
42         automatically with entries for all VLAN IDs,
43         with the default values specified for each object.
44
45         After this initialization, the writable objects in this
46         table need to be persistent upon reboot or restart of a
47         device.

69        This is the part of the complete MA table that is variable
70        across the Bridges in a Maintenance Domain, or across the
71        components of a single Bridge. That part of the MA table that
72        is constant across the Bridges and their components in a

```

```

1      Maintenance Domain is contained in the dotlagCfmMaNetTable.
2
3      This table uses three indices, first index is the
4      IEEE8021PbbComponentIdentifier that identifies the component
5      within the Bridge for which the information in the
6      ieee8021CfmMaCompEntry applies. The second is the index of the
7      Maintenance Domain table. The third index is the same as the
8      index of the ieee8021CfmMaNetEntry for the same MA.
9
10     The writable objects in this table need to be persistent
11     upon reboot or restart of a device.

34         in the range 53246 through 65535 that are associated with
35         this PIP. The bits correspond to Bridge Port numbers in
36         the range 53246 through 65535. The high-order bit of the first
37         octet corresponds to port number 1, and subsequent bits
38         of the octet string correspond to subsequent port numbers.
39         The following formula can be used to find the bit
40         corresponding to a particular port number B:
41            octet[(B-53246)/8] & (1 >> ((B-53246)%8))
42        If the bit for a particular port number is 1, that VIP is
43        associated with this PIP.
44
45        Note that ports numbers greater than 4094 cannot be used
46        with xSTP.
47
48        The value of this object may be truncated to remove
49        trailing octets of all zeros."

9      MAX-ACCESS not-accessible
10     STATUS current
11     DESCRIPTION
12         "The TPMR frames discard details table. Each row in
13         the table represents a discarded frame on a TPMR port.
14         By definition there are two ports per TPMR.
15
16         This table is maintained as a FIFO. A new entry is
17         inserted in the first row, and existing entries are
18         shuffled down, with the last entry being discarded.
19
20         Because of the FIFO behavior, the relationship between
21         the index and contents will change when an entry is
22         added to the table. This may result in apparent
23         duplication of row content during a table traversal."

67 ::= TEXTUAL-CONVENTION
68     STATUS current
69     DESCRIPTION
70         "For a given Congestion Notification Priority Value (CNPV), a
71         port can operate in one of four CND defense modes. The CND
72         defense mode determines whether congestion notification is
```

1 enabled or not, and if enabled, whether the port translates the  
2 CNPV to a non-CNPV value on input, and whether the port removes  
3 CN-TAGs on output.  
4

5       cptDisabled(1)       The congestion notification capability is  
6                               administratively disabled for this priority  
7                               value and port. This priority is not a CNPV.  
8                               The priority regeneration table controls the  
9                               remapping of input frames on this port for  
10                              this priority. CN-TAGs are neither added by  
11                              an end station nor stripped by a Bridge.  
12       cptInterior(2)       On this port and for this CNPV, the priority  
13                              parameters of input frames are not remapped,  
14                              regardless of the priority regeneration  
15                              table. CN-TAGs are not added by an end  
16                              station, and are removed from frames before  
17                              being output by a Bridge.  
18       cptInteriorReady(3)   On this port and for this CNPV, the priority  
19                              parameters of input frames are not remapped,  
20                              regardless of the priority regeneration  
21                              table. CN-TAGs can be added by an end  
22                              station, and are not removed from frames by  
23                              a Bridge.  
24       cptEdge(4)           On this port and for this CNPV, the priority  
25                              parameters of input frames are remapped to  
26                              an alternate (non-CNPV) value, regardless of  
27                              the priority regeneration table. CN-TAGs are  
28                              not added by an end station, and are removed  
29                              from frames before being output by a Bridge.  
30                              This mode is optional for an end station.

18
19 ieee8021CnCpTable
20 OBJECT-TYPE
21     SYNTAX      SEQUENCE OF Ieee8021CnCpEntry
22     MAX-ACCESS  not-accessible
23     STATUS      current
24     DESCRIPTION
25         "Each row in this table supplies values for one
26         Congestion Point (CP).
27
28         This table is indexed by component, port (interface), and
29         an arbitrary CP index. This arbitrary CP index is not
30         necessarily the Congestion Point Identifier (CPID) carried in
31         Congestion Notification Messages (CNMs).
32
33         Creating an entry in ieee8021CnCompntPriTable can create an
34         entry in this table, with the default values, on all ports in
35         the Bridge component or end station. Because more than one
36         Congestion Notification Priority Value (CNPV) can flow
37         through a single CP, the creation of an entry in
38         ieee8021CnCompntPriTable does not necessarily create a new
39         entry in this table. An end station can have more than one
40         CP for the same CNPV, so creating an entry in
41         ieee8021CnCompntPriTable can create multiple entries in this
42         table.
43
44         Because each port in a Bridge component or end station can have
45         a different relationship between CNPVs and CPs, the entries
46         created or deleted on each port can be different.
47
48         Deleting the last entry in ieee8021CnCompntPriTable for a
49         CNPV passing through the CP controlled by this entry deletes
50         the entry on some or all of the ports in the Bridge component
51         or end station.
52
53         Because each port in a Bridge component or end station can have
54         a different relationship between CNPVs and CPs, the entries
55         created or deleted on each port can be different.
56
57         The relationship between ieee8021CnCpIndex
58         values and CPs is an implementation dependent matter.
59
60         The contents of this table SHALL be maintained across a restart
61         of the system, except as noted in the description of
62         ieee8021CnCpIfIndex.

52
53         Creating an entry in ieee8021CnCompntPriTable can create an
54         entry in this table, with the default values, on all ports
55         in the end station. An end station can have more than one
56         RP for the same Congestion Notification Priority Value
57         (CNPV), so creating an entry in ieee8021CnCompntPriTable can
58         create multiple entries in this table.
59
60         Because each port in a Bridge component or end station can have
61         a different relationship between CNPVs and RPs, the entries
62         created or deleted on each port can be different.
63
64         Deleting the an entry in ieee8021CnCompntPriTable for a
65         CNPV passing through the RP controlled by this entry deletes
66         entries on some or all of the ports in the end station.
67
68         Because each port in an end station can have a
69         different relationship between CNPVs and RPs, the entries
70         created or deleted on each port can be different.
71
72     The relationship between ieee8021CnRpgIdentifier

```

```

1      values and RPs is an implementation dependent matter.
2
3      The contents of this table SHALL be maintained across a restart
4      of the system, except as noted in the description of
5      ieee8021CnRpgIfIndex.

```

1  DESCRIPTION
2      "The value of msrpLatencyMaxFrameSize parameter
3      which is used in the calculation of the maximum
4      latency through a Bridge. The maximum size is
5      defined to be 2000 octets by default, but may be
6      set to a smaller or larger value dependent on the
7      particular Bridge configuration. This parameter
8      does not imply any type of policing of frame size,
9      it is only used in the latency calculations.
10
11      The value of this object MUST be retained across
12      reinitializations of the management system."
13  REFERENCE   "12.22.1, 35.2.1.4g"

9     STATUS      current
10    DESCRIPTION
11        "The administrative state of MSRP operation on this port. The
12         value true(1) indicates that MSRP is enabled on this port
13         in all VLANs as long as ieee8021BridgeMsrpEnabledStatus is
14         also true(1). A value of false(2) indicates that MSRP is
15         disabled on this port in all VLANs: any MSRP frames received
16         will be silently discarded, and no MSRP registrations will be
17         propagated from other ports. Setting this to a value of
18         true(1) will be stored by the agent but will only take
19         effect on the MSRP protocol operation if
20         ieee8021BridgeMsrpEnabledStatus
21         also indicates the value true(1). This object affects
22         all MSRP Applicant and Registrar state machines on this
23         port. A transition from false(2) to true(1) will
24         cause a reset of all MSRP state machines on this port.
25
26         The value of this object MUST be retained across
27         reinitializations of the management system."

59         SYNTAX TruthValue
60         MAX-ACCESS read-create
61         STATUS current
62         DESCRIPTION
63             "The state of MIRP operation on this port. The value
64             true(1) indicates that MIRP is enabled on this port,
65             as long as ieee8021PbbMirpEnableStatus is also enabled
66             for this component. When false(2) but
67             ieee8021PbbMirpEnableStatus is still
68             enabled for the device, MIRP is disabled on this port.
69
70             If MIRP is enabled on a VIP, then the MIRP Participant is
71             enabled on that VIP's PIP. If MIRP is enabled on none of the
72             VIPs on a PIP, then the MIRP Participant on the PIP is

```

```

1      disabled; any MIRP packets received will be silently discarded,
2      and no MIRP registrations will be propagated from the PIP. A
3      transition from all VIPs on a PIP false(2) to at least one VIP
4      on the PIP true(1) will cause a reset of all MIRP state
5      machines on this PIP.
6
7      If MIRP is enabled on any port not a VIP, then the MIRP
8      Participant is enabled on that port. If MIRP is
9      disabled on a non-VIP port, then MIRP packets received will be
10     silently discarded, and no MIRP registrations will be
11     propagated from the port. A transition from false(2) to
12     true(1) will cause a reset of all MIRP state machines on a
13     non-VIP port.
14
15     The value of this object MUST be retained across
16     reinitializations of the management system."

18     }
19     STATUS current
20     DESCRIPTION
21         "An IPG generates this notification whenever
22         an administrative command cannot be
23         executed by the IPS state machine. For
24         example, when a requested manual switch
25         cannot be performed because of a signal
26         failure condition.
27
28         The management entity receiving the
29         notification can identify
30         the system from the network source
31         address of the notification and can
32         identify the IPG by the indices of
33         the OID of the ieee8021TeipsV2IpgConfigState
34         variable in the notification:
35
36         ieee8021BridgeBaseComponentId - Identifies
37         the component on the Bridge where the
38         protection group is configured.
39
40         ieee8021TeipsV2Ipgid - The ID of the protection group.

30  SYNTAX      OCTET STRING
31  MAX-ACCESS  read-write
32  STATUS      current
33  DESCRIPTION
34      "The administrative value of the ControlList parameter for the Port.
35      The octet string value represents the contents of the control list as
36      an ordered list of entries, each encoded as a TLV, as follows.
37      The first octet of each TLV is interpreted as an
38      unsigned integer representing a gate operation name:
39          0: SetGateStates
40          1: Set-And-Hold-MAC
41          2: Set-And-Release-MAC
42          3-255: Reserved for future gate operations
43
44      The second octet of the TLV is the length field,
45      interpreted as an unsigned integer, indicating the number of
46      octets of the value that follows the length. A length of
47      zero indicates that there is no value
48      (i.e., the gate operation has no parameters).
49
50      The third through (3 + length -1)th octets encode the
51      parameters of the gate operation, in the order that they
52      appear in the definition of the operation
53      in Table 8-6. Two parameter types are currently defined:
54
55      - GateState:
56          A GateState parameter is encoded in a single octet.
57          The bits of the octet represent the gate states for the
58          corresponding traffic classes; the MS bit corresponds
59          to traffic class 7,
60          the LS bit to traffic class 0. A bit value of 0 indicates
61          closed; a bit value of 1 indicates open.
62
63      - TimeInterval:
64          A TimeInterval is encoded in 4 octets as a 32-bit
65          unsigned integer, representing a number of nanoseconds.
66          The first octet encodes the most significant 8 bits of the
67          integer, and the fourth octet encodes the least
68          significant 8 bits.
69
70      The value of this object MUST be retained across
71      reinitializations of the management system."

15  ::= { ieee8021PSFPStreamFilterEntry 4}
16
17  ieee8021PSFPFilterSpecificationList OBJECT-TYPE
18      SYNTAX      OCTET STRING
19      MAX-ACCESS  read-create
20      STATUS      current
21      DESCRIPTION
22          "The FilterSpecificationList parameter contains a list of
23          filter specifications associated with this stream filter.
24
25          The octet string value represents the contents of the list as
26          an ordered list of entries, each encoded as a TLV, as follows.
27
28          The first octet of each TLV is interpreted as an
29          unsigned integer representing a filter specification type:
30              0: Maximum SDU Size.
31              1: Flow meter instance identifier.
32              2-255: Reserved for future filter specification types
33
34          The second and third octets of the TLV are the length field,
35          interpreted as an unsigned integer, indicating the number of
36          octets of the value that follows the length. A length of
37          zero indicates that there is no value
38          (i.e., the filter specification has no parameters).
39
40          The fourth through (4 + length -1)th octets encode the
41          parameters of the filter specification, as defined for each
42          filter specification type.
43
44          - Maximum SDU Size:
45              A single SDU size parameter is encoded in four octets, and
46              is interpreted as an unsigned integer value.
47
48          - Flow meter instance identifier:
49              A single flow meter instance identifier is encoded in
50              four octets, and is interpreted as an unsigned integer value.
51
52          The value of this object MUST be retained across
53          reinitializations of the management system."

68     MAX-ACCESS  read-create
69     STATUS      current
70     DESCRIPTION
71         "The administrative value of the ControlList parameter for the gate.
72         The octet string value represents the contents of the control list as

```

1 an ordered list of entries, each encoded as a TLV, as follows.  
2 The first octet of each TLV is interpreted as an  
3 unsigned integer representing a gate operation name:  
4 0: SetGateAndIPV  
5 1-255: Reserved for future gate operations  
6  
7 The second octet of the TLV is the length field,  
8 interpreted as an unsigned integer, indicating the number of  
9 octets of the value that follows the length. A length of  
10 zero indicates that there is no value  
11 (i.e., the gate operation has no parameters).  
12  
13 The third through (3 + length -1)th octets encode the  
14 parameters of the gate operation, in the order that they  
15 appear in the definition of the operation in Table 8-4.  
16 The first parameter is a StreamGateState value; the second  
17 parameter is an IPV value; the third parameter is a  
18 TimeInterval value; and the fourth parameter is an  
19 IntervalOctetMax value. IntervalOctetMax is optional.  
20  
21 - StreamGateState:  
22 A GateState parameter is encoded in a single octet, and  
23 is interpreted as an integer value.  
24 The value 1 indicates open; the value 2 indicates closed.  
25  
26 - IPV:  
27 An IPV is encoded in four octets as a 32-bit  
28 signed integer. A negative denotes the null value;  
29 zero or positive values denote internal priority values.  
30  
31 - TimeInterval:  
32 A TimeInterval is encoded in 4 octets as a 32-bit  
33 unsigned integer, representing a number of nanoseconds.  
34 The first octet encodes the most significant 8 bits of the  
35 integer, and the fourth octet encodes the least  
36 significant 8 bits.  
37 - IntervalOctetMax:  
38 An integer representing the maximum number of MSDU octets  
39 that are permitted to pass the gate during the specified  
40 TimeInterval. If this parameter is omitted, there is  
41 no maximum.  
42  
43 The value of this object MUST be retained across  
44 reinitializations of the management system."

21     DESCRIPTION
22         "This attribute provides the minimum delay independent
23         from frame length for a frame to forward from ingress
24         port to egress port.
25
26         The delay begins when the message timestamp point of the
27         ingress frame passes the reference plane marking the
28         boundary between the network media and PHY. The delay
29         ends when the message timestamp point of the egress
30         frame passes the reference plane marking the boundary
31         between the network media and PHY. The message timestamp
32         point is specified by IEEE Std 802.1AS for various media,
33         near the start of the frame.
34
35         Note: This delay includes all aspects of length-independent
36         delay for a frame that is forwarded, including handling of
37         error conditions."

1
2 ieee8021TsnRemoteMgmtMsrpMrpExternalControl OBJECT-TYPE
3     SYNTAX      TruthValue
4     MAX-ACCESS  read-write
5     STATUS      current
6     DESCRIPTION
7         "This attribute is used to indicate, whether MRP
8         attributes are propagated on the MRP Participant,
9         according to the specifications for MRP Attribute
10        Propagation (MAP) and specifications of the
11        MRP Application. When true(1), the MRP Participant is
12        removed from the MRP Application's MAP Context. The
13        MRP Participant performs all other aspects of MRP,
14        including MRP operation, MRP specifications, and
15        MRPDU encodings. The application component stores MAD
16        indications for registration received on the Port,
17        and invokes MAD requests for declarations on the Port.
18        When false(2), MRP attributes propagate on the
19        MRP Participant according to the specifications for
20        MRP Attribute Propagation (MAP) and specifications of
21        the MRP Application. Ports with the externalControl
22        attribute false(2) are considered as candidates for
23        the MRP Application's MAP Context. The remaining
24        attributes of this subtree are ignored by Ports with
25        the externalControl attribute false(2).
26        This managed object applies to the MSRP application.
27        A table is provided for each MAP Context (VLAN ID)."

## 1 18. Principles of Connectivity Fault Management operation

2 Connectivity Fault Management (CFM) comprises capabilities for detecting, verifying, and isolating  
3 connectivity failures in Virtual Bridged Networks. These capabilities can be used in networks operated by  
4 multiple independent organizations, each with restricted management access to each other's equipment.

5 CFM is designed to be transparent to the customer data transported by a network and to be capable of  
6 providing maximum fault coverage. Accordingly, CFM Entities (Clause 19) are specified as shims that make  
7 use of and provide the ISS or EISS (IEEE Std 802.1AC, 6.8, 6.17) at SAPs within the network. They can, in  
8 principle, be added between any of the other media-independent protocol entities that compose a Bridge  
9 Port, without requiring changes to those entities. Customer data is forwarded transparently by CFM Entities  
10 while CFM PDUs are generated and processed as specified in Clause 20. The formats of the various CFM  
11 PDUs are described in Clause 21, and the creation and placement of CFM Entities in Bridges are specified in  
12 Clause 22.

13 This clause provides the context necessary to understand each of the CFM protocols, and how CFM Entities  
14 in Bridges are selected and configured as Maintenance Points (MPs, 19.1) to participate in and operate those  
15 protocols.

16 CFM introduces the following concepts to support multiple independent operators, each supporting service  
17 instances for multiple independent customers:

- 18 a) A Maintenance Domain (18.1) is a part of a network that is controlled by a single operator and used  
19 to support connectivity between the Domain Service Access Points (DoSAPs, 18.1) that bound the  
20 Maintenance Domain.
- 21 b) A Maintenance Domain Level (MD Level, 18.3), carried in CFM PDUs, allows each of an  
22 operator's customers also to use CFM and to function as an operator if desired, multiplexing  
23 provided service instances over its own connectivity.
- 24 c) A Maintenance Association (MA, 18.2) is created by configuring CFM Entities that support an  
25 individual service instance's DoSAPs as MA Endpoints (MEPs), and is used to monitor connectivity  
26 provided by that instance through the Maintenance Domain.

27 MP (19.1) configuration of CFM Entities supports the hierarchical nesting of Maintenance Domains. The  
28 DoSAPs for a given service instance are Intermediate Service Access Points (ISAPs) for MAs monitoring  
29 connectivity through an enclosing Maintenance Domain. When a MEP is configured, a MA Intermediate  
30 Point (MIP) can also be configured at the appropriate level for its immediately enclosing Maintenance  
31 Domain. Below the innermost Maintenance Domain, every physical LAN can serve as an implied  
32 Maintenance Domain, and every Bridge Port as an implied MEP. In the innermost Maintenance Domain,  
33 every Bridge Port is an ISAP and can be configured with a MIP.

34 Maintenance Domains are nested, not overlapped. That is, if a given DoSAP for service instance 1  
35 in Maintenance Domain  $x$  is an ISAP for Maintenance Domain  $y$ , then all DoSAPs for service instance 1 in  
36 Maintenance Domain  $x$  are either ISAPs or DoSAPs for Maintenance Domain  $y$ , and no other Maintenance  
37 Domain. Conformance to this rule is not a condition for the correct operation of CFM. Rather, if this rule is  
38 violated, then CFM will detect the violation as an error condition, whatever the intentions of the  
39 administrators.

40 The information about individual service instances that is configured and recorded within a network to  
41 support CFM is entirely associated with MEPs, and thus scales linearly with the number of SAPs provided  
42 to customers. The transmission of CFM PDUs is stimulated by state machines associated with MEPs as are  
43 actions taken that require recording information from received PDUs. MIPs can add, check, and respond to  
44 information in received PDUs, thus supporting discovery of paths among MEPs and location of faults along  
45 those paths. MIPs can be configured per Maintenance Domain, thus allowing the amount of MIP

1 configuration information to scale linearly with the size of the network, and is thus a constant function of the  
2 ability of the network to support those MIPs, rather than being a product of the number of service instances  
3 supported. In contrast each MEP is associated with a SAP that provides access to a single service instance.

4 CFM functions are partitioned as follows:

- 5 — Path discovery
- 6 — Fault detection
- 7 — Fault verification and isolation
- 8 — Fault notification
- 9 — Fault recovery

10 Path discovery uses the Linktrace protocol (20.3) to determine the path taken to a target MAC address, MIP  
11 by MIP, from one MEP to another MP across an MA. This target MAC address can be that of a MIP, a MEP,  
12 or any other individual MAC address. A Linktrace Message (LTM, 20.3.1) is transmitted from a MEP to its  
13 neighboring MIPs, and from MIP to MIP, to the MP terminating the path. Each MIP along the path and the  
14 terminating MP return unicast Linktrace Replies (LTR, 20.3.2) to the originating MEP. LTMs are triggered  
15 by administrative action. The replies are cataloged by the originating MEP for examination by the  
16 administrator.

17 Fault detection uses the Continuity Check protocol (20.1) to detect both connectivity failures and unintended  
18 connectivity between service instances. Each MEP can periodically transmit a Continuity Check Message  
19 (CCM) announcing the identity of the MEP and its MA, and tracks the CCMs received from the other MEPs.  
20 All connectivity faults that can misdirect a CCM show up as differences between the CCMs received and the  
21 MEP's configured expectations. The state of the tracked CCMs is available to the administrator for  
22 examination.

23 Fault verification and fault isolation are administrative actions, typically performed after fault detection.  
24 Fault verification can also confirm successful initiation or restoration of connectivity. The administrator uses  
25 the Loopback protocol (20.2) to perform fault verification. A MEP can be ordered to transmit a Loopback  
26 Message (LBM, 20.2.1) to a MEP or MIP in the MA, whose MAC address can be discovered from CCMs  
27 (MEPs only) or LTMs/LTRs (MEPs or MIPs). The receiving MP responds by transforming the LBM into a  
28 unicast Loopback Reply (LBR, 20.2.2) sent back to the originating MEP. That MEP records the responses  
29 for examination by the administrator.

30 Fault notification is provided by a MEP that has detected a connectivity fault in its MA, because expected  
31 CCMs were not received, because unexpected or invalid CCMs were received, or because a CCM carried a  
32 notification of the failure of its associated Bridge Port. A single fault may be detected by multiple MEPs and  
33 may result in the generation of multiple Fault Alarms. In the absence of alarm suppression mechanisms in  
34 CFM, network management systems receiving such Fault Alarms can deploy other means to identify if a  
35 Fault Alarm identifies the primary fault for which a fault corrective action can be initiated, or represents a  
36 secondary fault for which no corrective action can be taken.

37 For VLANs, fault recovery is provided by the active topology protocols of Clause 13 while fault recovery  
38 for TESIs is provided by the Protection Switching mechanisms of 26.10. Fault recovery actions performed  
39 by the network administrator, such as the correction of configuration errors or replacement of failed  
40 components, are outside the scope of this standard.

## 1 18.1 Maintenance Domains and DoSAPs

2 A “domain” may be defined as a network or part of a network that is capable of offering connectivity to  
3 systems outside this region. It comprises a set of DoSAPs at which the domain is capable of or intended to  
4 offer connectivity to systems outside the domain. Each DoSAP is an instance either of the EISS or of the  
5 ISS. A Maintenance Domain is then a domain or part of a domain for which faults in connectivity are to be  
6 managed.

7 A Maintenance Domain is, or is intended to be, fully connected internally. That is, a DoSAP associated with  
8 a Maintenance Domain has connectivity to every other DoSAP in the Maintenance Domain, in the absence  
9 of faults. It is, in principle at least, capable of connecting (i.e., supporting service between) any of its  
10 DoSAPs. The factors (apart from faults) that can prevent desired connectivity are second-order, e.g.,  
11 exhaustion of resources that would support a proposed connection, an administrative decision to limit  
12 multipoint services, misconfiguration of security parameters, unwillingness of customers or attached  
13 Maintenance Domains to use a particular connection configuration. The purpose of CFM is to monitor and  
14 diagnose the ability of a Maintenance Domain to meet its operators’ intentions for connectivity, as expressed  
15 in the configuration of CFM.

16 Figure 18-1 illustrates a single Maintenance Domain, consisting of five Bridges, from the point of view of  
17 an operator. The operator has six DoSAPs to offer to customers.

**Figure 18-1—One Maintenance Domain: operator’s view**

18 Each Maintenance Domain can be separately administered. Each Maintenance Domain is assigned a  
19 Maintenance Domain Name. This should be chosen to be unique among all those used or available to an  
20 operator, and to facilitate easy identification of administrative responsibility for the Maintenance Domain.  
21 CFM PDU formats support the creation of Maintenance Domain Names that are unique over the domain for  
22 which CFM is to protect against accidental concatenation of service instances. Ideally, these names are  
23 globally unique.

24 There are a number of methods to fulfill the requirements to both maintain connectivity within, and control  
25 access to, a Maintenance Domain. A Maintenance Domain can be, for example,

- 26 a) An MST Region, identified and kept separate from other Maintenance Domains, by its MST  
27 Configuration Name (8.9.2, 13.8).
- 28 b) A number of such MST Regions (13.5.3), interconnected via the CIST (13.5.2), and kept separate  
29 from other Maintenance Domains by configuring the managed objects controlling the CIST  
30 topology.
- 31 c) An entire Virtual Bridged Network, and kept separate from other Maintenance Domains by means  
32 not specified in this standard.
- 33 d) A subset of the DoSAPs of a VLAN Bridged Network, assigned to the use of a particular higher-  
34 level provider among many.

- 1 e) A subset of the DoSAPs of the concatenated network in item c).
- 2 f) A single physical link between two providers or between a provider and a customer.
- 3 g) A single VLAN on a single physical link between two providers or between a provider and a
- 4 customer.

## 5 18.2 Service instances and MAs

6 When a network administrator configures a service instance for a customer, the network administrator  
7 configures some number of the DoSAPs to be accessible by that customer, assigning whatever identifiers the  
8 systems require to segregate that service instance from others supported by that Maintenance Domain (e.g.,  
9 VIDs), as well as configuring other service properties (such as bandwidth profiles) for the DoSAPs. Creation  
10 of a service instance establishes a connectionless connectivity (IEEE Std 802.1AC) among the selected  
11 DoSAPs.

12 Configuring a MEP at each of the DoSAPs of a service instance creates an MA to monitor that  
13 connectionless connectivity. The MA is identified by a Short MA Name that is unique within the  
14 Maintenance Domain. Together, the Maintenance Domain Name and the Short MA Name form the  
15 Maintenance Association Identifier (MAID) that is carried in CFM PDUs to identify inadvertent  
16 connections among MEPs. A small integer, the MA Endpoint Identifier (MEPID) uniquely identifies each  
17 MEP among those configured on a single MA.

18 NOTE 1—In order to accommodate the requirements of service providers as expressed in ITU-T G.8013/Y.1731, the  
19 Maintenance Domain Name can be configured to be null, in which case the Short MA Name needs to be globally unique,  
20 in order to provide complete protection against the accidental concatenation of service instances. Suitable choices for  
21 globally unique Short MA Names are defined in ITU-T G.8013/Y.1731.

22 Figure 18-2 illustrates a single service instance created from the Maintenance Domain of Figure 18-1, again  
23 from the point of view of an operator. It offers four DoSAPs to a customer (C1). Each DoSAP is marked  
24 with its MEPID.

Figure 18-2—One service instance: operator's view

25 Figure 18-3 illustrates that same service instance from the point of view of customer C1. The customer has  
26 four items of customer equipment attached to the four DoSAPs 1–4. The means by which the operator  
27 connects the four DoSAPs to create the service instance are invisible to the customer.

28 NOTE 2—The term “service instance” has been used to mean an “end-to-end service supplied to a customer.” One  
29 cannot predict whether an apparently end-to-end service instance will be used by a customer to create another service  
30 instance at a still higher level to yet another customer. Therefore, no specific term is provided by this standard to label an  
31 “end-to-end” service instance.

32 The CFM protocol state machines and variables (see Clause 20) are used by MEPs to conduct protocol  
33 exchanges within a Maintenance Domain. Each MIP functions symmetrically with respect to the SAPs of its  
34 containing MA and service instance, and is modeled as comprising two MIP Half Functions (MHFs).  
35 Figure 18-4 specifies the symbols used for MEPs, MHFs, and MIPs in this standard, e.g., in Figure 18-7.

Figure 18-3—One service instance: customer's view

Figure 18-4—MEP and MIP Symbols

### 18.3 Maintenance Domain Levels

A Maintenance Domain can provide service instances to an enclosing Maintenance Domain or utilize service instances provided by an enclosed Maintenance Domain. An explicit Maintenance Domain Level (MD Level) is included in CFM PDUs to indicate the nesting relationships among Maintenance Domains, because systems can be organized into Maintenance Domains as administrative needs dictate, without necessarily adding headers to data frames to enforce a layered organization.

As part of the nested decomposition facility provided by Maintenance Domains, the CFM protocols hide information. The components of a given Maintenance Domain interior to the DoSAPs presented to the enclosing Maintenance Domain are invisible, through the CFM protocols and managed objects, to the Maintenance Domains enclosing that given Maintenance Domain, except for configured points of visibility. No part of a Maintenance Domain lower than (nested within) a given Maintenance Domain is unintentionally visible to any higher Maintenance Domain. No part of a Maintenance Domain is ever visible to any Maintenance Domain except its immediately higher (enclosing) Maintenance Domain. This enables the separation of responsibility for network administration. The administrator of an end-to-end service on the largest scale can be insulated from the administration of the networks comprising that service, and so on, in principle, down to the administration of individual LANs. This prevents, for example, a customer from learning the internal topology of an operator's network.

1 In order to facilitate the diagnosis of connectivity failures, an administrator can make a DoSAP visible as an  
2 ISAP to the immediately enclosing Maintenance Domain by configuring it as a MIP. The diagnostic  
3 functions provided by CFM detect connectivity failures between any pair of MEPs in an MA. The MIPs  
4 allow these failures to be isolated to smaller segments of the network; loss of connectivity between a pair of  
5 MIPs corresponds to a MEP connectivity failure at a lower MD Level. In the lowest Maintenance Domains,  
6 the MIPs can be configured on individual Bridge Ports.

7 Figure 18-5 illustrates the nesting of Maintenance Domains, service instances, and MAs. It illustrates nested  
8 service instances, each configured with one MA in a Maintenance Domain. There are seven Maintenance  
9 Domains, and hence seven service instances illustrated. At the (white) “provider” MD Level, the service  
10 instance is offered to a single “customer” C1. That customer creates a (gray) service instance of his own,  
11 configured with an MA that verifies the integrity of the service instance offered by the provider. Several  
12 levels of nested Maintenance Domains are shown:

- 13 a) Covering the widest physical extent, a Maintenance Domain (and MA and service instance) at the  
14 customer MD Level has a MEP in each of four devices labeled C1 in Figure 18-5. The four DoSAPs  
15 a, b, g, and h can be configured as MIPs for this MA.
- 16 b) Covering the physical range corresponding to the limits of the end-to-end provider’s network are the  
17 MEPs a, b, g, and h belonging to the provider MD Level. The four DoSAPs c, d, e, and f can be  
18 configured as MIPs for this MA.
- 19 c) Each of the two operator networks has a Maintenance Domain at the operator MD Level. These  
20 DoSAPs are marked a through h. The unlabeled SAPs in both operators’ Maintenance Domains can  
21 be configured as MIPs for their respective MAs.
- 22 d) Three “physical” layer Maintenance Domains are shown as well. (Two are labeled “PMDL,” for  
23 “physical MD Level.”) Note that not all physical links are given Maintenance Domains.
  - 24 1) A network of devices is being used, in some unspecified fashion, to offer the operators’ Bridges  
25 an emulated shared-medium LAN with four DoSAPs. A Maintenance Domain has been created  
26 to verify the connectivity of that LAN.

27 NOTE—This central emulated LAN could equally be a network of Bridges that are separated via nonstandard  
28 configuration from the operator clouds on either side, a network of PBBs, a network of Ethernet over SONET circuits  
29 with a central interconnect device, or an ATM Emulated LAN.<sup>33</sup>

- 30 2) Physical-level Maintenance Domains have been created at the edge of the network (on the left  
31 side) to monitor two LANs, perhaps because they include Repeaters or are otherwise  
32 unreliable.

33 Figure 18-6 expands the upper right corner of Figure 18-5, including Bridges 4 and 5 and device 6.  
34 Examining device 6 (C1), readers can see that the highest MA, at the “customer” MD Level, requires a MEP  
35 in its Port q. The side of the DoSAP of this service instance that offers access to the service instance faces  
36 the center of device 6, just like the service offered by a LAN. On the other hand, in Port g, there are two  
37 service instances, each with a MEP: the white service instance at the provider MD Level, and the gray  
38 service instance at the operator MD Level. Neither of these service instances include the wire attached to  
39 Port g. Thus, ensuring the proper operation of the LAN connecting Port q to Port g is the responsibility of  
40 the MA at the customer MD Level, and not the other MAs. Port e has two MEPs, one facing in each  
41 direction.

42 Port g in Figure 18-6 also is an example of the fact that only the MD Level distinguishes the provider and  
43 operator Level Maintenance Domains at Port g. The single service instance in the example network shown  
44 in Figure 18-5 and Figure 18-6 is carried on a single VLAN with a single VID through the right-hand  
45 operator’s Maintenance Domain. Within that Maintenance Domain, it cannot be distinguished whether a

<sup>33</sup> See ATM Forum af-lane-0021.000; “LAN Emulation over ATM 1.0”;  
<https://www.broadband-forum.org/ftp/pub/approved-specs/af-lane-0021.000.pdf>.

Figure 18-5—MAs: one service instance in a provider network

Figure 18-6—MAs: Expansion of Figure 18-5

1 data frame on that VID belongs to the operator, provider, or customer Maintenance Domain; it belongs to all  
2 of them. However, the MD Level permits CFM PDUs to be associated with different Maintenance Domains  
3 even when they share the same VID.

4 Port j and Port r have been added to Figure 18-6; they are not present in Figure 18-5. Both represent  
5 DoSAPs that have not been configured to support either a service instance or an MA. For the integrity of the  
6 network to be ensured by CFM, these DoSAPs should be configured to be Disabled.

1 Ports k, m, n, and s can be configured as ISAPs for the gray service instance, providing a MIP at the operator  
2 MD Level. Port e can be configured with a MIP for the provider MD Level, and Port g with a MIP for the  
3 customer MD Level.

4 Figure 18-7 illustrates the use of MD Levels to allow the use of CFM by a user of connectivity provided by  
5 two bridged Maintenance Domains and by the operators of each of those Maintenance Domains. It  
6 illustrates a vertical slice through Figure 18-5, including two of the customer's devices, and the path through  
7 the network connecting them. One can see from Figure 18-7 why MD Levels are required to identify CFM  
8 PDUs; there would otherwise be no way for Bridge Port b, for example, to tell whether a given CFM PDU is  
9 to be sunk (MD Levels 2 or 3) or passed (MD Level 5).

**Figure 18-7—MEPS, MIPs, and MD Levels**

10 Assignment of numerical MD Levels to the “customer” role, the “service provider” role, or the “operator”  
11 MD Levels is somewhat arbitrary, since those terms imply business relationships that cannot be  
12 standardized. See J.3 for a more detailed discussion of the assignment of MD Levels.

## 19. CFM entity operation

This clause specifies:

- a) How the MPs that instantiate a CFM MA attach to ISS-SAPs or EISS-SAPs (19.1).
- b) How MPs are addressed in networks (19.4).
- c) The architecture of MEPs (19.2), MIPs (19.3), MHFs (19.3), Linktrace Output Multiplexers (LOMs, 19.5), and Linktrace Responders (19.6), including their identification, addressing, and decomposition into components that provide the CFM functions.

NOTE—Clause 18 introduces the principles of CFM operation and the network architectural concepts that support it. Clause 20 specifies the protocols operated by the components of each MP, and Clause 21 specifies the PDU formats used by those protocols. The use of CFM within systems and networks is further described in Clause 22.

The models of operation in this clause provide a basis for specifying the externally observable behavior of MEPs and MIPs, and are not intended to place additional constraints on implementations; these can adopt any internal model of operation compatible with the externally observable behavior specified. Conformance of equipment to this standard is purely in respect of observable protocol.

### 19.1 Maintenance Points (MPs)

The primary CFM protocol shims are called Maintenance Points (MPs). (See 19.6 for the other CFM protocol shim.) An MP can be either a MEP or an MHF. (See also 19.5 for a third type of CFM shim.) A MEP or an MHF each have two principle SAPs, an Active SAP, through which CFM PDUs produced and consumed by the MP are exchanged, and a Passive SAP, through which data frames and unprocessed CFM PDUs pass. Figure 19-1 illustrates the principle SAPs, and the symbols used for MEPs, MIPs, and MHFs in other figures, e.g., Figure 22-1. Note that an MP can be a Down MP or an Up MP, depending on whether the Passive SAP is above or below the Active SAP, respectively, in a shim diagram.

Figure 19-1—CFM Protocol shims

NOTE—The difference between Up MPs and Down MPs is explained more fully in 19.2.3 and 22.1.1.

### 19.2 MA Endpoints (MEPs)

A MEP can be created in either a Bridge Port (22.2) or an end station attachment to a LAN.

## 1 19.2.1 MEP identification

2 A MEP is associated with exactly one MA. It is identified for management purposes by two parameters,  
3 although other, additional parameters are used to manage the MEP:

- 4 a) The MAID, identifying the MA
- 5 b) A MEPID specific to this MEP

6 The MEP is identified for data forwarding purposes by:

- 7 c) A set of VIDs, including a Primary VID, inherited from the MA; or
- 8 d) An I-SID in the case of a Backbone Service Instance MA; or
- 9 e) A set of 3-tuples <ESP-DA, ESP-SA, ESP-VID> inherited from the MA when the MA is associated  
10 with a TESI; or
- 11 f) A SEG-ID inherited from the MA when the MA is associated with an Infrastructure Segment.

12 From the MA, the MEP inherits a Maintenance Domain, and from this it inherits:

- 13 g) A Maintenance Domain Level (MD Level), inherited from its Maintenance Domain and
- 14 h) One of the following inherited from its MA:
  - 15 1) A Primary VID or
  - 16 2) an I-SID in the case of a backbone service instance or
  - 17 3) a TE-SID in the case of a TESI or
  - 18 4) a SEG-ID in the case of an Infrastructure Segment

19 A MEP is associated with two Bridge Ports. For a Down MEP, both associations are with the same Bridge  
20 Port. For an Up MEP, the two associations can be with either the same, or with different, Bridge Ports (see  
21 19.4, J.6). The two Bridge Ports are:

- 22 i) The Bridge Port on which the MEP is configured.
- 23 j) The Bridge Port on which the MEP is implemented, and from which it inherits its individual MAC  
24 address.

25 The set of MEPs configured with identical values for MAID define an MA. Thus, one can say that the MA,  
26 and not the MEPs, possesses this parameter. However, an MA is a diffuse entity that can be spread among a  
27 number of geographically separated Bridges. Each Bridge has its own Maintenance Association managed  
28 object for an MA, from which its MEP's MAID, MD Level, and Primary VID, I-SID, series of <ESP-DA,  
29 ESP-SA, ESP-VID> 3-tuples, or SEG-ID are derived. In the case of a VLAN-associated MA, the selection  
30 of which of the MA's VIDs is the Primary VID can be overridden for a specific MEP. Although this  
31 information can be incorrectly configured (i.e., configured differently than some other Bridge), the  
32 Maintenance Association managed object ensures the uniform configuration of MEPs in a single Bridge.

33 Each individual MEP is configured with a MEPID that is unique within that MA. Again, the Maintenance  
34 Association managed object helps to maintain uniqueness, as it ties together the configuration parameters of  
35 the MEPs in a single Bridge and the same MA and ensures the uniqueness of the MEPIDs, at least in that  
36 Bridge.

37 The MAID can take a number of forms (see 21.6.5.1), including a Domain Name-based string. To prevent  
38 incorrect operation in the face of unanticipated connections among systems, the MAID is unique over the  
39 domain for which CFM is to provide such protection. If the MAID is globally unique, then that domain is  
40 global. CFM can detect connectivity errors only over a set of MEPs in which MAIDs are unique.

41 The MEPID is an integer in the range 1–8191. It provides each MEP with the unique identity required for  
42 the MEPs to verify the correct connectivity of the MA.

43 NOTE—The range of the MEPID has been chosen to be large enough to accommodate most network needs, but small  
44 enough to be used as an index into a table of remote MEPs, and not require a table lookup, in a MEP Continuity Check  
45 Receiver (19.2.8) implemented in hardware.

## 19.2.2 MEP functions

The MEP:

- a) Periodically transmits CCMs according to the managed objects defined in item e) in 12.14.6.1.3.
  - b) Validates received CFM PDUs as specified in 20.1, 20.2, 20.3, and 20.51.
  - c) Discards those CFM PDUs at a lower MD Level to that configured in the MEP (20.7.1).
  - d) Transmits LBMs and receives LBRs as defined in 20.2, according to the managed objects defined in 12.14.7.3.
  - e) Transmits LTMs, and transmits and receives LTRs as defined in 20.3, according to the managed objects defined in 12.14.7.4.
  - f) Responds to LBMs with LBRs as defined in 20.2.2.
  - g) Responds to LTMs with LTRs as defined in 20.3.2.
  - h) Maintains the MEP CCM Database as defined in 20.1.3.
  - i) May maintain the MIP CCM Database as defined in 20.1.3.
  - j) Maintains the variables in 20.9.
- a) May decapsulate and transmit the payload of received Send Frame Messages (SFMs) (29.2.6).
  - b) May pass the received Reflected Frame Messages (RFMs) to RFM-Receiver (29.2.4).

Although defined as having either ISS or EISS interfaces, a MEP is highly constrained in its use of the EISS. Specifically,

- c) Every frame passing through the MEP, in either direction, is emitted with its `vlan_identifier` and `drop_eligible` parameters unchanged from the value received.
- d) All PDUs generated by the MEP, namely CCMs, LBMs, LBRs, LTMs, and LTRs, use the MEP's configured Primary VID as the `vlan_identifier` parameter.

## 19.2.3 MEP architecture

Figure 19-2 illustrates the component entities of a MEP. Entities that simply pass, redirect, or filter frames without altering them, and that have no internal state, are shown with dashed outlines; those that generate or transform frames, or that have an internal state, are shown with continuous outlines. State machines describing the latter entities are specified in Clause 20. Figure 19-2 shows that the two enclosing SAPs are not equivalent. The upper SAP in the figure is the Passive SAP. It lies closer to the DoSAP of the monitored service instance. The lower SAP in the figure is the Active SAP, the one that faces the monitored service instance. Thus, Figure 19-2 illustrates one of the Down MEPs shown in Figure 22-1. To illustrate one of the Up MEPs of Figure 22-1, Figure 19-2 would have to be inverted. Note also in the diagram that there are two paths, one of which is present only in the Up MEP, and one of which is present only in the Down MEP.

Figure 19-2—MA Endpoint (MEP)

## 1 19.2.4 MP Type Demultiplexer

2 There are two MP Type Demultiplexers in a MEP, the Active and the Passive Type Demultiplexers, and one  
3 in an MHF. All have the same purpose: to separate the data frames from those carrying CFM PDUs using the  
4 CFM encapsulation (21.2), output non-CFM frames to one output, and output the CFM frames to a second  
5 output. Frames containing CFM PDUs are sent to the Level Demultiplexer, and non-CFM frames are passed  
6 through the MEP intact.

7 NOTE—The model used for functional entities in this standard assumes that the operations of the components shown in  
8 Figure 19-2 and Figure 19-3 are atomic with respect to each other, so that the demultiplexing and multiplexing of  
9 frames, e.g., of CFM and non-CFM frames, cannot change the order of delivery of these frames. Although such  
10 reordering has no adverse consequences on this standard, and although it would not normally violate the frame ordering  
11 requirements of 6.5.3 (because CFM and non-CFM frames would seldom have the same source and destination MAC  
12 address pairs), this reordering could cause the frame loss measurement operations of ITU-T G.8013/Y.1731 to fail to  
13 operate correctly. IEEE Std 802.1AX also can disrupt the operation of ITU-T G.8013/Y.1731 frame loss measurement  
14 operations.

## 15 19.2.5 MP Multiplexer

16 There are two MP Multiplexers in a MEP or in an MHF, the Active and the Passive Multiplexers. An MP  
17 Multiplexer merges frames from multiple inputs and outputs them to a single output. No frame queuing is  
18 specified or implied by this standard.

## 19 19.2.6 MP Level Demultiplexer

20 There are two MP Level Demultiplexers in a MEP, the Active and Passive Level Demultiplexers. Both  
21 separate CFM PDUs according to the MD Level contained within the PDU, and the MD Level configured in  
22 the MEP, and output them to different outputs. Specifically,

- 23 a) Any CFM PDU received that is too short to contain an MD Level header field shall be discarded.
- 24 b) Otherwise, the MD Level header field of the CFM PDU is compared to the MD Level configured for  
25 the MP [item b) in 12.14.5.1.3, item b) in 12.14.3.2.2, 20.7.1], and the CFM PDU is directed to one  
26 of the three outputs of the MP Level Demultiplexer, according to whether the CFM PDU's MD  
27 Level is less than, equal to, or greater than the MP's MD Level.

## 28 19.2.7 MP OpCode Demultiplexer

29 There are two MP OpCode Demultiplexers in a MEP, the Equal and the Low OpCode Demultiplexers, and  
30 one in an MHF. Each MP OpCode Demultiplexer separates CFM PDUs that carry different values in their  
31 OpCode fields (see 21.4.3), and either discards them or passes them to the appropriate state machine. Those  
32 PDUs that do not match any of the OpCodes recognized by an MP OpCode Demultiplexer, or that are too  
33 short to contain an OpCode, are discarded by either of a MEP's MP OpCode Demultiplexers, and passed to  
34 the Passive MHF Multiplexer by an MHF's MP OpCode Demultiplexer. Those PDUs that do match a  
35 recognized OpCode are stored in a variable and cause another Boolean variable to be set, according to  
36 Table 19-1. These variables, in turn, trigger state machine actions. The three MP OpCode Demultiplexers  
37 separate different sets of OpCodes; see Figure 19-2 (in 19.2.3) and Figure 19-3 (in 19.3.3).

## 38 19.2.8 MEP Continuity Check Receiver

39 The MEP Continuity Check Receiver receives CCMs whose MD Levels are equal to or less than the MD  
40 Level of the MEP. The MEP Continuity Check Receiver processes those at or lower than its own MD Level,  
41 to update the MEP CCM Database. The MEP Continuity Check Receiver maintains one instance of the  
42 Remote MEP state machine (20.20) for each active remote MEP configured for this MA. In addition, the  
43 MEP Continuity Check Receiver maintains a single instance each of the Remote MEP Error state machine  
44 (20.22) and the MEP Cross Connect state machine (20.24).

**Table 19-1—Actions taken by MP OpCode Demultiplexers**

| OpCode       | MEP Equal OpCode Demultiplexer                    | MEP Low OpCode Demultiplexer                | MHF OpCode Demultiplexer                                                                              |
|--------------|---------------------------------------------------|---------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <b>CCM</b>   | Sets CCMreceivedEqual and CCMequalPDU for 20.18   | Sets CCMreceivedLow and CCMlowPDU for 20.18 | Sets MHFrecvdCCM and MHFCCMPDU for 20.15 and transfers CCM to Passive MHF Multiplexer                 |
| <b>LBM</b>   | Sets LBMreceived and LBMPDU for 20.29             | Discards PDU                                | Sets LBMreceived and LBMPDU for 20.29 and in non-PBB-TE MHFs transfers LBM to Passive MHF Multiplexer |
| <b>LBR</b>   | Sets LBRreceived and LBRPDU for 20.34             | Discards PDU                                | Transfers LBR to Passive MHF Multiplexer                                                              |
| <b>LTM</b>   | Transfers LTM to MEP Linktrace SAP                | Discards PDU                                | Transfers LTM to MHF Linktrace SAP                                                                    |
| <b>LTR</b>   | Sets LTRreceived and LTRPDU for 20.45             | Discards PDU                                | Transfers LTR to Passive MHF Multiplexer                                                              |
| <b>Other</b> | Discards PDU                                      | Discards PDU                                | Transfers PDU to Passive MHF Multiplexer                                                              |
| <b>SFM</b>   | Sets SFMreceived (29.3.8.5) and SFMPDU (29.3.8.3) | Discards PDU                                | Sets SFMreceived (29.3.8.5) and SFMPDU (29.3.8.3). Transfers the SFM to Passive MHF Multiplexer       |
| <b>RFM</b>   | Sets RFMreceived (29.3.6.1) and RFMPDU (29.3.6.2) | Discards PDU                                | Sets RFMreceived (29.3.6.1) and RFMPDU (29.3.6.2). Transfers the RFM to Passive MHF Multiplexer       |

1 If a MEP's Continuity Check Receiver state machine's allRMEPsDead variable (20.9.4) is set, and if the  
2 MEP is not associated with any VID or I-SID and is a Down MEP (i.e., in position 5 in Figure 22-9), then  
3 the MAC\_Operational parameter presented to the Passive SAP by the MEP is false, whatever the state of the  
4 MAC\_Operational parameter received from the Active SAP. Thus, a completely failed MA causes the  
5 attached Bridge Port to appear as a failed link.

6 Optionally, the MEP Continuity Check Receiver may maintain the MIP CCM Database as described in  
7 19.3.10.

8 Various error conditions, including the receipt of CCMs at a lower MD Level than that of the MEP, cause the  
9 Remote MEP state machine to detect a defect that can in turn generate a Fault Alarm.

#### 10 **19.2.9 MEP Continuity Check Initiator**

11 The Continuity Check Initiator transmits CCMs at the MD Level of the MEP only. The state machine for the  
12 Continuity Check Initiator is described in 20.12.

#### 13 **19.2.10 MP Loopback Responder**

14 The Loopback Responder receives LBMs at the MD Level of the MP only, validates and filters them  
15 according to destination\_address (19.4) and the PBB-TE MIP TLV (21.7.5) in the case of a PBB-TE MA  
16 and transmits LBRs in response. The state machine for the MP Loopback Responder is described in 20.29.

### 1 **19.2.11 MEP Loopback Initiator**

2 The Loopback Initiator transmits LBMs at the MD Level of the MEP only, and validates, filters according to  
3 destination\_address (19.4), and counts the LBRs returned by other MPs' Loopback Responders. The state  
4 machine for the Loopback Initiator is described in 20.32.

### 5 **19.2.12 MEP Linktrace Initiator**

6 The Linktrace Initiator transmits LTMs at the MD Level of the MEP only, and validates, filters according to  
7 destination\_address (19.4), and catalogs the LTRs returned by other Bridges' Linktrace Responders. The  
8 state machine for the Linktrace Initiator is described in 20.45. In an Up MEP the Linktrace Initiator  
9 transmits its LTMs to the Bridge's Linktrace Responder. In a Down MEP, the Linktrace Initiator transmits its  
10 LTMs through the MEP's own Active Multiplexer toward the MEP's Active SAP.

### 11 **19.2.13 MEP LTI SAP**

12 An Up MEP, but not a Down MEP, has a MEP LTI SAP, an instance of the ISS or EISS. This SAP is used to:

- 13 a) Transmit LTMs originated by the MEP's Linktrace Initiator.
- 14 b) Receive LTRs from the Linktrace Responder.

### 15 **19.2.14 MEP Linktrace SAP**

16 Every MEP has a MEP Linktrace SAP, an instance of the ISS or EISS. This SAP is used to relay received  
17 LTMs to the Linktrace Responder.

18 NOTE—Both the MEP LTI SAP and MEP Linktrace SAP are required so that the MEP knows, when an LTR is returned  
19 to it by the Linktrace Responder, whether the LTR is a response to an LTM generated by the MEP and thus to direct it to  
20 the MEP Linktrace Initiator, or whether the LTR is a response to an LTM previously received by the MEP and thus to  
21 forward it out the Active SAP.

### 22 **19.2.15 MEP CCM Database**

23 The MEP CCM Database is maintained by the Remote MEP state machines (20.20), one entry for each of  
24 the other MEPs configured in the MA. In addition to the Remote MEP variables (20.19) used by the Remote  
25 MEP state machine, each entry holds information obtained from the remote MEP's CCMs as listed in  
26 12.14.7.6.3. See also 20.1.3.

### 27 **19.2.16 MEP Fault Notification Generator**

28 The Fault Notification Generator uses the MAdefectIndication variable (see 20.9.3) in order to generate a  
29 Fault Alarm to the administrator of the Maintenance Domain to which the MA is attached. This can be  
30 accomplished by sending an SNMP Notification. The state machine for the Fault Notification Generator is  
31 described in 20.37.

### 32 **19.2.17 MEP Decapsulator Responder (DR)**

33 The MEP DR is an optional component entity within an MEP shim required only by DDCFM. Its position  
34 relative to other MP component entities is shown in Figure 19-2. When the destination\_address of the SFM  
35 matches with the MEP's MAC address, the MEP DR (29.2.6) will decapsulate the SFM, change the  
36 source\_address field of the decapsulated data frame if it is required, and send the frame to the LOM SAP of  
37 selected port(s) (29.3.9.1).

## 19.2.18 MEP RFM Receiver

The MEP RFM Receiver is an optional component entity within a MEP shim required only by DDCFM. It is placed next to the OpCode Demultiplexer functions receiving RFM frames. When the destination\_address of the RFM matches with the MP's MAC address, the MEP RFM Receiver will pass the received RFM to the corresponding, nonstandardized RFM Analyzer.

## 19.3 MIP Half Function

A MIP consists of two MIP Half Functions (MHFs) on a single Bridge Port, an Up MHF and a Down MHF. (See J.6 for a more detailed explanation.) An MHF may maintain a MIP CCM Database, separate from the MEP CCM Databases.

### 19.3.1 MHF identification

Every MHF is characterized by one configuration parameter for management purpose, and all of the MHFs of a MIP have identical values for that configuration parameter:

a) The Maintenance Domain to which the MHF is assigned.

For data flow purposes, the MHF is characterized by:

b) A Maintenance Domain Level (MD Level), inherited from its Maintenance Domain or from the Default MD Level managed object.

c) A set of Primary VIDs, one from each MA associated with the MHF's Maintenance Domain; or a set of I-SIDs, one for each MA associated with the MHF's Maintenance Domain.

NOTE—When multiple VIDs are used for a single service instance, an MHF is aware of each MA's VID set and Primary VID. Unlike the MEP, however, the MHF has no occasion to use a MAID, so is not identified by a MAID.

An MHF is associated with two Bridge Ports. For a Down MHF, both associations are with the same Bridge Port; for an Up MHF, the two associations can be with either the same, or with different, Bridge Ports (see 19.4, J.6). The two Bridge Ports are:

d) The Bridge Port on which the MHF is configured.

e) The Bridge Port on which the MHF is implemented and from which it inherits its individual MAC address.

### 19.3.2 MHF functions

Each MHF:

a) Validates received LTMs as specified in 20.1, 20.2, 20.3, and 20.51.

b) Optionally, validates received CCMs and builds the MIP CCM Database.

c) Responds to LBMs with LBRs as defined in 20.2.2.

d) Responds to LTMs by forwarding them and responding with LTRs as defined in 20.3.2.

e) May decapsulate and transmit the payload of the received SFM (29.4.3).

f) May pass the received RFM (29.4.2).

Although defined as having either ISS or EISS interfaces, an MHF is highly constrained in its use of the EISS. Specifically,

g) Every frame passing through the MHF, in either direction, is emitted with its vlan\_identifier and drop\_eligible parameters unchanged from the value received.

h) All LBMs forwarded by the MHF carry the same vlan\_identifier and drop\_eligible parameters as the received LBM.

### 1 **19.3.5 MHF Type Demultiplexer**

2 The MHF Type Demultiplexer is identical to the MP Type Demultiplexer described in 19.2.4.

### 3 **19.3.6 MHF OpCode Demultiplexer**

4 An example of the MP OpCode Demultiplexer described in 19.2.7. The MHF OpCode Demultiplexer is  
5 fully described in that subclause.

6 NOTE—As indicated by the split arrows labeled “CCM” and “LBM” in Figure 19-3, some of the frames output from the  
7 MHF OpCode Demultiplexer are supplied to two other entities, and not just one.

### 8 **19.3.7 MHF Multiplexer**

9 The MHF Multiplexer is identical to the MP Multiplexer described in 19.2.5. There are two MHF  
10 Multiplexers in an MHF, the Active MHF Multiplexer and the Passive MHF Multiplexer.

### 11 **19.3.8 MHF Loopback Responder**

12 The MHF Loopback Responder is identical to the MP Loopback Responder described in 19.2.10.

### 13 **19.3.9 MHF Continuity Check Receiver**

14 The optional MHF Continuity Check Receiver receives CCMs, validates them, filters them by  
15 destination\_address parameter (19.4), and contributes to the MIP CCM Database. From Figure 19-3, readers  
16 can see that all CCMs at the same MD Level as the MHF are presented to the MHF Continuity Check  
17 Receiver. No other information in the received CCMs is examined. In particular, the MAID in the CCM is  
18 not compared to the MHF’s MAID.

19 The MHF Continuity Check Receiver, and the MIP CCM Database it maintains, are not required for  
20 conformance to this standard.

### 21 **19.3.10 MIP CCM Database**

22 The MIP CCM Database is optionally maintained by an MHF or MEP. It is a list of every distinct {FID,  
23 source\_address, Port number} triple from all of the CCMs presented to all of the Bridge’s MPs’ Continuity  
24 Check Receivers since the Bridge was last reset. Entries in the MIP CCM Database are timed out very  
25 slowly, on the order of one day, so that their information is available for fault isolation long after the  
26 information is no longer used for frame forwarding.

### 27 **19.3.11 MHF Linktrace SAP**

28 Every MHF has an MHF Linktrace SAP, an instance of the ISS or EISS. This SAP is used to relay received  
29 LTMs to the Linktrace Responder, and to pass LTRs from Linktrace Responder to the MHF’s Active SAP.

### 30 **19.3.12 MHF DR**

31 The MHF DR is identical to the MEP DR described in 19.2.17.

### 32 **19.3.13 MHF RFM Receiver**

33 The MHF RFM Receiver is identical to the MEP RFM Receiver described in 19.2.18.

## 19.4 MP addressing

The CFM entities within an MP use the Group addresses for CCM and LTM PDUs listed in Table 8-18 and Table 8-19 and in the case of PBB-TE, SPBM, and ECMP path MAs, the individual MAC addresses or the group MAC addresses that are associated with the monitored services (20.1, 20.2, 20.3). In addition, they recognize and in the case of PBB-TE, SPBM, and ECMP path MEPs use the individual MAC address of the port on which the MP is operating. This is the port on which the MP is configured, if the Bridge created the MP using the Individual MP address model (J.6.1), and is a CFM Port, if the Bridge created the MP using the Shared MP address model (J.6.2). CFM entities associated with a TESI may also use the ESP-SA parameter in the tuple identifying the corresponding ESP.

A Down MP shall not be assigned an individual MAC address [item i) in 12.14.7.1.3] that is the same as the individual MAC address configured for an MP on any other Bridge Port, because if two Bridge Ports are connected to the same LAN, but have the same MAC address, then both would respond to an LBM sent to that MAC address. The CFM protocol is specifically designed to allow an Up MP to be assigned an individual MAC address that is the same as the individual MAC address configured for an Up MP on some other Bridge Port, because it is impossible to tell, from outside the Bridge, from which Up MP a given CFM PDU was actually transmitted, or to which physical entity a given CFM PDU was delivered. See J.6 for a discussion of the assignment of individual MAC addresses to MPs.

All the CFM entities within one MP use the same CCM and LTM addresses, and individual MAC address. The various multiplexing and demultiplexing entities pay no attention to the destination\_address parameter of a received CFM PDU. Only the entities responsible for processing received CFM PDUs check a received frame's destination\_address parameter. Each of these entities recognizes frames whose destination\_address parameters match the individual MAC address of the MP or are a group address. Each of these entities (except the MEP Continuity Check Receiver) filters and does not process frames whose destination\_address parameters are not a group address and do not match the individual MAC address of the MP.

NOTE—Even though in the original version of IEEE Std 802.1ag-2007, the MEP Continuity Check Initiator could only transmit multicast CCMs, the MEP Continuity Check Receiver recognized unicast CCMs. In general the definitions of the various CFM receiving entities were more liberal in recognizing certain Individual or group MAC addresses than the corresponding definitions of the CFM transmitting entities a property that allows for the PBB-TE enhancements of CFM, and for improved compatibility with ITU-T G.8013/Y.1731.

## 19.5 Linktrace Output Multiplexer (LOM)

The third type of CFM protocol shim is the LOM. An LOM has two principle SAPs, an Active SAP, through which CFM PDUs are transmitted, and a Passive SAP, through which pass data frames and unprocessed CFM PDUs. Figure 19-4 illustrates these SAPs and the symbol used for the LOM in other figures, e.g., Figure 22-1. An LOM can be only a Down LOM; its Passive SAP is always above the Active SAP in a shim diagram.

Figure 19-4—LOM shim

1 As illustrated in Figure 19-5, the LOM has only a single active entity, the LOM Multiplexer. It injects LTMs  
2 from the Linktrace Responder among the frames passing from the LOM's Passive SAP to its Active SAP.  
3 Frames received from the LOM's Linktrace SAP are transmitted through only the Active SAP, and not  
4 through the Passive SAP. All frames received on either the Active or Passive SAP are passed through the  
5 LOM unchanged, and only to the Passive or Active SAP, respectively.

**Figure 19-5—LOM architecture**

6 NOTE 1—An LOM is not an MP, but an entity that assists the Linktrace Responder (19.6), also not an MP.

7 NOTE 2—The LOM exists on every Bridge Port in order to allow the Linktrace Responder to transmit an LTM on a  
8 particular Bridge Port without the possibility of that LTM being reflected back toward the Bridge's Forwarding process.  
9 However, the LOM has no constituent entity that differentiates CFM frames from any other frames.

## 10 19.6 Linktrace Responder

11 A single Linktrace Responder serves all of the MHFs and MEPs in a Bridge. It is connected to every MP and  
12 LOM in the Bridge, via the Linktrace SAPs and LTI SAPs in those MPs and LOMs.

13 NOTE—A Linktrace Responder is not an MP, but an entity that assists the MPs (MEP and MHF, 19.2 and 19.3) in  
14 performing their functions.

15 In order to minimize the possibility of generating an unbounded number of responses to an LTM, an LTM is  
16 always transmitted from a Bridge on a single Bridge Port (20.3). If the LLC entity of a Bridge Port (see  
17 Figure 22-1) were used to transmit an LTM on a particular Bridge Port, the Bridge Port connectivity entity  
18 (8.5.1) would direct the LTM to the LAN, but it would also pass that frame up toward the Frame filtering  
19 entity (8.6.3), as it does for BPDUs. BPDUs are never transmitted to other Bridge Ports, however, because  
20 the Frame filtering entity filters them, based on their destination MAC addresses. The placement of MHFs at  
21 different MD Levels on different Bridge Ports, all for the same VID, precludes filtering LTMs in this  
22 manner. Therefore, the Linktrace Responder filters incoming LTMs by the destination\_address parameter  
23 (19.4), and a path is required that will direct an LTM only down the Bridge Port, toward the LAN, and not  
24 toward the Frame filtering entity.

25 This path is provided by the Linktrace SAPs in the MEP (Figure 19-2), the MHF (Figure 19-3), and the  
26 LOM (Figure 19-5). The Linktrace SAPs are also used to direct a received LTM to the Linktrace Responder  
27 when the LTM first encounters an MP at the appropriate MD Level.

28 Referring to Figure 22-1, readers can see that an LTM originated by a Down MEP Linktrace Initiator is  
29 directed out to the LAN and is thus output on a single Bridge Port, as desired. The situation is different for  
30 an LTM originated by an Up MEP. The Bridge in which an Up MEP resides is, in effect, the first hop of the  
31 Linktrace protocol. The MEP LTI SAP is required in order to provide a path through which the MEP can  
32 direct its originated LTM to the Linktrace Responder. This path can also be used by the Linktrace Responder

1 to return the resultant LTR to the MEP Linktrace Initiator. See Figure 20-16 for a diagrammatic explanation  
2 of these paths.

3 Table 19-2 summarizes the SAP connections between the MPs and LOM on the one hand, and the Linktrace  
4 Responder, on the other.

**Table 19-2—SAP use for LTMs and LTRs**

| Entity taking action |     | Sends originated LTM to     | Relays received LTM to      | Sends to Active SAP an LTR received on | Sends to Active SAP an LTM received on |
|----------------------|-----|-----------------------------|-----------------------------|----------------------------------------|----------------------------------------|
| Up                   | MEP | MEP LTI SAP                 | MEP Linktrace SAP           | MEP Linktrace SAP                      | Not applicable <sup>a</sup>            |
|                      | MHF | Not applicable <sup>b</sup> | MHF Linktrace SAP           | MHF Linktrace SAP                      | Not applicable <sup>a</sup>            |
| Down                 | MEP | Not applicable <sup>c</sup> | MEP Linktrace SAP           | MEP Linktrace SAP                      | Not applicable <sup>a</sup>            |
|                      | MHF | Not applicable <sup>b</sup> | MHF Linktrace SAP           | MHF Linktrace SAP                      | Not applicable                         |
| LOM                  |     | Not applicable <sup>b</sup> | Not applicable <sup>d</sup> | Not applicable <sup>a</sup>            | LOM Linktrace SAP                      |

<sup>a</sup> The Linktrace Responder only forwards LTMs through an LOM.

<sup>b</sup> The MHF and LOM have no MEP Linktrace Initiator, so cannot originate LTMs.

<sup>c</sup> The Down MEP transmits the LTMs it originates through its Active SAP.

<sup>d</sup> The LOM is not an MP; it cannot detect received LTMs.

5 A single instance of the LTR Transmitter state machine is instantiated by the Linktrace Responder. It is  
6 described in 20.50.

## 20. CFM protocols

MEPs and MIPs can participate in the following CFM protocols:

- a) Continuity Check protocol (20.1)
- b) Loopback protocol (20.2)
- c) Linktrace protocol (20.3)
- d) DDCFM protocol (29.3)

The detailed operation of these protocols by the MEP (19.2) and MHF (19.3) components introduced in Clause 19 is specified in terms of a number of state machines, and the variables and procedures associated with each machine. The state machines defined adhere to the conventions in Annex E and Figure 13-14.

This clause specifies the following:

- e) Relationships among the various CFM state machines and their variables (20.4).
- f) Requirements for decrementing the timer counters used by a number of CFM state machines (20.5).
- g) Maintenance Domain variables (20.7) that control all MAs belonging to the Maintenance Domain.
- h) MA variables (20.8) that control all MEPs and MHFs belonging to the MA.
- i) MEP variables (20.9) that control the MEP's overall operation, and either apply to the majority of state machines or facilitate communication of information between the individual MEP state machines.
- j) MEP Continuity Check Initiator (19.2.9) variables (20.10), procedures (20.11), and state machine (20.12).
- k) (optional) MHF Continuity Check Receiver (19.3.9) variables (20.13), procedures (20.14), and state machine (20.15).
- l) MEP Continuity Check Receiver (19.2.8) variables (20.16), procedures (20.17), and state machine (20.18).
- m) Remote MEP variables (20.19) and state machines (20.20) used by the MEP Continuity Check Receiver to track each active Remote MEP [item ae) in 12.14.7.1.3].
- n) Remote MEP Error variables (20.21) and the Remote MEP Error state machine (20.22) used by MEP Continuity Check Receiver to track received invalid CCMs.
- o) MEP Cross Connect variables (20.23) and state machine (20.24) used by the MEP Continuity Check Receiver to track received CCMs that could indicate a cross connect defect.
- p) MP Loopback Responder (19.2.10) variables, (20.27), procedures (20.28), and state machine (20.29).
- q) MEP Loopback Initiator (19.2.11) variables (20.30), transmit procedures (20.31) and state machine (20.32), and receive procedures (20.33) and state machine (20.34).
- r) MEP Fault Notification Generator (19.2.16) variables (20.35), procedures (20.36), and state machine (20.37).
- s) MEP Linktrace Initiator (19.2.12) variables (20.41) and transmit procedures (20.42), and receive variables (20.43), procedures (20.44), and state machine (20.45).
- t) Linktrace Responder variables (20.46), procedures (20.47), and state machine (20.48), used by the Linktrace Responder (19.6).
- u) LTR Transmitter state machine (20.50) used only by the Linktrace Responder.

To facilitate extension of this standard while maximizing interoperability, this clause further specifies:

- v) Rules for CFM PDU validation and versioning (20.51) that support specific goals for extensibility and interoperability (20.51.1).
- w) Rules for the identification of incoming CFM PDUs (20.52).
- x) Rules for the use of transaction identifier and sequence number fields (20.53).

1 The models of operation in this clause provide a basis for specifying the externally observable behavior of  
2 MHFs and MIPs, and are not intended to place additional constraints on implementations; these can adopt  
3 any internal model of operation compatible with the externally observable behavior specified. Conformance  
4 of equipment to this standard is purely in respect of observable protocol.

5 NOTE—Clause 18 introduces the principles of CFM operation and the network architectural concepts that support it.  
6 Clause 19 breaks down the CFM protocol entities into their components. Clause 21 specifies the PDU formats used by  
7 the CFM protocols. The use of CFM within systems and networks is further described in Clause 22.

## 8 **20.1 Continuity Check protocol**

9 The Continuity Check protocol is performed by the MEP Continuity Check Initiator (19.2.9), the MEP  
10 Continuity Check Receiver (19.2.8) of the MEP, and optionally, in the MHF Continuity Check Receiver  
11 (19.3.9) of the MHF.

12 For the purposes of Fault detection and the Continuity Check protocol, readers can define an MA as “a set of  
13 MEPs, all of which are configured with the same MAID and MD Level, each of which is configured with a  
14 MEPID unique within that MAID and MD Level, and all of which are configured with the complete list of  
15 MEPIDs.” The CCM (21.6) provides a means to detect connectivity failures in an MA. Each MEP can be  
16 configured to periodically transmit a CCM. A connectivity failure is then defined as one of the following:

- 17 a) Inability of a MEP to receive three consecutive CCMs from any one of the other MEPs in its MA,  
18 indicating either a MEP failure or a network failure.
- 19 b) Reception by a MEP of a CCM with an incorrect transmission interval, indicating a configuration  
20 error.
- 21 c) Reception by a MEP of a CCM with an incorrect MEPID or MAID, indicating a configuration error  
22 or a cross connect error.
- 23 d) Reception by a MEP of a CCM with an MD Level lower than that of the MEP, indicating a  
24 configuration error or a cross connect error.
- 25 e) Reception by a MEP of a CCM containing a Port Status TLV or Interface Status TLV indicating a  
26 failed Bridge Port or aggregated port.
- 27 f) Reception by a PBB-TE MEP implementing the Traffic field, over a period of time that is 4.75 times  
28 the CCM interval or equal to 50 ms, whichever is larger, of CCMs with Traffic fields not matching  
29 the local Traffic field declaration, indicating a mismatch on the presence or absence of Backbone  
30 Service Instance entries on the CBPs that are associated with the monitored TESI.

31 In order to take the fullest advantage of CFM, the operator defines “correct connectivity” as being the  
32 configuration of the MEPs. If an MA is defined for every service instance, then the Continuity Check  
33 protocol can detect 100% of all connectivity faults, cross connection errors, or misconfigurations that occur  
34 within the boundaries of the configured MAs.

35 The transmission rate for CCMs is configurable, to accommodate different needs for error reporting, and  
36 different capabilities of network devices. The loss of three CCMs can be detected in as little as 10.8 ms (see  
37 Table 21-15). The reception of a cross connected CCM is an instantaneous occurrence.

38 A MEP uses its own configured timer to detect the loss of CCMs, rather than using the transmission rate of  
39 the sender (signaled in the CCM), in order to minimize the complexity of a MEP tracking hundreds of other  
40 MEPs. The timer is reset when a valid CCM is received, and a defect declared if the timer expires. The timer  
41 value is chosen such that the loss of three consecutive CCMs from a given remote MEP triggers a defect for  
42 that remote MEP, and the timer accuracy chosen to ensure against a premature defect indication. In addition,  
43 state machines in the MEP track the receipt of CCMs from remote MEPs with unexpected information,  
44 CCMs from remote MEPs not configured in the receiving MEP, CFM PDUs from a lower MD Level, or  
45 CCMs from MEPs in another MA.

1 Depending on the associated MA, a CCM is carried:

- 2 g) In a multicast frame, with a destination\_address parameter chosen according to the transmitting  
3 MEP's MD Level, according to Table 8-18; or
- 4 h) In the case of a PBB-TE, SPBM, or ECMP associated MA, in a unicast or multicast frame with a  
5 destination\_address identified by the monitored MA.

6 The CCM does not generate a response. Therefore, in an MA with  $n$  MEPs,  $n$  CCMs need to be transmitted  
7 periodically, one from each MEP. Compared to a full mesh of point-to-point messages in terms of frames  
8 carried on wires, multicast CCMs require less bandwidth than the point-to-point messages, except of course  
9 for MAs with only two MEPs. And for each MEP, only one transmission and  $n - 1$  receptions are required,  
10 instead of  $n - 1$  of each. In addition, even in MAs with only two MEPs, using multicast instead of unicasts  
11 for CCMs obviates the need for configuration or discovery of those MEPs' MAC addresses.

12 Of more importance than frame count is the fact that making the CCM a multicast frame enables the  
13 detection of a cross connect error when MEPs from two different service instances are accidentally  
14 connected. This type of error can result from a wiring error or a misconfiguration of VID mapping  
15 parameters at the boundary between two Maintenance Domains. Were CCMs unicast to specific MAC  
16 addresses, then a merging of two service instances, e.g., the accidental concatenation of two point-to-point  
17 services into a 4-SAP LAN service, would go undetected; unicast CCMs would still be delivered properly.  
18 This scenario also points out why globally unique MAIDs are important.

19 NOTE—The TESI Multiplex Entity (6.19) helps PBB-TE associated MEPs to avoid this type of cross connect problem  
20 for unicast CCMs by checking the source\_address to determine CCMs destined to PBB-TE MAs. Correspondingly the  
21 assignment of globally unique MAIDs is not as important for PBB-TE MAs as it is for other types of MAs but in general  
22 a globally unique MAID will provide guaranties for full coverage on all possible misconfiguration errors.

23 Cataloging the receipt of CCMs ensures that a MEP, say, MEP 1, knows that it is receiving them from  
24 exactly the correct set of remote MEPs; it does not ensure that the CCMs transmitted by that same MEP are  
25 being received by the remote MEPs. For example, suppose that in a 10-MEP MA, all of MEP 1's CCMs are  
26 being lost. All of the other MEPs in the MA would know about MEP 1's problem, because they would not  
27 be receiving 1's CCMs. But, MEP 1 itself would be unaware of the problem. In order for the operator to  
28 decide whether an MA is working properly, every MEP in the MA would have to be inspected.

29 For this reason, the Remote Defect Indication (RDI), a single bit, is carried by the CCM. The absence of RDI  
30 in a CCM indicates that the transmitting MEP is receiving CCMs from all configured MEPs. In the case of  
31 MEP 1's unidirectional connectivity, MEP 1 would receive the RDI in the CCM from each remote MEP that  
32 is not receiving MEP 1's (or any other MEP's) CCMs. Thus, every MEP, including the receive-only MEP 1,  
33 is aware that a problem exists. The presence of RDI enables a system administrator to inspect any single  
34 MEP belonging to an MA, and discover whether there is any MEP in the MA that is detecting a defect, as  
35 well as which particular MEPs have defects.

36 A sequence number should be transmitted in every CCM. The receiver may use this sequence number to  
37 detect and count CCM losses. Detection of occasional CCM losses can enable a network administrator to  
38 notice suboptimal network conditions such as overloaded links, and correct them before connectivity defects  
39 and their consequent Fault Alarms occur.

40 An ECMP path MA is used to test multiple paths between a pair of endpoints. This type of MA has only two  
41 MEPs, at two SPT Region boundary ports. An ECMP path MEP cycles through a set of flow hash values  
42 intended to direct the CCM frames along (and thus test) different paths to the other MEP in the MA. The  
43 path taken by CCM frames with a given flow hash depends on the current state of the network (i.e., paths are  
44 subject to rerouting triggered by topology changes). Each flow hash is used in at least three consecutive  
45 CCM frames so that a fault on a particular path will be detected and reported back via an RDI signal. To  
46 avoid false positive or false negative detections of a loss of connectivity, the rate of CCM transmission  
47 should be greater than the maximum difference in latency between any pair of paths.

## 1 20.1.1 MAC status reporting in the CCM

2 The CCM can carry information about the status of the port on which the transmitting MEP is configured in  
3 the Port Status TLV (21.5.4) and Interface Status TLV (21.5.5). This information is not strictly within the  
4 scope of the MA bounded by the MEPs transmitting and receiving the CCM. But, by providing port status  
5 information in an Up MEP's CCMs, this TLV allows the detection of an error immediately outboard of the  
6 MA. This in turn supports fault isolation where a problem has arisen at the point of connection to a service  
7 instance, rather than within the equipment supporting the service instance. The Port Status TLV and  
8 Interface Status TLV are particularly useful where the boundary between the equipment used by two  
9 operators to support a service instance is a link or connection that could fail. Use of the Port Status TLV and  
10 Interface Status TLV allows monitoring to be uninterrupted from end to end, without requiring management  
11 access by both operators to a single item of interface equipment, or relying on monitoring by the user of the  
12 concatenated service. The Port Status TLV and Interface Status TLV allow errors that are immediately  
13 outboard of the MA to be distinguished easily from those properly attributed to the MA itself.

14 Figure 18-7 provides an example. Consider a failure of the access link that connects the customer equipment  
15 (1) directly to Port b of Provider Bridge 2. Without the Interface Status TLV, none of the MEPs at the  
16 operator or service provider MD Level would be notified of the error. The Interface Status TLV allows the  
17 failure to be signaled in CCMs transmitted by the Port b service provider and operator MD Level MEPs.

## 18 20.1.2 Defects and Fault Alarms

19 Defects are separated from Fault Alarms (19.2.16), as is standard practice for service providers.<sup>34</sup> The loss  
20 of CCMs or the reception of a cross connected CCM is a defect. A Fault Alarm is a Management operation  
21 (12.14.7.7), an unsolicited announcement by a Bridge. If the CFM MIB module (17.5) is implemented and is  
22 operating, an SNMP Notification is sent. If the CFM YANG module (Clause 48) is implemented and is  
23 operating, a YANG Notification is sent. Notifications are sent when the MEP Fault Notification Generator  
24 state machine (20.37), or the MEP Mismatch Fault Notification Generator state machine (20.40), detects that  
25 a configured time period (default, 2.5 s) has passed with one or more defects indicated, and Fault Alarms are  
26 enabled. Each of these state machine can transmit no further Fault Alarms until it is reset by the passage of a  
27 configured time period (default, 10 s) during which no defect indication is present. The normal operator  
28 procedure upon receiving a Fault Alarm is to inspect the reporting MEP's managed objects, diagnose the  
29 fault, correct the fault, examine the MEP's managed objects to see whether the state machine has reset, and  
30 repeat those steps until the Fault Alarm has cleared.

31 A number of separate defects are maintained by a MEP, as shown in Table 20-1. The defects are ranked by  
32 priority. If a higher priority defect occurs after a lower priority defect has triggered a Fault Alarm, but before  
33 the Fault Alarm has reset, then the MEP will immediately issue another Fault Alarm. This enables the  
34 operator to reliably prioritize Fault Alarms. For example, cross connect errors are typically of greater  
35 concern in a service provider environment than loss of connectivity errors.

36 Only the highest priority defect is reported in the Fault Alarm. Table 20-1 shows the relationships between  
37 the variables that indicate defects, the priorities of these defects, and the enumerated value reported in the  
38 Fault Alarm for each defect. The mmdefectIndication (20.38.2) is independent from the other CFM defects  
39 and is reported independently by the operation of the MEP Mismatch Fault Notification Generator state  
40 machine (20.40).

<sup>34</sup> See, for example, ITU-T G.806 (2006) [B49].

**Table 20-1—Fault Alarm defects and priorities**

| Defect                           |                            | Priority                      |            |
|----------------------------------|----------------------------|-------------------------------|------------|
| Variable                         | highestDefect<br>(20.35.9) | highestDefectPri<br>(20.35.8) | Importance |
| xconCCMdefect<br>(20.23.3)       | DefXconCCM                 | 5                             | Most       |
| errorCCMdefect<br>(20.21.3)      | DefErrorCCM                | 4                             |            |
| someRMEPCCMdefect<br>(20.35.5)   | DefRemoteCCM               | 3                             |            |
| someMACstatusDefect<br>(20.35.6) | DefMACstatus               | 2                             |            |
| someRDIddefect<br>(20.35.7)      | DefRDICCM                  | 1                             | Least      |

### 20.1.3 CCM reception

Every active MEP receives and catalogs CCMs in its MEP CCM Database. Every CCM shall be examined to be sure that its MAID matches that configured in the receiving MP. This check is optional for CCMs associated with PBB-TE MAs. A receiving MEP checks to ensure that its own MEPID does *not* match that in the received CCM. (This could indicate either a duplicate MEPID or a network forwarding loop.) The information in the CCM is cataloged in the MEP CCM Database, indexed by the received MEPID. The information kept in the MEP CCM Database is listed in 12.14.7.6.3.

The MIP CCM Database is optionally maintained by a MEP Continuity Check Receiver or an MHF Continuity Check Receiver. It is a list of every distinct {FID, source\_address, Port number} triple from all of the CCMs presented to all of the Bridge's Down MHFs' MHF Continuity Check Receivers since the Bridge was last reset. (See 8.8.8 for a discussion of VIDs and FIDs.) An entry in the CCM Database is retained for at least 24 h after the last CCM with its triple is received and is removed from the MIP CCM Database after, at most, 48 h. If the resources allocated for the MIP CCM Database are not sufficient to maintain all of the entries for the required time, then the least-recently updated entries should preferentially be removed to make room for new entries. See 20.3.2 for a description of the use of the MIP CCM Database.

## 20.2 Loopback protocol

The Loopback protocol is used for Fault verification and isolation. To verify the connectivity between MEPs and MIPs, a MEP can be instructed by a system administrator to issue one or more LBMs. The LBM is initiated by a MEP with specified destination address, priority, and drop\_eligible parameters, the destination\_address being the individual MAC address of another MP within the same MA as the transmitting MEP. In the case of PBB-TE and SPBM VID MAs, the destination\_address parameter for an LBM is always a MAC address associated with the terminating CBP(s). In order to identify intermediate MHFs in PBB-TE and SPBM VID MAs, an additional TLV, the PBB-TE MIP TLV (21.7.5), is carried as the first TLV in an LBM, with the receiving MHF's MAC address in its MIP MAC address field (21.7.5.1). The receiving MP responds to the LBM with an LBR.

The Loopback protocol is performed by the MEP Loopback Initiator (19.2.11) and the MP Loopback Responder (19.2.10), the latter residing in either a MEP or an MHF.

## 1 20.2.1 LBM transmission

2 LBMs are transmitted by operator command as specified in 12.14.7.3. Each LBM transmitted contains a  
3 Loopback Transaction Identifier field (21.7.3) that is incremented with each transmission. That enables the  
4 transmitting MEP to correlate the returned LBRs with the transmitted LBMs. In a PBB-TE or SPBM VID  
5 MA, a PBB-TE MIP TLV is carried by the transmitted LBM as the first TLV if the targeted MP is a MIP.  
6 The MIP MAC address field (21.7.5.1) in the TLV is set to the `destination_address` parameter of the  
7 appropriate managed object [item b) in 12.14.7.3.2]. The PBB-TE MIP TLV provides also the Reverse VID  
8 field [21.7.5.2, item f) in 12.14.7.3.2] to be used in the VID field by a MIP transmitted LBR, and, when the  
9 LBM is to be sent on a point-to-multipoint TESI, the Reverse MAC field (21.7.5.3) associated with MAC  
10 addresses to be used by the LBR. The LBM can carry an arbitrary amount of data to help diagnose faults that  
11 are sensitive to the amount or pattern of data in a frame [item d) in 12.14.7.3.2]. It can be sent with any  
12 priority or drop\_eligible parameters [item e) in 12.14.7.3.2].

13 No means for specifying the rate at which the LBMs are to be sent is provided. A Bridge shall not transmit  
14 LBMs at a rate that would cause the queues serving that Bridge Port to overflow and drop LBMs, were there  
15 no other traffic being inserted into those queues.

## 16 20.2.2 LBM reception and LBR transmission

17 When an LBM is received by an MP Loopback Responder (19.2.10), it may be examined for validity and  
18 discarded if invalid. Regardless of whether the LBM is examined for validity, it shall be discarded if the  
19 `source_address` is a Group and not an individual MAC address. Also, if the `destination_address` does not  
20 match the MAC address of the receiving MP, and the MP Loopback Responder does not reside in a PBB-TE  
21 or SPBM VID MHF, the MP shall discard the LBM. If the receiving MP Loopback Responder resides in a  
22 non-PBB-TE and non-SPBM VID associated MHF and the `destination_address` is a group MAC address, the  
23 MHF shall discard the LBM. If the MP Loopback Responder state machine resides in a PBB-TE MEP and  
24 the received LBM carries a PBB-TE MIP TLV, the MEP shall discard the LBM. If the MP Loopback  
25 Responder state machine resides in an SPBM VID MEP and the received LBM carries a PBB-TE MIP TLV,  
26 the MEP may process the LBM if the MIP MAC address field matches the MEP's address and shall  
27 otherwise discard the LBM. PBB-TE and SPBM VID MHFs forward all received LBMs and only stop and  
28 process those that carry a PBB-TE MIP TLV containing in their MIP MAC address field the MAC address  
29 of the receiving MIP [item f) in 20.8.1]. If the frame passes these tests, the receiving MP generates an LBR  
30 and transmits it to the originating MEP. Every `M_UNITDATA.indication` (or `EM_UNITDATA.indication`)  
31 parameter and octet in the `mac_service_data_unit` in the LBM is copied to the LBR's  
32 `M_UNITDATA.request` (or `EM_UNITDATA.request`) with the following exceptions:

- 33 a) The `source_address` parameter of the received LBM is used as the `destination_address` parameter for  
34 the transmitted LBR. In the case of a PBB-TE MHF, this `destination_address` value will be  
35 overwritten by the value of the group MAC address in the Reverse MAC field of the PBB-TE MIP  
36 TLV, if this is present. In the case of a PBB-TE MEP, the `destination_address` parameter for the  
37 transmitted LBR is the value of the ESP-DA of the MA's ESP that has the replying MEP's MAC  
38 address [item i) in 12.14.7.1.3] in its ESP-SA field.
- 39 b) The `source_address` parameter for the LBR is the MAC address of the replying MP. If the MP is  
40 associated with a PBB-TE MHF, the `source_address` is set to the `destination_address` of the received  
41 LBM if this is an individual MAC address or otherwise to the value carried in the Reverse MAC  
42 field, contained in the PBB-TE MIP TLV.
- 43 c) If the LBM was received at a PBB-TE MHF and contains a PBB-TE MIP TLV, then the  
44 `vlan_identifier` in the LBR is set to the value in the Reverse VID field; otherwise, the `vlan_identifier`  
45 in the LBR is set to the value of the Primary VID associated with the replying MP [item d) in  
46 12.14.7.1.3, item a) in 12.14.3.2.2, item c) in 12.14.5.3.2].
- 47 d) The OpCode field is changed from LBM to LBR.

- 1 e) (Only in PBB-TE MAs) The `vlan_identifier` for the LBR is the Primary VID [item d) in 12.14.7.1.3]  
2 associated with the replying PBB-TE MEP; otherwise, if the received LBM contained a PBB-TE  
3 MIP TLV, the value in the Reverse VID field is used as the `vlan_identifier` parameter.

4 The receiver of an LBM shall not interpret any of the other fields or TLVs in the LBM. The contents of any  
5 TLVs that do not violate the validation criteria of 20.51, but are not specified in this standard, and any valid  
6 Organization-Specific TLV not known to the receiving MP, shall be ignored, and not interpreted, by the  
7 receiver, except that their contents shall be copied to the LBR.

8 NOTE—This standard provides no means for transmitting an LBM with a group MAC address. The MP Loopback  
9 Responder responds to LBMs sent to the CCM Group address because ITU-T G.8013/Y.1731 provides for transmitting  
10 such messages. See J.4.

### 11 20.2.3 LBR reception

12 When an LBR is received by a MEP Loopback Initiator (19.2.11), it is checked to see whether the  
13 `destination_address` parameter matches the MAC address of the receiving MEP, and discarded if not. Next it  
14 is checked to see whether its Loopback Transaction Identifier field matches that of a recently transmitted  
15 LBM, and the appropriate counter incremented, either the in-sequence counter [item y) in 12.14.7.1.3] or the  
16 out-of-sequence counter [item z) in 12.14.7.1.3].

17 If the Shared MP address model for implementing CFM is used by a particular Bridge, then as mentioned in  
18 20.52, there is an ambiguity in the identification of the particular Up MP to which an LBR is destined.  
19 Therefore, a Bridge using this model uses a single variable for managing the Loopback Transaction  
20 Identifier fields for all MPs sharing the same MAC address, MAID, and MD Level.

21 The receiver of an LBR may compare its contents bit-for-bit with the remembered contents of the  
22 corresponding LBM, and increment a variable [item aa) in 12.14.7.1.3] if they do not match.

## 23 20.3 Linktrace protocol

24 The Linktrace protocol is performed by the MEP Linktrace Initiator (19.2.12), associated with a single MEP,  
25 and the Linktrace Responder (19.6) associated with a Bridge.

26 A Linktrace Message (LTM) is transmitted by a MEP Linktrace Initiator in order to perform path discovery  
27 and fault isolation. The LTM carries a target MAC address. It is carried in a frame, with a  
28 `destination_address` taken from Table 8-19 according to the MD Level of the transmitting MEP, or the  
29 ESP-DA field of the appropriate ESP in the case of a PBB-TE MA (20.31.1), or an individual or group  
30 address in the case of an SPBM VID MA, and is relayed as such through the bridged network until it reaches  
31 an MP at the appropriate MD Level. That MP intercepts the LTM and deflects it to a Bridge's Linktrace  
32 Responder. The Linktrace Responder determines whether its Bridge's MAC Relay Entity would forward an  
33 ordinary data frame with the specified target MAC address and `vlan_identifier` to an egress Bridge Port, or  
34 would filter or flood it. If the single egress port is found, or if the receiving MP is the terminating MP, or if  
35 the MP is associated with a PBB-TE MA or an SPBM VID MA, the Linktrace Responder sends a unicast  
36 Linktrace Reply (LTR) to the originator of the LTM, whose MAC address was also carried as payload in the  
37 LTM. The LTR is sent after a random delay in the range  $0 < \text{delay} \leq 1 \text{ s}$ , to mitigate the load on the  
38 originating MEP. In addition, if the MP through which the LTM was received was an MHF, the Linktrace  
39 Responder forwards an altered version of the LTM in the direction of the target MAC address. The MEP  
40 Linktrace Initiator that originated the initial LTM collects the LTRs. These provide sufficient information to  
41 construct the sequence of MPs that would be traversed by a data frame sent to the target MAC address.

1 Path discovery in a connectionless environment is more challenging than a connection-oriented  
2 environment. In Bridged Networks, it can be especially challenging, since the MAC address of the target of  
3 an LTM can be deleted from the FDB by a TCN immediately after a network topology change, and ages out  
4 and is deleted a few minutes (Max Age) after last being learned when a fault results in isolating the target  
5 from the MEP originating the LTM.

6 CFM offers three ways to address the problem of ageing out MAC addresses:

- 7 a) Launching the Linktrace protocol automatically, immediately following the detection of a fault, such  
8 that it gets exercised within the Max Age window.
- 9 b) Maintaining information about the destination MP at the intermediate points along the path by using  
10 the optional MIP CCM Database, 19.3.9 and 20.1.3.
- 11 c) Maintaining normal path information by issuing periodic LTMs during normal operations.

12 NOTE—Periodic LTMs allow a system administrator to determine the MIPs along the paths among MEPs during  
13 normal operations, thus establishing a baseline for subsequent fault isolation. However, triggering LTMs at rates  
14 approaching the CCM transmission interval could overwhelm the Bridges' ability to process CFM PDUs. See also 22.5.

### 15 20.3.1 LTM origination

16 LTMs are transmitted by a MEP Linktrace Initiator in response to an operator command (12.14.7.4). The  
17 nextLTMtransID [item b) in 12.14.7.4.3, 20.41.1] of each LTM transmitted is retained for at least 5 s after  
18 the LTM is transmitted. The LTM Transaction Identifier values transmitted by a given MEP are unique over  
19 this time period in order to match LTRs returned by slow MPs to the LTM that triggered the slow LTR.  
20 Initializing the nextLTMtransID to a random value<sup>35</sup> and incrementing it once per LTM transmitted satisfies  
21 this criterion. For each LTM transmitted, the MEP Linktrace Initiator creates an entry in a Linktrace  
22 database (20.41.2). This entry is indexed by nextLTMtransID for retrieval when a corresponding LTR is  
23 received.

24 The transmitting Bridge can maintain a separate sequence of LTM Transaction Identifiers per MEP if  
25 multiple MEPs in the same service instance and at the same MD Level have different MAC addresses, but  
26 uses a common sequence of LTM Transaction Identifiers for MEPs that share both of these characteristics.

27 In the case of a VID-based MA, the destination\_address of an LTM is the group MAC address reserved for  
28 LTMs and appropriate to the MD Level of the originating MEP according to Table 8-19. In the case of a  
29 PBB-TE MEP, the destination\_address of an LTM is the entry in the ESP-DA field of the 3-tuple of the MA's  
30 ESP that has the MEP's MAC address in its ESP-SA field. In the case of an SPBM VID MEP, the  
31 destination\_address of an LTM is the individual B-MAC address of a remote system or the SPBM group  
32 MAC address (27.15) associated with an I-SID associated with the source MEP.

33 The Target MAC Address field [item c) in 12.14.7.4.2, 21.8.6] in the LTM can be any individual MAC  
34 address. However, since MEPs are required to periodically transmit CCMs, a MEP's MAC address is likely  
35 to be known to the MIPs along the path. Conversely, a MIP's MAC address, because the MIP does not  
36 initiate any CFM PDUs, can be unknown to intermediate Bridges unless it has recently replied to an LBM or  
37 LTM.

38 In the case of a PBB-TE MA, a PBB-TE MIP TLV is carried by the LTM, containing the Reverse VID  
39 [21.7.5.2, item e) in 12.14.7.4.2], to be used in the VID field by a MIP transmitted LTR, and, when the LTM  
40 is to be sent on a point-to-multipoint TESI, the Reverse MAC field (21.7.5.3) associated with MAC  
41 addresses to be used by the corresponding LTRs. The MIP MAC address field (21.7.5.1) in a PBB-TE MIP  
42 TLV associated with an LTM is null.

<sup>35</sup> For this purpose, a pseudo-random value is sufficient, provided that the same value is not produced each time a system is reinitialized.

1 The MEP Linktrace Initiator in a Down MEP transmits the LTM through its Active SAP, toward the LAN  
2 attached to its Bridge Port. The MEP Linktrace Initiator in an Up MEP transmits the LTM through its MEP  
3 LTI SAP to its own Bridge's Linktrace Responder. That Linktrace Responder handles the LTM as described  
4 in 20.3.2. The Linktrace Responder can forward the LTM through the LOM Linktrace SAP and can respond  
5 through the MEP LTI SAP with an LTR. Thus, when an LTM is initiated in an Up MEP, the originating  
6 Bridge is the first hop.

### 7 **20.3.2 LTM reception, forwarding, and replying**

8 An LTM at a particular MD Level is forwarded as an ordinary data frame until it encounters a MEP at an  
9 equal or higher MD Level, or an MHF at an equal MD Level. A MEP at a higher MD Level discards the  
10 LTM without further processing. An MP at an equal MD Level directs the LTM to its Bridge's Linktrace  
11 Responder. Since, for a given MD Level, different Bridge Ports on a given Bridge can be configured with  
12 MHFs, MEPs, both, or neither, an LTM can be both forwarded as ordinary data and processed by the  
13 Bridge's Linktrace Responder. An LTM that is originated by an Up MEP is forwarded directly to its Bridge's  
14 Linktrace Responder and not through the MEP's Active SAP toward the Frame filtering process.

15 The Linktrace Responder is responsible for processing and forwarding LTMs, and for replying to them with  
16 LTRs. All LTMs are subject to the validation criteria of 20.51.4; invalid or incorrectly addressed LTMs are  
17 discarded without further processing. After processing the LTM, the Linktrace Responder can return an LTR  
18 through the SAP on which the LTM was received and can forward at most one altered copy of the received  
19 LTM through an LOM on a different Bridge Port. It never forwards an LTM past a MEP at the LTM's own  
20 MD Level or higher, i.e., a MEP that bounds the LTM's MA. An LTM carries an LTM TTL field (21.8.4)  
21 that is decremented each time the LTM passes through a Linktrace Responder. The LTM is not forwarded if  
22 this field is 0 or 1 when the LTM is received.

23 The Linktrace Responder replies to the LTM if:

- 24 a) An ordinary data frame, with the same `vlan_identifier` as the LTM, a `destination_address` equal to the  
25 Target MAC Address field (21.8.6) of the LTM and received on the same Bridge Port as the LTM,  
26 would be forwarded through exactly one other Bridge Port (or to just the Management Port); or
- 27 b) The `UseFDBOnly` bit of the Flags field of the LTM is 0, the Target MAC Address field (21.8.6) of  
28 the LTM is found in the Bridge's MIP CCM Database (19.3.10), and that entry in the MIP CCM  
29 Database identifies a Bridge Port (or the Management Port), other than the one on which the LTM  
30 was received; or
- 31 c) The MAC address of the MP that received the LTM equals the Target MAC Address field of the  
32 LTM;

33 and

- 34 d) LTM TTL field is nonzero when the LTM is received.

35 The single output Port identified in the preceding item a) or item b) is called the Egress Port. The Linktrace  
36 Responder forwards a copy of the LTM through the LOM on the Egress Port, with a new `source_address`  
37 parameter and the LTM TTL field decremented by 1, only if all of the following conditions are met:

- 38 e) An LTR was generated for the reasons specified in the preceding item a) or item b), but not item c);
- 39 f) The LTM was received via an MHF Linktrace SAP or a MEP LTI SAP, and not a MEP Linktrace  
40 SAP;
- 41 g) The Egress Port does not have a MEP at or above the LTM's MD Level; and
- 42 h) The received LTM TTL field was greater than 1.

1 The `source_address` parameter in the forwarded LTM does not change if the MA is associated to a TESI.  
2 NOTE 1—When tracing the path to a known MAC address, all of the Bridges on a shared medium will receive the LTM.  
3 Making transmission of the LTR and forwarding of the LTM conditional on the FDB query ensures that at most one of  
4 those Bridges will reply. Similarly an LTM can be flooded, through a region of the network that has not yet learned the  
5 target MAC address, without provoking a storm of LTRs.

6 LTMs are forwarded immediately in order to minimize the time required to complete a Linktrace operation.  
7 LTRs are enqueued for delivery at a later time. If the LTM was received by a Down MEP or a Down MHF,  
8 the LTR includes a Reply Ingress TLV (21.9.8) describing that MP. If not received by a Down MEP, and if  
9 the Egress Port has an Up MEP or Up MHF configured for the LTM's MA, the LTR includes a Reply Egress  
10 TLV (21.9.9). These TLVs report, to the originating MEP, the MIPs and/or the MEP along the path to the  
11 targeted MAC address.

12 If an LTM is forwarded to a shared medium LAN, and if one or more of the other Bridges attached to that  
13 LAN have only two Bridge Ports forwarding data for the LTM's `vlan_identifier` (including that shared  
14 medium), and if the MAC address in the LTM's Target MAC Address field (21.8.6) is not present in those  
15 Bridge's FDBs (or if the targeted MAC address is present in more than one Bridge's MIP CCM Database),  
16 then more than one of those receiving Bridges can respond to the LTM with an LTR. Also, an anomaly in the  
17 operation of Bridge or LAN, e.g., an FDB is recording its information incorrectly, can cause LTR responses  
18 along multiple paths.

19 The Reply TTL field in the LTR is sufficient for the originating MEP Linktrace Initiator to order the LTRs  
20 returned along a single path. The LTMs (21.8) also include the LTM Egress Identifier TLV (21.8.8). The  
21 LTRs (21.9) also include the LTR Egress Identifier TLV (21.9.7). The information in these TLVs allows the  
22 originating MEP to unambiguously construct the tree of paths taken by the LTM, if LTRs are returned along  
23 multiple paths.

24 NOTE 2—If an MA cannot be configured to transmit CCMs more quickly than Max Age causes MAC addresses to be  
25 removed from the Bridges' FDBs, then the best practice for the system administrator is to trigger an LTM transmission  
26 only after triggering a few LBMs to the target MAC address. This helps to ensure that the target MAC address is known  
27 to the intermediate Bridges, so that the LBM will return a result, and so that LTRs will be returned only along a single  
28 path.

29 NOTE 3—If unusual conditions prompt responses along multiple paths, the delay in transmitting the LTR reduces the  
30 chance that the originating MEP's receiving capabilities will be overwhelmed by the returned LTRs.

31 NOTE 4—The forwarded LTM uses, as its source address, the address of the MP through which the LTM is forwarded,  
32 not the source address of the original LTM. This means that a Bridge's Linktrace Responder need not be fully  
33 synchronized with its Relay Entity, as the latter can change the active topology rapidly without the risk of an adjacent  
34 Bridge learning the wrong direction for the source MAC address from an LTM. However, in the case of TESIs, the  
35 forwarded LTM simply uses the source address of the original LTM since the previous considerations do not apply in a  
36 PBB-TE Region. The LTM TTL field ensures that an LTM that is being processed while the active topology is changing  
37 will not be forwarded in a persistent loop.

38 The MEP Linktrace Initiator ignores any TLVs received in an LTR that do not violate the validation criteria  
39 of 20.51, but are not specified in this standard, and it ignores any valid Organization-Specific TLV not  
40 known to it. Except as otherwise specified in 20.47.3 and 20.47.4, all TLVs, whether known or ignored by  
41 the Linktrace Responder, are copied from the received LTM to the forwarded LTM, and from the received  
42 LTM to the LTR.

43 NOTE 5—Forwarding all unknown TLVs in both the LTM and the LTR enables future revisions of this standard, and  
44 designers of Organization-Specific TLVs, to add new capabilities.

### 45 20.3.3 LTR reception

46 LTRs are transmitted by a Linktrace Responder in response to a received LTM and returned in a unicast  
47 frame to the MEP Linktrace Initiator that originated the LTM. The MEP Linktrace Initiator validates the  
48 received LTR, discarding it if invalid, if the `destination_address` parameter does not match the MAC address  
49 of the Bridge Port on which the MEP resides, or if the LTR Transaction Identifier field does not match any  
50 of those stored in the MEP's Linktrace database (20.41.2), created when the LTM was originated.

Each validated LTR triggers the creation of a new entry in the Linktrace database, accessible as a managed object through the Read Linktrace Reply command (12.14.7.5). If no entry exists in the Linktrace database for this MEP, corresponding to the LTR Transaction Identifier field, the MEP Linktrace Initiator creates a new entry, with an index value [item c) in 12.14.7.5.2] of 1. If an entry does exist matching that field, it creates a new entry, with an index value one greater than the last matching LTR. In either case, the MEP Linktrace Initiator stores the contents of the LTR in this new entry.

See J.5 for a description of a method to reconstruct the path(s) taken by an LTM, based on the information in the Linktrace database.

## 20.4 CFM state machines

The relationships among a MEP's state machines are illustrated in Figure 20-1. That figure uses conventions similar to those of 13.24 and of Figure 13-13: open arrows denote variables that are set by one state machine and both read and set by another; closed arrows denote variables that are set by the owning state machine, and only read by other state machines. Not included in Figure 20-1 are the MEP Continuity Check Initiator state machine, the MP Loopback Responder state machine used in the MEP, and all of the MHF and Linktrace Responder state machines, because they operate independently.

## 20.5 CFM state machine timers

The timer variables declared in this subclause are part of the specification of the operation of CFM. The accompanying descriptions of their meaning and use are provided to aid in the comprehension of the protocol only and are not part of the specification.

One instance of the following shall be implemented:

- a) LTFwhile (20.5.1)

One instance of the following shall be implemented per MEP:

- b) CCIwhile (20.5.2)
- c) errorCCMwhile (20.5.3)
- d) xconCCMwhile (20.5.4)
- e) LBIwhile (20.5.5)
- f) FNGwhile (20.5.6)

One instance of the following shall be implemented per PBB-TE MEP implementing the Traffic field (21.6.1.4):

- g) mmCCMwhile (20.5.7)
- h) mmLocwhile (20.5.8)
- i) mmFNGwhile (20.5.9)

One instance per MEP of the following shall be implemented for each remote MEP in the MEP's MA (those MEPs in the MA other than the MEP, itself):

- j) rMEPwhile (20.5.10)

The "granularity" of a timer variable is the periodicity with which it is decremented.

### 20.5.1 LTFwhile

A timer variable used by the LTR Transmitter state machine to time out the expected transmission of LTRs.

Figure 20-1—MEP state machines—overview and relationships

## 1 **20.5.2 CCIwhile**

2 Timer counter for transmitting CCMs. CCIwhile has a granularity finer than or equal to 1/4 of the time  
3 represented by the CCMinterval variable.

## 4 **20.5.3 errorCCMwhile**

5 Timer counter for timing out invalid CCMs. errorCCMwhile has a granularity finer than or equal to 1 ms.

## 6 **20.5.4 xconCCMwhile**

7 Timer counter for timing out cross connect CCMs. xconCCMwhile has a granularity finer than or equal to  
8 1 ms.

## 9 **20.5.5 LBIwhile**

10 A timer variable used by the MEP Loopback Initiator transmit state machine to time out the expected  
11 reception of LBRs.

## 12 **20.5.6 FNGwhile**

13 A timer variable used by the MEP Fault Notification Generator state machine to wait for defects to stabilize  
14 and disappear.

## 15 **20.5.7 mmCCMwhile**

16 Timer counter for declaring mismatch defects based on the received Traffic field. mmCCMwhile has a  
17 granularity finer than or equal to 1 ms.

## 18 **20.5.8 mmLocwhile**

19 Timer counter for declaring mismatch defects based on inconsistencies in locally declared values (20.9.9).  
20 mmLocwhile has a granularity finer than or equal to 1 ms.

## 21 **20.5.9 mmFNGwhile**

22 A timer variable used by the MEP Mismatch Fault Notification Generator state machine (20.40) to wait for  
23 defects to stabilize and disappear.

## 24 **20.5.10 rMEPwhile**

25 Timer counter for timing out CCMs. rMEPwhile has a granularity finer than or equal to 1/4 of the time  
26 represented by the CCMinterval variable. A Bridge shall not set rMEPCCMdefect within  
27  $(3.25 \times \text{CCMtime}(\text{CCMinterval}))$  seconds of the receipt of a CCM, and shall set rMEPCCMdefect  
28 within  $(3.5 \times \text{CCMtime}(\text{CCMinterval}))$  seconds after the receipt of the last CCM. This variable is readable  
29 as a managed object [item c) in 12.14.7.6.3].

30 NOTE—In order to generate a Defect upon the loss of three CCMs, but not generate a Defect when only two CCMs  
31 have been lost, a minimum resolution is required for rMEPwhile. The granularity specified for rMEPwhile, when used  
32 with the state machine in Figure 20-5, generates a Defect in a maximum of  $(3.5 \times \text{CCMtime}(\text{CCMinterval}))$  seconds, and  
33 a minimum of  $(3.25 \times \text{CCMtime}(\text{CCMinterval}))$  seconds.

## 1 20.6 CFM procedures

2 The following procedure is global to the system:

- 3 a) CCMtime() (20.6.1)

### 4 20.6.1 CCMtime()

5 CCMtime() takes, as a parameter, a value of the form used in the CCMinterval variable (20.8.1) and the  
6 CCM Interval field in a CCM PDU (21.6.1.3). It returns, as a value, the corresponding time interval, in the  
7 form used by the CCIwhile or rMEPwhile timer, as appropriate (20.5.2, 20.5.10).

## 8 20.7 Maintenance Domain variable

9 The following variable is local to a single Maintenance Domain and is accessible by more than one state  
10 machine:

- 11 a) mdLevel (20.7.1)

### 12 20.7.1 mdLevel

13 The integer MD Level of the Maintenance Domain. This variable is available as a managed object [item b]  
14 in 12.14.5.1.3].

## 15 20.8 MA variables

16 The following variable is local to a single MA and is accessible by more than one state machine:

- 17 a) CCMinterval (20.8.1)

### 18 20.8.1 CCMinterval

19 The configured time between CCM transmissions. The value configured for this variable shall be one of the  
20 nonzero values in Table 21-15. This variable is available as a managed object [item e) in 12.14.6.1.3].

## 21 20.9 MEP variables

22 The following variables are local to a single MEP and are accessible by more than one state machine:

- 23 a) MEPactive (20.9.1)  
24 b) enableRmepDefect (20.9.2)  
25 c) MAdefectIndication (20.9.3)  
26 d) allRMEPsDead (20.9.4)  
27 e) lowestAlarmPri (20.9.5)  
28 f) presentRDI (20.9.6)  
29 g) MEPprimaryVID (20.9.7)

30 The following variables may be present only in PBB-TE MAs, are local to a single PBB-TE MEP and are  
31 accessible by more than one state machine:

- 32 h) presentTraffic (20.9.8)  
33 i) presentmmLoc (20.9.9)

The following variables are present only in Infrastructure Segment MAs, are local to a single Infrastructure Segment MEP, and are accessible by more than one state machine:

- j) ISpresentTraffic (20.9.10)
- k) ISpresentmmLoc (20.9.11)

The following variable is present only in ECMP path MAs, is local to a single ECMP path MEP, and is accessible by more than one state machine:

- l) EpMEP (20.9.12)

## 20.9.1 MEPactive

A Boolean indicating the administrative state of the MEP. True indicates that the MEP is to function normally, and false that it is to cease functioning. This variable is available as a managed object [item e) in 12.14.7.1.3].

NOTE—MEPactive controls the BEGIN input to the MEP state machines. Therefore, for any MEP that has been completely configured, it is as much an indication of the operative state of the MEP as a control over that state.

## 20.9.2 enableRmepDefect

A Boolean indicating whether frames on the service instance monitored by this MEP's MA are enabled to pass through this Bridge Port by the spanning tree protocol (Clause 13) and VLAN topology management (Clause 11). Set true either if they are enabled, or if the MEP is not associated with a single value of the Port State and VID member set, else false. In a Bridge, the value of enableRmepDefect is determined from the Port State (8.4) of the spanning tree instance that controls the MEP's Primary VID, and that VID's member set (8.8.10), as shown in Table 20-2. This variable also controls the value output in the Port Status TLV (21.5.4).

**Table 20-2—Deriving enableRmepDefect and Port Status TLV in a Bridge**

| Port State (8.4)                                                          | Bridge Port in Primary VID's member set | Port Status TLV (21.5.4) | enableRmepDefect |
|---------------------------------------------------------------------------|-----------------------------------------|--------------------------|------------------|
| Disabled, blocked, listening, broken, discarding <sup>a</sup> or learning |                                         | psBlocked                | False            |
| Forwarding                                                                | No                                      | psBlocked                | False            |
|                                                                           | Yes                                     | psUp                     | True             |

<sup>a</sup> “Discarding” is used in place of the values disabled, blocked, listening, or broken defined in IETF RFC 4318.

A MEP that is:

- a) Configured in an MA that is not associated with a VID
- b) On a Bridge that is running multiple instances of the spanning tree
- c) On a Bridge Port that is not excluded by Static VLAN Registration Entries from membership in VIDs belonging to more than one spanning tree instance

can be unable to generate an unambiguous value for the Port Status TLV, because different MSTIs can be in different Port States. For a MEP in that position, enableRmepDefect is always true.

### 1 **20.9.3 MAdefectIndication**

2 A Boolean indicating the operational state of the MEP's MA. True indicates that at least one of the remote  
3 MEPs configured on this MEP's MA has failed, and false indicates either that all are functioning, or that the  
4 MEP has been active for less than the time-out period. MAdefectIndication is true whenever an enabled  
5 defect is indicated. That is, MAdefectIndication is true if and only if, for one or more of the variables  
6 someRDId defect, someRMEPCCMdefect, someMACstatusDefect, errorCCMdefect, or xconCCMdefect,  
7 that variable is true and the corresponding priority of that variable from Table 20-1 is greater than or equal to  
8 the value of the variable lowestAlarmPri.

### 9 **20.9.4 allRMEPsDead**

10 A Boolean indicating that this MEP is receiving none of the remote MEPs' CCMs. allRMEPsDead is the  
11 logical AND of all of the rMEPCCMdefect variables.

### 12 **20.9.5 lowestAlarmPri**

13 An integer value indicating the lowest defect priority (see Table 20-1) that can trigger the generation of a  
14 Fault Alarm. This variable is a managed object [item k) in 12.14.7.1.3].

### 15 **20.9.6 presentRDI**

16 A Boolean value indicating the state of the RDI bit in CCMs transmitted by this MEP. presentRDI is true if  
17 and only if one or more of the variables someRMEPCCMdefect, someMACstatusDefect, errorCCMdefect,  
18 or xconCCMdefect is true, and if the corresponding priority of that variable, from Table 20-1, is greater than  
19 or equal to the value of the variable lowestAlarmPri.

### 20 **20.9.7 MEPprimaryVID**

21 An integer specifying a VID, one of the VIDs assigned to the MEP's MA, which is to be used as the Primary  
22 VID for this MEP. This variable is related to the managed object item d) in 12.14.7.1.3. It is not necessarily  
23 numerically equal to that object, however. MEPprimaryVID always contains the numerical value of the  
24 Primary VID. The managed object may contain 0, to indicate that the Primary VID is that of the MEP's MA,  
25 or contain the Primary VID itself, if the MA's VID is overridden for this particular MEP. In the case of a  
26 MEP associated with a PBB-TE MA, this value is not directly configurable but it takes the value of the  
27 ESP-VID field in the 3-tuple of the PBB-TE MA's ESP that has the MEP's MAC address in its ESP-SA  
28 field.

### 29 **20.9.8 presentTraffic**

30 A Boolean value indicating if at least one backbone service instance is configured to use the TESI's ESP  
31 upon which this PBB-TE MEP is transmitting CCMs. presentTraffic is TRUE if and only if the Backbone  
32 Service Instance table, of the CBP associated with this MEP, contains an entry that has in its B-VID and  
33 Default Backbone Destination fields the values of ESP-VID and ESP-DA of the monitored TESI's ESP that  
34 originates at the MEP.

### 35 **20.9.9 presentmmLoc**

36 presentmmLoc is the logical AND of presentRDI (20.9.6) and presentTraffic (20.9.8).

## 1 **20.9.10 ISpresentTraffic**

2 A Boolean value indicating if at least one TESI protected by the IPG is configured to use the segment  
3 monitored by the Infrastructure Segment MEP. ISpresentTraffic is TRUE if and only if the port upon which  
4 this MEP is configured is the outbound port of the entry in the FDB corresponding to the TESI protected by  
5 the IPG.

## 6 **20.9.11 ISpresentmmLoc**

7 ISpresentmmLoc is the logical AND of presentRDI (20.9.6) and ISpresentTraffic (20.9.10).

## 8 **20.9.12 EpMEP**

9 Boolean. This variable is used to condition actions related to ECMP path MEPs. It is true for ECMP path  
10 MEPs and false otherwise.

## 11 **20.10 MEP Continuity Check Initiator variables**

12 The following variables are local to the MEP Continuity Check Initiator state machine:

- 13 a) CClenabled (20.10.1)
- 14 b) CCIsentCCMs (20.10.2)
- 15 c) MACstatusChanged (20.10.3)
- 16 d) Npaths (20.10.4)
- 17 e) flowHash[] (20.10.5)
- 18 f) pathN (20.10.6)
- 19 g) CCMcnt (20.10.7)

### 20 **20.10.1 CClenabled**

21 Controls the transmission of CCMs. When set to true, CCMs are transmitted. When set to false, CCM  
22 transmission ceases. This variable is available as a managed object [item g) in 12.14.7.1.3].

### 23 **20.10.2 CCIsentCCMs**

24 Integer value. CCIsentCCMs is initialized to 1 when the MEP is created and may be used thereafter by  
25 xmitCCM() to fill the Sequence Number field of a transmitted CCM. This variable is available as a managed  
26 object [item w) in 12.14.7.1.3].

### 27 **20.10.3 MACstatusChanged**

28 Boolean. MACstatusChanged triggers the transmission of one extra CCM. If the Port Status TLV (21.5.4) or  
29 Interface Status TLV (21.5.5) is being transmitted by the MEP, and if CCMinterval indicates a transmission  
30 interval of 10 s or slower, MACstatusChanged is set to true whenever the value reported in either of those  
31 two TLVs changes. MACstatusChanged is reset to false by the MEP Continuity Check Initiator state  
32 machine.

### 33 **20.10.4 Npaths**

34 Integer value. The number of paths being tested by this MEP. The value is 1 (default) except in the case of  
35 ECMP path MEPs that may test a set of paths by using one destination address and different flow hash  
36 values.

## 1 20.10.5 flowHash[ ]

2 This variable is applicable only for ECMP path MEPs.

3 Array of 16-bit values. A set of flow hash values used to test a set of paths to a given destination address.

4 The default is a single NULL value.

## 5 20.10.6 pathN

6 This variable is applicable only for ECMP path MEPs.

7 Integer value in the range 0..(Npaths – 1) and all arithmetic using this variable is modulo Npaths. The index  
8 of the current path (flow hash) being used in CCMs sent from the MEP. This value is shared with the Remote  
9 MEP state machine to enable correlation of received RDIs with the cycle of paths being tested.

## 10 20.10.7 CCMcnt

11 This variable is applicable only for ECMP path MEPs.

12 Integer value in the range 0..3 and all arithmetic using this variable is modulo 4. This variable is a counter  
13 used to send each flowHash[] value in four successive CCMs.

## 14 20.11 MEP Continuity Check Initiator procedures

15 The following procedure is local to the MEP Continuity Check Initiator state machine:

16 a) xmitCCM() (20.11.1)

### 17 20.11.1 xmitCCM()

18 xmitCCM() constructs and transmits a CCM on the Active SAP using an M\_UNITDATA.request as follows:

- 19 a) Sets the destination\_address parameter to the value from Table 8-18 corresponding to the MEP's  
20 MD Level. In the case of a PBB-TE associated MEP, SPBM path MEP, or ECMP path MEP, the  
21 destination\_address parameter is set to the MAC address indicated by the ESP-DA field of the ESP  
22 having in its ESP-SA field the MAC address of the MEP. In the case of an SPBM VID MEP  
23 (27.18.1), the destination\_address parameter is set to the SPBM group MAC address (27.15)  
24 associated with the source MEP and the SPBM default I-SID. In the case of an SPBM group MEP,  
25 the destination\_address parameter is set to the SPBM group MAC address (27.15) assigned to the  
26 source MEP's CBP for the SPBM group MA's I-SID.
- 27 b) Sets the source\_address parameter to the MAC address of the MEP [item i) in 12.14.7.1.3].
- 28 c) Sets the priority parameter according to the MEP's managed objects [item h) in 12.14.7.1.3].
- 29 d) Sets the drop\_eligible parameter to false.
- 30 e) In the case of ECMP with flow filtering, the time\_to\_live and flow\_hash parameters must be set.  
31 The time\_to\_live parameter is set to the TTL Value in the Flow Filtering Control Table entry on the  
32 CBP for the source MEP's VID [item d) in 12.16.5.5.2]. In the case of an SPBM VID MEP or  
33 SPBM group MEP, the flow\_hash parameter is set to zero. In the case of an ECMP path MEP, the  
34 flow\_hash parameter is set to the value of flowHash[pathN].
- 35 f) Places the MEP's MD Level (20.7.1) in the MD Level field (21.4.1).
- 36 g) Fills the CCM Interval field (21.6.1.3) with the CCM transmission interval [20.8.1, item e) in  
37 12.14.6.1.3].
- 38 h) Fills the RDI field (21.6.1.1) with the presentRDI variable (20.9.6).
- 39 i) Should copy CCI sent CCMs (20.10.2) to the Sequence Number field of the CCM (21.6.3), else  
40 copies 0 into that field.

- 1 j) Places the MEP's MAID into the appropriate fields of the CCM [item a) in 12.14.1.2.2, item b) in
- 2 12.14.5.3.2, and 21.6.5.1 through 21.6.5.6].
- 3 k) Places the MEP's MEPID [item g) in 12.14.6.1.3] into the Maintenance association Endpoint
- 4 Identifier field (21.6.4).
- 5 l) As controlled by the managed objects item e) in 12.14.3.1.3, item d) in 12.14.5.1.3, and item d) in
- 6 12.14.6.1.3, places a Sender ID TLV (21.5.3) in the CCM, identifying the transmitting system.
- 7 m) Optionally, places a Port Status TLV (21.5.4) in the CCM, reporting the status of the Bridge Port.
- 8 n) Optionally, places an Interface Status TLV (21.5.5) in the CCM, reporting the status of the Bridge
- 9 Port.
- 10 o) Increments CCI<sub>sentCCMs</sub> by 1, wrapping around from 232 – 1 to 0.
- 11 p) Only in the case of a PBB-TE MEP, optionally fills the Traffic field (21.6.1.4) with the
- 12 presentTraffic variable (20.9.8).
- 13 q) Only in the case of an Infrastructure Segment MEP, optionally fills the Traffic field (21.6.1.4) with
- 14 the value IS<sub>presentTraffic</sub> (20.9.10).

## 15 20.12 MEP Continuity Check Initiator state machine

16 Each MEP Continuity Check Initiator (19.2.9) instantiates one MEP Continuity Check Initiator state  
17 machine. The MEP Continuity Check Initiator state machine implements the function specified by the state  
18 diagram in Figure 20-2, the variable declarations in 20.10 and the procedures in 20.11.

**Figure 20-2—MEP Continuity Check Initiator state machine**

19 NOTE—Figure 20-2 indicates that the setting of MACstatusChanged causes CCIwhile to be reset and thus changes the  
20 phase of the CCM transmission cycle. An alternative formulation of state machine could transmit an extra CCM, but not  
21 reset CCIwhile. Whether setting MACstatusChanged in a MEP causes CCIwhile to be reset is not specified by this  
22 standard.

## 23 20.13 MHF Continuity Check Receiver variables

24 The following variables are defined for the MHF Continuity Check Receiver:

- 25 a) MHFrecvdCCM (20.13.1)
- 26 b) MHFCCMPDU (20.13.2)

### 20.13.1 MHFrecvCCM

A Boolean value set to true by the MHF OpCode Demultiplexer (19.3.6) when a CCM at the MHF's MD Level is received. Cleared by the MHF Continuity Check Receiver state machine.

### 20.13.2 MHFCCMPDU

Structure. Loaded with the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the CCM PDU received by the MHF OpCode Demultiplexer (19.3.6) when a CCM at the MHF's MD Level is received.

## 20.14 MHF Continuity Check Receiver procedures

The following procedure is defined for the MHF Continuity Check Receiver:

a) MHFprocessCCM() (20.14.1)

### 20.14.1 MHFprocessCCM()

MHFprocessCCM() shall validate the received CCM according to 20.51.4 and discard the received CCM if invalid. Otherwise, MHFprocessCCM() records the FID, source\_address, and Port number of the received CCM in the MHF's MIP CCM Database.

## 20.15 MHF Continuity Check Receiver state machine

The MHF Continuity Check Receiver state machine implements the functions specified by the state diagram in Figure 20-3, using the variables in 20.13 and procedures in 20.14.

Figure 20-3—MHF Continuity Check Receiver state machine

## 20.16 MEP Continuity Check Receiver variables

The following variables are defined for the MEP Continuity Check Receiver:

- a) CCMreceivedEqual (20.16.1)
- b) CCMequalPDU (20.16.2)
- c) CCMreceivedLow (20.16.3)
- d) CCMlowPDU (20.16.4)

- 1 e) recvdMacAddress (20.16.5)
- 2 f) recvdRDI (20.16.6)
- 3 g) recvdInterval (20.16.7)
- 4 h) recvdPortState (20.16.8)
- 5 i) recvdInterfaceStatus (20.16.9)
- 6 j) recvdSenderId (20.16.10)
- 7 k) recvdFrame (20.16.11)
- 8 l) CCMsequenceErrors (20.16.12)

9 The following variable is present only in PBB-TE MEP or Infrastructure Segment MEP that supports the  
10 Traffic field (21.6.1.4), is local to a single PBB-TE MEP or Infrastructure Segment MEP, and is accessible  
11 by the MEP Mismatch state machines (20.26):

- 12 m) recvdTrafficBit (20.16.13)

### 13 **20.16.1 CCMreceivedEqual**

14 Boolean flag. Set by the MEP Equal OpCode Demultiplexer (19.2.7) when a CCM at the MEP's MD Level  
15 is received. Cleared by the MEP Continuity Check Receiver state machine.

### 16 **20.16.2 CCMequalPDU**

17 Structure. Loaded with the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the  
18 CCM PDU received by the MEP Equal OpCode Demultiplexer (19.2.7) when a CCM at the MEP's MD  
19 Level is received.

### 20 **20.16.3 CCMreceivedLow**

21 Boolean flag. Set by the MEP Low OpCode Demultiplexer (19.2.7) when a CCM below the MEP's MD  
22 Level is received. Cleared by the MEP Continuity Check Receiver state machine.

### 23 **20.16.4 CCMlowPDU**

24 Structure. Loaded with the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the  
25 CCM PDU received by the MEP Low OpCode Demultiplexer (19.2.7) when a CCM below the MEP's MD  
26 Level is received.

### 27 **20.16.5 recvdMacAddress**

28 Set by the MEPprocessEqualCCM() procedure with the source\_address from the last-received CCM from  
29 the remote MEP served by this copy of the Remote MEP state machine.

### 30 **20.16.6 recvdRDI**

31 Boolean flag. Set by MEPprocessEqualCCM() according to the RDI field of the last-received valid CCM.

### 32 **20.16.7 recvdInterval**

33 Timer counter indicating timer counter equivalent of the value encoded in the CCM Interval field of a  
34 received CCM. Set by MEPprocessEqualCCM().

## 1 20.16.8 recvdPortState

2 (optional) Enumerated variable indicating the contents of the Port Status TLV (21.5.4) of the last-received  
3 valid CCM or psNoPortStateTLV: Indicates either that no CCM has been received or that no Port Status TLV  
4 was present in the last CCM received. Set by MEPprocessEqualCCM().

## 5 20.16.9 recvdInterfaceStatus

6 (optional) Enumerated variable indicating the contents of the Interface Status TLV (21.5.5) of the  
7 last-received valid CCM or isNoInterfaceStatusTLV: Indicates either that no CCM has been received or that  
8 no Interface Status TLV was present in the last CCM received. Set by MEPprocessEqualCCM().

## 9 20.16.10 recvdSenderId

10 (optional) Enumerated variable indicating the contents of the Sender ID TLV (21.5.3) of the last-received  
11 valid CCM or isNoSenderIdTLV: Indicates either that no CCM has been received or that no Sender ID TLV  
12 was present in the last CCM received. Set by MEPprocessEqualCCM().

## 13 20.16.11 recvdFrame

14 Octet string holding a frame received by MEPprocessEqualCCM(). recvdFrame can be reconstructed either  
15 from the M\_UNITDATA.indication information presented to the MEP through the Active SAP, or from the  
16 EM\_UNITDATA.indication presented to the EISS Multiplex Entity. The size of recvdFrame indicates the  
17 size of the reconstructed frame. When set to the value NULL, the size of recvdFrame is 0.

## 18 20.16.12 CCMsequenceErrors

19 The total number of out-of-sequence CCMs received from all remote MEPs. This variable is readable as a  
20 managed object [item v) in 12.14.7.1.3].

## 21 20.16.13 rcvdTrafficBit

22 Boolean flag that is applicable only for PBB-TE MEPs and Infrastructure Segment MEPs supporting the  
23 Traffic field (21.6.1.4). Set by MEPprocessEqualCCM() according to the Traffic field of the last-received  
24 valid CCM.

## 25 20.17 MEP Continuity Check Receiver procedures

26 The following procedures are defined for the Continuity Check Receiver:

- 27 a) MEPprocessEqualCCM() (20.17.1)
- 28 b) MEPprocessLowCCM() (20.17.2)

### 29 20.17.1 MEPprocessEqualCCM()

30 Called by the MEP Continuity Check Receiver state machine whenever a CCM is received at the MD Level  
31 of the MEP. MEPprocessEqualCCM() processes the CCM contained in CCMequalPDU as follows:

- 32 a) MEPprocessEqualCCM() shall process the CCM according to 20.51.4.2, and may validate the CCM  
33 according to 20.51.4.3, and discard any frames that fail the validation.
- 34 b) Otherwise, if the MAID of the received CCM does not exactly match the MAID configured in the  
35 receiving MEP [item a) in 12.14.1.2.2, item b) in 12.14.5.3.2], then MEPprocessEqualCCM() sets  
36 xconCCMreceived (20.23.1) true (this procedural step being optional in the case of a PBB-TE MEP  
37 or Infrastructure Segment MEP, SPBM path MEP, or ECMP path MEP), reconstructs the frame

- 1 containing the CCM into recvdFrame, and places a timer counter value into recvdInterval  
2 corresponding to the value of the CCM Interval field in the received CCM.
- 3 c) Otherwise, if:
- 4 1) MEPID in the received CCM is not configured in the receiving MEP [item g) in 12.14.6.1.3],  
5 or  
6 2) MEPID in the received CCM matches the MEPID of the receiving MEP [item b) in  
7 12.14.6.3.2], or  
8 3) CCM Interval field in the received CCM does not match that configured for the receiving MEP  
9 [item e) in 12.14.6.1.3],  
10 then MEPprocessEqualCCM() sets errorCCMreceived (20.21.1) true, reconstructs the frame  
11 containing the CCM into recvdFrame, and places a timer counter value into recvdInterval  
12 corresponding to the value of the CCM Interval field in the received CCM.
- 13 d) Otherwise, MEPprocessEqualCCM()
- 14 1) Copies the source\_address parameter into recvdMacAddress.  
15 2) Copies the RDI field to recvdRDI.  
16 3) Optionally copies the Port Status TLV to recvdPortState.  
17 4) Optionally copies the Interface Status TLV to recvdInterfaceStatus.  
18 5) Optionally copies the Sender ID TLV to recvdSenderId.  
19 6) Optionally updates the Bridge's MIP CCM Database.  
20 7) Sets the rCCMreceived variable (20.19.6) for the particular instance of the Remote MEP state  
21 machine corresponding to the Maintenance association Endpoint Identifier field in the CCM.  
22 8) Only in the case of a PBB-TE MEP or Infrastructure Segment MEP, optionally copies the  
23 Traffic field (21.6.1.4) to recvdTrafficBit (20.16.13).

24 MEPprocessEqualCCM() should also:

- 25 e) Compare the Sequence Number field in the received CCM to the value saved in the MEP CCM  
26 Database.  
27 f) If both values are not 0, and if the new value is not 1 greater than the last, increment  
28 CCMsequenceErrors (20.16.12).  
29 g) Store the received Sequence Number in the MEP CCM Database.

### 30 **20.17.2 MEPprocessLowCCM()**

31 Called by the MEP Continuity Check Receiver state machine whenever a CCM is received with an MD  
32 Level that is less than the MEP's MD Level (mdLevel, 20.7.1). MEPprocessLowCCM() processes the CCM  
33 contained in CCMlowPDU as follows:

- 34 a) MEPprocessLowCCM() shall process the CCM according to 20.51.4.2, and may validate the CCM  
35 according to 20.51.4.3, and discard any frames that fail the validation.  
36 b) Otherwise, MEPprocessLowCCM() sets xconCCMreceived (20.23.1) true, reconstructs the frame  
37 containing the CCM into recvdFrame, and places a timer counter value into recvdInterval  
38 corresponding to the value of the CCM Interval field in the received CCM.

## 39 **20.18 MEP Continuity Check Receiver state machine**

40 The MEP Continuity Check Receiver state machine implements the functions specified by the state diagram  
41 in Figure 20-4, using the variables in 20.16 and procedures in 20.17.

## 20.19 Remote MEP variables

The following variables are local to the Remote MEP state machine:

- a) rMEPCCMdefect (20.19.1)
- b) rMEPlastRDI and rMEPlastRDI[i] (20.19.2)
- c) rMEPlastPortState (20.19.3)
- d) rMEPlastInterfaceStatus (20.19.4)
- e) rMEPlastSenderId (20.19.5)
- f) rCCMreceived (20.19.6)
- g) rMEPmacAddress (20.19.7)
- h) rMEPportStatusDefect (20.19.8)
- i) rMEPinterfaceStatusDefect (20.19.9)
- j) lastPathN (20.19.10)

Figure 20-4—MEP Continuity Check Receiver state machine

### 20.19.1 rMEPCCMdefect

Reports the state of the remote MEP. When true, no CCM has been received from the remote MEP for at least  $(3.25 \times \text{CCMtime}(\text{CCMinterval}))$  seconds.

### 20.19.2 rMEPlastRDI and rMEPlastRDI[i]

Boolean flag. Contains the RDI flag from the last-received CCM. This variable is readable as a managed object [item e) in 12.14.7.6.3]. In the case of an ECMP path MEP, if  $N_{\text{paths}} > 1$ , there is a set of variables  $\text{rMEPlastRDI}[i]$  of size  $N_{\text{paths}}$  (20.10.4). In this case the variable  $\text{rMEPlastRDI}$  is the logical OR of the members of the set  $\text{rMEPlastRDI}[i]$ . Each member of the set  $\text{rMEPlastRDI}[i]$  is set if an RDI is received while  $\text{pathN} = i$  and is reset if no RDI is received while  $\text{pathN} = i$  in the last CCM cycle of the MEP Continuity Check Initiator state machine.

### 1 **20.19.3 rMEPlastPortState**

2 Enumerated value. Contains the value obtained from the Port Status TLV (21.5.4) of the last-received CCM  
3 or a value indicating that the last-received CCM contained no Port Status TLV. This variable is readable as a  
4 managed object [item f) in 12.14.7.6.3].

### 5 **20.19.4 rMEPlastInterfaceStatus**

6 Enumerated value. Contains the value obtained from the Interface Status TLV (21.5.5) of the last-received  
7 CCM or a value indicating that the last-received CCM contained no Interface Status TLV. This variable is  
8 readable as a managed object [item g) in 12.14.7.6.3].

### 9 **20.19.5 rMEPlastSenderId**

10 Enumerated value. Contains the value obtained from the Sender ID TLV (21.5.3) of the last-received CCM  
11 or a value indicating that the last-received CCM contained no Sender ID TLV. This variable is readable as a  
12 managed object [item h) in 12.14.7.6.3].

### 13 **20.19.6 rCCMreceived**

14 Boolean flag set true by MEPprocessEqualCCM() to indicate that a CCM has been received that matches the  
15 configured expectations of a particular Remote MEP state machine. Cleared to false by the Remote MEP  
16 state machine.

### 17 **20.19.7 rMEPmacAddress**

18 One field in each entry in the MEP CCM Database for a remote MEP, containing source\_address of the  
19 last-received CCM from that remote MEP. This variable is readable as a managed object [item d) in  
20 12.14.7.6.3].

### 21 **20.19.8 rMEPportStatusDefect**

22 A Boolean indicating that the remote MEP is reporting a failure in its Port Status TLV (21.5.4). It is true only  
23 if the last received CCM contained a Port Status TLV that contained some value other than psUp, i.e., the  
24 remote MEP's Bridge Port is not forwarding data. It is equal to (rMEPlastPortState!= psUp &&  
25 rMEPlastPortState!= psNoPortStateTLV: Indicates either that no CCM has been received or that no Port  
26 Status TLV was present in the last CCM received).

### 27 **20.19.9 rMEPinterfaceStatusDefect**

28 A Boolean indicating that the remote MEP is reporting a failure in its Interface Status TLV (21.5.5). It is true  
29 only if the last received CCM contained an Interface Status TLV that contained some value other than isUp,  
30 i.e., the remote MEP's Bridge Port is not available for forwarding data. It is equal to  
31 (rMEPlastInterfaceStatus!= isUp && rMEPlastInterfaceStatus!= isNoInterfaceStatusTLV: Indicates either  
32 that no CCM has been received or that no Interface Status TLV was present in the last CCM received).

### 33 **20.19.10 lastPathN**

34 This variable is applicable only for ECMP path MEPs.

35 Integer value. The variable lastPathN holds the previous value of the pathN variable.

## 20.20 Remote MEP state machine

- The Remote MEP state machine implements the function specified by the state diagram in Figure 20-5 and the variable declarations in 20.19, and utilizes the procedures in 20.17.

Figure 20-5—Remote MEP state machine

## 20.21 Remote MEP Error variables

- The following variables are local to the Remote MEP Error state machine:

- errorCCMreceived (20.21.1)
- errorCCMlastFailure (20.21.2)
- errorCCMdefect (20.21.3)

## 20.21.1 errorCCMreceived

Boolean flag set true by MEPprocessEqualCCM() if an invalid CCM is received. Cleared to false by the Remote MEP Error state machine.

## 20.21.2 errorCCMlastFailure

Octet string with the same characteristics as recvdFrame. Value controlled by the Remote MEP Error state machine. Readable as a managed object [item t) in 12.14.7.1.3]. Size is sufficient to retain a frame containing a maximum-length CCM in errorCCMlastFailure.

## 20.21.3 errorCCMdefect

A Boolean flag set and cleared by the Remote MEP Error state machine to indicate that one or more invalid CCMs has been received, and that 3.5 times that CCM's transmission interval has not yet expired. This variable is readable as a managed object [item r) in 12.14.7.1.3].

## 20.22 Remote MEP Error state machine

The Remote MEP Error state machine implements the function specified by the state diagram in Figure 20-6 and the variable declarations in 20.21.

Figure 20-6—Remote MEP Error state machine

## 20.23 MEP Cross Connect variables

The following variables are local to the MEP Cross Connect state machine:

- a) xconCCMreceived (20.23.1)
- b) xconCCMlastFailure (20.23.2)
- c) xconCCMdefect (20.23.3)

### 20.23.1 xconCCMreceived

Boolean flag set true by MEPprocessEqualCCM() when a cross connect CCM is received. Cleared to false by the MEP Cross Connect state machine.

### 20.23.2 xconCCMlastFailure

Octet string with the same characteristics as recvdFrame. Value controlled by the MEP Cross Connect state machine. Readable as a managed object [item u) in 12.14.7.1.3]. Size is sufficient to retain a frame containing a maximum-length CCM.

### 20.23.3 xconCCMdefect

A Boolean flag set and cleared by the MEP Cross Connect state machine to indicate that one or more cross connect CCMs has been received, and that 3.5 times of at least one of those CCMs' transmission interval has not yet expired. This variable is readable as a managed object [item s) in 12.14.7.1.3].

## 20.24 MEP Cross Connect state machine

The MEP Cross Connect state machine implements the function specified by the state diagram in Figure 20-7 and the variable declarations in 20.23.

Figure 20-7—MEP Cross Connect state machine

## 20.25 MEP Mismatch variables

The following variables are local to the MEP Mismatch state machines for a PBB-TE MEP or Infrastructure Segment MEP implementing the Traffic field (21.6.1.4):

- a) mmCCMreceived (20.25.1)
- b) mmCCMdefect (20.25.2)
- c) mmCCMTime (20.25.3)

- 1 d) disableLocdefect (20.25.4)
- 2 e) mmLocdefect (20.25.5)

### 3 **20.25.1 mmCCMreceived**

4 Boolean flag set to TRUE when rcvdTrafficBit (20.16.13) does not match the presentTraffic (20.9.8) in the  
5 case of a PBB-TE MEP or rcvdTrafficBit (20.16.13) does not match the ISpresentTraffic (20.9.10) in the  
6 case of an Infrastructure segment MEP.

### 7 **20.25.2 mmCCMdefect**

8 A Boolean flag set and cleared by the MEP Mismatch state machines to indicate that one or more CCMs  
9 with Traffic fields not matching the presentTraffic (20.9.8) have been received in the case of a state machine  
10 associated with a PBB-TE MEP or that one or more CCMs with ISpresentTraffic (20.9.10) has been  
11 received in the case of a state machine associated with an Infrastructure Segment MEP, over a period that is  
12 greater than 3.5 times the configured CCM transmission rate and given by the mmCCMTime (20.25.3). This  
13 variable is readable as a managed object [item ah] in 12.14.7.1.3].

### 14 **20.25.3 mmCCMTime**

15 The time used to initiate the mmCCMwhile timer. This is the time taken for a remote IB-BEB to send a  
16 CCM with the correct information in the Traffic field and is tied to the target protection switching time, i.e.,  
17 50 ms, as a mismatch would be normal prior to the completion of a protection switch. In the most generic  
18 case it is equal to the Detection Time + Restoration Procedure Time + Restoration Transfer time. This gives  
19 a time of  $3.5 \times \text{CCM interval} + \text{Restoration Procedure Time} + 1.25 \times \text{CCM interval}$ . As a result its value is  
20 set to  $\max(50 \text{ ms}, 4.75 \times \text{CCMtime}(\text{CCMinterval}) + 10 \text{ ms})$ .

### 21 **20.25.4 disableLocdefect**

22 A Boolean that disables the indication of the mmLocdefect. The variable is always set to TRUE for PBB-TE  
23 MAs that are not part of a TE protection group. On a PBB-TE MEP associated with the working entity in  
24 one or more TE protection groups to which its monitoring TESI MA is assigned, disableLocdefect is TRUE  
25 if and only if either p.SF (26.10.3.3.2) or LoP (26.10.3.3.4) is TRUE on any of these TE protection groups.  
26 On a PBB-TE MEP associated with only one protection entity in all the TE protection groups to which it is  
27 assigned, disableLocdefect is TRUE if and only if FS (26.10.3.3.5) is TRUE on this TE protection group.

### 28 **20.25.5 mmLocdefect**

29 A Boolean flag set and cleared by the MEP Local Mismatch state machine to indicate that presentmmLoc  
30 (20.9.9) or ISpresentmmLoc (20.9.11) is set to TRUE, over a period of 50 ms [item ai] in 12.14.7.1.3].

## 31 **20.26 MEP Mismatch state machines**

32 The MEP Mismatch state machines implement the functions specified by the state diagrams in Figure 20-8,  
33 Figure 20-9, and the variable declarations in 20.25. There is one MEP Traffic Field Mismatch state machine  
34 and one MEP Local Mismatch state machine per PBB-TE MEP or Infrastructure Segment MEP  
35 implementing the Traffic field (21.6.1.4).

Figure 20-8—MEP Traffic Field Mismatch state machine

Figure 20-9—MEP Local Mismatch state machine

## 1 **20.27 MP Loopback Responder variables**

2 The following variables are local to the MP Loopback Responder state machine:

- 3 a) LBMreceived (20.27.1)
- 4 b) LBMPDU (20.27.2)

### 5 **20.27.1 LBMreceived**

6 Boolean variable, set to true by an MP OpCode Demultiplexer when an LBM is received, and cleared by an  
7 MP Loopback Responder state machine.

### 8 **20.27.2 LBMPDU**

9 Structure. Loaded with the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the  
10 LBM PDU received by the an MP OpCode Demultiplexer (19.2.7) when an LBM is received.

## 11 **20.28 MP Loopback Responder procedures**

12 The following procedures are defined for the Loopback Responder:

- 13 a) ProcessLBM() (20.28.1)
- 14 b) xmitLBR() (20.28.2)

### 15 **20.28.1 ProcessLBM()**

16 Called by the MP Loopback Responder state machine whenever an LBM is received. ProcessLBM()  
17 processes the LBM in LBMPDU as follows:

- 18 a) If :
  - 19 1) the destination\_address parameter contains an individual MAC address that does not match the
  - 20 MAC address of the receiving MP and
  - 21 2) the MP Loopback Responder state machine does not reside in a PBB-TE or SPBM VID MHF,
  - 22 ProcessLBM() discards the LBM and performs no further processing.
- 23 b) If the destination\_address parameter contains a Group address and the MP Loopback Responder
- 24 state machine resides in an MHF associated with neither PBB-TE nor SPBM (rather than in a MEP),
- 25 ProcessLBM() discards the LBM and performs no further processing.
- 26 c) If the source\_address parameter is a Group, and not an individual MAC address, ProcessLBM()
- 27 discards the frame and performs no further processing.
- 28 d) ProcessLBM() shall process the LBM according to 20.51.4.2, and may validate the LBM according
- 29 to 20.51.4.3, and discard any frames that fail the validation.
- 30 e) If the MP Loopback Responder state machine resides in a PBB-TE MEP and the LBM carries a
- 31 PBB-TE MIP TLV, ProcessLBM() discards the LBM and performs no further processing.
- 32 f) If the MP Loopback Responder state machine resides in a PBB-TE or SPBM VID MHF and:
  - 33 1) There is no PBB-TE MIP TLV or
  - 34 2) There is a PBB-TE MIP TLV but the address carried in the MIP MAC address field does not
  - 35 match the MAC address of the receiving MIP,
  - 36 ProcessLBM() forwards the LBM to the Passive MHF Multiplexer and performs no further
  - 37 processing.
- 38 g) Otherwise, ProcessLBM() calls xmitLBR() to generate and transmit an LBR.

## 1 20.28.2 xmitLBR()

2 Called by ProcessLBM() to transmit an LBR. xmitLBR() constructs an LBR from the LBM contained in  
3 LBMPDU, and transmits it to the Active SAP using an M\_UNITDATA.request as follows:

- 4 a) Sets the destination\_address parameter to the source\_address of the received LBM if the MP is not  
5 associated with a PBB-TE MA; otherwise to:
  - 6 1) The value of the ESP-DA of the MA's ESP that has the replying MEP's MAC address [item i)  
7 in 12.14.7.1.3] in its ESP-SA field, if the MEP is a PBB-TE MEP; or otherwise to
  - 8 2) The value carried in the Reverse MAC field contained in the PBB-TE MIP TLV of the received  
9 LBM, if this is a group MAC address; otherwise to
  - 10 3) The source\_address of the received LBM.
- 11 b) Sets the source\_address parameter to the MAC address of the replying MP if the MP is not a  
12 PBB-TE MHF; or otherwise to:
  - 13 1) The destination\_address of the received LBM if this is an individual MAC address; or  
14 otherwise to
  - 15 2) The value carried in the Reverse MAC field contained in the PBB-TE MIP TLV of the received  
16 LBM.
- 17 c) If the LBM was received at a PBB-TE MHF and contains a PBB-TE MIP TLV, then the  
18 vlan\_identifier in the LBR is set to the value in the Reverse VID field; otherwise, the vlan\_identifier  
19 in the LBR is set to the value of the Primary VID associated with the replying MP [item d) in  
20 12.14.7.1.3, item a) in 12.14.3.2.2, item c) in 12.14.5.3.2].
- 21 d) In the case of ECMP with flow filtering, the flow\_hash parameter is set to zero and the time\_to\_live  
22 parameter is set to 63.
- 23 e) The priority parameter and the drop-eligible parameter are copied from the LBM.
- 24 f) Changes the OpCode field (21.4.3) from LBM to LBR.
- 25 g) Copies the remainder of the LBM's mac\_service\_data\_unit verbatim to the LBR.
- 26 h) If the replying MP is a MEP, increments the LBR transmission counter by 1 [item ad) in  
27 12.14.7.1.3].

## 28 20.29 MP Loopback Responder state machine

29 The MP Loopback Responder state machine implements the functions specified by the state diagram in  
30 Figure 20-10, using the variables in 20.27 and the procedures in 20.28. Although the definition of the MP  
31 Loopback Responders in 19.2.10 and 19.3.8 requires the instantiation of an MP Loopback Responder state  
32 machine in every MP, in practice, the number of MP Loopback Responder state machines implemented in a  
33 system cannot be determined from external observation of the system.

## 34 20.30 MEP Loopback Initiator variables

35 The following variables are local to the MEP Loopback Initiator transmit state machine and the MEP  
36 Loopback Initiator receive state machine:

- 37 a) LBMsToSend (20.30.1)
- 38 b) nextLBMtransID (20.30.2)
- 39 c) expectedLBRtransID (20.30.3)
- 40 d) LBIactive (20.30.4)
- 41 e) xmitReady (20.30.5)
- 42 f) LBRreceived (20.30.6)
- 43 g) LBRPDU (20.30.7)

\* MEPactive in a MEP; not present (always true) in an MHF

**Figure 20-10—MP Loopback Responder state machine**

### 1 20.30.1 LBMstoSend

2 The integer number of LBMs that the MEP Loopback Initiator transmit state machine is to transmit. Set by a  
3 management operation [item c) in 12.14.7.3.2]. Setting this variable to a nonzero value starts transmission of  
4 LBMs. LBMsToSend is decremented by 1 by the MEP Loopback Initiator transmit state machine with each  
5 transmission.

### 6 20.30.2 nextLBMtransID

7 The value to place in the Loopback Transaction Identifier field of the next LBM transmitted by xmitLBM().  
8 nextLBMtransID is incremented by 1 by the MEP Loopback Initiator transmit state machine with each  
9 transmission. This variable is available as a managed object [item x) in 12.14.7.1.3].

### 10 20.30.3 expectedLBRtransID

11 The value expected to be found in the Loopback Transaction Identifier field of the next LBR received by  
12 ProcessLBR(). Altered by ProcessLBR() (see 20.33.1).

### 13 20.30.4 LBIactive

14 A Boolean flag indicating whether the MEP Loopback Initiator transmit state machine is (true) or is not  
15 (false) actively engaged in a requested operation. Set to true by the MEP Loopback Initiator transmit state  
16 machine after LBMsToSend is set to a nonzero value by a management operation. Reset to false by the MEP  
17 Loopback Initiator transmit state machine 5 s after the last LBM is transmitted or the last LBR is received,  
18 whichever comes later.

### 19 20.30.5 xmitReady

20 A Boolean flag set to true by the Bridge Port to indicate that another LBM can be transmitted. Reset to false  
21 by the MEP Loopback Initiator transmit state machine.

### 22 20.30.6 LBRreceived

23 Boolean flag. Set by the MEP Equal OpCode Demultiplexer (19.2.7) when an LBR at the MEP's MD Level  
24 is received. Cleared by the MEP Loopback Initiator receive state machine.

## 1 20.30.7 LBRPDU

2 Structure. Loaded with the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the LBR  
3 PDU received by the MEP Equal OpCode Demultiplexer (19.2.7) when an LBR at the MEP's MD Level is  
4 received.

## 5 20.31 MEP Loopback Initiator transmit procedures

6 The following procedure is local to the MEP Loopback Initiator transmit state machine:

- 7 a) xmitLBM() (20.31.1)

### 8 20.31.1 xmitLBM()

9 xmitLBM() is called by the MEP Loopback Initiator transmit state machine. It constructs and transmits an  
10 LBM on the Active SAP using an M\_UNITDATA.request as follows:

- 11 a) Sets the destination\_address parameter from the appropriate managed object [item b) in 12.14.7.3.2]  
12 or in the case of an SPBM VID MEP [item g) in 12.14.7.3.2]. If the MEP is configured on a PBB-TE  
13 MA, the destination\_address parameter is set to the MAC address indicated by the value of the  
14 ESP-DA field of the MA's ESP that has the MEP's MAC address indicated in its ESP-SA field.
- 15 b) Sets the source\_address parameter to the MAC address of the MEP [item i) in 12.14.7.1.3].
- 16 c) Sets the priority and drop\_eligible parameters from the appropriate managed object [item e) in  
17 12.14.7.3.2].
- 18 d) In the case of ECMP with flow filtering, the flow\_hash parameter is set from the appropriate  
19 managed object [item h) in 12.14.7.3.2] and the time\_to\_live parameter is set to 63.
- 20 e) Copies nextLBMtransID (20.30.2) to the Loopback Transaction Identifier field (21.7.3) of the LBM.
- 21 f) If the MEP is configured on a PBB-TE MA, constructs a PBB-TE MIP TLV using in the MIP MAC  
22 address field the target address parameter from the appropriate managed object [item b) in  
23 12.14.7.3.2] and in the Reverse VID field the parameter [item f) in 12.14.7.3.2]; if the MEP is a root  
24 in a point-to-multipoint TESI, the Reverse MAC field is also included in the PBB-TE MIP TLV  
25 carrying the ESP-SA value of any of the MA's point-to-point ESPs; if the MEP is a leaf in a  
26 point-to-multipoint TESI, the Reverse MAC field carries the ESP-DA of the point-to-multipoint  
27 ESP; the PBB-TE MIP TLV is not used if the LBM target address in 12.14.7.3.2 is associated with  
28 any of the values in the ESP-DA field of the monitored MA's ESPs.
- 29 g) If the MEP is configured on an SPBM VID MA, constructs a PBB-TE MIP TLV using in the MIP  
30 MAC address field the target address parameter from the appropriate managed object [item b) in  
31 12.14.7.3.2].
- 32 h) Constructs a Data TLV from the appropriate managed object [item d) in 12.14.7.3.2] if and only if  
33 that managed object has a nonzero length.
- 34 i) As controlled by the managed objects item e) in 12.14.3.1.3, item d) in 12.14.5.1.3, and item d) in  
35 12.14.6.1.3, places a Sender ID TLV (21.5.3), identifying the transmitting system, in the LBM.
- 36 j) Increments nextLBMtransID (20.30.2) by 1, wrapping around from  $2^{32} - 1$  to 0.

## 37 20.32 MEP Loopback Initiator transmit state machine

38 A MEP creates a single instance of the MEP Loopback Initiator transmit state machine. The MEP Loopback  
39 Initiator transmit state machine implements the function specified by the state diagram in Figure 20-11 and  
40 the procedures in 20.31. It shares with the MEP Loopback Initiator receive state machine the variable  
41 declarations in 20.30.

## 20.33 MEP Loopback Initiator receive procedures

The following procedure is local to the MEP Loopback Initiator receive state machine:

a) ProcessLBR() (20.33.1)

Figure 20-11—MEP Loopback Initiator transmit state machine

### 20.33.1 ProcessLBR()

Called by the MEP Loopback Initiator receive state machine whenever an LBR is received. ProcessLBR() processes the LBR in LBRPDU as follows:

- a) If the I/G bit of the source\_address indicates a Group address, or if the destination\_address does not match the MAC address of the receiving MP, ProcessLBR() discards the received LBR.
- b) ProcessLBR() shall process the LBM according to 20.51.4.2, and may validate the received LBR according to 20.51.4.3, and discard it if invalid.
- c) If the LBR is not discarded, and if and only if LBIactive is true, the Loopback Transaction Identifier field of the LBR is compared to expectedLBRtransID:
  - 1) If the two values are equal, then the number of correct LBRs received [item y] in 12.14.7.1.3] is incremented by 1.
  - 2) If the two values are unequal, then the value from the received Loopback Transaction Identifier field is copied into expectedLBRtransID, and the number of incorrect LBRs received [item z] in 12.14.7.1.3] is incremented by 1.
  - 3) Regardless of whether the two values were equal, expectedLBRtransID is then incremented by 1.

- 1 d) ProcessLBR() may perform a bit-by-bit comparison of the received LBR against the LBM with the
- 2 matching Loopback Transaction Identifier, except for the OpCode field, and increment a managed
- 3 object [item aa) in 12.14.7.1.3] if they do not match.

#### 4 20.34 MEP Loopback Initiator receive state machine

5 A MEP creates a single instance of the MEP Loopback Initiator receive state machine. The MEP Loopback  
6 Initiator receive state machine implements the function specified by the state diagram in Figure 20-12 and  
7 the procedures in 20.33. It shares with the MEP Loopback Initiator transmit state machine the variable  
8 declarations in 20.30.

Figure 20-12—MEP Loopback Initiator receive state machine

#### 9 20.35 MEP Fault Notification Generator variables

10 The following variables are local to the MEP Fault Notification Generator state machine:

- 11 a) fngPriority (20.35.1)
- 12 b) fngDefect (20.35.2)
- 13 c) fngAlarmTime (20.35.3)
- 14 d) fngResetTime (20.35.4)
- 15 e) someRMEPCCMdefect (20.35.5)
- 16 f) someMACstatusDefect (20.35.6)
- 17 g) someRDIdefect (20.35.7)
- 18 h) highestDefectPri (20.35.8)
- 19 i) highestDefect (20.35.9)

##### 20 20.35.1 fngPriority

21 An integer specifying the priority of the last defect reported in a Fault Alarm. fngPriority takes the same  
22 values as highestDefectPri (20.35.8).

##### 23 20.35.2 fngDefect

24 An enumerated value specifying the last defect reported in a Fault Alarm. fngDefect takes the same values  
25 as highestDefect (20.35.9).

### 1 **20.35.3 fngAlarmTime**

2 The time that one or more defects must be present before a Fault Alarm is issued. Default value 2.5 s. Also a  
3 managed object [item l) in 12.14.7.1.3].

### 4 **20.35.4 fngResetTime**

5 The time, after a Fault Alarm, that no defects must be present before another Fault Alarm is enabled. Default  
6 value 10 s. Also a managed object [item m) in 12.14.7.1.3].

### 7 **20.35.5 someRMEPCCMdefect**

8 A Boolean indicating the aggregate state of the Remote MEP state machines. True indicates that at least one  
9 of the Remote MEP state machines is not receiving valid CCMs from its remote MEP, and false that all  
10 Remote MEP state machines are receiving valid CCMs. someRMEPCCMdefect is the logical OR of all of  
11 the rMEPCCMdefect variables for all of the Remote MEP state machines on this MEP. This variable is  
12 readable as a managed object [item q) in 12.14.7.1.3].

### 13 **20.35.6 someMACstatusDefect**

14 A Boolean indicating that one or more of the remote MEPs is reporting a failure in its Port Status TLV  
15 (21.5.4) or Interface Status TLV (21.5.5). It is true either if some remote MEP is reporting that its interface is  
16 not isUp (i.e., at least one remote MEP's interface is unavailable), or if all remote MEPs are reporting a Port  
17 Status TLV that contains some value other than psUp (i.e., all remote MEPs' Bridge Ports are not forwarding  
18 data). It is thus the logical OR of the following two terms:

- 19 a) The logical AND, across all remote MEPs, of the rMEPportStatusDefect variable OR
- 20 b) The logical OR, across all remote MEPs, of the rMEPinterfaceStatusDefect variable.

21 This variable is readable as a managed object [item p) in 12.14.7.1.3].

### 22 **20.35.7 someRDId defect**

23 A Boolean indicating the aggregate health of the remote MEPs. True indicates that at least one of the  
24 Remote MEP state machines is receiving valid CCMs from its remote MEP that has the RDI bit set, and  
25 false that no Remote MEP state machines are receiving valid CCMs with the RDI bit set. someRDId defect is  
26 the logical OR of all of the rMEPlastRDI and rMEPlastRDI[i] variables for all of the Remote MEP state  
27 machines on this MEP. This variable is readable as a managed object [item o) in 12.14.7.1.3].

### 28 **20.35.8 highestDefectPri**

29 An integer value indicating the priority of the defect named in the variable highestDefect. See also Table  
30 20-1.

### 31 **20.35.9 highestDefect**

32 An enumerated value indicating the highest priority defect among the variables xconCCMdefect (20.23.3),  
33 errorCCMdefect (20.21.3), someRMEPCCMdefect (20.35.5), someMACstatusDefect (20.35.6), and  
34 someRDId defect (20.35.7), as limited by lowestAlarmPri (20.9.5). This variable is readable as a managed  
35 object [item c) in 12.14.7.7.2]. The variables, their priorities, and the enumerated values of highestDefect are  
36 shown in Table 20-1.

## 20.36 MEP Fault Notification Generator procedures

The following procedure is local to the MEP Fault Notification Generator state machine:

a) `xmitFaultAlarm()` (20.36.1).

### 20.36.1 `xmitFaultAlarm()`

Transmits a Fault Alarm (12.14.7.7). The identity of the MEP and the variable `fngDefect` (20.35.2), specifying the cause of the Fault Alarm, are transmitted in the Fault Alarm PDU. The format and method of transmission of the Fault Alarm is not specified in this standard.

## 20.37 MEP Fault Notification Generator state machine

A MEP creates a single instance of the MEP Fault Notification Generator state machine. The MEP Fault Notification Generator state machine implements the function specified by the state diagram in Figure 20-13, the variables in 20.35, and the procedure in 20.36. The current state of the MEP Fault Notification Generator state machine is available in a managed object [item f) in 12.14.7.1.3].

Figure 20-13—MEP Fault Notification Generator state machine

## 1 **20.38 MEP Mismatch Fault Notification Generator variables**

2 The following variables are local to the MEP Mismatch Fault Notification Generator state machine for a  
3 PBB-TE MEP or Infrastructure Segment MEP implementing the Traffic field (21.6.1.4):

- 4 a) mfngAllowed (20.38.1)
- 5 b) mmdefectIndication (20.38.2)
- 6 c) mfngAlarmTime (20.38.3)
- 7 d) mfngResetTime (20.38.4)

### 8 **20.38.1 mfngAllowed**

9 A Boolean indicating the mismatch defect is allowed to generate a Fault Alarm. Its value is configurable as  
10 a managed object [item ag] in 12.14.7.1.3].

### 11 **20.38.2 mmdefectIndication**

12 A Boolean indicating the presence of the mismatch defect that is allowed to generate a Fault Alarm. It  
13 corresponds to the logical AND of the variables mfngAllowed (20.38.1), mmCCMdefect (20.25.2), and  
14 mmLocdefect (20.25.5).

### 15 **20.38.3 mfngAlarmTime**

16 The time that one or more defects must be present before a mismatch Fault Alarm is issued. Default value  
17 2.5 s. Also a managed object [item l] in 12.14.7.1.3].

### 18 **20.38.4 mfngResetTime**

19 The time, after a mismatch Fault Alarm, that no defects must be present before another mismatch Fault  
20 Alarm is enabled. Default value 10 s. Also a managed object [item m] in 12.14.7.1.3].

## 21 **20.39 MEP Mismatch Fault Notification Generator procedures**

22 The following procedure is local to the MEP Mismatch Fault Notification Generator state machine for a  
23 PBB-TE MEP or Infrastructure Segment MEP implementing the Traffic field (21.6.1.4):

- 24 a) xmitFaultAlarm() (20.36.1)

### 25 **20.39.1 xmitFaultAlarm()**

26 Transmits a Fault Alarm (12.14.7.7). The identity of the MEP and a value indicating that the cause of the  
27 Fault Alarm is a mismatch defect, are transmitted in the Fault Alarm PDU. The format and method of  
28 transmission of the Fault Alarm is not specified in this standard.

## 29 **20.40 MEP Mismatch Fault Notification Generator state machine**

30 A PBB-TE MEP or Infrastructure Segment MEP implementing the Traffic field (21.6.1.4) creates a single  
31 instance of the MEP Mismatch Fault Notification Generator state machine. The MEP Mismatch Fault  
32 Notification Generator state machine implements the function specified by the state diagram in  
33 Figure 20-14, the variables in 20.38, and the procedure in 20.39. The current state of the MEP Mismatch  
34 Fault Notification Generator state machine is available in a managed object [item ak] in 12.14.7.1.3].

Figure 20-14—MEP Mismatch Fault Notification Generator state machine

## 20.41 MEP Linktrace Initiator variables

The following variables are local to the MEP Linktrace Initiator variables:

- a) nextLTMtransID (20.41.1)
- b) ltmReplyList (20.41.2)

### 20.41.1 nextLTMtransID

The value to place in the LTM Transaction Identifier of the next LTM transmitted by xmitLTM(). nextLTMtransID is incremented by 1 by the MEP Linktrace Initiator variables with each transmission. This variable is also a managed object [item ab) in 12.14.7.1.3].

## 1 **20.41.2 ltmReplyList**

2 The list of recently-issued LTM entries and their corresponding LTRs. An LTM entry, with no attached LTR  
3 entries, is added to this list by xmitLTM() each time an LTM is transmitted, and an LTR entry is attached to  
4 an LTM entry in this list, by ProcessLTR(), each time an LTR corresponding to an LTM in the list is  
5 received. The MEP does not remove any entry from this list before 5 s have elapsed since the transmission  
6 of the corresponding LTM, unless the addition of another LTM or LTR entry would exceed the maximum  
7 resources allocated for this list. This variable constitutes the Linktrace database for a given MEP and is also  
8 a managed object (12.14.7.5.3).

9 Each LTR entry contains the following variables:

- 10 a) ltrFlags (20.41.2.1)
- 11 b) ltrReplyTTL (20.41.2.2)
- 12 c) ltrLastEgressId (20.41.2.3)
- 13 d) ltrNextEgressId (20.41.2.4)
- 14 e) ltrRelayAction (20.41.2.5)
- 15 f) ltrIngressAction (20.41.2.6)
- 16 g) ltrIngressAddress (20.41.2.7)
- 17 h) ltrIngressPortIdSubtype (20.41.2.8)
- 18 i) ltrIngressPortId (20.41.2.9)
- 19 j) ltrEgressAction (20.41.2.10)
- 20 k) ltrEgressAddress (20.41.2.11)
- 21 l) ltrEgressPortIdSubtype (20.41.2.12)
- 22 m) ltrEgressPortId (20.41.2.13)
- 23 n) ltrSenderIdTlv (20.41.2.14)
- 24 o) ltrOrgSpecTlv (20.41.2.15)

### 25 **20.41.2.1 ltrFlags**

26 The bit string returned in the Flags field (21.9.1) of the LTR, including the FwdYes and TerminalMEP bits.

### 27 **20.41.2.2 ltrReplyTTL**

28 The integer value returned in the Reply TTL field (21.9.4) of the LTR.

### 29 **20.41.2.3 ltrLastEgressId**

30 The octet string returned in the Last Egress Identifier field (21.9.7.1) of the LTR Egress Identifier TLV.

### 31 **20.41.2.4 ltrNextEgressId**

32 The integer value returned in the Next Egress Identifier field (21.9.7.2) of the LTR Egress Identifier TLV.

### 33 **20.41.2.5 ltrRelayAction**

34 The enumerated value returned in the Relay Action field (21.9.5) of the LTR. The enumerated values are  
35 listed in Table 21-27.

### 36 **20.41.2.6 ltrIngressAction**

37 The enumerated value returned in the Ingress Action field (21.9.8.1) of the Reply Ingress TLV (21.9.8) of  
38 the LTR. The enumerated values are listed in Table 21-30. An enumerated value of 0 indicates that no Reply  
39 Ingress TLV was returned in the LTR.

#### 1 **20.41.2.7 ltrIngressAddress**

2 The MAC address of the MP on the Ingress Port. Contents are undefined if no Reply Ingress TLV was  
3 returned in the LTR.

#### 4 **20.41.2.8 ltrIngressPortIdSubtype**

5 An enumerated value as specified by IEEE Std 802.1AB, indicating the format of ltrIngressPortId. Contents  
6 are undefined if no Reply Ingress TLV was returned in the LTR.

#### 7 **20.41.2.9 ltrIngressPortId**

8 An octet string as specified by IEEE Std 802.1AB, identifying the Ingress Port, in the format identified in  
9 ltrIngressPortIdSubtype.

#### 10 **20.41.2.10 ltrEgressAction**

11 The enumerated value returned in the Egress Action field (21.9.9.1) of the Reply Egress TLV (21.9.9) of the  
12 LTR. The enumerated values are listed in Table 21-32. A value of 0 indicates that no Reply Egress TLV was  
13 returned in the LTR.

#### 14 **20.41.2.11 ltrEgressAddress**

15 The MAC address of the MP on the Egress Port. Contents are undefined if no Reply Egress TLV was  
16 returned in the LTR.

#### 17 **20.41.2.12 ltrEgressPortIdSubtype**

18 An enumerated value as specified by IEEE Std 802.1AB, indicating the format of ltrEgressPortId. Contents  
19 are undefined if no Reply Ingress TLV was returned in the LTR.

#### 20 **20.41.2.13 ltrEgressPortId**

21 An octet string as specified by IEEE Std 802.1AB, identifying the Egress Port, in the format identified in  
22 ltrEgressPortIdSubtype.

#### 23 **20.41.2.14 ltrSenderIdTlv**

24 An octet string identifying the transmitting system, as received in the Sender ID TLV (21.5.3), if one was  
25 present in the LTR.

#### 26 **20.41.2.15 ltrOrgSpecTlv**

27 An octet string containing the Organization-Specific TLVs (21.5.2), if any were present in the LTR.

### 28 **20.42 MEP Linktrace Initiator procedures**

29 The following procedure is local to the MEP Linktrace Initiator:

30 a) xmitLTM() (20.42.1)

#### 31 **20.42.1 xmitLTM()**

32 xmitLTM() is called whenever the Transmit Linktrace Message management operation (12.14.7.4) is  
33 invoked. It constructs and transmits an LTM on the Active SAP, or on the MEP LTI SAP if the operation is  
34 invoked on an Up MEP, using an M\_UNITDATA.request as follows:

35 a) Sets the destination\_address parameter to the value from Table 8-19 corresponding to the MEP's  
36 MD Level. If the MEP is configured on a PBB-TE MA, the destination\_address parameter is the

- 1 MAC address indicated by the value of the ESP-DA field of the MA's ESP that has the MEP's MAC
- 2 address indicated in its ESP-SA field. If the MEP is configured on an SPBM VID MA, the
- 3 destination\_address parameter is set to the value configured in the LTM management request [item
- 4 f) in 12.14.7.4.2].
- 5 b) Sets the source\_address parameter and Original MAC Address field (21.8.5) to the MAC address of
- 6 the MEP [item i) in 12.14.7.1.3].
- 7 c) If the MEP is configured on a PBB-TE MA, constructs a PBB-TE MIP TLV using in the MIP MAC
- 8 address field a null field and in the Reverse VID field the parameter [item e) in 12.14.7.4.2]; if the
- 9 MEP is a root in a point-to-multipoint TESI, the Reverse MAC field is also included in the PBB-TE
- 10 MIP TLV carrying the ESP-SA value of any of the MA's point-to-point ESPs; if the MEP is a leaf in
- 11 a point-to-multipoint TESI, the Reverse MAC field carries the ESP-DA of the point-to-multipoint
- 12 ESP.
- 13 d) In the case of ECMP with flow filtering, the flow\_hash parameter is set to the value specified in the
- 14 appropriate managed object [item g) in 12.14.7.4.2] and the time\_to\_live parameter is set to 63.
- 15 e) Sets the priority parameter to the same value as for CCMs [item h) in 12.14.7.1.3].
- 16 f) Copies nextLTMtransID [item ab) in 12.14.7.1.3] to the LTM Transaction Identifier field (21.8.3) of
- 17 the LTM.
- 18 g) Sets the LTM Egress Identifier TLV (21.8.8) to a value that is unique among all Bridges in the
- 19 Management Domain.
- 20 h) Sets the Target MAC Address field (21.8.6) from the appropriate managed object [item c) in
- 21 12.14.7.4.2].
- 22 i) Sets the LTM TTL field (21.8.4) from the appropriate managed object [item d) in 12.14.7.4.2].
- 23 j) Sets the UseFDBOnly bit of the Flags field (21.8.1) from the appropriate managed object [item b) in
- 24 12.14.7.4.2], and sets all other bits of the Flags field to 0.
- 25 k) As controlled by the managed objects item e) in 12.14.3.1.3, item d) in 12.14.5.1.3, and item d) in
- 26 12.14.6.1.3, places a Sender ID TLV (21.5.3), identifying the transmitting system, in the LTM.
- 27 l) Creates a new entry in the ltmReplyList variable (20.41.2) for this LTM, identified by the LTM
- 28 Transaction Identifier in nextLTMtransID (20.41.1).
- 29 m) Increments nextLTMtransID (20.41.1) by 1, wrapping around from  $2^{32} - 1$  to 0.

30 If the addition of this LTM entry would exceed the resources allocated to ltmReplyList, then the oldest LTM  
31 entries in ltmReplyList are deleted until sufficient resources are available to hold the new LTM entry.

## 32 20.43 MEP Linktrace Initiator receive variables

33 The following variables are local to the MEP Linktrace Initiator receive state machine:

- 34 a) LTRreceived (20.43.1)
- 35 b) LTRPDU (20.43.2)

### 36 20.43.1 LTRreceived

37 Boolean flag. Set by the MEP Equal OpCode Demultiplexer (19.2.7) when an LTR at the MEP's MD Level  
38 is received. Cleared by the MEP Linktrace Initiator receive state machine.

### 39 20.43.2 LTRPDU

40 Structure. Loaded with the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the LTR  
41 PDU received by the MEP Equal OpCode Demultiplexer (19.2.7) when an LTR at the MEP's MD Level is  
42 received.

## 20.44 MEP Linktrace Initiator receive procedures

The following procedure is local to the MEP Linktrace Initiator receive state machine:

- a) ProcessLTR() (20.44.1)

### 20.44.1 ProcessLTR()

The ProcessLTR() procedure is called by the MEP Linktrace Initiator receive state machine whenever an LTR is received, and processes the LTR contained in the LTRPDU variable as follows:

- a) If the destination\_address of the LTR does not match the MAC address of the MEP, or if the LTR fails the validation criteria of 20.51.4, ProcessLTR() shall discard the LTR without counting it, and no further processing takes place.
- b) Otherwise, if the LTR Transaction Identifier field matches an LTM entry in the ltmReplyList variable, then a new LTR entry is attached to that LTM entry, containing the information returned in the LTR.
- c) Otherwise, the number of unexpected LTRs received [item ac) in 12.14.7.1.3] is incremented by 1.

If the addition of this LTR entry would exceed the resources allocated to ltmReplyList, then the oldest LTM entries in ltmReplyList (the oldest LTR entries, if only one LTM entry is present) are deleted until sufficient resources are available to hold the new LTR entry.

## 20.45 MEP Linktrace Initiator receive state machine

One instance of the MEP Linktrace Initiator receive state machine is instantiated by each MEP Linktrace Initiator. The MEP Linktrace Initiator receive state machine implements the function specified by the state diagram in Figure 20-15, the variables in 20.43, and the procedures in 20.44.

Figure 20-15—MEP Linktrace Initiator receive state machine

## 20.46 Linktrace Responder variables

The following variables are local to the Linktrace Responder:

- a) nPendingLTRs (20.46.1)
- b) LTMreceived (20.46.2)
- c) LTMPDU (20.46.3)

### 20.46.1 nPendingLTRs

An integer value used to track the number of LTRs that have been enqueued for transmission by enqueueLTR() and not yet transmitted by xmitOldestLTR(). Can be reset to 0 by clearPendingLTRs().

## 1 **20.46.2 LTMreceived**

2 A Boolean value set when a valid LTM is received and cleared by the LTM Receiver state machine.

## 3 **20.46.3 LTMPDU**

4 Structure. Loaded with the M\_UNITDATA.indication or EM\_UNITDATA.indication parameters of the  
5 LTM PDU received by the MEP Equal OpCode Demultiplexer (19.2.7) when an LTM at the MEP's MD  
6 Level is received.

## 7 **20.47 LTM Receiver procedures**

8 The following procedures are local to the LTM Receiver state machine:

- 9 a) ProcessLTM() (20.47.1)
- 10 b) clearPendingLTRs() (20.47.2)
- 11 c) ForwardLTM() (20.47.3)
- 12 d) enqueueLTR() (20.47.4)

### 13 **20.47.1 ProcessLTM()**

14 Called by the LTM Receiver state machine when an LTM is received and processes the LTM contained in  
15 the LTMPDU, making the decision whether to call ForwardLTM() to forward the LTM, and whether to call  
16 enqueueLTR() to enqueue an LTR for transmission, according to 20.3.2. The received LTM is first validated.

- 17 a) ProcessLTM() validates the received LTM according to 20.51.3. If the LTM is invalid, no further  
18 validation steps are performed.
- 19 b) Otherwise, the LTM TTL field (21.8.4) of the received LTM is examined. If its value is 0, the LTM  
20 is invalid, and no further validation steps are performed.
- 21 c) Otherwise, if the vlan\_identifier identifies an ESP-VID or SPBM VID the LTM is valid, and no  
22 further validation steps are performed.
- 23 d) Otherwise, if the destination\_address parameter of the LTM is a Group address, the LTM is valid,  
24 and no further validation steps are performed.
- 25 e) Otherwise, if both:
  - 26 1) The LTM was received from a Linktrace SAP, and not from the originating Up MEP through its  
27 MEP LTI SAP and
  - 28 2) The destination\_address parameter of the LTM is the individual MAC address of the receiving  
29 MP [item i) in 12.14.7.1.3 for a MEP, the MAC address of the Bridge Port for an MHF],  
30 then the LTM is valid.
- 31 f) Otherwise, the LTM is invalid.

#### 32 **20.47.1.1 LTM paths through a Bridge**

33 If the LTM is valid, processing proceeds according to the following subclauses. Otherwise, ProcessLTM()  
34 discards the LTM, and no further processing takes place.

35 Figure 20-16 illustrates a number of (but not all) possible paths taken by an LTM through a Bridge. The gray  
36 circles indicate the processing of an LTM and the possible forwarding of a modified copy of the LTM. The  
37 LTR path is not shown.

1

**Figure 20-16—Linktrace Responder, MEPs, MHFs, and LOMs**

2 NOTE—All of the MPs shown in Figure 20-16 are at the same MD Level.

- 3 a) An LTM is detected by a Down MEP as it enters Port 1. It is deflected to the Linktrace Responder through the MEP Linktrace SAP.
- 4
- 5 b) An LTM is detected by an MHF as it enters Port 2. It is deflected to the Linktrace Responder through the MHF Linktrace SAP, which determines that the Target MAC Address would be forwarded out Port 1, on which there is a MEP. The LTM is not actually forwarded to the MEP.
- 6
- 7
- 8 c) An LTM enters on Port 5, which has no MHF, and if it is a multicast, the LTM is distributed to Ports 2, 3, 4, and 6 by the Frame filtering function (8.6.3). The original, unaltered LTM passes out Port 4. The Up MEP in Port 3 and the MHFs in Ports 2 and 6 deliver the LTM to the Linktrace Responder. The Linktrace Responder discards the LTMs received on Port 2 and 3, but forwards an updated version of the LTM through the LOM on Port 6.
- 9
- 10
- 11
- 12
- 13 d) The Up MEP on Port 8 generates an LTM, which it forwards to the Linktrace Responder. The Linktrace Responder decides to forward an updated version of the LTM through the LOM on Port 7. (The Linktrace Responder might equally well have forwarded it through some other Port's MHF.)
- 14
- 15
- 16 e) The Down MEP on Port 8 generates an LTM and transmits it through its Active SAP to the LAN attached to Port 8.
- 17

18 If an LTM is forwarded, the forwarding takes place immediately. If an LTR is generated in response to the  
19 LTM, it is enqueued for later transmission by the LTR Transmitter state machine (20.50).

## 20 20.47.1.2 Ingress Port, vlan\_identifier, and Egress Port determination

21 In 20.3.2 and Figure 20-16, item a) through item e) all require ProcessLTM() to determine the Ingress and  
22 Egress Ports for this received LTM. The Ingress Port is the Bridge Port on which the LTM entered the  
23 Bridge, whether through a MEP, an MHF, or an LOM. In item d)), where an LTM is generated by an Up  
24 MEP and passed through a MEP LTI SAP to the Linktrace Responder, the Ingress Port is the Bridge Port of  
25 the originating MEP.

26 If received from an EISS SAP, the vlan\_identifier of the received LTM is included in the  
27 EM\_UNITDATA.indication. If received from an ISS SAP, the vlan\_identifier of the received LTM is that  
28 configured in the MEP, MHF, or LOM that received the LTM, or if none, is the PVID (IEEE Std 802.1AC)  
29 of the Ingress Port.

1 The Egress Port is the Bridge Port on which a data frame whose destination\_address is equal to the Target  
2 MAC Address carried in the LTM, or in the case of an MP associated with a PBB-TE MA, the  
3 destination\_address of the LTM, and whose vlan\_identifier matched that of the LTM, would be forwarded.  
4 This determination is made in two steps:

5 a) ProcessLTM() first queries the FDB (8.8). The set of potential transmission ports, normally created  
6 by Active topology enforcement (8.6.1), is the set of all Bridge Ports that are both in the active set of  
7 the vlan\_identifier of the LTM and that are in the Forwarding state for that vlan\_identifier, except  
8 that the Ingress Port is excluded from the set. The query uses the Target MAC Address field of the  
9 LTM as the destination\_address of the lookup, the Original MAC Address field of the LTM as the  
10 source\_address, and the vlan\_identifier of the LTM. In the case of an MP associated with a PBB-TE  
11 or SPBM VID MA, the query uses the destination\_address and the vlan\_identifier of the LTM as the  
12 corresponding parameters for the lookup. If the MP is associated with ECMP with flow filtering, the  
13 query uses the flow\_hash parameter in the lookup process, when required. The output from this  
14 query is a (perhaps reduced) set of potential transmission ports. If the resultant set contains one and  
15 only one Bridge Port, that Bridge Port is the Egress Port, and item b)) is not performed. If the  
16 resultant set contains more than one Bridge Port, and the MP is associated with a PBB-TE MA,  
17 those Bridge Ports are all Egress Ports, and step b is not performed.

18 NOTE 1—If there are only two Bridge Ports that are members of the VID's member set, the Ingress Port was  
19 one of those two Bridge Ports, and the Ingress Port is not connected to a shared medium, then this step can  
20 identify the Egress Port even if the FDB is not used for this vlan\_identifier.

21 NOTE 2—This query cannot produce an Egress Port that is the same as the Ingress Port, since the Ingress Port  
22 is not included in the set of potential transmission ports.

23 b) If the FDB could not produce a unique Egress Port, and the MPs serving the vlan\_identifier of the  
24 LTM are maintaining a MIP CCM Database, and the UseFDBonly bit of the Flags field of the LTM  
25 is 0, then ProcessLTM() queries the MIP CCM Database to see whether the target MAC address and  
26 vlan\_identifier have been retained in that database. If so, and if the Port number in the MIP CCM  
27 Database is not the same as the Ingress Port, that Port number identifies the Egress Port.

28 It is possible that neither of these two steps are able to determine the Egress Port; when a unique Egress Port  
29 cannot be determined, an LTM is never forwarded by MHFs other than PBB-TE MHFs or SPBM VID  
30 MHFs. PBB-TE MHFs associated with point-to-multipoint TESIs forward LTMs even if multiple Egress  
31 Ports are identified. MHFs associated with SPBM VID MAs forward group addressed LTMs even if  
32 multiple Egress Ports are identified.

### 33 20.47.1.3 LTM is received by a Down MEP

34 In case a) in 20.47.1.1, illustrated in Figure 20-16, the LTM is received by a Down MEP, and delivered to the  
35 Linktrace Responder through its MEP Linktrace SAP (19.2.14). In this case, ProcessLTM() performs the  
36 following steps:

- 37 a) If the Target MAC Address carried in the LTM is the MAC address of the receiving MEP, then the  
38 LTM has reached its target. ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the  
39 MEP Linktrace SAP of the receiving Down MEP.
- 40 b) Otherwise, if the spanning tree state of the Bridge Port and vlan\_identifier of the LTM is not  
41 Forwarding, the LTM is discarded and no further processing takes place.
- 42 c) Otherwise, the Ingress and Egress Ports are determined according to 20.47.1.2. If a unique Egress  
43 Port cannot be determined, then the LTM is discarded, and no further processing takes place.
- 44 d) Otherwise, i.e., a unique Egress Port was found, ProcessLTM() calls enqueueLTR() (20.47.4) to  
45 enqueue an LTR for the Linktrace SAP through which the LTM was received. The LTM is  
46 discarded, and no further processing takes place.

#### 1 **20.47.1.4 LTM is received by a Down MHF or originated by an Up MEP**

2 In case b) in 20.47.1.1, illustrated in Figure 20-16, the LTM is received by a Down MHF. In case d) in  
3 20.47.1.1, illustrated in Figure 20-16, the LTM is originated by an Up MEP. In either case, ProcessLTM()  
4 performs the following steps:

- 5 a) If the LTM was generated by an Up MEP, item b)) and item c)) are skipped, and processing  
6 continues with item d)), as follows.
- 7 b) If the Target MAC Address carried in the LTM is the MAC address of the receiving MHF, then the  
8 LTM has reached its target. ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the  
9 Linktrace SAP through which the LTM was received. The LTM is discarded, and no further  
10 processing takes place.
- 11 c) Otherwise, if the spanning tree state of the Bridge Port and vlan\_identifier of the LTM is not  
12 Forwarding, the LTM is discarded and no further processing takes place.

13 NOTE—This test prevents spurious LTRs from being generated on Backup Ports on a shared medium.

- 14 d) Otherwise, the Ingress and Egress Ports are determined according to 20.47.1.2. If an Egress Port  
15 cannot be determined, then the LTM is discarded, and no further processing takes place.
- 16 e) There are three cases for further processing of the LTM, depending on whether, as it passes through  
17 the Egress Port, a frame with the LTM's vlan\_identifier would first encounter an Up MEP, an Up  
18 MHF, or neither. These described in item f)), item g)), item h)), and item i)), as follows.
- 19 f) If an Up MHF would be encountered on the Egress Port, then:
  - 20 1) ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the MHF Linktrace SAP of  
21 the Egress Port's Up MHF.
  - 22 2) If the target MAC address carried in the LTM is the Egress Port Up MHF's MAC address, then  
23 the LTM is discarded, and no further processing takes place.
  - 24 3) Otherwise, if the LTM TTL field equals 0 or 1, the LTM is discarded and no further processing  
25 takes place.
  - 26 4) Otherwise, ProcessLTM() calls ForwardLTM() (20.47.3) to forward an altered copy of the LTM  
27 through the LOM Linktrace SAP of the LOM on the identified Egress Port.
- 28 g) If an Up MEP at the MD Level of the LTM would be encountered on the Egress Port, then:
  - 29 1) ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the MHF Linktrace SAP of  
30 the Ingress Port's Down MHF, or the MEP LTI SAP of the Up MEP, that delivered the LTM to  
31 the Linktrace Responder.
  - 32 2) The LTM is discarded, and no further processing takes place.
- 33 h) Otherwise, if an Up MEP higher than the MD Level of the LTM would be encountered on the Egress  
34 Port, then the LTM is discarded, and no further processing takes place.
- 35 i) If neither an Up MHF, nor an Up MEP at an MD Level higher than or equal to the LTM, would be  
36 encountered on the Egress Port, then:
  - 37 1) ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the MHF Linktrace SAP of  
38 the Ingress Port's Down MHF.
  - 39 2) If the LTM TTL field equals 0 or 1, the LTM is discarded and no further processing takes place.
  - 40 3) Otherwise, ProcessLTM() calls ForwardLTM() (20.47.3) to forward an altered copy of the LTM  
41 through the LOM Linktrace SAP of the LOM that a frame with the LTM's vlan\_identifier  
42 would first encounter when passing out through the identified Egress Port.

### 1 20.47.1.5 LTM is received by an Up MEP

2 In case c) in 20.47.1.1, illustrated in Figure 20-16, an LTM enters a Bridge on a Bridge Port that has no MEP  
3 or MHF and therefore only an LOM. The LTM can therefore be received by an Up MEP such as the one on  
4 Port 3 of Figure 20-16. Processing of an LTM received on an Up MEP proceeds as follows:

- 5 a) If the Target MAC Address carried in the LTM is the MAC address of the receiving MEP, then the  
6 LTM has reached its target. ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the  
7 MEP Linktrace SAP of the receiving Up MEP. The LTM is discarded, and no further processing  
8 takes place.
- 9 b) Otherwise, the Ingress and Egress Ports are determined according to 20.47.1.2. If the Egress Port  
10 cannot be determined, or if the Egress Port is not the Bridge Port on which the receiving MEP is  
11 configured, then the LTM is discarded and no further processing takes place.
- 12 c) Otherwise, (i.e., the Egress Port is that of the receiving Up MEP) ProcessLTM() calls enqueueLTR()  
13 (20.47.4) to enqueue an LTR for the MEP Linktrace SAP of the receiving Up MEP. The LTM is then  
14 discarded.

### 15 20.47.1.6 LTM is received by an Up MHF

16 In case c) in 20.47.1.1, illustrated in Figure 20-16, an LTM enters a Bridge on a Bridge Port that has no MEP  
17 or MHF and therefore only an LOM. The LTM can therefore be received by an Up MHF such as the ones on  
18 Port 2 and Port 6 of Figure 20-16. Processing of an LTM received on an Up MHF proceeds as follows:

- 19 a) If the Target MAC Address carried in the LTM is the MAC address of the receiving Up MHF (i.e.,  
20 that of the Bridge Port on which that MHF resides), then the LTM has reached its target.  
21 ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the MHF Linktrace SAP of the  
22 receiving Up MHF. The LTM is discarded, and no further processing takes place.
- 23 b) Otherwise, the Ingress and Egress Ports are determined according to 20.47.1.2. If the Egress Port  
24 cannot be determined, or if the Egress Port is not the Bridge Port on which the receiving MHF is  
25 configured, then the LTM is discarded, and no further processing takes place.
- 26 c) Otherwise,
  - 27 1) ProcessLTM() calls enqueueLTR() (20.47.4) to enqueue an LTR for the MHF Linktrace SAP of  
28 the receiving Up MHF.
  - 29 2) If the LTM TTL field equals 0 or 1, the LTM is discarded and no further processing takes place.
  - 30 3) Otherwise, ProcessLTM() calls ForwardLTM() (20.47.3) to forward an altered copy of the LTM  
31 through the MHF Linktrace SAP of the LOM on the same Bridge Port as the Up MHF that  
32 received the LTM.

### 33 20.47.2 clearPendingLTRs()

34 Clears the queue of pending LTRs for this MP. Resets nPendingLTRs to 0.

### 35 20.47.3 ForwardLTM()

36 Constructs and transmits a single LTM. Using the original input LTM and the Linktrace Responder SAP  
37 through which the LTM (LTR) is to be output, ForwardLTM() performs the following steps:

- 38 a) Uses the MAC address of the LOM owning the SAP specified for output as the source\_address  
39 parameter of the LTM.
- 40 b) Uses the destination\_address and priority parameters of the input LTM as the destination\_address  
41 and priority of the forwarded LTM.
- 42 c) Sets the drop\_eligible parameter of the forwarded LTM to false.
- 43 d) Uses the same value for the vlan\_identifier parameter for the forwarded LTM that was presented  
44 with the received LTM.

- 1 e) In the case of ECMP with flow filtering, the flow\_hash parameter and the time\_to\_live parameter of  
2 the forwarded LTM are set to values presented with the received LTM.
- 3 f) In PBB-TE related MAs, uses the destination\_address, source\_address, and vlan\_identifier of the  
4 input LTM and sets the drop\_eligible parameter of the forwarded LTM to FALSE.
- 5 g) Copies, verbatim, all fields and TLVs, regardless of whether known to the Linktrace Responder,  
6 from the input LTM to the forwarded LTM, except that ForwardLTM():
  - 7 1) Places in the forwarded LTM TTL field the value from the input LTM TTL field decremented  
8 by 1.
  - 9 2) Changes the value in the LTM Egress Identifier TLV to identify the forwarding Linktrace  
10 Responder.
  - 11 3) Deletes the Sender ID TLV (21.5.3), if present in the LTM.
  - 12 4) Optionally, places a Sender ID TLV (21.5.3), identifying the forwarding system, in the LTM.
- 13 h) Transmits the forwarded LTM on the specified SAP.

#### 14 **20.47.4 enqueueLTR()**

15 Constructs and enqueues a single LTR for later transmission by xmitOldestLTR() as follows. Using the input  
16 LTM and the Linktrace Responder SAP through which the LTR is to be output, enqueueLTR() performs the  
17 following steps:

- 18 a) Uses the MAC address contained in the LTM's Original MAC Address field as the  
19 destination\_address of the LTR. If the MP is associated with a PBB-TE MA, the LTR uses as  
20 destination\_address,
  - 21 1) The value carried in the Reverse MAC field, contained in the PBB-TE MIP TLV of the  
22 received LTM, if this is a group MAC address; otherwise,
  - 23 2) The source\_address of the received LTM.
- 24 b) Uses the MAC address of the MP owning the SAP specified for output as the source\_address of the  
25 LTR, if the MP is not a PBB-TE MHF; otherwise, the LTR uses as the source\_address:
  - 26 1) The value of the destination\_address of the received LTM if this is an individual MAC address;  
27 otherwise,
  - 28 2) The value carried in the Reverse MAC field, contained in the PBB-TE MIP TLV of the  
29 received LTM,
- 30 c) If the LTR includes a Reply Egress TLV [see the following item r)], uses the Primary VID of the  
31 MP on that Egress Port as the vlan\_identifier of the LTR, else it uses the Primary VID of the MP on  
32 the Ingress Port as the vlan\_identifier of the LTR. In PBB-TE related MA's, sets the vlan\_identifier  
33 parameter as the value carried in the Reverse VID field contained in the PBB-TE MIP TLV of the  
34 received LTM.
- 35 d) Sets the priority parameter to the same value as for CCMs [item h) in 12.14.7.1.3].
- 36 e) In the case of ECMP with flow filtering, the flow\_hash parameter is set to zero and the time\_to\_live  
37 parameter is set to 63.
- 38 f) Sets the drop\_eligible parameter to FALSE.
- 39 g) Places its own version in the Version field.
- 40 h) If its own version is lower than that of the received LTM, sets all bits and fields in the transmitted  
41 PDU that are reserved in its own version, including all bits between the portion of the last header  
42 field defined for its own version and the first TLV, to 0.
- 43 i) Sets the FwdYes bit of the Flags field to 1 if the LTM was forwarded by the Linktrace Responder, or  
44 0 if not.
- 45 j) Sets the TerminalMEP bit of the Flags field to 1 if the MP reported in either the Reply Ingress TLV  
46 or the Reply Egress TLV is a MEP, or 0 if not.
- 47 k) Copies the Flags field, excepting the FwdYes bit and the TerminalMEP bit, from the LTM to the  
48 LTR.

- 1 l) Copies the LTM Transaction Identifier field from the LTM to the LTR Transaction Identifier field of  
2 the LTR.
- 3 m) Copies the LTM Egress Identifier TLV (21.8.8) value from the LTM to the Last Egress Identifier  
4 field (21.9.7.1) of the LTR Egress Identifier TLV, or places 0 in that field, if there is no LTM Egress  
5 Identifier TLV in the received LTM (see J.4).
- 6 n) Sets the Next Egress Identifier field (21.9.7.2) of the LTR Egress Identifier TLV to a value that  
7 identifies the forwarding Linktrace Responder (see 21.8.8).
- 8 o) Places one less than the value in the LTM TTL field of the LTM in the Reply TTL field of the LTR;
- 9 p) Sets the Relay Action field according to Table 21-27.
- 10 q) If the LTM was not received by a Down MEP or Down MHF, does not place a Reply Ingress TLV in  
11 the LTR; otherwise,  
12 1) Fills the Ingress Action field of a Reply Ingress TLV (21.9.8) with the appropriate value  
13 according to Table 21-30;  
14 2) Places the receiving MP's MAC address in the Ingress MAC Address field of the Reply Ingress  
15 TLV; and  
16 3) Optionally, fills the remainder of the Reply Ingress TLV with the receiving MP's Port ID  
17 information.
- 18 r) If the LTM was received by a Down MEP, or if no Egress Port was identified, or if no Up MEP nor  
19 Up MHF belonging to the LTM's MA is configured on the Egress Port, does not place a Reply  
20 Egress TLV in the LTR; otherwise,  
21 1) Fills the Egress Action field of a Reply Egress TLV (21.9.9) with the appropriate value  
22 according to Table 21-32;  
23 2) Places the Egress Port's Up MP's MAC address in the Egress MAC Address field of a Reply  
24 Egress TLV in the LTM; and  
25 3) Optionally, fills the remainder of the Reply Egress TLV with Egress Port's Port ID information.
- 26 s) As controlled by the managed objects item e) in 12.14.3.1.3, item d) in 12.14.5.1.3, and item d) in  
27 12.14.6.1.3, places a Sender ID TLV (21.5.3), identifying the replying Bridge, in the LTM.
- 28 t) Copies, verbatim, all other TLVs in the input LTM to the LTR, except for the Sender ID TLV  
29 (21.5.3), which is not copied.
- 30 NOTE 1—Forwarding all unknown TLVs in both the LTM and the LTR enables future revisions of this standard, and  
31 designers of Organization-Specific TLVs, to add new capabilities.
- 32 NOTE 2—The resultant LTR can be larger than the maximum frame size for the media-dependent sublayer on which the  
33 LTR is to be transmitted, causing the LTR to be discarded.
- 34 u) Increments nPendingLTRs by 1.

## 20.48 LTM Receiver state machine

One instance of the LTM Receiver state machine is instantiated by Bridge's Linktrace Responder. The LTM Receiver state machine implements the function specified by the state diagram in Figure 20-17, the variables in 20.46, and the procedures in 20.47.

\* MEPActive in a MEP; not present (always true) in an MHF

Figure 20-17—LTM Receiver state machine

## 20.49 LTR Transmitter procedure

The following procedure is local to the LTR Transmitter state machine:

- a) xmitOldestLTR() (20.49.1)

### 20.49.1 xmitOldestLTR()

If and only if nPendingLTRs is nonzero, dequeues a single LTR and transmits it, and decrements nPendingLTRs by 1.

## 20.50 LTR Transmitter state machine

One instance of the LTR Transmitter state machine is instantiated by Bridge's Linktrace Responder. The LTR Transmitter state machine implements the function specified by the state diagram in Figure 20-18, the variables in 20.46, and the procedures in 20.47.

This state machine implements the requirement of (20.3.2) to wait a random time interval after receiving an LTM before transmitting an LTR by means of a free running 1 s timer, the expiry of which triggers all LTR transmissions. This method avoids the need to create and manage a timer for every LTM received. Any other implementation that meets the requirements of 20.3.2 can be used in place of this state machine.

## 20.51 CFM PDU validation and versioning

The purpose of this subclause is to state specific goals to be achieved by CFM with respect to the relationship of this and future versions of this standard, and to define the procedures necessary to meet those goals.

**Figure 20-18—LTR Transmitter state machine**

### 20.51.1 Goals of CFM PDU versioning

The goals of CFM with respect to the relationship of this and future versions of this standard are to ensure that:

- a) Implementations of this standard will interoperate with implementations of future versions of this standard.
- b) Implementers will be able to offer proprietary, nonstandard extensions to this standard with enhanced functionality.
- c) Conformant but extended implementations of this standard will not restrict the ability of future versions of this standard to extend the standard functionality.

### 20.51.2 PDU transmission

In order to ensure that future versions of CFM will be compatible with implementations of this standard, certain requirements are placed on transmitted CFM PDUs:

- a) The fixed header fields shall be transmitted exactly as specified in this standard.
- b) All bits defined as “reserved” in this standard, e.g., unused bits in the Flags field, shall be transmitted as 0.
- c) Additional fields shall not be added to the fixed header specified in this standard.
- d) Code points reserved in this standard, or in ITU-T G.8013/Y.1731, e.g., additional values for the OpCode field in the fixed header (Table 21-3), the Type field in a TLV (Table 21-5), or the reserved values in Table 21-18 for the Maintenance Domain Name Format, shall not be transmitted in any CFM PDU.
- e) Additional fields shall not be added to any TLV specified in this standard.

Organization-Specific TLVs can be defined by any organization possessing an OUI or a CID, and may be transmitted by an implementation conformant to this standard.

NOTE—The preceding is not an exhaustive list of the restrictions on the transmission of CFM PDUs; it is only a list of the specifications that are most important to future compatibility.

### 1 20.51.3 PDU validation

2 CFM PDUs that fail certain specified tests are discarded by MPs. This requirement is described here as a  
3 two-pass processing algorithm, first a Validation Pass, and then an Execution Pass. The Validation Pass is  
4 performed first. If and only if it succeeds, the Execution Pass is performed. This description does not  
5 preclude other algorithms. For example, an MP could process a CFM PDU in one pass, building a tentative  
6 list of changes to the affected state machines and databases, and commit the changes only after the  
7 processing has succeeded. However, the behavior of such an implementation shall be indistinguishable, in  
8 terms of externally observable behavior (i.e., Management Objects and protocol frames) from the two-pass  
9 algorithm described in this subclause.

### 10 20.51.4 Validation pass

11 During the Validation pass, no changes are made to any CFM database other than the updating of certain  
12 management counter variables. No protocol state machines are affected, and no changes are made to any  
13 CFM PDUs that can be transmitted by the receiving MP. The description of the Validation pass is split into  
14 three parts:

- 15 a) Operations required of an MP Level Demultiplexer (20.51.4.1)
- 16 b) Operations required of all MP components when performing the Validation pass (20.51.4.2)
- 17 c) Operations that are required of some MP components, and optional for others (20.51.4.3)

#### 18 20.51.4.1 Validation pass operations required of an MP Level Demultiplexer

19 If the following test fails, the receiving MP Level Demultiplexer (19.2.6) shall consider the CFM PDU  
20 invalid and discard it:

- 21 a) The length of the `mac_service_data_unit` is long enough to contain a complete MD Level field.

#### 22 20.51.4.2 Validation pass operations required of MP components

23 All bits declared “reserved” in this standard, e.g., unused bits in the Flags field, shall be ignored by the  
24 receiving MP.

25 The receiving MP processes the CFM PDU in accordance with the numerically lower of 1) the Version field  
26 in the CFM PDU and 2) the highest Version number known to the receiving implementation. That is, a  
27 Version 1 implementation receiving a Version 0 CFM PDU processes it according to Version 0 of this  
28 standard, and it processes a Version 2 CFM PDU according to Version 1. The IEEE 802.1 Working Group  
29 places the imposition on future versions of this standard that all earlier version implementations can process  
30 their CFM PDU properly.

31 As an example of the use of this rule, if a new Flags field bit is defined in Versions 2 and 3, then a Version 3  
32 implementation receiving a Version 1 CFM PDU will ignore that bit, even though the bit is defined in both  
33 Version 2 and Version 3, and even though the bit is actually set.

34 NOTE 1—One effect of this rule is that an implementation conformant to this Version of this standard, Version 0,  
35 ignores the Version field in a received CFM PDU.

36 The following criteria shall not be used by a CFM entity to validate a received CFM PDU:

- 37 a) The fixed header can be longer than the length specified by the version of this standard indicated by  
38 the CFM PDU’s Version field.
- 39 b) Bits can be set in reserved bits of the Flags field.
- 40 c) A TLV can have a Type field not specified by this standard.

- 1 d) A TLV's Length field can be larger than the value (if any) specified in this standard. (This allows  
2 TLVs to be extended in future Versions.)
- 3 e) Either the First TLV Offset field, or the Length field of the last TLV, in the CFM PDU, can indicate  
4 a position for the first (next) TLV that coincides with the end of the `mac_service_data_unit`  
5 containing the CFM PDU. That is, the End TLV can be missing from the CFM PDU if the frame is  
6 longer than or equal to the minimum frame size for the media-dependent MAC sublayer.

7 NOTE 2—These latter criteria cannot be used by a CFM entity to validate a received CFM PDU. This helps to ensure  
8 that the CFM PDUs transmitted by future versions of this standard will be considered valid by implementations of the  
9 current version (0) of this standard. These criteria can, however, be used by test equipment in order to test the  
10 conformance of a system to this standard, e.g., to the rules in 20.51.2.

#### 11 20.51.4.3 Validation pass operations required of some receiving MP components

12 The following Validation pass tests are required of some receiving MP components, and are optional for  
13 other MP components, as specified in other subclauses. If performed, and if any test fails, the receiving  
14 System shall consider the CFM PDU invalid and discard it.

- 15 a) The fixed header length, as determined by the First TLV Offset field (21.4.5), is not shorter than the  
16 length specified by the version selected according to 20.51.4.2.
- 17 b) The fixed-length header does not run over the end of the `mac_service_data_unit`.
- 18 c) A TLV Length field does not run over the end of the `mac_service_data_unit`.
- 19 d) A TLV Length field does not indicate a length that is shorter than the minimum length for that TLV  
20 as specified by the Version field of the CFM PDU.
- 21 e) Every header field and TLV in the CFM PDU meets the validity criteria specified in the header field  
22 and TLV definitions in Clause 21 (see the Validation Test headings in that clause).

#### 23 20.51.5 Execution pass

24 The CFM PDU is processed in the Execution Pass. Changes to the CFM databases can be made, the state  
25 machines can change states, and the contents of future CFM PDUs can be affected by these changes. The  
26 receiving MP:

- 27 a) Processes the CFM PDU in accordance with the numerically lower of 1) the Version field in the  
28 CFM PDU; and 2) the highest Version number known to the receiving implementation.
- 29 b) Processes only those fields in the fixed header portion of the CFM PDU that are defined in the  
30 selected Version of the standard, and ignores any extra octets in the fixed header, if the fixed header  
31 is longer than the length specified by the selected Version.
- 32 c) Ignores any TLV with a Type field not specified by the selected Version.
- 33 d) Does not process any part of the CFM PDU following the End TLV (the lack of an End TLV is not  
34 an error).
- 35 e) Ignores any octets following those specified by the selected Version, if any TLV's Length field is  
36 larger than the value (if any) specified the selected Version.
- 37 f) Ignores all bits undefined in this standard, e.g., unused bits in the Flags field.

38 Unlike the loss of ST BPDUs, the loss of CFM PDUs cannot completely disrupt the function of the network.  
39 Also, unlike other control protocols such as the IEEE 802.3 Slow Protocols, CFM PDUs can be presented at  
40 an arbitrarily high rate. Therefore, a Bridge shall ensure that receiving CFM PDUs on all Bridge Ports at the  
41 maximum possible rate supported by the MAC Services underlying those ports shall not significantly  
42 increase the probability of the failure of the Bridge to maintain loop-free forwarding paths in the bridged  
43 network. Rather, the Bridge's CPU can be protected against excess CFM PDUs in a similar manner as for  
44 other potential Denial of Service attacks.

## 1 20.51.6 Future extensions

2 It is expected that future versions of this protocol will utilize the above versioning rules in order to extend  
3 the CFM PDU format in any number of ways, including perhaps:

- 4 a) Adding new fields to the header by increasing the minimum size of the First TLV Offset field, and  
5 placing the new header fields after the First TLV Offset field in the Version 0 header.
- 6 b) Adding new TLVs and extending the lengths of existing TLVs with new fields.
- 7 c) Adding a new TLV, that is the first TLV to be processed, by renaming the First TLV Offset field to  
8 the “First Version 0 TLV Position,” adding a new “Version X Header Length” field following the  
9 fields in the Version 0 header, and inserting one or more Version X TLVs just ahead of the first  
10 required Version 0 TLV.
- 11 d) Adding new information, perhaps fixed-length information, that is required to follow the End TLV  
12 specified in Version 0.

13 Other methods for extending the CFM PDU format are certainly possible. It is therefore critical that  
14 Version 0 implementations adhere to the versioning requirements of this clause.

15 NOTE—The extension options discussed in this clause are reserved for use by future versions of this standard. Each one  
16 is a violation of 20.51.2, 20.51.4, and/or 20.51.5. The Organization-Specific TLV is the only available compliant  
17 extension to this standard.

## 18 20.52 PDU identification

19 A received CFM PDU is associated with a particular MP. Every data frame, including one carrying a CFM  
20 PDU, has some means, either explicit or implicit, by which that frame can be associated by the receiver with  
21 a particular service instance. In a Bridge that is not VLAN aware, there is only one service instance. In a  
22 VLAN Bridge, the `vlan_identifier` (6.8) identifies the service instance. The means by which the appropriate  
23 receiving MP for processing a received CFM PDU is selected are as follows:

- 24 a) The direction (PHY side or MAC Relay Entity side) from which the CFM PDU was received.
- 25 b) The implicit or explicit association of the frame with a particular service instance (the  
26 `vlan_identifier`).
- 27 c) The MD Level field in the CFM Header.

28 Once the frame containing the CFM PDU has been delivered to the appropriate entity within an MP, the  
29 `destination_address` can be used to decide whether the CFM PDU is to be processed or discarded, as  
30 specified in the description of each entity.

31 The MAID and/or Maintenance association Endpoint Identifier field is not used to identify the receiving MP.  
32 Thus, if the Individual MP address model (see J.6) is used by a particular Bridge, and each MP uses its  
33 Bridge Port’s individual MAC address, then the VID, MD Level, and flow direction uniquely identify the  
34 receiving MEP. If the Shared MP address model is used by a Bridge, so that Up MPs in the Bridge can share  
35 a MAC address, then the specific Bridge Port that is the target of an LBM can be genuinely ambiguous. This  
36 ambiguity allows the designer to trade the value of detailed information against cost of obtaining that  
37 information.

## 38 20.53 Use of transaction IDs and sequence numbers

39 Each CCM, LBM, and LTM has a field (21.6.3, 21.7.3, and 21.8.3) that is incremented for each PDU  
40 transmitted of each type, so that consecutively transmitted PDUs are in numerical order. The variables that  
41 control these fields are `CCIsentCCMs` (20.10.2, for CCM), `nextLBMtransID` (20.30.2, for LBM), and  
42 `nextLTMtransID` (20.41.1, for LTM).

1 In theory, every MEP in a Bridge has a CCI<sub>sent</sub>CCMs variable, a nextLBMtransID variable, and a  
2 nextLTMtransID variable, independently from every other MEP. Therefore, any number of MEPs in a single  
3 Bridge could be transmitting independent streams of LBMs and LTMs as long as they have different MAC  
4 addresses. (If they had the same MAC address, they could not tell each others' LBRs and LTRs apart.)

5 In practice, there can be fewer instances of these variables and their corresponding state machines than one  
6 each per MEP. The managed objects in Clause 12, particularly the definitions of the MEP's LBR counters  
7 [item y) in 12.14.7.1.3 and item z) in 12.14.7.1.3] and the responses permitted to the Transmit Loopback  
8 Messages command (12.14.7.3.3), are specified so that any number of MEP Loopback Initiator transmit  
9 state machines, from one to the number of MEPs, can be implemented. Each state machine can increment its  
10 own nextLBMtransID variable to determine the next transmitted Loopback Transaction Identifier field.  
11 Similarly, the allowed responses to the Transmit Linktrace Message command (12.14.7.4.3) provide the  
12 same latitude for the number of nextLTMtransID variables implemented. The resources for transmitting  
13 LTMs or streams of LBMs can then be used serially, rather than simultaneously, by different MEPs in the  
14 same Bridge.

15 On the other hand, every MEP that is incrementing its CCI<sub>sent</sub>CCMs variable has its own instance of that  
16 variable, and thus its own MEP Continuity Check Initiator state machine, because the Remote MEP state  
17 machines receiving those CCMs are tracking each MEP's sequence of CCMs independently. A MEP can  
18 also transmit 0 in every CCM's Sequence Number field.

## 21. Encoding of CFM PDUs

This clause specifies the method of encoding CFM PDUs. The specifications include the following:

- a) Format used to encapsulate or decapsulate a CFM PDU in a frame (21.2).
- b) Format of the Common CFM Header, used in all CFM PDUs (21.4).
- c) Format used for all Type, Length, Value (TLV) information elements that can be included in CFM PDUs (21.5).
- d) Formats of the Continuity Check Message (CCM, 21.6), the Loopback Message and Loopback Reply (LBM and LBR, 21.7), the Linktrace Message (LTM, 21.8), Linktrace Reply (LTR, 21.9), Send Frame Message (SFM, 29.4.3), and the Reflected Frame Message (RFM, 29.4.2).

NOTE—Clause 18 introduces the principles of CFM operation and the network architectural concepts that support it. Clause 19 breaks down the CFM protocol entities into their components. Clause 20 specifies the protocols operated by the components of each MP. The use of CFM within systems and networks is further described in Clause 22.

### 21.1 Structure, representation, and encoding

All CFM PDUs shall contain an integral number of octets.

The octets in a CFM PDU are numbered starting from 1 and increasing in the order they are put into the MSDU that accompanies a request to or indication from the instance of the MAC Internal Sublayer Service (ISS or EISS) used by a CFM entity.

The bits in an octet are numbered from 1 to 8 in order of increasing bit significance, where 1 is the LSB in the octet.

Where octets and bits within a CFM PDU are represented using a diagram, octets shown higher on the page than subsequent octets and octets shown to the left of subsequent octets at the same height on the page are lower numbered; bits shown to the left of other bits within the same octet are higher numbered.

Where two or more consecutive octets are represented as hexadecimal values, lower numbered octet(s) are shown to the left and each octet following the first is preceded by a hyphen, e.g., 01-80-C2-00-00-00.

When consecutive octets are used to encode a binary number, the lower octet number has the more significant value. When consecutive bits within an octet are used to encode a binary number, the higher bit number has the most significant value. When bits within consecutive octets are used to encode a binary number, the lower octet number composes the more significant bits of the number. A flag is encoded as a single bit, and is set (True) if the bit takes the value 1, and clear (False) otherwise. The remaining bits within the octet can be used to encode other protocol fields.

### 21.2 CFM encapsulation

The means for identifying CFM PDUs consists of two octets containing the EtherType value shown (in hexadecimal notation) in Table 21-1.

**Table 21-1—CFM PDU Encapsulation EtherType**

| Name                                        | Value |
|---------------------------------------------|-------|
| IEEE 802.1Q CFM PDU Encapsulation EtherType | 89-02 |

## 1 21.3 CFM request and indication parameters

### 2 21.3.1 destination\_address parameter

3 There are three classes of CFM PDUs in terms of the CFM entities to which they are addressed:

- 4 a) Those addressed to all MEPs in a service instance (CCM).
- 5 b) Those addressed to the set of MPs immediately adjacent to the transmitting MP, at a certain MD  
6 Level, in a service instance (LTM).
- 7 c) Those addressed to a single, specific MP (LBM, LBR, LTR).

8 Frames carrying CFM PDUs belonging to two different MAs, but at the same MD Level, are distinguished  
9 from each other in the same manner as data frames are distinguished from each other in the corresponding  
10 service instances monitored by those MAs.

11 In a VLAN Bridge, it is the VID that distinguishes service instances. CCMs monitoring a service instance  
12 distinguished by its VID use the group MAC addresses listed in Table 8-18 as the destination\_address.  
13 LTMs monitoring a VID-distinguished service instance use those shown in Table 8-19. All but the last three  
14 bits of the destination\_address are fixed by the OpCode, either CCM or LTM. As shown in these two tables,  
15 the last three bits of the destination\_address match the MD Level field of the CFM PDU Header. CFM PDUs  
16 belonging to MAs monitoring service instances distinguished by their I-SID use the same set of destination  
17 addresses as those belonging to MAs monitoring VLAN service instances. MAs monitoring TESIs are  
18 distinguished from MAs monitoring VLAN services by the vlan\_identifier parameters and from each other  
19 by the 3-tuples <ESP-DA, ESP-SA, ESP-VID> of their ESPs. CFM PDUs belonging to PBB-TE MAs use  
20 the MAC address identified in the ESP-DA fields of their ESP identifiers.

### 21 21.3.2 source\_address parameter

22 The individual MAC address of the MP transmitting the PDU. This is the MAC address of the transmitting  
23 MP. An MP's MAC address is not necessarily unique; MPs configured on the same Bridge Port can share the  
24 same MAC address. The principles used to allocate Organization Unique Identifiers (OUIs) required that  
25 universally unique MAC addresses (those with the U/L bit = 0, see 8.2 of IEEE Std 802-2014 [B7]) not be  
26 used to create MP MAC addresses separately from a physical instance of an IEEE 802 MAC. See J.6 for a  
27 discussion of possible assignments of MAC addresses to MPs.

28 **Validation Test:** The source\_address parameter contains an Individual, and not a Group, MAC address.

## 29 21.4 Common CFM Header

30 The format of a CFM PDU is shown in Table 21-2. A CFM PDU is identified by the encapsulation described  
31 in 21.2. Octets 1 through 4, including the MD Level, Version, OpCode, Flags, and First TLV Offset fields,  
32 constitute the Common CFM Header.

### 33 21.4.1 MD Level

34 (most significant 3 bits) Integer identifying the Maintenance Domain Level (MD Level) of the frame.  
35 Higher numbers correspond to higher MAs, those with the greatest physical reach, with the highest values  
36 for customers' CFM frames. Lower numbers correspond to lower MAs, those with more limited physical  
37 reach, with the lowest values for single Bridges or physical links.

### 38 21.4.2 Version

39 (least significant 5 bits) The protocol version number, always 0. Ignored on receipt.

**Table 21-2—Common CFM Header format**

| Field                       | Octet                 |
|-----------------------------|-----------------------|
| MD Level                    | 1 (high-order 3 bits) |
| Version                     | 1 (low-order 5 bits)  |
| OpCode                      | 2                     |
| Flags                       | 3                     |
| First TLV Offset            | 4                     |
| Varies with value of OpCode | 5                     |
| End TLV (0)                 | First TLV Offset + 5  |

### 1 21.4.3 OpCode

2 (1 octet) The OpCode field specifies the format and meaning of the remainder of the CFM PDU. Certain  
3 values of the OpCode field are reserved for allocation by IEEE 802.1 and/or other organizations. The values  
4 for the various CFM PDU types are shown in Table 21-3. When assigning new OpCode values, pairs of  
5 CFM PDUs that operate in stimulus-response fashion, such as the LBM/LBR or the LTM/LTR pairs, will  
6 use even/odd pairs of values such that the odd (numerically larger) of the two values is the stimulus, and the  
7 even (numerically smaller) the response.

**Table 21-3—OpCode Field range assignments**

| CFM PDU or organization            | OpCode range |
|------------------------------------|--------------|
| Reserved for IEEE Std 802.1        | 0            |
| Continuity Check Message (CCM)     | 1            |
| Loopback Reply (LBR)               | 2            |
| Loopback Message (LBM)             | 3            |
| Linktrace Reply (LTR)              | 4            |
| Linktrace Message (LTM)            | 5            |
| Reflected Frame Message (RFM)      | 6            |
| Send Frame Message (SFM)           | 7            |
| Reserved for IEEE Std 802.1Q       | 8–31         |
| Defined by ITU-T G.8013/Y.1731     | 32–63        |
| Reserved for IETF (RFC 7319 [B44]) | 64–95        |
| Reserved for IEEE Std 802.1        | 96–255       |

### 8 21.4.4 Flags

9 (1 octet) The use of the Flags field is defined separately for each OpCode.

## 21.4.5 First TLV Offset

(1 octet) The offset, starting from the first octet following the First TLV Offset field, up to the first TLV in the CFM PDU. The value of the First TLV Offset field shall be transmitted as indicated in the specification for each of the OpCode field values, as follows (21.6.2, 21.7.2, 21.8.2, and 21.9.2).

## 21.5 TLV format

TLV stands for *Type*, *Length*, *Value* and denotes a method of encoding variable-length and/or optional information in a PDU. TLVs are not aligned to any particular word or octet boundary. TLVs follow each other with no padding between TLVs.

### 21.5.1 General format for CFM TLVs

The TLV format is shown in Table 21-4.

**Table 21-4—TLV format**

| Field   | Octet |
|---------|-------|
| Type    | 1     |
| Length  | 2–3   |
| (Value) | 4     |

#### 21.5.1.1 Type

(1 octet) Required. If 0, no Length or Value fields follow. If not 0, at least the Length field follows the Type field. The Type field is encoded as shown in Table 21-5.

#### 21.5.1.2 Length

(2 octets) Required if the Type field is not 0. Not present if the Type field is 0. The 16 bits of the Length field indicate the size, in octets, of the Value field. 0 in the Length field indicates that there is no Value field.

#### 21.5.1.3 Value

(Length specified by the Length field) Optional. Not present if the Type field is 0 or if Length field is 0.

### 21.5.2 Organization-Specific TLV

Type = 31. Any organization can define TLVs for use in CFM. The format for such TLVs is shown in Table 21-6. The “OUI/CID” is an organizationally unique identifier or a Company ID, obtainable from IEEE.<sup>36</sup> The Subtype is required, so that an additional OUI/CID will not be required if more Organization-Specific TLV are required by an owner of an OUI/CID.

<sup>36</sup> Interested applicants should contact the IEEE Standards Department of The Institute of Electrical and Electronics Engineers (<https://standards.ieee.org/regauth/index.html>).

**Table 21-5—Type Field values**

| TLV or organization                | Type field |
|------------------------------------|------------|
| End TLV                            | 0          |
| Sender ID TLV                      | 1          |
| Port Status TLV                    | 2          |
| Data TLV                           | 3          |
| Interface Status TLV               | 4          |
| Reply Ingress TLV                  | 5          |
| Reply Egress TLV                   | 6          |
| LTM Egress Identifier TLV          | 7          |
| LTR Egress Identifier TLV          | 8          |
| PBB-TE MIP TLV                     | 9          |
| Data Part 1 TLV (29.3.3.2)         | 10         |
| Data Part 2 TLV (29.3.3.2)         | 11         |
| Truncated Data TLV (29.3.3.2)      | 12         |
| Reserved for IEEE Std 802.1Q       | 13–30      |
| Organization-Specific TLV          | 31         |
| Defined by ITU-T G.8013/Y.1731     | 32–63      |
| Reserved for IETF (RFC 7319 [B44]) | 64–95      |
| Reserved for IEEE Std 802.1        | 96–255     |

**Table 21-6—Organization-Specific TLV format**

| Field            | Octet            |
|------------------|------------------|
| Type = 31        | 1                |
| Length           | 2–3              |
| OUI/CID          | 4–6              |
| Subtype          | 7                |
| Value (optional) | 8 – (Length + 3) |

<sup>1</sup> This TLV category is provided to allow different organizations, such as IEEE 802.1, IEEE 802.3, ITU-T, as  
<sup>2</sup> well as individual software and equipment vendors, to define TLVs that advertise information to remote  
<sup>3</sup> entities attached to the same media, subject to the following restrictions:

- <sup>4</sup> a) Information transmitted in an Organization-Specific TLV shall not require the recipient to violate  
<sup>5</sup> any requirement in this standard.
- <sup>6</sup> b) Information transmitted in one Organization-Specific TLV shall not be used to provide a means for  
<sup>7</sup> sending messages that are larger than would fit within a single CFM PDU.
- <sup>8</sup> c) Organization-Specific TLVs shall conform to 20.51.

### 21.5.3 Sender ID TLV

Type = 1. Identifies the Bridge on which the transmitting MP is configured and may also include a management address for that Bridge. The allowed values are those contained in the Chassis ID TLV and Management Address TLV in IEEE Std 802.1AB, modified to fit into a CFM TLV, as shown in Table 21-7. Whether the Sender ID TLV is transmitted, and what information is included in the TLV, are controlled by managed objects [item e) in 12.14.3.1.3, item d) in 12.14.5.1.3, item d) in 12.14.6.1.3].

**Table 21-7—Sender ID TLV format**

| Field                            | Octet                                                                                |
|----------------------------------|--------------------------------------------------------------------------------------|
| Type = 1                         | 1                                                                                    |
| Length                           | 2–3                                                                                  |
| Chassis ID Length                | 4                                                                                    |
| Chassis ID Subtype               | 5                                                                                    |
| Chassis ID                       | 6 – (Chassis ID Length + 5)                                                          |
| Management Address Domain Length | (Chassis ID Length + 6)                                                              |
| Management Address Domain        | (Chassis ID Length + 7) – (Chassis ID Length + Management Address Domain Length + 6) |
| Management Address Length        | (Chassis ID Length + Management Address Domain Length + 7)                           |
| Management Address               | (Chassis ID Length + Management Address Domain Length + 8) – (Length + 3)            |

**Validation Test:** The Length field is large enough to contain all of the fields indicated as being present by the Chassis ID Length, Management Address Domain Length, and/or Management Address Length fields.

#### 21.5.3.1 Chassis ID Length

(1 octet) The length, in octets, of the Chassis ID field. 0 if no Chassis ID is specified. Always present.

**Validation Test:** The Chassis ID Length field either is 0, or is less than (TLV Length field value – 1).

#### 21.5.3.2 Chassis ID Subtype

(1 octet) The **chassis ID subtype**, as specified by IEEE Std 802.1AB, identifying the type of the component referenced by the Chassis ID field. Not present if the Chassis ID Length field contains 0.

#### 21.5.3.3 Chassis ID

(Length specified by the Chassis ID Length field) Identifies the chassis. Specified by IEEE Std 802.1AB. Not present if the Chassis ID Length field contains 0.

#### 21.5.3.4 Management Address Domain Length

(1 octet) The Management Address Domain Length field contains the length, in octets, of the Management Address Domain field. If 0, or if the TLV's Length field indicates that the Management Address Domain Length field is not present, then the Management Address Domain, Management Address Length, and Management Address fields are not present.

### 21.5.3.5 Management Address Domain

(Length specified by the Management Address Domain Length field) The Management Address Domain field specifies the format and type of the contents of the Management Address field, as well as a management mechanism. The format of the Management Address Domain field shall be that of an Object Identifier (OID), as specified by section 8.19 in ITU-T X.690 (2002). The OID references a TDomain (IETF RFC 2579). Standard values that are useful for the Management Address Domain field include, but are not limited to,

- transportDomainUdpIpv4, indicating Simple Network Management Protocol (SNMP) over User Datagram Protocol (UDP) over IPv4 (IETF RFC 3419).
- transportDomainUdpIpv6, indicating SNMP over UDP over IPv6 (IETF RFC 3419).
- snmpIeee802Domain, indicating SNMP over the MAC Service (IETF RFC 4789).

This field is not present if the Management Address Domain Length field is not present or contains a 0.

### 21.5.3.6 Management Address Length

(1 octet) The length, in octets, of the Management Address field. This field is not present if the Management Address Domain Length field is not present or contains a 0.

### 21.5.3.7 Management Address

(Length specified by the Management Address Length field) Identifies a TransportDomain (IETF RFC 3419, IETF RFC 4789) through which the Bridge in which the transmitting MP is configured can be managed. The format of the Management Address field is specified by the MIB module defining the TransportDomain. This field is not present if the Management Address Domain Length field is not present or contains a 0, or if the Management Address Length field is not present or contains a 0.

NOTE—The contents of the Management Address Domain and Management Address are defined in terms of MIB modules. Therefore, a published MIB module is required in order to define a specific value that can be used in the Management Address Domain field. However, the use of Management Address Domain field by a system does not require that the system be manageable via SNMP; the published MIB module could define, for example, a TransportDomain for a proprietary Command Line Interpreter over ITU-T X.25 [B52].

### 21.5.4 Port Status TLV

Type = 2. The Port Status TLV indicates the ability of the Bridge Port on which the transmitting MEP resides to pass ordinary data, regardless of the status of the MAC. The value of this TLV is driven by the MEP variable enableRmepDefect (20.9.2), as shown in Table 21-9. The format of this TLV is shown in Table 21-8. Any change in the Port Status TLV's value triggers one extra transmission of that Bridge Port's MEPs' CCMs.

**Table 21-8—Port Status TLV format**

| Field          | Octet |
|----------------|-------|
| Type = 2       | 1     |
| Length         | 2–3   |
| See Table 21-9 | 4     |

**Validation Test:** The Port Status TLV contains one of the values listed in Table 21-9.

**Table 21-9—Port Status TLV values**

| mnemonic  | Ordinary data passing freely through the Port | value |
|-----------|-----------------------------------------------|-------|
| psBlocked | No: enableRmepDefect = false                  | 1     |
| psUp      | Yes: enableRmepDefect = true                  | 2     |

<sup>1</sup> A MEP that is configured in a Bridge in a position that is not associated with a single value for the Port State  
<sup>2</sup> and VID member set, e.g., a MEP in position 5 in Figure 22-9, on a Bridge running multiple spanning tree  
<sup>3</sup> instances via MSTP, shall not transmit the Port Status TLV.

#### <sup>4</sup> 21.5.5 Interface Status TLV

<sup>5</sup> Type = 4. The Interface Status TLV indicates the status of the interface on which the MEP transmitting the  
<sup>6</sup> CCM is configured (which is not necessarily the interface on which it resides, see J.6), or the next lower  
<sup>7</sup> interface in the IETF RFC 2863 IF-MIB. The format of this TLV is shown in Table 21-10. The enumerated  
<sup>8</sup> values are shown in Table 21-11. These values correspond to the values for ifOperStatus in IETF RFC 2863.

**Table 21-10—Interface Status TLV format**

| Field           | Octet |
|-----------------|-------|
| Type = 4        | 1     |
| Length          | 2–3   |
| See Table 21-11 | 4     |

<sup>9</sup> **Validation Test:** The Interface Status TLV field contains one of the values listed in Table 21-11.

**Table 21-11— Interface Status TLV values**

| mnemonic         | Interface Status<br>(IETF RFC 2863 ifOperStatus) | value |
|------------------|--------------------------------------------------|-------|
| isUp             | up                                               | 1     |
| isDown           | down                                             | 2     |
| isTesting        | testing                                          | 3     |
| isUnknown        | unknown                                          | 4     |
| isDormant        | dormant                                          | 5     |
| isNotPresent     | notPresent                                       | 6     |
| isLowerLayerDown | lowerLayerDown                                   | 7     |

## 21.5.6 Data TLV

Type = 3. Zero or more octets of arbitrary data. Serves several purposes, including reflected data frame in RFM, to be decapsulated data in SFM, the transmission of different frame sizes to test Maximum Service Data Unit Size capabilities and the testing for data-specific error dependencies. The Data TLV may be included in the LBM and the LBR, the RFM, and the SFM, but not in any other CFM PDU. The contents of the Data TLV shall not be examined or interpreted by the receiver of any CFM PDU except an LBR. The format of the Data TLV is shown in Table 21-12.

**Table 21-12—Data TLV format**

| Field    | Octet            |
|----------|------------------|
| Type = 3 | 1                |
| Length   | 2–3              |
| Data     | 4 – (Length + 3) |

## 21.5.7 End TLV

Required. Type = 0. Length and Value fields are not present. The End TLV is the last TLV in the CFM PDU. (Lack of the End TLV does not invalidate a received CFM PDU, but certain cases where frames receive extra headers, e.g., MACsec or additional VLAN tags, can cause errors if it is not present.) The format of the End TLV is shown in Table 21-13.

**Table 21-13—End TLV format**

| Field    | Octet |
|----------|-------|
| Type = 0 | 1     |

## 21.6 CCM format

The format of the CCM is shown in Table 21-14. In order to limit the resources required to generate and receive CCMs, the following restrictions apply to the format of the CCM:

- a) The Maintenance Domain Name and Short MA Name are encoded in a manner such that an MP can treat all of the fields from the Maintenance Domain Name Format field through the Short MA Name field as a unit when deciding whether a received CCM does or does not belong to the receiving MP's MA. That is, the MP can perform a binary comparison of these fields in a received CCM to the fields it would transmit in its own CCMs. This means, for example, that two Maintenance Domain Names differing, e.g., only by trailing spaces or by upper/lower case substitutions, can be interpreted to denote different MAs.
- b) The portion of the PDU allocated for the MAID is limited to 48 octets, in order to minimize the memory requirements of a hardware implementation of a MEP.

An MP shall be able to receive and process any valid CCM PDU that is 128 octets in length or less, starting with the MD Level/Version octet and including the End TLV. An MP shall not transmit a CCM PDU exceeding this length. An MP may discard as invalid any received CCM PDU that exceeds this length.

**Table 21-14—CCM format**

| Field                                                                   | Octet                                                        |
|-------------------------------------------------------------------------|--------------------------------------------------------------|
| Common CFM Header                                                       | 1–4                                                          |
| Sequence Number                                                         | 5–8                                                          |
| Maintenance association Endpoint Identifier                             | 9–10                                                         |
| Maintenance Association Identifier                                      | 11–58                                                        |
| Defined by ITU-T G.8013/Y.1731                                          | 59–74                                                        |
| Reserved for definition in future versions of the protocol <sup>a</sup> |                                                              |
| Optional CCM TLVs                                                       | First TLV Offset + 5 <sup>b</sup>                            |
| End TLV (0)                                                             | First TLV Offset + 5,<br>if no Optional CCM TLVs are present |

<sup>a</sup> This field has 0 length in this version 0 of CFM. It is shown in order to stress that additional information can be present in future versions of CFM, and that a version 0 receiver ignores its contents, if present.

<sup>b</sup> Octet 75 for transmitted CCMs.

## 21.6.1 Flags

(1 octet) The Flags field of the Common CFM Header is split into four parts for the CCM as follows:

- a) RDI field (21.6.1.1)
- b) Reserved field (21.6.1.2)
- c) CCM Interval field (21.6.1.3)
- d) Traffic field (21.6.1.4)

### 21.6.1.1 RDI

The MSB of the Flags field is the RDI bit. This bit is set to 1 if the transmitting MEP's presentRDI variable (20.9.6) is set, and 0 if not.

### 21.6.1.2 Reserved

The bits of the Flags field not including the RDI field, the Traffic field, and the CCM Interval field are set to 0 by the transmitting MP, and are not to be examined by the receiving MP [item b) in 20.51.2].

### 21.6.1.3 CCM Interval

The least significant 3 bits of the Flags field constitute the CCM Interval field. The CCM Interval field is encoded as specified in Table 21-15.

NOTE—The maximum CCM Lifetime in Table 21-15 is equal to 3.5 times the CCM Interval. The minimum CCM Lifetime is the maximum CCM Lifetime minus 1/4 of the CCM Interval, the minimum required granularity of the timer variables CCIwhile, rMEPwhile, errorCCMwhile, and xconCCMwhile.

**Validation Test:** The CCM Interval field does not contain the value 0.

### 21.6.1.4 Traffic field

In the case of a PBB-TE MA or Infrastructure Segment MA, the second most significant bit of the Flags field is the Traffic bit. This bit if supported, is used to indicate the presence of backbone service instances in the monitored TESI or the assignment of TESIs in the monitored Infrastructure Segments. This bit is set to 1

**Table 21-15—CCM Interval field encoding**

| Transmission Interval | max. CCM Lifetime | min. CCM Lifetime | CCM Interval field |
|-----------------------|-------------------|-------------------|--------------------|
| invalid               |                   |                   | 0                  |
| 3 1/3 ms<br>(300 Hz)  | 11 2/3 ms         | 10 5/6 ms         | 1                  |
| 10 ms                 | 35 ms             | 32.5 ms           | 2                  |
| 100 ms                | 350 ms            | 325 ms            | 3                  |
| 1 s                   | 3.5 s             | 3.25 s            | 4                  |
| 10 s                  | 35 s              | 32.5 s            | 5                  |
| 1 min                 | 3.5 min           | 3.25 min          | 6                  |
| 10 min                | 35 min            | 32.5 min          | 7                  |

1 if the transmitting MEP's presentTraffic variable (20.9.8) is set in the case of a PBB-TE MEP or the  
2 transmitting MEP's IspresentTraffic variable (20.9.10) is set in the case of a Infrastructure Segment MEP,  
3 and 0 if not. This field is not examined if the receiving MPs are not PBB-TE or Infrastructure Segment  
4 MEPs supporting the traffic field.

#### 5 21.6.2 First TLV Offset

6 (1 octet) The First TLV Offset field of the Common CFM Header in a CCM is transmitted as 70.

7 **Validation Test:** The First TLV Offset field of the Common CFM Header in a CCM contains a value greater  
8 than or equal to 70.

#### 9 21.6.3 Sequence Number

10 (4 octets) A MEP either transmits a 0 in this field or copies to it the contents of the CCIsentCCMs variable  
11 (20.10.2).

#### 12 21.6.4 Maintenance association Endpoint Identifier

13 (2 octets) Contains an integer value. This TLV specifies from which MEP the CCM was transmitted.

14 **Validation Test:** MEPID is in the range 1–8191.

#### 15 21.6.5 Maintenance Association Identifier

16 (48 octets) This field contains the MAID of the transmitting MEP. It is divided into six subfields, plus, if  
17 necessary, a pad of octets contains 0 to fill out its fixed length. The subfields are as follows:

- 18 a) Maintenance Domain Name Format (21.6.5.1)
- 19 b) Maintenance Domain Name Length (21.6.5.2)
- 20 c) Maintenance Domain Name (21.6.5.3)
- 21 d) Short MA Name Format (21.6.5.4)
- 22 e) Short MA Name Length (21.6.5.5)
- 23 f) Short MA Name (21.6.5.5)

<sup>1</sup> The total length of these fields, including padding, if present, shall be exactly 48 octets. There are two  
<sup>2</sup> possible formats of the Maintenance Association Identifier field, as shown in Table 21-16 and Table 21-17,  
<sup>3</sup> depending on whether the Maintenance Domain Name is present.

**Table 21-16—CCM Maintenance Association Identifier field format:  
Maintenance Domain present**

| Field                                  | Octet                                                    |
|----------------------------------------|----------------------------------------------------------|
| Maintenance Domain Name Format (not 1) | 1                                                        |
| Maintenance Domain Name Length         | 2                                                        |
| Maintenance Domain Name                | $3 - (\text{mdnl}^a + 2)$                                |
| Short MA Name Format                   | $(\text{mdnl} + 3)$                                      |
| Short MA Name Length                   | $(\text{mdnl} + 4)$                                      |
| Short MA Name                          | $(\text{mdnl} + 5) - (\text{mdnl} + \text{smanl}^b + 4)$ |
| 0 pad, if necessary                    | $(\text{mdnl} + \text{smanl} + 5) - 48$                  |

<sup>a</sup> Maintenance Domain Name Length.

<sup>b</sup> Short MA Name Length.

**Table 21-17—CCM Maintenance Association Identifier field format:  
Maintenance Domain not present**

| Field                              | Octet                      |
|------------------------------------|----------------------------|
| Maintenance Domain Name Format (1) | 1                          |
| Short MA Name Format               | 2                          |
| Short MA Name Length               | 3                          |
| Short MA Name                      | $4 - (\text{smanl}^a + 3)$ |
| 0 pad, if necessary                | $(\text{smanl} + 4) - 48$  |

<sup>a</sup> Short MA Name Length.

#### <sup>4</sup> 21.6.5.1 Maintenance Domain Name Format

<sup>5</sup> (1 octet) Specifies the format of the Maintenance Domain Name field. The Maintenance Domain Name  
<sup>6</sup> Format is encoded according to Table 21-18.

#### <sup>7</sup> 21.6.5.2 Maintenance Domain Name Length

<sup>8</sup> (1 octet) Specifies the length in octets of the Maintenance Domain Name field. Not present if the  
<sup>9</sup> Maintenance Domain Name Format field specifies “No Maintenance Domain Name present” (1).

<sup>10</sup> **Validation Test:** The Maintenance Domain Name Length in a CCM, if present, is greater than or equal to 1,  
<sup>11</sup> and less than or equal to 43.

**Table 21-18—Maintenance Domain Name Format**

| Maintenance Domain Name Format field  | Value  |
|---------------------------------------|--------|
| Reserved for IEEE Std 802.1           | 0      |
| No Maintenance Domain Name present    | 1      |
| Domain Name-based string <sup>a</sup> | 2      |
| MAC address + 2-octet integer         | 3      |
| Character string <sup>b</sup>         | 4      |
| Reserved for IEEE Std 802.1           | 5–31   |
| Defined by ITU-T G.8013/Y.1731        | 32–63  |
| Reserved for IEEE Std 802.1           | 64–255 |

<sup>a</sup> This is a string the terminal substring of which is an IETF RFC 1035 DNS Name, and the remainder of which is a text string, following the syntax of a DNS Name, denoting the identity of a particular Maintenance Domain.

<sup>b</sup> This is an IETF RFC 2579 DisplayString, with the exception that character codes 0–31 (decimal) are not used.

### 21.6.5.3 Maintenance Domain Name

(Length specified by the Maintenance Domain Name Length field) Contains the Maintenance Domain Name, in the format specified by the Maintenance Domain Name Format field. Not present if the Maintenance Domain Name Format field specifies “No Maintenance Domain Name present” (1).

### 21.6.5.4 Short MA Name Format

(1 octet) Specifies the format of the Short MA Name field. The Short MA Name Format is encoded according to Table 21-19.

**Table 21-19—Short MA Name Format**

| Short MA Name Format field                           | Value  |
|------------------------------------------------------|--------|
| Reserved for IEEE Std 802.1                          | 0      |
| Primary VID                                          | 1      |
| Character string <sup>a</sup>                        | 2      |
| 2-octet integer                                      | 3      |
| IETF RFC 2685 VPN ID                                 | 4      |
| Reserved for IEEE Std 802.1                          | 5–31   |
| ICC-based format as specified in ITU-T G.8013/Y.1731 | 32     |
| Defined by ITU-T G.8013/Y.1731                       | 33–63  |
| Reserved for IEEE Std 802.1                          | 64–255 |

<sup>a</sup> This is an IETF RFC 2579 DisplayString, with the exception that character codes 0–31 (decimal) are not used.

### 21.6.5.5 Short MA Name Length

(1 octet) Specifies the length in octets of the Short MA Name field.

**Validation Test:** The Short MA Name Length in a CCM contains a value greater than or equal to 1.

**Validation Test:** The Short MA Name Length in a CCM does not indicate that the Short MA Name runs over the 48-octet limit for the MAID.

### 21.6.5.6 Short MA Name

(Length specified by the Short MA Name Length field) Contains the Short MA Name, in the format specified by the Short MA Name Format field.

### 21.6.6 Defined by ITU-T G.8013/Y.1731

(16 octets) The use of this field is defined by ITU-T G.8013/Y.1731. A value of 0 should be transmitted in this field.

### 21.6.7 Optional CCM TLVs

The following TLVs should be included, as allowed by their specifications, in every CCM transmitted:

- a) Sender ID TLV (21.5.3)
- b) Port Status TLV (21.5.4)
- c) Interface Status TLV (21.5.5)

The following TLV may be included in any CCM transmitted:

- d) Organization-Specific TLV (21.5.2)

The Optional CCM TLVs in this subclause may be placed in any order by the MEP transmitting the CCM. The receiving MP shall not depend upon any particular ordering of the Optional CCM TLVs in a CCM for its proper operation.

### 21.7 LBM and LBR formats

The format of the LBM and LBR is shown in Table 21-20.

**Table 21-20—LBM and LBR formats**

| Field                                                                   | Octet                                                              |
|-------------------------------------------------------------------------|--------------------------------------------------------------------|
| Common CFM Header                                                       | 1–4                                                                |
| Loopback Transaction Identifier                                         | 5–8                                                                |
| Reserved for definition in future versions of the protocol <sup>a</sup> |                                                                    |
| Additional LBM/LBR TLVs                                                 | First TLV Offset + 5 <sup>b</sup>                                  |
| End TLV (0)                                                             | First TLV Offset + 5,<br>if no Additional LBM/LBR TLVs are present |

<sup>a</sup> This field has 0 length in this version 0 of CFM. It is shown in order to stress that additional information can be present in future versions of CFM, and that a version 0 receiver ignores its contents, if present.

<sup>b</sup> Octet 9 for transmitted LBMs.

### 21.7.1 Flags

(1 octet) In an LBM, the Flags field of the Common CFM Header is set to 0 by the transmitting MP, and is not examined by the receiving MP.

### 21.7.2 First TLV Offset

(1 octet) The First TLV Offset field of the Common CFM Header in an LBM or LBR is transmitted as 4.

**Validation Test:** The First TLV Offset field of the Common CFM Header in an LBM or LBR contains a value greater than or equal to 4.

### 21.7.3 Loopback Transaction Identifier

(4 octets) A MEP copies the contents of the nextLBMtransID variable (20.30.2) to this field.

### 21.7.4 Additional LBM/LBR TLVs

The following TLV shall be included in every LBM transmitted by a MEP to a MIP configured on a PBB-TE MA as specified in 21.7.5. The TLV will not be present in any other type of MA.

a) PBB-TE MIP TLV (21.7.5)

The following TLV should be included in every LBM transmitted:

b) Sender ID TLV (21.5.3)

The following TLV can be included by management action in any LBM transmitted:

c) Data TLV (21.5.6)

The following TLV may be included in any LBM transmitted:

d) Organization-Specific TLV (21.5.2)

The PBB-TE MIP TLV, if present, shall be placed first. The other Additional LBM/LBR TLVs may be placed in any order by the MEP transmitting the LBM.

### 21.7.5 PBB-TE MIP TLV

Type = 9. Used only in MAs monitoring PBB-TE services. It enables MIPs to selectively intercept LBMs that are targeting them. The PBB-TE MIP TLV is not used if the target address of the LBM or LTM is associated with any of the values in the ESP-DA field of the monitored MA's ESPs; otherwise, it shall be present; The format of the PBB-TE MIP TLV is illustrated in Table 21-21.

**Table 21-21—PBB-TE MIP TLV format**

| Field           | Octet |
|-----------------|-------|
| Type = 9        | 1     |
| Length          | 2–3   |
| MIP MAC address | 4–9   |
| Reverse VID     | 10–11 |
| Reverse MAC     | 12–17 |

1 **Validation Test:** The MIP MAC address field contains an individual MAC address.

2 **Validation Test:** The Reverse MAC field contains an Individual, or a group MAC address as specified in  
3 21.7.5.3.

4 **Validation Test:** The Length field either is 8, indicating that no Reverse MAC field is present, or is 14, and  
5 thus contains the Reverse MAC field.

#### 6 **21.7.5.1 MIP MAC address**

7 The MIP MAC address contains the destination MAC address for LBMs transmitted by the MEP [item b) in  
8 12.14.7.3.2]. In the case of LTMs, this field is null.

#### 9 **21.7.5.2 Reverse VID**

10 The Reverse VID field is used by the MIPs in order to set the `vlan_identifier` parameters on LBRs and LTRs.  
11 Its value is provided by the operator on the initiation of the LBM [item f) in 12.14.7.3.2] or the LTM [item e)  
12 in 12.14.7.4.2]. In the case of point-to-point TESIs, its value is the ESP-VID of the MA's ESP that has the  
13 MEP's MAC address in its ESP-DA field.

#### 14 **21.7.5.3 Reverse MAC**

15 This Reverse MAC field refers to the ESP-SA of any of the point-to-point ESPs of the MA, if the LBM/LTM  
16 is initiated on a root PBB-TE MEP or to the ESP-DA of the point-to-multipoint ESP of the MA, if the  
17 LBM/LTM is initiated on any of the leaf MEPs.

### 18 **21.8 LTM format**

19 The format of the LTM is shown in Table 21-22.

**Table 21-22—LTM format**

| Field                                                                   | Octet                                                          |
|-------------------------------------------------------------------------|----------------------------------------------------------------|
| Common CFM Header                                                       | 1–4                                                            |
| LTM Transaction Identifier                                              | 5–8                                                            |
| LTM TTL                                                                 | 9                                                              |
| Original MAC Address                                                    | 10–15                                                          |
| Target MAC Address                                                      | 16–21                                                          |
| Reserved for definition in future versions of the protocol <sup>a</sup> |                                                                |
| Additional LTM TLVs                                                     | First TLV Offset + 5 <sup>b</sup>                              |
| End TLV (0)                                                             | First TLV Offset + 5, if no<br>Additional LTM TLVs are present |

<sup>a</sup> This field has 0 length in this version 0 of CFM. It is shown in order to stress that additional information can be present in future versions of CFM and that a version 0 receiver ignores its contents, if present.

<sup>b</sup> Octet 22 for transmitted LTMs.

## 21.8.1 Flags

(1 octet) In the LTM, the Flags field of the Common CFM Header specifies certain options as shown in Table 21-23.

**Table 21-23—LTM Flags field**

| Mnemonic   | Meaning                                                                                                                                                             | Bit     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| UseFDBonly | If set, indicates that only MAC addresses learned in a Bridge's FDB, and not information saved in the MIP CCM Database, is to be used to determine the Egress Port. | 8 (MSB) |
| Reserved   | Transmitted as 0, and ignored by the receiver.                                                                                                                      | 7–1     |

## 21.8.2 First TLV Offset

(1 octet) The First TLV Offset field of the Common CFM Header in an LTM is transmitted as 17.

**Validation Test:** The First TLV Offset field of the Common CFM Header in an LTM contains a value greater than or equal to 17.

## 21.8.3 LTM Transaction Identifier

(4 octets) A MEP copies the contents of the nextLTMtransID variable (20.41.1) to this field.

## 21.8.4 LTM TTL

(1 octet) The number of hops remaining to this LTM. Decrement by 1 by each Linktrace Responder that handles the LTM. One less than this value is returned in the LTR. If 0 or 1 on input, the LTM is not transmitted to the next hop. If 0 on input, no LTR is returned. The value of the LTM TTL field in the LTM transmitted by the originating MEP is controlled by a managed object [item d) in 12.14.7.4.2]; the default value if none is specified is 64.

## 21.8.5 Original MAC Address

(6 octets) The MAC address of the MEP that originated the LTM. This can be different from the source MAC address of an LTM because each MIP along the path puts its own MAC address in the source MAC address field, while retaining the Original MAC Address Field.

**Validation Test:** The Original MAC Address field contains an Individual, and not a Group, MAC address.

## 21.8.6 Target MAC Address

(6 octets) Specifies an individual MAC address, the path to which the LTM is intended to trace. Any individual MAC address can be specified in this field. See also 20.3.1.

**Validation Test:** The Target MAC Address field contains an Individual, and not a Group, MAC address.

## 21.8.7 Additional LTM TLVs

The following TLV shall be included in every LTM by each MP originating or forwarding an LTM:

- a) LTM Egress Identifier TLV (21.8.8)

The following TLVs may be included in an LTM by each MP originating or forwarding an LTM:

- b) Sender ID TLV (21.5.3)
- c) Organization-Specific TLV(s) (21.5.2)

The following TLV shall be included in every LTM transmitted by a MEP configured on a PBB-TE MA.

The TLV will not be present in any other type of MA.

- d) PBB-TE MIP TLV (21.7.5)

The Additional LTM TLVs may be placed in any order by the MP transmitting the LTM.

## 21.8.8 LTM Egress Identifier TLV

Type = 7. Identifies the MEP Linktrace Initiator that is originating, or the Linktrace Responder that is forwarding, this LTM. The low-order (highest numbered) six octets contain an EUI-48 IEEE MAC address unique to the system in which the MEP Linktrace Initiator or Linktrace Responder resides. The high-order (lowest numbered) two octets contain an integer value sufficient to uniquely identify the transmitted LTM; a constant value (e.g., 0) is sufficient for this purpose, since a Bridge initiates or forwards only a single copy of an LTM. The format of the LTM Egress Identifier TLV is illustrated in Table 21-24.

**Table 21-24—LTM Egress Identifier TLV format**

| Field             | Octet |
|-------------------|-------|
| Type = 7          | 1     |
| Length            | 2–3   |
| Egress Identifier | 4–11  |

NOTE—For most Bridges, the address of any MAC attached to the Bridge will suffice for the low-order six octets, and 0 for the high-order octets. In some situations, e.g., if multiple virtual Bridges utilizing emulated LANs are implemented in a single physical system, the high-order two octets can be used to differentiate among the transmitting entities.

## 21.9 LTR format

The format of the LTR is shown in Table 21-25.

**Validation Test:** The Reply Ingress TLV (21.9.8), the Reply Egress TLV (21.9.9), or both, are present.

### 21.9.1 Flags

(1 octet) In the LTR, the Flags field of the Common CFM Header specifies certain options as shown in Table 21-26.

**Table 21-25—LTR format**

| Field                                                                   | Octet                                                          |
|-------------------------------------------------------------------------|----------------------------------------------------------------|
| Common CFM Header                                                       | 1–4                                                            |
| LTR Transaction Identifier                                              | 5–8                                                            |
| Reply TTL                                                               | 9                                                              |
| Relay Action                                                            | 10                                                             |
| Reserved for definition in future versions of the protocol <sup>a</sup> |                                                                |
| Additional LTR TLVs                                                     | First TLV Offset + 5 <sup>b</sup>                              |
| End TLV (0)                                                             | First TLV Offset + 5,<br>if no Additional LTR TLVs are present |

<sup>a</sup> This field has 0 length in this version 0 of CFM. It is shown in order to stress that additional information can be present in future versions of CFM, and that a version 0 receiver ignores its contents, if present.

<sup>b</sup> Octet 11 for transmitted LTRs.

**Table 21-26—LTR Flags field**

| Mnemonic    | Meaning                                                                                                       | Bit     |
|-------------|---------------------------------------------------------------------------------------------------------------|---------|
| UseFDBonly  | Copied from LTM.                                                                                              | 8 (MSB) |
| FwdYes      | The LTM was (1) or was not (0) forwarded.                                                                     | 7       |
| TerminalMEP | The MP reported in the Reply Egress TLV (Reply Ingress TLV, if the Reply Egress TLV is not present) is a MEP. | 6       |
| Reserved    | Copied from LTM.                                                                                              | 5–1     |

## 1 21.9.2 First TLV Offset

2 (1 octet) The First TLV Offset field of the Common CFM Header in an LTR is transmitted as 6.

3 **Validation Test:** The First TLV Offset field of the Common CFM Header in an LTR contains a value greater  
4 than or equal to 6.

## 5 21.9.3 LTR Transaction Identifier

6 (4 octets) The value from the LTM Transaction Identifier field in the LTM that triggered the transmission of  
7 this LTR.

## 8 21.9.4 Reply TTL

9 (1 octet) One less than the value from the LTM TTL field in the LTM that triggered the transmission of this  
10 LTR. If the LTM TTL field contained a 0, no LTR is transmitted.

## 21.9.5 Relay Action

(1 octet) Reports how the data frame targeted by the LTM would be passed through the MAC Relay Entity to the Egress Bridge Port, as shown in Table 21-27.

**Validation Test:** The value in the Relay Action field is one of the values enumerated in 21.9.5.

**Table 21-27—Relay Action field values**

| Mnemonic | Relay action                                                                              | Value |
|----------|-------------------------------------------------------------------------------------------|-------|
| RlyHit   | The LTM reached an MP whose MAC address matches the target MAC address.                   | 1     |
| RlyFDB   | The Egress Port was determined by consulting the FDB [item a) in 20.47.1.2].              | 2     |
| RlyMPDB  | The Egress Port was determined by consulting the MIP CCM Database [item b) in 20.47.1.2]. | 3     |

## 21.9.6 Additional LTR TLVs

The following TLV shall be included in an LTR according to 20.3.2:

a) LTR Egress Identifier TLV (21.9.7)

One or both of the following TLVs shall be included in an LTR according to 20.3.2:

b) Reply Ingress TLV (21.9.8)

c) Reply Egress TLV (21.9.9)

The following TLVs may be included in an LTR:

d) Sender ID TLV (21.5.3)

e) Organization-Specific TLV (21.5.2)

The Additional LTR TLVs may be placed in any order by the MP transmitting the LTR. The receiving MEP shall not depend upon any particular ordering of the Additional LTR TLVs in an LTR for its proper operation.

## 21.9.7 LTR Egress Identifier TLV

Type = 8. Identifies the source and destination of the LTM that triggered transmission of this LTR. The format of the LTR Egress Identifier TLV is illustrated in Table 21-28.

**Table 21-28—LTR Egress Identifier TLV format**

| Field                  | Octet |
|------------------------|-------|
| Type = 8               | 1     |
| Length                 | 2–3   |
| Last Egress Identifier | 4–11  |
| Next Egress Identifier | 12–19 |

### 21.9.7.1 Last Egress Identifier

(8 octets) Identifies the MEP Linktrace Initiator that originated, or the Linktrace Responder that forwarded, the LTM to which this LTR is the response. This field takes the same value as the LTM Egress Identifier TLV of that LTM, or the value 0, if no LTM Egress Identifier TLV was present in that LTM.

### 21.9.7.2 Next Egress Identifier

(8 octets) Identifies the Linktrace Responder that transmitted this LTR, and can forward the LTM to the next hop. This field takes the same value as the LTM Egress Identifier TLV of the forwarded LTM, if any. If the FwdYes bit of the Flags field is false, the contents of this field are undefined, i.e., any value can be transmitted, and the field is ignored by the receiver.

### 21.9.8 Reply Ingress TLV

Type = 5. The format of the Reply Ingress TLV is shown in Table 21-29. The Reply Ingress TLV is transmitted if and only if the Bridge Port on which the LTM was received has an MP in the MA specified by the LTM.

**Table 21-29—Reply Ingress TLV format**

| Field                   | Octet             |
|-------------------------|-------------------|
| Type = 5                | 1                 |
| Length                  | 2–3               |
| Ingress Action          | 4                 |
| Ingress MAC Address     | 5–10              |
| Ingress Port ID Length  | 11                |
| Ingress Port ID Subtype | 12                |
| Ingress Port ID         | 13 – (Length + 3) |

**Validation Test:** The value in the Ingress Action field is one of the values enumerated in 21.9.8.1.

**Validation Test:** The Ingress MAC Address field contains an Individual, and not a Group, MAC address.

**Validation Test:** The Length field either is 7, indicating that no Ingress Port ID field is present, or is (9 + the Ingress Port ID Length field) or larger, and thus contains the Ingress Port ID field.

#### 21.9.8.1 Ingress Action

(1 octet) Reports how the data frame targeted by the LTM would be received on the receiving MP, as shown in Table 21-30.

#### 21.9.8.2 Ingress MAC Address

(6 octets) The MAC address that can be used as the Destination MAC address of an LBM intended for the ingress MP.

**Table 21-30—Ingress Action field values**

| Mnemonic   | Ingress action                                                                                                                                                         | Value |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| IngOK      | The target data frame would be passed through to the MAC Relay Entity.                                                                                                 | 1     |
| IngDown    | The Bridge Port's MAC_Operational parameter is false. <sup>a</sup>                                                                                                     | 2     |
| IngBlocked | The target data frame would not be forwarded if received on this Port due to active topology enforcement (8.6.1). (See Figure 22-1 to see how this is possible.)       | 3     |
| IngVID     | The ingress port is not in the member set of the LTM's VID, and ingress filtering is enabled, so the target data frame would be filtered by ingress filtering (8.6.2). | 4     |

<sup>a</sup> This value could be returned, for example, by an operational Down MEP that has another Down MEP at a higher MD Level on the same Bridge Port that is causing the Bridge Port's MAC\_Operational parameter to be false.

### 1 21.9.8.3 Ingress Port ID Length

2 (1 octet) The length, in octets, of the Ingress Port ID field. Cannot be 0. If the Length field of the Reply  
3 Ingress TLV is less than 8, then the Ingress Port ID Length field, Ingress Port ID Subtype field, and Ingress  
4 Port ID field are not present.

### 5 21.9.8.4 Ingress Port ID Subtype

6 (1 octet) The **port ID subtype**, as specified by IEEE Std 802.1AB, identifying the format of the Ingress Port  
7 ID field. If the Length field of the Reply Ingress TLV is less than 8, then the Ingress Port ID Subtype field is  
8 not present.

### 9 21.9.8.5 Ingress Port ID

10 (Length specified by the Ingress Port ID Length field) The Ingress Port, identified by the **port ID** specified  
11 by IEEE Std 802.1AB, in the chassis identified in the Sender ID TLV. If the Length field of the Reply  
12 Ingress TLV is less than 8, then the Ingress Port ID field is not present.

## 13 21.9.9 Reply Egress TLV

14 Type = 6. The format of the Reply Egress TLV is shown in Table 21-31. The Reply Egress TLV is included  
15 in the LTR if and only if the Bridge Port on which the LTM would be relayed could be identified, and is an  
16 MP in the MA specified by the LTM.

17 **Validation Test:** The value in the Egress Action field is one of the values enumerated in 21.9.9.1.

18 **Validation Test:** The Egress MAC Address field contains an Individual, and not a Group, MAC address.

19 **Validation Test:** The Length field either is 7, indicating that no Egress Port ID field is present, or is (9 + the  
20 Egress Port ID Length field) or larger, and thus contains the Egress Port ID field.

### 21 21.9.9.1 Egress Action

22 (1 octet) Reports how the data frame targeted by the LTM would be passed through Egress Bridge Port, as  
23 shown in Table 21-32.

**Table 21-31—Reply Egress TLV format**

| Field                  | Octet             |
|------------------------|-------------------|
| Type = 6               | 1                 |
| Length                 | 2–3               |
| Egress Action          | 4                 |
| Egress MAC Address     | 5–10              |
| Egress Port ID Length  | 11                |
| Egress Port ID Subtype | 12                |
| Egress Port ID         | 13 – (Length + 3) |

**Table 21-32—Egress Action field values**

| Mnemonic   | Egress action                                                                                                                                                                                 | Value |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| EgrOK      | The targeted data frame would be forwarded.                                                                                                                                                   | 1     |
| EgrDown    | The Egress Port can be identified, but that Bridge Port’s MAC_Operational parameter is false.                                                                                                 | 2     |
| EgrBlocked | The Egress Port can be identified, but the data frame would not pass through the Egress Port due to active topology management (8.6.1), i.e., the Bridge Port is not in the Forwarding state. | 3     |
| EgrVID     | The Egress Port can be identified, but the Bridge Port is not in the LTM’s VID’s member set, so would be filtered by egress filtering (8.6.4).                                                | 4     |

#### 1 21.9.9.2 Egress MAC Address

2 (6 octets) The MAC address that can be used as the Destination MAC address of an LBM intended for the  
3 egress MP.

#### 4 21.9.9.3 Egress Port ID Length

5 (1 octet) The length, in octets, of the Egress Port ID field. Cannot be 0. If the Length field of the Reply  
6 Egress TLV is less than 8, then the Egress Port ID Length field, Egress Port ID Subtype field, and Egress  
7 Port ID field are not present.

#### 8 21.9.9.4 Egress Port ID Subtype

9 (1 octet) The **port ID subtype**, as specified by IEEE Std 802.1AB, identifying the format of the Egress Port  
10 ID field. If the Length field of the Reply Egress TLV is less than 8, then the Egress Port ID Subtype field is  
11 not present.

#### 12 21.9.9.5 Egress Port ID

13 (Length specified by the Egress Port ID Length field) The Egress Port, identified by the **port ID** specified by  
14 IEEE Std 802.1AB, in the chassis identified in the Sender ID TLV. If the Length field of the Reply Egress  
15 TLV is less than 8, then the Egress Port ID field is not present.

## 22. CFM in systems

The relationships among MPs, and between the MPs and the other entities in a Bridge, are configurable. This configuration determines how CFM is used in a network and determines what parts of the Bridges and LANs comprising a network are protected by an MA. This clause provides both specifications and explanatory text to assist the implementor and system administrator to make efficient use of CFM. This clause:

- a) Specifies how the EISS Multiplex Entity (6.17) is used to support MPs for multiple MAs associated with service instances supported by EISS-SAPs (22.1).
- b) Specifies the creation of MPs in a Bridge (22.2).
- c) Suggests methods for the efficient assignment of MD Levels to Maintenance Domains (22.3).
- d) Specifies the use of MPs in stations (22.4).
- e) Clarifies issues related to the scaling of resources required to run CFM (22.5).
- f) Shows how MPs can be placed in Provider Bridges (22.6).
- g) Suggests methods for using CFM in the enterprise environment, as opposed to the provider environment (22.7).
- h) Provides guidance for the implementation of CFM in Bridges designed before the development of this standard (22.8).

NOTE—Clause 18 introduces the principles of CFM operation and the network architectural concepts that support it. Clause 19 breaks down the CFM protocol entities into their components. Clause 20 specifies the protocols operated by the components of each MP, and Clause 21 specifies the PDU formats used by those protocols.

### 22.1 CFM shims in Bridges

CFM is instantiated by configuring an MA, which maintains a single service instance. If multiple MAs, monitoring VLAN service instances, are configured on a single Bridge Port, the `vlan_identifier` parameter of the EISS and the MD Level in the CFM PDUs are used to multiplex CFM PDUs for the various MAs. Non-CFM data frames for these service instances are distinguished only by `vlan_identifier`: the particular service instance to which a non-CFM data frame belongs, if multiple service instances share the same VID, distinguished only by MD Level, is undetermined. MAs that monitor backbone or TESIs use I-SIDs or a combination of destination addresses, source addressees, and ESP-VIDs, respectively as service distinguishing parameters, instead of VIDs.

#### 22.1.1 Preliminary positioning of MPs

Figure 22-1 illustrates how MPs are associated with particular VIDs or TESIs. The EISS Multiplex Entity (6.17) distributes frames across an array of ISS- or EISS-SAPs, each of which can have a “column” of MPs at different MD Levels and orientations (Up or Down). Several MEPs and MHFs are shown, distinguished by VID and MD Level in this manner.

NOTE—For MPs monitoring backbone service instances, it is the Backbone Service Instance Multiplex Entity (6.18) that is used to distinguish MPs by I-SIDs and associate MPs with particular backbone service instances as illustrated in Figure 26-2.

An MP that has its Passive SAP closer to the MAC Relay Entity than its Active SAP is called a “Down MEP” or “Down MHF,” because it points down, away from the MAC Relay Entity, in Figure 22-1. An MP that has its Passive SAP further away from the MAC Relay Entity than its Active SAP is called an “Up MEP” or “Up MHF.” The Bridge Port in Figure 22-1 is configured with five Up MEPs, three Up MHFs, three Down MHFs, and three Down MEPs. A single LOM is positioned below the per-VID Down MEPs.

Figure 22-1 illustrates a Down MEP, at MD Level 1, configured on the ISS below the Bridge Port connectivity entity. The service instance its MA protects encompasses all data frames passing through the Bridge Port, no matter what VID they are associated with.

Figure 22-1—MEPs and MIPs distinguished by VID (incomplete picture)

## 22.1.2 CFM and the Forwarding Process

Figure 22-1 is incomplete, because it does not illustrate the relationship of CFM to the various components of the Forwarding Process (8.6). These components are illustrated in Figure 8-12. Readers can notice two facts about Figure 8-12:

- a) The functions in Figure 8-12 can be divided into two groups. The first group, described in 8.6.1 through 8.6.5, consists of filtering functions that determine a set of potential transmission ports for

- 1 each frame received at a reception port. The second group, described in 8.6.6 through 8.6.8, consists  
2 of queuing functions that control the transmission of the frame at each port in the resulting set of  
3 potential transmission ports.  
4 b) The parameters passed from component to component in Figure 8-12 are exactly those of the EISS;  
5 therefore, each of the components in Figure 8-12 could be described as a shim.

6 From these facts, readers can reconstruct Figure 8-12 in a manner that is functionally identical, but is better  
7 suited to illustrate the relationship between CFM and the Forwarding Process. This reconstruction is shown  
8 in Figure 22-2.

Figure 22-2—Alternate view of Forwarding process

### 22.1.3 Up/Down separation of MPs

An additional transformation to Figure 22-1 is required before the relationship between the Forwarding Process and CFM can be shown clearly. By adding a further pair of EISS Multiplex Entities between the Up MPs and the Down MPs in Figure 22-1, the entire set of Up MPs can be shown as a single shim, as can the entire set of Down MPs. This transformation is illustrated in Figure 22-3.

**Figure 22-3—Combining per-VLAN MPs into two shims**

Figure 22-4 combines Figure 22-1 with Figure 22-2, and shows the relationship of CFM to the various components of the Forwarding Process. MEPs and MHFs source and sink CFM PDUs. CFM PDUs are treated by the Port filtering entities in the same manner as ordinary data. Thus, the five Up MEPs of Figure 22-4 can transmit and receive CFM PDUs through the Bridge even when the Bridge Port is blocked. Similarly, the two Down MEPs in Figure 22-4 operate normally, transmitting CFM PDUs to and receiving them from the LAN, even if the Bridge Port is blocked. However, no frames, neither CFM PDUs nor ordinary data, can pass through the Port filtering entities when the VID to which those frames or CFM PDUs belong is filtered.

Also shown in Figure 22-4 are the positions of the DoSAPs and ISAPs introduced in Clause 18. The DoSAP provides access to a service instance (an instance of the MAC Service) and exists independently of any MA that might be created to protect it. The DoSAPs and ISAPs therefore can be associated with the specific inter-shim SAPs at the points indicated in Figure 22-4. The DoSAPs and ISAPs are attached to the Port filtering entities, because that is where the decisions are made on whether frames belonging to the service instance are or are not allowed to pass through the Bridge Port.<sup>37</sup> It does not matter to which side of the EISS Multiplex Entity one considers the DoSAPs and ISAPs to be attached. Except for the topmost Down MEP in each stack of Down MPs, the DoSAP is not coincident with the Passive SAP of the MEP protecting the DoSAP's service instance; the DoSAP is separated from its MA by the MHFs and/or MEPs at higher MD Levels. Even for that topmost Down MEP, an MHF for a higher MD Level can separate that MEP from its DoSAP. This gap is illustrated in Figure 22-5 and Figure 22-6, where the service instance, DoSAP to DoSAP, is shown in gray, but the MEPs protecting that service are separated from the DoSAPs by MHFs belonging to a service instance at a higher MD Level.

<sup>37</sup> The DoSAP is not attached to an MP's Passive SAP because the DoSAP and its associated service instance exist regardless of whether the service instance is protected by an MA.

Figure 22-4—More complete picture of MP placement in a Bridge Port

1 In the “stack” of MPs on a single Bridge Port, the following rules apply:

- 2 a) All Up MEPs belonging to MAs that are attached to specific VIDs are placed above the Port filtering  
3 entities (8.6.1, 8.6.2, and 8.6.4). Separately for each VID, there can be from zero to eight Up MEPs,  
4 ordered by increasing MD Level, from the upper EISS toward Port filtering. In the case of PBB-TE  
5 MAs, more than one Up MEP can share the VID and MD Level.
- 6 b) For each MA there can be at most one MIP, consisting of an Up MHF just above, and a Down MHF  
7 just below, the Port filtering entities. Both MHFs are at the same MD Level, higher than the highest  
8 MEP on the same VID, if any. Backbone Service Instance MHFs use the Backbone Service Instance  
9 Multiplex Entity (6.18) and are placed as depicted in Figure 26-2.
- 10 c) Up to eight Down MEPs belonging to MAs that are attached to the same list of VIDs are placed  
11 between the Down MHF, if any, and the Queuing entities (8.6.6, 8.6.7, and 8.6.8). They are placed in  
12 order of decreasing MD Level, from the Port filtering entities to the Queuing entities, including any  
13 Down MHF.
- 14 d) No Down MEPs exist for PBB-TE MAs.
- 15 e) An LOM is positioned below the Down MPs belonging to MAs that are attached to specific VIDs to  
16 handle forwarded LTMs.
- 17 f) Up to eight Down MEPs, ordered from highest MD Level to lowest, belonging to MAs not attached  
18 to any specific VID, can be placed below Bridge Port connectivity (8.5.1). They are ordered by  
19 decreasing MD Level going away from the MAC Relay Entity (see also 22.1.8).
- 20 g) Up to 8 Up MEPs, ordered from highest MD Level to lowest, belonging to Backbone Service  
21 Instance MAs that are identified by the same I-SID, can be placed below the Bridge Port  
22 connectivity (8.5.1) using the Backbone Service Instance Multiplex Entity (6.18) as depicted in  
23 Figure 26-2. They are ordered by decreasing MD Level going away from the multiplexed SAP.
- 24 h) Up to 8 Down MEPs, ordered from highest MD Level to lowest, belonging to Backbone Service  
25 Instance MAs that are identified by the same I-SID, can be placed below the Bridge Port  
26 connectivity (8.5.1) using the Backbone Service Instance Multiplex Entity (6.18) as depicted in  
27 Figure 26-2. They are ordered by decreasing MD Level going away from the MAC Relay Entity.
- 28 i) All of the Down MEPs below Bridge Port connectivity have lower MD Levels than any Down MP  
29 attached to a VID that is emitted untagged by the Support of the EISS.
- 30 j) Any shim that introduces an EtherType tag insulates the MPs above and below it, removing any MD  
31 Level restriction between the separated groups of MPs.

32 A single Port on a Bridge could, in theory, have MHFs for multiple service instances at different MD Levels.  
33 However, that would require a vector of 4094 MD Level registers instead of one register to identify the CFM  
34 PDUs to be deflected to the Bridge’s Higher Layer Entities. This capability is optional.

#### 35 22.1.4 Service instances over multiple Bridges

36 Figure 22-4 completes the sequence of expansions starting with Figure 18-5 and continuing with  
37 Figure 18-6 and Figure 18-7. In this sequence, Figure 22-4 illustrates Bridge Port b of Bridge 2 in Figure 18-  
38 5 through Figure 18-7. The service instances illustrated in those three figures all use VID 9 in Figure 22-4.  
39 The Up MEPs for VID 9 at MD Levels 3 and 2 are the Up MEPs protecting the provider MD Level and the  
40 operator MD Level service instances, respectively, and the pair of MHFs at MD Level 5 on VID 9 provide a  
41 customer MD Level MIP. Figure 22-4 also illustrates two other sets of service instances sharing the same  
42 Bridge Port using VIDs 2 and 7.

43 Additional views of service instances spanning two Bridges are shown in Figure 22-5 and Figure 22-6.  
44 Figure 22-5 shows a service instance protected by Up MPs, and Figure 22-6 shows a service instance  
45 protected by Down MPs.

Figure 22-5—Service instance spanning two Bridges protected by Up MPs

Figure 22-6—Service instance spanning two Bridges protected by Down MPs

## 1 22.1.5 Multiple VID service instances

2 A service instance can be implemented using multiple VIDs. It is always the case that the VLAN tag  
3 uniquely determines the VLAN service instance for a given frame. A VID-based MA or a PBB-TE MA with  
4 multiple VIDs does not require any more MIPs or MEPs than the corresponding MA with a single VID. All  
5 of the VIDs belonging to a given VID or TESI share the same MA. That is, one MAID is used for all CFM  
6 PDUs on the various VIDs in the same VID or TESI and Maintenance Domain. The choice of VID used to  
7 tag a given CFM PDU depends on the OpCode and the ESP, as specified in Clause 20.

## 8 22.1.6 Untagged CFM PDUs

9 A MEP placed anywhere below the Support of the EISS entity (6.9) or the Bridge Port connectivity entity  
10 (8.5.1) differs in three important respects from a MEP placed above the Support of the EISS entity:

- 11 a) The lower position would not have the Queuing entities available to it. For example, the reflection of  
12 a high-speed stream of LBMs (as LBRs) could seriously disrupt the flow of data frames, and thus  
13 bring into question the utility of the Queuing entities, CFM, or both.
- 14 b) A MEP in the lower position is necessarily VLAN untagged; the VLAN tagging functions are  
15 performed in the Support of the EISS entity.
- 16 c) A MEP in the lower position protects all data passing through the Bridge Port or if it is associated  
17 with a backbone service instance only data with this instance as specified in (26.8); it does not  
18 separately protect the different VLANs.

19 Point c) above does not mean that the lower position is the only one that can protect all of the traffic on a  
20 single link. MEPs placed above the Queuing entities can be associated with a VLAN whose VID is the  
21 PVID, for which this Bridge Port belongs to the untagged set. That VID can be statically configured in the  
22 member set to not be allowed to pass through the Frame filtering entity (8.6.3). MEPs so configured can then  
23 transmit and receive only untagged frames, and thus protect all of the data on the link. Their untagged CFM  
24 PDUs can be visible to complex “links” such as PBNs, even though the C-VLAN-tagged CFM PDUs are not  
25 visible inside the PBN.

26 The option to create MEPs below the Bridge Port connectivity entity for VID identified service instances  
27 cannot be omitted, however, because of considerations given in 22.1.8. This subclause also explains why  
28 only MEPs, and not MHFs, can be placed below the Bridge Port connectivity entity.

## 29 22.1.7 MPs and non-VLAN-aware Bridges

30 The positioning of MPs in Bridges that are not VLAN aware (i.e., MAC Bridges) is illustrated in Figure 22-  
31 7. Because there are no VLANs, no EISS Multiplex Entity is needed. However, the Up MPs are still above  
32 the Port filtering entities, so the transformation introduced in 22.1.2 is still retained.

33 Down MPs can be placed either above or below the Queuing entities and Bridge Port connectivity in  
34 Figure 22-7; the difference between the two locations is that:

- 35 a) In the upper location, frame queues are available to CFM, so that CFM frames and data frames can  
36 be scheduled appropriately for output, and
- 37 b) Placing a Down MEP in the lower location protects the LLC path used by the Higher Layer Entities,  
38 e.g., BPDUs, as well as the normal data forwarding path.

39

**Figure 22-7—MP placement in a non-VLAN-aware Bridge Port**

## 22.1.8 MPs and other standards

The relationship of MPs and the shims defined by two other standards, IEEE Std 802.1AX (Link Aggregation) and IEEE Std 802.1AE (MAC Security), is illustrated in Figure 22-8. This figure shows Down MEPs positioned both above and below Link Aggregation and illustrates a number of points.

MPs could, in theory, be placed either above or below the MAC Security shim. No loss of data integrity beyond the protected link would be incurred by placing CFM below MAC Security; the only attacks that could be generated would be variants of a denial of service attack. However, there are several reasons for restricting MPs to positions above the MAC Security shim:

- a) The denial of service attacks available by the introduction of bogus CFM PDUs have more potential for disrupting management operations, in more complex ways, than do attacks based on other unprotected protocols, namely those defined by IEEE Std 802.3. For example, bogus cross connect CCMs could be introduced, leading to undesirable interactions between different providers' management systems.
- b) MAC Security ensures that all data frames are legitimate, in the sense that they were last transmitted by a trusted device. Allowing the introduction of unprotected CFM PDUs violates the principle that data frames and CFM PDUs follow the same paths, distinguished only by the CFM protocol encapsulation.
- c) Allowing the CFM and MAC Security shims to be interchanged by management operations could significantly complicate the implementation of a Bridge, with no commensurate benefit to the user.

As described in 22.1.6, placing an MP below the Queuing entities, whether above or below the Link Aggregation shim, is not desirable, as that MP is not able to use the Queuing entities. For this reason, it is preferable to use a Down MEP that is attached to a specific VID, and is thus above the Queuing entities, to protect the link.

**Figure 22-8—MP placement relative to other standards**

1 When Link Aggregation is employed, Down MEPs attached to no VID can be useful for protecting the  
2 individual IEEE 802.3 LANs. The method used in Link Aggregation to select the outgoing IEEE 802.3 link  
3 is undefined. It is not necessarily possible for an MP above the Queuing entities to protect all of a Bridge  
4 Port's data; CCM PDUs could take one IEEE 802.3 link, and data frames another. Therefore, provision is  
5 made in this standard for configuring Down MEPs in an MA attached to no VID below the Bridge Port  
6 connectivity entity, and below Link Aggregation, when employed. The following considerations are  
7 important when configuring Down MEPs:

- 8 d) It is best to disable the Bridge Port before issuing a high-speed stream of LBRs (relative to the  
9 physical link speed), either from or toward a Down MEP attached to no VID; otherwise, the  
10 Queuing entities might be unable to achieve any guarantees for throughput or latency.
- 11 e) The rate of CCMs generated by Down MEPs attached to VIDs should be taken into account when  
12 configuring the Queuing entities to achieve particular guarantees for throughput or latency.
- 13 f) If Link Aggregation is present, Down MEPs attached to no VID should be configured below Link  
14 Aggregation.

- 1 g) The creation of MHFs below Link Aggregation presents two problems that preclude it from this  
2 standard:
- 3 1) IEEE Std 802.3 provides no means for Link Aggregation to use a destination MAC address to  
4 direct a CFM PDU down the correct link to reach a particular MP at one or the other end of  
5 that link.
- 6 2) The utility of isolating the short segment between the Port filtering entities and the links being  
7 aggregated, which is completely internal to a Bridge, is very limited, especially considering the  
8 wide range of methods employed for implementing Link Aggregation.

## 9 22.1.9 CFM and IEEE 802.3 OAM

10 The following differences between CFM and the IEEE Std 802.3 specification of Operations,  
11 Administration, and Maintenance (OAM) are relevant to making a decision whether to employ one, the  
12 other, or both of these protocols.

- 13 a) IEEE 802.3 OAM has provision for a loopback mode in which all frames are returned to the sender.  
14 CFM does not.
- 15 NOTE—IEEE 802.3 OAM confines loopbacked frames to the individual IEEE 802.3 LAN, effectively  
16 disabling any attached Bridge Port. Use of simple frame loopback through a Bridged Network could be  
17 expected to seriously impact the operation of the network.
- 18 b) IEEE 802.3 OAM has provision for acquiring statistics from a remote interface. CFM does not.
- 19 c) IEEE 802.3 OAM has provision for generating error conditions when configured thresholds are  
20 exceeded for parameters such as the number of frames received with Cyclic Redundancy Check  
21 (CRC) errors. CFM does not.
- 22 d) IEEE 802.3 OAM has provision for organizations other than IEEE 802 to define both new TLVs and  
23 new operation codes using OUIs/CIDs. CFM allows only TLVs to be defined using OUIs/CIDs.
- 24 e) IEEE 802.3 OAM performs a continuity check once per second. CFM can be programmed to  
25 perform the continuity check over a wide range of intervals.
- 26 f) IEEE 802.3 OAM is defined only for IEEE 802.3 media. CFM can be used over any medium, or  
27 bridged network, that can carry IEEE 802 frames.
- 28 g) IEEE 802.3 OAM protects a single link. CFM can protect a single link or a network of bridged  
29 networks, over multiple nested ranges.
- 30 h) CFM can protect the connectivity of shared media. IEEE 802.3 OAM has no such capability.
- 31 i) CFM can perform in-band loopback tests at any rate up to the physical line rate, during normal  
32 operations. IEEE 802.3 OAM has no such capability.
- 33 j) CFM can perform Linktrace functions through a Bridged Network. IEEE 802.3 OAM has no such  
34 capability.
- 35 k) CFM can detect unintentional connectivity, as well as lack of connectivity. IEEE 802.3 OAM  
36 cannot.

## 37 22.2 Maintenance Entity creation

38 MPs are created using the managed objects described in 12.14. Before a MEP or MHF can be created, either  
39 an entry in the Default MD Level managed object, or the Maintenance Domain and MA to which the MEP  
40 or MHF belongs, are created. In this context, a Default MD Level managed object, Maintenance Domain, or  
41 an MA are strictly managed objects in a single Bridge. In order to realize the network-wide definitions of  
42 Maintenance Domains and MAs given in 18.1 and 18.2, the Bridges in a Maintenance Domain are  
43 configured with identical information in these managed objects. During transitional periods when this  
44 information is changing, Fault Alarms will likely be generated.

45 NOTE—The correct operation of CFM does not depend on the configuration restrictions in this subclause. Rather,  
46 violating these restrictions is likely to generate Fault Alarms that might or might not be erroneous. In other words, if no  
47 Fault Alarms are generated, then all monitored MAs have connectivity. If any Fault Alarm is generated, then either

1 connectivity has been lost or the network is improperly configured. Determining which of these two is the cause of a  
2 Fault Alarm depends on the intentions of the operators and is therefore beyond the scope of this standard.

### 3 **22.2.1 Creating Maintenance Domains and MAs**

4 The operator creates either a Default MD Level managed object or a Maintenance Domain managed object  
5 in a Bridge for every Maintenance Domain whose CFM PDUs can pass through that Bridge and are to be  
6 processed. The operator can also create a MA managed object in a Bridge for some or all of the MAs whose  
7 CFM PDUs can pass through that Bridge and are to be processed. Whether a service instance can pass  
8 through a Bridge depends on the following:

- 9 a) Enable Ingress Filtering per-Bridge Port parameter (8.6.2).
- 10 b) Static Filtering Entries (8.8.1).
- 11 c) Static VLAN Registration Entries (8.8.2).
- 12 d) PIP configuration parameters (6.10).
- 13 e) CBP configuration parameters (6.11).
- 14 f) Dynamic VLAN Registration Entries (8.8.5).
- 15 g) Operation of MSTP (Clause 13), which in turn, can be affected by the state of the MAC\_Operational  
16 parameters (IEEE Std 802.1AC) of the ISSs in the Bridge Port.

17 The first five of these methods are altered only by modifying managed objects and can therefore be  
18 considered static for the purposes of configuring CFM. The last two methods are dynamic, in that they  
19 depend not only on configuration, but on protocols that respond to network events, such as the addition or  
20 loss of a link or Bridge. For example, a VLAN can pass through a Bridge unless there is a Static VLAN  
21 Registration Entry prohibiting its VID from passing through every Bridge Port, and Ingress Filtering is  
22 enabled on every Bridge Port. If a Bridge's Maintenance Domain requires only insignificant resources to  
23 support MHF configuration, then the most reliable network is one that assumes that all service instances will  
24 require MHFs at some MD Level higher than that of that Maintenance Domain.

### 25 **22.2.2 Creating MEPs**

26 There are four kinds of Maintenance Association managed objects: those that are attached to one or more  
27 specific VIDs in the Bridge, those that are attached to no VID, those that are attached to an I-SID, and those  
28 that are attached to a TESI or ECMP path.

29 Once the appropriate Maintenance Domain and MA have been created, a MEP can be created, modified, or  
30 deleted using the MA managed object defined in 12.14.6. MEPs are always created explicitly. MEP creation  
31 is controlled by creating a Maintenance association Endpoint managed object using the following  
32 parameters:

- 33 a) Whether the MA to which the MEP belongs is associated with specific VID(s), I-SID, TESI, or  
34 ECMP path, and if so, which parameters [item b) in 12.14.6.1.3], including a specification of the  
35 MA's Primary VID [item d) in 12.14.7.1.3].
- 36 b) Whether the MEP is a Down MEP (pointing away from the MAC Relay Entity), or an Up MEP,  
37 (pointing toward the MAC Relay Entity) [item c) in 12.14.6.3.2].

38 Given those two values in the MEP managed object, Table 22-1 shows where, in Figure 22-9, the MEP is  
39 created. In Figure 22-9, which shows a PNP or a CNP, the VID selects which of the MEP positions is  
40 selected for Table 22-1 column 3 values 1 and 4. Only one row of MEPs is shown in positions 1, 4, and 5,  
41 even though up to eight rows can exist at each of these points. Because the MEPs are always placed in order  
42 by MD Level, with the highest MD Level nearest the MHFs, at the center of each stack, there is thus no  
43 ambiguity. The third column, starting from the left, in the EISS Multiplex Entity depicted in Figure 22-9

1 corresponds to an ESP-VID or SPBM VID. Only MIPs can be placed in this column for a PNP. MEPs can be  
2 created on a CBP and PIP as shown in Figure 26-2.

Table 22-1—MEP creation

| MA has VID<br>[item b) in 12.14.6.1.3] | MEP direction<br>[item c) in 12.14.7.1.3] | Position of MEP<br>in Figure 22-9 |
|----------------------------------------|-------------------------------------------|-----------------------------------|
| Yes                                    | Up                                        | 1                                 |
|                                        | Down                                      | 4                                 |
| No                                     | Up                                        | disallowed                        |
|                                        | Down                                      | 5                                 |

Figure 22-9—Creating MEPs and MIPs

3 If any MEPs are configured on an MA, then in any given Bridge, either all of those MEPs are Up MEPs or  
4 all of them are Down MEPs; a Bridge refuses to create an Up (Down) MEPs if a Down (Up) MEP already is  
5 configured in that MA in that Bridge. An MA can be configured with Up MEPs in one Bridge and Down  
6 MEPs in another Bridge or Station. Any given VID can be configured on any number of MAs (including  
7 zero) containing either Down MEPs or no MEPs at all, plus zero or one MA containing Up MEPs. No VID  
8 can be configured on more than one MA on which are configured Up MEPs.

9 These restrictions, along with the configuration errors in 22.2.4, enable MEPs to be configured so that they  
10 bound an MA, no matter what action is taken by the spanning tree protocols within a Maintenance Domain.

### 22.2.3 Creating MIPs

Managed objects control the creation of MIPs, but indirectly, rather than explicitly, as for MEPs. Every MA defined in a Bridge can cause the management entity to create MIPs on every Bridge Port. On each Bridge Port, the following conditions trigger the management entity to reevaluate the creation of MIPs for a given VID (or list of VIDs) or I-SID  $x$  on that port:

- a) The Bridge is initialized.
- b) A MEP is created or deleted on VID(s) or I-SID  $x$  on that Bridge Port.
- c) An Up MEP is created or deleted on VID(s)  $x$ , which is (are) not allocated to a TESI, on any Bridge Port or an Up MEP is created or deleted on I-SID  $x$ .
- d) A change occurs in whether VID(s) or I-SID  $x$  can or cannot pass through the Bridge Port (22.2.1).
- e) A change occurs in the Default MD Level managed object (12.14.3).
- f) A change occurs in a Maintenance Association managed object associated with VID(s) or I-SID  $x$ .

A MIP for VID-based service instances and TESIs is created by creating a pair of MHFs in positions 2 and 3 in Figure 22-9. MIPs associated with I-SIDs are created on the two sides of the multiplexed SAPs in the Backbone Service Instance Multiplex Entity as depicted in Figure 26-2. MAs that are associated with no VID are not considered in this subclause. For a given VID on a given Bridge Port, and in the absence of any of the configuration errors in 22.2.4, there are at most two MAs at each MD Level that can affect MIP creation, plus at most one entry in the Default MD Level managed object. If one or more of the configuration errors in 22.2.4 are present, this standard does not specify what MIPs the Bridge creates.

When required, the Maintenance Entity performs the MIP evaluation on each Bridge Port for each VID. For each Bridge Port  $p$  and service identifier  $x$ , which can be a list of VIDs, or an I-SID, the Maintenance Entity creates a list of active MD Levels. This list contains the following:

- g) MD Level of each of the MAs (if any) that monitors service  $x$  and has a MEP configured on Bridge Port  $p$ .
- h) MD Level of each of the MAs (if any) that monitors a service  $x$ , and has at least one Up MEP configured on some Bridge Port in this Bridge other than Bridge Port  $p$ .
- i) MD Level of each of the MAs (if any) that monitors service  $x$  and has no MEPs configured on any Bridge Port in this Bridge.
- j) MD Level of the entry in the Default MD Level managed object (12.14.3) for service  $x$ .

Exactly one MD Level  $d$  in this active list is eligible for MIP creation. It is the lowest MD Level in the list of active MD Levels such that there is no MEP configured on Bridge Port  $p$  and service  $x$  at MD Level  $d$  or at any higher MD Level. This is the lowest MD Level in the list, if there is no such MEP configured. The Maintenance Entity then uses Table 22-2 to determine whether the MIP is to be created.

**Table 22-2—MIP creation**

| Enumeration<br>[item d) in 12.14.3.1.3,<br>item c) in 12.14.6.1.3, or<br>item c) in 12.14.6.1.3] | A MEP is configured<br>on Bridge Port $p$ | MIP created |
|--------------------------------------------------------------------------------------------------|-------------------------------------------|-------------|
| defMHFnone:                                                                                      | —                                         | No          |
| defMHFexplicit                                                                                   | False                                     | No          |
|                                                                                                  | True                                      | Yes         |
| defMHFdefault                                                                                    | —                                         | Yes         |

1 The enumeration controlling whether the MIP is created is taken from:

- 2 k) The Maintenance Association managed object [item c) in 12.14.6.1.3] for the MA that monitors  
3 service  $x$ , and has at least one Up MEP configured on some Bridge Port in the Bridge [see item h)];  
4 or
- 5 l) That MA's Maintenance Domain managed object [item c) in 12.14.5.1.3], if that MA exists, but its  
6 Maintenance Association managed object contains the value `defMHFdefer`; or
- 7 m) The Default MD Level managed object [item d) in 12.14.3.1.3] if no such MA exists [see item j)].

8 The enumerated values used in the managed objects item d) in 12.14.3.1.3, item c) in 12.14.5.1.3, and  
9 item c) in 12.14.6.1.3 to control the creation of a MIP for a service instance identified by the parameter  $x$  on  
10 a Bridge Port are as follows:

- 11 n) **defMHFnone**—No MHFs can be created for this VID(s) or I-SID (the default value).
- 13 o) **defMHFdefault**—MHFs can be created for this VID(s) or I-SID on any Bridge Port through which  
15 the VID(s) or I-SID can pass where:
  - 16 1) There are no lower active MD levels, or
  - 17 2) There is a MEP at the next lower active MD level on the port.
- 18 p) **defMHFexplicit**—MHFs can be created for this VID(s) or I-SID only on Bridge Ports through  
20 which this VID(s) or I-SID can pass, and only if there is a MEP at the next lower active MD level on  
21 the port.
- 22 q) **defMHFdefer**—In the Maintenance Association managed object [item c) in 12.14.6.1.3] only, the  
24 control of MHF creation is deferred to the corresponding variable in the enclosing Maintenance  
25 Domain [item c) in 12.14.5.1.3].

## 26 22.2.4 CFM configuration errors

27 While making the MIP creation evaluation described in 22.2.3, or whenever a MEP is created or deleted, the  
28 management entity can encounter errors in the configuration. Because of this, the Management entity  
29 maintains a Configuration Error List managed object (12.14.4) that lists, for every VID or I-SID, the Bridge  
30 Ports that have MIP configuration errors. Every time the MIP creation evaluation is performed or a MEP is  
31 created or deleted, this list is updated to reflect which Bridge Ports and VIDs are in error and which are not.  
32 A Bridge Port is placed in the list if and only if one of the following errors occurs:

- 33 a) **CFMleak**—MA  $x$  is associated with a specific VID list or I-SID, one or more of the VIDs or I-SID  
35 in MA  $x$  can pass through the Bridge Port, no Up MEP is configured for MA  $x$  on the Bridge Port,  
36 no Down MEP is configured on any Bridge Port for MA  $x$ , and some other MA  $y$ , at a higher MD  
37 Level than MA  $x$ , and associated with at least one of the VID(s) or the I-SID also in MA  $x$ , does  
38 have a MEP configured on the Bridge Port.
- 39 b) **ConflictingVIDs**—MA  $x$  is associated with a specific VID list or I-SID, an Up MEP is configured  
41 on MA  $x$  on the Bridge Port, and some other MA  $y$ , associated with at least one of the VID(s) or I-  
42 SID also in MA  $x$ , and at the same MD Level as MA  $x$ , also has an Up MEP configured on some  
43 Bridge Port.
- 44 c) **ExcessiveLevels**—The number of different MD Levels at which MIPs are to be created on this port  
46 exceeds the Bridge's capabilities (see 22.3).
- 47 d) **OverlappedLevels**—A MEP is created for one VID or I-SID at one MD Level, but a MEP is  
49 configured on another VID or I-SID at that MD Level or higher, exceeding the Bridge's capabilities  
50 (see 22.3).

51 A Bridge uses detection of the ExcessiveLevels error to refuse an operation on a managed object and thus  
52 avoids adding Bridge Ports to the error lists. This is because this incremental operation is known to be the  
53 one that exceeds the capabilities of the Bridge. However, a Bridge uses only the detection of the  
54 ExcessiveLevels error to refuse an operation on a managed object. That is because the other errors can arise  
55 as a result of a management operation, e.g., the deletion of a Static VLAN Registration Entry, that has no

1 knowledge of CFM and cannot report the error. Furthermore, the root cause of either error might not be the  
2 last MA to be configured and could be under the control of another administration. Therefore, management  
3 operations that trigger errors other than ExcessiveLevels are performed, not rejected. The lists of Bridge  
4 Ports in error are maintained (12.14.4), so that the system administrator(s) can agree on a course of action,  
5 outside this standard, to correct the problem.

## 6 **22.3 MPs, Ports, and MD Level assignment**

7 It is possible to configure MPs at different MD Levels for different VIDs on a single Bridge Port. However,  
8 this imposes upon an implementation the burden to be able to configure up to 8189 MD Levels for the VIDs  
9 on a Port, 4094 for MHFs and 4095 for MEPs, each requiring 3 bits of storage. An implementation may not  
10 support different MD Levels for MIPs on different VIDs on a single Port, hence the ExcessiveLevels and  
11 OverlappedLevels error responses (22.2.4). At least one MD Level shall be supported for each port in a  
12 Bridge, such that MIPs can operate at that MD Level, and all CFM PDUs below that MD Level are filtered  
13 or processed, according to the configuration of MEPs on the port.

14 In Figure 18-7, the left-most Maintenance Entity at the lowest MD Level (0) has one MEP in the customer's  
15 equipment 1 and one in Provider Bridge 2. When Down MEPs are used in this manner to create a  
16 Maintenance Entity that interconnects two administrations, those administrations can agree upon a particular  
17 MD Level (and MAID and MEPIDs) to use. To enhance the chances for interoperability, the MD Level for  
18 Down MEPs should be the lowest not already in use by an existing MA, typically 0.

19 Assigning MD Levels with gaps between the levels used, as in Figure 18-7, can be wasteful of resources,  
20 especially MAC Address Registration Entries in the FDB. Minimizing the number of MD Levels, and  
21 concentrating the MD Levels used toward MD Level 0, minimizes the required resources, since CFM PDUs  
22 carrying higher MD Levels than those used in a Bridge are treated as ordinary multicasts by that Bridge.  
23 However, if one creates a Maintenance Domain at MD Level 0, and subsequently needs a level beneath that  
24 one, for example if a PBN is substituted for a physical connection, then the MD Level of the original  
25 Maintenance Domain might have to be changed. If there is another Maintenance Domain above the one at  
26 MD Level 0, that one would have to be changed, first, and so on. Similarly, if an existing Maintenance  
27 Domain at MD Level 3 is partitioned into several Domains, a new Maintenance Domain at MD Level 4  
28 would be needed to ensure end-to-end connectivity across the extent of the old Maintenance Domain.

29 Such difficulties can be avoided in several ways:

- 30 a) The MD Levels of different Maintenance Domains can be insulated from each other by VLAN tags.  
31 Appropriate placement of the MEPs in Bridge Ports can ensure that the tags insulate the MD Levels,  
32 and that no reconfiguration will be necessary.
- 33 b) If it is expected that an additional MD Level will be needed because a physical link will likely  
34 become virtualized, MD Level 0 can be left vacant.
- 35 c) If it is expected that an additional MD Level will be needed because a Maintenance Domain will  
36 likely be partitioned, a gap can be left between that Maintenance Domain's MD Level and the lowest  
37 MD Level offered to a customer of that Maintenance Domain.

38 See J.2 for a description of an MD Level assignment plan that can be used in the most general case.

## 22.4 Stations and CFM

Stations, as well as Bridges, can implement CFM. For the purposes of CFM, and for no other purposes, a Station is modeled as a Bridge, with the following exceptions:

- a) This standard defines no entities above the layer of Down MPs in Figure 22-8. In particular, a Station has no Port filtering entities, Up MPs, or Forwarding Process. A CFM-capable Station is therefore a set of one or more disconnected Bridge Ports.
- b) A Station shall not support the creation of MIPs or Up MEPs. Only Down MEPs can be implemented in a Station.
- c) CFM PDUs not processed and not discarded by a MEP shall be ignored, and not processed, by the Station.
- d) A Station shall create no entries in the Configuration Error List managed object (12.14.4) except for CFMleak errors.

## 22.5 Scalability of CFM

CFM can create a considerable load on the resources of a Bridge. Ideally, a Bridge has the capability to reflect LBMs as LBRs at line rate, so that the capacity and reliability of a network can be tested. The total load imposed by LBMs, LBRs, LTMs, and LTRs cannot be predicted, as these are all under the control of the system administrator, and any number of streams of these PDUs can be generated.

The load imposed by CCMs is more regular, so reasonable predictions of the load they impose can be made. Based on a figure of 109 octets as the minimum frame size, from the start of the destination MAC address of one frame to the start of the destination MAC address of the next frame,<sup>38</sup> Table 22-3 shows the load that is imposed by CCM transmission and reception upon a Bridge Port with a single configured MEP, as a function of the CCM transmission interval, the number of MEPs in the MA, and the speed of the link. One row in the table shows the number of CCMs per second transmitted or received. The number in each of the other rows is the fraction of the total bandwidth required by those CCMs. Table 22-4 extends this calculation by multiplying all numbers by 1000, for the case where 1000 VIDs, each with a MEP, are configured on the Bridge Port, again with the specified transmission interval and average number of MEPs per MA.

Counting 4094 allowed VIDs in a VLAN tag, three kinds of MEPs, Up VID MEPs, Down VID MEPs, and Down no-VID MEPs, and eight MD Levels, a single Bridge Port with no Link Aggregation can, in theory, support 65 504 MEPs and 8188 MHFs.

**Table 22-3—Bandwidth required for CCMs for 1 MA**

| Transmit interval | 3.3 ms  |        | 10 ms  |        | 1 s    |        | 60 s   |        |
|-------------------|---------|--------|--------|--------|--------|--------|--------|--------|
| MEPs in each MA   | 10      | 2      | 10     | 2      | 10     | 2      | 10     | 2      |
| CCM / s           | 3000    | 600    | 1000   | 200    | 10     | 2      | 0.167  | 0.033  |
| 10 Mb/s           | 26.160% | 5.232% | 8.720% | 1.744% | 0.087% | 0.017% | 0.001% | 0.000% |
| 100 Mb/s          | 2.616%  | 0.523% | 0.872% | 0.174% | 0.009% | 0.002% | 0.000% | 0.000% |
| 1 Gb/s            | 0.262%  | 0.052% | 0.087% | 0.017% | 0.001% | 0.000% | 0.000% | 0.000% |
| 10 Gb/s           | 0.026%  | 0.005% | 0.009% | 0.002% | 0.000% | 0.000% | 0.000% | 0.000% |
| 100 Gb/s          | 0.003%  | 0.001% | 0.001% | 0.000% | 0.000% | 0.000% | 0.000% | 0.000% |

<sup>38</sup> First TLV Offset = 70, 12 for MAC addresses, 6 for Type and fixed header, 1 for End TLV, 20 for inter-frame gap and preamble.

**Table 22-4—Bandwidth required for CCMs for 1000 MAs**

| Transmit interval | 3.3 ms    |         | 10 ms     |         | 1 s     |         | 60 s   |        |
|-------------------|-----------|---------|-----------|---------|---------|---------|--------|--------|
| MEPs in each MA   | 10        | 2       | 10        | 2       | 10      | 2       | 10     | 2      |
| CCM / s           | 3 000 000 | 600 000 | 1 000 000 | 200 000 | 10 000  | 2000    | 167    | 33     |
| 10 Mb/s           | > 100%    | > 100%  | > 100%    | > 100%  | 87.200% | 17.440% | 1.453% | 0.291% |
| 100 Mb/s          | > 100%    | > 100%  | > 100%    | > 100%  | 8.720%  | 1.744%  | 0.145% | 0.029% |
| 1 Gb/s            | > 100%    | 52.320% | 87.200%   | 17.440% | 0.872%  | 0.174%  | 0.015% | 0.003% |
| 10 Gb/s           | 26.160%   | 5.232%  | 8.720%    | 1.744%  | 0.087%  | 0.017%  | 0.001% | 0.000% |
| 100 Gb/s          | 2.616%    | 0.523%  | 0.872%    | 0.174%  | 0.009%  | 0.002%  | 0.000% | 0.000% |

## 22.6 CFM in Provider Bridges

The S-VLAN component of a Provider Bridge is, for the purposes of this standard, an example of a VLAN Bridge. Fortunately, the many combinations possible when configuring CFM on Customer Bridges and Provider Bridges, connected using Port-based, C-tagged, or Remote Customer Service Interfaces (RCSIs), can be simplified.

### 22.6.1 MPs and C-VLAN components

When a C-VLAN component is integrated into a Provider Edge Bridge to form a C-tagged service interface, there is little justification for making all possible CFM entities manageable. Subclause 15.4 describes a C-tagged service interface, illustrated in Figure 15-4. Figure 22-10 recasts Figure 15-4, illustrating the minimum set of CFM functions that a C-tagged service interface is required to support, if its Provider Bridge supports CFM. Almost all of the CFM components have been removed from the C-VLAN component. As a result, the transformations made in 22.1.2 and 22.1.3 are unnecessary, and the subclause references collapse to match those in Figure 15-4. The S-VLAN component contains almost the full suite of CFM entities. One set of shims has been moved from the CNP to the CEP, however.

The managed objects in 12.14 support the creation of up to eight MEPs below the Bridge Port Transmit and Receive process (8.5). These MEPs belong to MAs associated with no VID. A MEP in this position would be of little use in a CNP, since there is no need to pair it with a MEP in the PEP to protect an Internal LAN. However, a MEP attached to no VID in the CEP could be used to protect the LAN to the customer equipment.

In order to support protection of the CEP's LAN, while maximizing interoperability, whenever (Down) MEPs are created (12.14.6.3) in an MA associated with no VID, a Provider Edge Bridge shall allow those MEPs to be created using the interface number [item d) in 12.14.6.3.2] for a CEP.

### 22.6.2 Maintenance C-VLAN on a Port-based service interface

Assume that a customer's C-VLAN Bridge is attached to an S-VLAN Bridge as in Figure 22-4, and that the customer wants to pair a Down MEP in the C-VLAN Bridge with a similar Down MEP in the C-VLAN Bridge on the other side of the PBN, thus creating an MA to provide end-to-end protection of the service instance offered by the Provider. In order to obtain the advantage of inserting the CFM PDUs above the Queuing entities, the customer would not use MEPs below the Bridge Port Transmit and Receive process (8.5). The customer could create one MA for each C-VID. However, this would have drawbacks in that:

Figure 22-10—CFM in a Provider Edge Bridge C-tagged service interface

- 1

a)

The extra MAs beyond the first MA would provide very little protection on a Port-based service.
- 2

b)

Each extra MA would add to the overhead of CFM PDUs.
- 3

c)

The C-tagged CFM PDUs would not be detected by any of the CFM entities in any Provider Bridge,
- 4

so no MIPs would be present in the customer’s MAs.
- 5

If the customer, instead, creates an MA on only one C-VLAN, the Maintenance C-VLAN, and configures
- 6

the two C-VLAN Bridges to pass the Maintenance C-VLAN across the PBN untagged, then:
- 7

d)

The service instance is protected.
- 8

e)

The provider can configure a MIP on the S-VLAN carrying the customer’s service instance that is
- 9

visible in the customer’s MA.

### 1 22.6.3 Maintenance C-VLAN on a C-tagged service interface

2 Assume that a customer's C-VLAN Bridge, illustrated by Figure 22-4 (less, of course, the box for "Support  
3 of the ISS for attachment to a PBN (6.13)"), is attached to a Provider Edge Bridge as in Figure 22-10.  
4 Assume that the customer has purchased several service instances, which have C-tagged service interfaces to  
5 other of the customer's C-VLAN Bridges at several different locations. Let us further suppose that the  
6 customer wants to pair Down MEPs in the C-VLAN Bridge to create MAs to provide end-to-end protection  
7 of the service instances. In order to obtain the advantage of inserting the CFM PDUs above the Queuing  
8 entities, the customer would not use MEPs below the Bridge Port Transmit and Receive process (8.5). The  
9 customer could create one MA for each C-VID.

10 There would be more justification in creating an MA per C-VLAN than for the Port-based service instance  
11 described in 22.6.2. However, if the customer is reasonably confident that the provider will carry each  
12 C-VLAN in the correct S-VLAN, then the customer can create multiple Maintenance C-VLANs, one per  
13 provider service instance (S-VLAN), and thus one per PEP in the C-VLAN component. By configuring each  
14 of these PEPs to pass that one C-VLAN untagged to the corresponding CNP in the S-VLAN component, the  
15 CFM PDUs in that one customer MA are visible to the S-VLAN component. The provider can configure a  
16 MIP for that S-VID that is visible to the customer's MA. The customer can have one MA protecting each  
17 service instance.

### 18 22.6.4 MPs and Port-mapping S-VLAN components

19 When a Port-mapping S-VLAN component is used to provide RCSI, there is little justification for making  
20 all possible CFM entities manageable. The other Provider Bridge components can provide the necessary  
21 MPs for service OAM. There is one MP that can only be provided by the Port-mapping S-VLAN component  
22 and that is the point below the Bridge Port Transmit and Receive process (8.5) on the RCAP. This MP can be  
23 used to protect the LAN to the neighboring PBN.

24 Figure 22-11 extends Figure 22-10, showing the minimum set of CFM entities required for a C-tagged  
25 RCSI, if the Provider Bridge supports CFM. The S-VLAN component and C-VLAN component support the  
26 same set of CFM entities as in Figure 22-10. The Port-mapping S-VLAN component that provides the  
27 RCSI supports at least one more CFM entity, as shown, that can protect the LAN to the neighboring PBN.

28 Similarly, in the case of a Port-based RCSI or an internal PNP the required service CFM entities can be  
29 provided by the S-VLAN component. Thus the only CFM entity required from the Port-mapping S-VLAN  
30 component is the one shown in Figure 22-11 which is independent of the number and type of internal Ports  
31 provided.

1

Figure 22-11—CFM in a Provider Edge Bridge C-tagged RCSI

## 22.7 Management Port MEPs and CFM in the enterprise environment

Figure 22-12 illustrates the placement of Management Port MEPs. It is similar to the CFM Port illustrated in Figure J-1. However, the Management Port MEPs are configured explicitly for the Management Port. They do not represent information for any other Bridge Port in their CFM PDUs. Therefore, there is only one MEP for each MA. Furthermore, there can be no MHFs configured on a Management Port, because there can be no MEP further along the path to terminate the MA.

**Figure 22-12—Up MEPs in a Management Port**

NOTE—The fact that a CFM Port could be configured on a Management Port, and thus instantiate MHFs on the Management Port, does not contradict the preceding paragraph. Those MHFs are configured on a Bridge Port, and instantiated on the Management Port (CFM Port), not configured on the Management Port.

Although this standard uses the terminology of Provider Bridges and describes the functions of CFM in terms of Provider Bridges, it can be applied to any Bridge, whether a Provider Bridge, C-VLAN Bridge, or MAC Bridge. The normative definitions and functions specified by this standard do not depend on, for example, whether the VLAN tag used to associate frames with VLANs use the customer format or the provider format. Certainly, no business relationships are required to implement this standard.

Given that both the users and the providers of an enterprise network are, by definition, all members of the same company, the utility of CFM in the enterprise environment is less than in the provider/customer environment. The network administrator of an enterprise network can find a number of uses for CFM, however.

The default values for MEP and MIP configuration make CFM easy to configure for the typical enterprise network. Figure 22-13 illustrates two Bridge Ports, the Management Port, and one Bridge Port connected to a LAN, using the default configuration as follows:

- A single Maintenance Domain can be configured at MD Level 0.
- An MA for each VID is configured in each Bridge.
- A single MEP for each VID is configured on a Management Port in each Bridge. Typically, this is a port with no external interface, often the one used to manage the Bridge.
- Through the Maintenance Domain managed object previously created, it is easy to define a MIP on every Bridge Port on every VID.

1 This simple configuration enables the administrator to use LBMs and LTMs to diagnose network faults  
2 among the Bridges of the network. In addition, specific high-priority VLANs, e.g., a VLAN interconnecting  
3 key routers and file servers for a large enterprise, could be explicitly monitored via CFM.

4 In a large enterprise, separate Maintenance Domains can be established, along with an accompanying  
5 enterprise-wide Maintenance Domain at a higher MD Level, in order to define and enforce separate spheres  
6 of responsibility for separate network administrations, e.g., in different departments in a university. The  
7 boundaries between Maintenance Domains might well coincide with administratively imposed boundaries  
8 between MSTP Regions.

Figure 22-13—CFM in the enterprise environment

## 22.8 Implementing CFM on Bridges that implement earlier revisions of IEEE Std 802.1Q

It might or might not be easy to implement CFM in a VLAN Bridge that implement earlier revisions of IEEE Std 802.1Q. The problems are best illustrated by a three-port Bridge as illustrated in Figure 22-14. Each of the three Bridge Ports A, B, and C is configured with MEPs and MIPs at the MD Levels shown in the figure.

Figure 22-14—CFM in the enterprise environment

If a CCM at MD Level 3 enters the Bridge from Bridge Port C, that CCM will be passed to both of the other Bridge Ports A and B. It will not exit Bridge Port A, however, because there is a MEP at MD Level 3 on that Bridge Port. It will, however, pass through Bridge Port B to the other operator Bridge. One can easily imagine configuring MAC Address Registration Entry in the Bridge for the MD Level 3 group address shown in Table 8-18 that permits that group address to pass through the Bridge Ports B and C, but not through Bridge Port A, and also sends the CCM to a CFM module in the Bridge's Higher Layer Entities, perhaps residing on the Management Port of 22.7, for processing. It is precisely so that MAC Address Registration Entries can be used in this manner that CCMs and LTMs are required to use the group addresses in Table 8-19 and Table 8-18.

A potential problem for some implementations can be seen if readers ask what happens if that same CCM at MD Level 3 enters from Bridge Port A. In that case, the CCM does not exit either of Bridge Ports B or C, because Bridge Port A has a MEP at MD Level 3 to stop it; MAC Address Registration Entries prevent frames from leaving a Bridge Port, not from entering one. Many Bridges have the ability to filter incoming frames based on the destination MAC address and/or the contents of the frame; either facility will enable this CCM to be stopped. In order to support both a Down MEP attached to no VID, and a Down MEP attached to a tagged VID at a lower MD Level than the no-VID MEP, the Bridge filters frames based on both the MAC address and whether the frame is tagged.

## 23. MAC status propagation

Individual LANs, each operating its own MAC and media access method-specific procedures, can be connected by one or more TPMRs to form a composite LAN that is transparent to other Bridges and stations and their configuration protocols. The MAC Status Protocol (MSP) ensures that changes in the connectivity provided by the composite LAN results in changes in the MAC\_Operational status parameter (IEEE Std 802.1AC) at each of the attached Bridges and stations, just as if they were connected to an individual LAN.

NOTE 1—MSP is designed only for use with point-to-point LANs.

MAC\_Operational provides rapid notification of connectivity failures and prompts the necessary initial protocol behavior to ensure that new connectivity has not caused an instantaneous data loop. If this MAC status parameter were not propagated by a TPMR, Bridge protocols would have to rely on periodic transmissions to detect connectivity changes. On their own these periodic transmissions take longer to detect failures, and cannot detect the possibility of data loops until they have been created, as illustrated by the following examples.

Figure 23-1 shows a TPMR connecting two Bridge Ports.

Figure 23-1—TPMR connecting two Bridge Ports

Assume that Bridge A is the spanning tree Designated Bridge for the LAN that comprises the individual LANs **a** and **b** and the TPMR, and that Bridge B's spanning tree Root Port is shown. If **a** fails and the TPMR does not propagate MAC\_Operational, Bridge B will not reselect its Root Port until it has timed out the last BPDU from A.

Figure 23-2 shows a link that uses two TPMRs, perhaps because LAN **c** uses a non-IEEE-802 technology together with an appropriate convergence function.

Figure 23-2—TPMR chain connecting Bridge Ports

Without MAC\_Operational propagation, failure of **c** will not be immediately visible to either Bridge. Worse, if **c** fails and is restored after a while, both A and B will believe themselves to be Designated Bridge for the composite LAN, and will forward frames until one receives a BPDU from the other, even if a data loop has been created.

1 When working correctly the MAC Service provides bidirectional connectivity or no connectivity at all.  
2 MAC\_Operational is TRUE for each of two peers connected to the same LAN if they can communicate, and  
3 FALSE for either or both if they cannot. Protocols, such as the spanning tree protocols, that make use of  
4 MAC\_Operational to detect new connectivity and initialize state machines rely on the last peer that sees  
5 MAC\_Operational transition TRUE to enforce any necessary behavior after a connectivity change. For  
6 example, it is the last of two connected Bridge Ports to be powered on that enforces the necessary delay prior  
7 to setting operEdge TRUE (13.27).

8 NOTE 2—MAC\_Operational being TRUE within a single station does not guarantee connectivity to any peer. Even if  
9 connected by a point-to-point LAN, the peer could have just reinitialized. It is not possible, given only the use of the  
10 LAN medium for communication, to arrange for two peers to transition MAC\_Operational at exactly the same time.

11 This clause defines media-independent propagation of MAC status between TPMRs and to attached  
12 stations, as follows. It:

- 13 a) Models MAC status propagation within the Bridge architecture used to describe a TPMR (23.1).
- 14 b) Provides an overview of MSP (23.2).
- 15 c) Specifies state machines for MSP operation (23.3–23.9).
- 16 d) Specifies the addressing, protocol identification, format, encoding, and validation of MAC Status  
17 Protocol Data Units (MSPDUs, 23.13–23.16).

18 The term *MAC status propagation* (3.163) describes the overall process of communicating a  
19 MAC\_Operational parameter value through one or more TPMRs. MSP can use *link status notification*<sup>39</sup>  
20 (3.132) between some Bridges and end stations and *MAC status notification* (3.162) between others. These  
21 two notification methods differ, as follows:

- 22 e) Link status notification uses frames to convey information about MAC\_Operational. It does not  
23 interrupt or prevent other communication between adjacent Bridges. However, it requires both the  
24 source and destination of the notification to implement additional protocol. Since it does not prevent  
25 communication it cannot, by itself, prevent loops caused by new connectivity.
- 26 f) MAC status notification uses a layer management interaction with the local MAC Entity to change  
27 MAC\_Operational for a peer user of the MAC Service provided by an individual LAN. It is  
28 equivalent to bringing a link down, and is generally effective for MACs with specific point-to-point  
29 support. It also interrupts all other communication, including the use of in-band management to  
30 rectify an underlying problem.

31 Where management of a TPMR is permitted through one of its ports, the failure of an individual LAN not in  
32 the communication path does not cause MAC status propagation to prevent management connectivity. In  
33 Figure 23-2, for example, the failure of LAN **b** does not prevent connectivity to TPMR 2 from Bridge A.  
34 When **b** recovers, MAC\_Operational for Bridge A's Port is "blipped," i.e., taken FALSE for a brief period  
35 and allowed to return TRUE, thus meeting the requirement for transition when connectivity changes. While  
36 this slows the recognition of newly available connectivity, that is rarely an issue since several seconds  
37 hysteresis should be applied to any MAC\_Operational status transition to prevent higher layer protocols  
38 "flapping."

<sup>39</sup> The use of the term link status notification in this standard is not to be confused with the term used in SNMP to refer to a type of trap notification.

## 23.1 Model of operation

The model of operation presented in this clause allows the description of MSP functionality to be consistent with that of the general Bridge architecture and operation (8.2, 8.3). Implementations of a TPMR may adopt any internal model of operation compatible with the externally visible behavior specified.

The additional entities that model MSP operation, and their relationship to the other processes and entities that model the operation of a TPMR are illustrated in Figure 23-3. They comprise the following:

- a) A MAC Status Shim (MSS, 23.1.1) for each Port, which allows MSP to control the value of MAC\_Operational presented to the TPMR Port connectivity function (8.5.2) and hence to the frame transmission and reception functions of the MAC Relay Entity, Higher Layer Entities, and MAC Status Propagation Entity (MSPE).
- b) The MSPE, which implements MSP, controlling each MSS to ensure that frames are not forwarded by the MAC Relay Entity until status propagation is complete, transmitting and receiving frames to support link status notification, and controlling the individual LAN's MAC to provide MAC status notification.

NOTE—In a TPMR the priority signaling functions shown in Figure 23-3 are provided by 6.20 Support of the ISS with signaled priority.

MSPDUs are sent to a standard group address. They are received by the MSPE, but are forwarded by the MAC Relay Entity (like any other frame) in order to communicate without a delay in each TPMR. The MSPE attaches to each Port by a TPMR Port connectivity function (8.5.2) that allows it to transmit to and receive from the attached individual LAN only, as shown in Figure 23-3.

Figure 23-3—MSSs and the MSPE

### 1 23.1.1 MAC Status Shim (MSS)

2 The MSS allows MSP to control the transmission and reception of frames through a Port by all the entities  
3 (including the MAC Relay Entity) supported by the TPMR Port Connectivity function (8.5.2). Each transmit  
4 request from the latter at the MSS's upper ISS-SAP results in a corresponding transmit request at the lower  
5 ISS-SAP supported by the LAN MAC and each receive indication from the lower ISS-SAP results in a  
6 corresponding receive indication at the upper ISS-SAP, without omission or duplication, and with identical  
7 parameters, if and only if MAC\_Operational for the upper ISS-SAP is TRUE.

8 The values of the MAC status parameters presented at the upper ISS-SAP are determined as follows:

- 9 — **MAC\_Enabled:** The value of this parameter is FALSE if the value of STM's disableMSS variable is  
10 TRUE. Otherwise, the value of this parameter is TRUE. STM communicates the value of its  
11 disableMSS variable using a Layer Management Interface (LMI).
- 12 — **MAC\_Operational:** The value of this parameter is TRUE if and only if the MSS's MAC\_Enabled  
13 parameter is TRUE and the value of the MAC\_Operational parameter provided by the LAN MAC at  
14 the lower ISS-SAP is TRUE.

15 The MSPE uses the LMI to control and receive status from each MSS and individual LAN MAC, allowing  
16 generic management requests and indications to be tailored to the requirements of different MACs, as well  
17 as providing a way for one MSS to propagate status to another (via the MSPE), even though  
18 MAC\_Operational for the MSS's upper ISS-SAP is FALSE.

### 19 23.1.2 Relationship of CFM to the MSS

20 MEPs may be placed above or below the MSS. A MEP placed in the lower position and partnered with  
21 another MEP so that the pair spans a chain of TPMRs would obscure the LAN MAC's MAC\_Operational  
22 parameter and interfere with the operation of MSP. For this reason, MEPs that protect individual LANs  
23 should be placed below MSS, and MEPs that protect chains of TPMRs should be placed above MSS.

## 24 23.2 MAC Status Protocol (MSP) overview

25 This clause provides examples of MSP operation as time sequence diagrams that show the following:

- 26 a) Exchange of MSPDUs transmitted and received to support link status notification.
- 27 b) The values of MAC\_Operational and MAC\_Enabled provided by the following:
  - 28 1) Each MSS, at its upper ISS-SAP, to the TPMR Port connectivity function.
  - 29 2) Each LAN MAC to the MSS, at the latter's lower ISS-SAP.

30 The value of MAC\_Operational provided by the MSS is TRUE if, and only if the MSS' MAC\_Enabled is  
31 TRUE and the value of MAC\_Operational provided to the MSS by the LAN MAC is TRUE. The latter can  
32 be TRUE only if MAC\_Enabled is TRUE for both the LAN MAC and its peer in the other station connected  
33 to the LAN. The MSPE can use the LMI to disable the MSS in order to prevent communication until MAC  
34 status propagation has occurred, and to disable the LAN MAC in order to provide MAC status notification  
35 to a peer service user. This clause uses the symbols defined in Table 23-1 to show combinations of the MAC  
36 status parameter values for each Port.

**Table 23-1—Time sequence diagram symbols**

|                |                        |  |  |  |  |  |
|----------------|------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>MSS</b>     | <b>MAC_Operational</b> | T                                                                                 | F                                                                                 | F                                                                                 | F                                                                                   | F                                                                                   |
|                | <b>MAC_Enabled</b>     | T                                                                                 | T                                                                                 | F                                                                                 | F                                                                                   | —                                                                                   |
| <b>LAN MAC</b> | <b>MAC_Operational</b> | T                                                                                 | F                                                                                 | F                                                                                 | T                                                                                   | F                                                                                   |
|                | <b>MAC_Enabled</b>     | T                                                                                 | T                                                                                 | T                                                                                 | T                                                                                   | F                                                                                   |

T = TRUE, F = FALSE, — = either TRUE or FALSE

1 Throughout this protocol description, the term *LAN* is used to refer to individual LANs connecting adjacent  
2 TPMRs or a TPMR and an adjacent Bridge. A *chain* is a series or part of a series of TPMRs connected by  
3 LANs, and a *link* is the connectivity provided by a chain between non-TPMR devices that communicate at a  
4 higher (sub) layer and perceive the entire link as a single transparent LAN.

5 The number of TPMRs in the following examples is deliberately high, four where one or two might be more  
6 common, in order to show all the necessary aspects of protocol behavior.

7 Signaling the addition of new or restored connectivity is considered first, as it is more difficult than signaling  
8 failure. Figure 23-4 shows the response to a new or recovered LAN connection in a link between two  
9 Bridges that do not implement MSP—and thus require MAC status notification.

**Figure 23-4—Adding connectivity**

10 Before the LAN that connects TPMR 1 to TPMR 2 is MAC\_Operational, each MSPE disables its MSS ()  
11 This allows the MSPE to intercept the new connectivity as the LAN MAC asserts MAC\_Operational ()  
12 TPMR 2 propagates the new status to its other Port, transmitting an *add* MSPDU. TPMR 2 does not

1 necessarily know that TPMR 3 implements MSP (or indeed is a TPMR) but uses the default MSP  
2 configuration—waiting before resorting to MAC status notification and starting a *linkNotifyWhile* timer (as  
3 do TPMRs 3 and 4) on receipt of the *add* (which is forwarded by the Relay Entity). Each TPMR responds to  
4 the *add* with an *ack* that clears the timer, but the Bridge at the end of the chain does not (as it does not  
5 implement MSP). When TPMR 4's timer expires, its MSPE disables the LAN MAC (✂), ensuring that  
6 *MAC\_Operational* becomes FALSE (👎) for the Bridge's Port, and starts a *macNotifyWhile* timer. When  
7 that timer expires, the MSPE reenables the LAN MAC so that the Bridge Port's *MAC\_Operational* can  
8 become TRUE (👍) once more. As well as disabling the LAN MAC for its Port 2, TPMR 4 also transmitted  
9 an *add confirm* through Port 1, and receipt of this *add confirm* by TPMR 2 causes the latter to cancel its retry  
10 timer (*linkNotifyWhen*). The initial value of *macNotifyWhile* (*MacNotifyTime*) is sufficient for the *add*  
11 *confirm* to reach the TPMR 2, and for that TPMR's MSPE to enable the MSS, thus ensuring that there is  
12 connectivity between the Bridges connected by the link when they have both reported *MAC\_Operational*  
13 TRUE to their local protocol clients.

14 In Figure 23-4 the MSP configuration of TPMR 2's Port 2 differs from that for Port 1 of TPMR 1. The latter  
15 is explicitly configured to use MAC status notification immediately without waiting to see if its peer  
16 implements MSP.

17 Figure 23-5 illustrates the operation of MSP when the connectivity provided by an individual LAN is lost.  
18 The MSPE for each of the TPMR ports directly attached to the failed LAN begins by disabling the MSS for  
19 that Port (👎) to ensure that connectivity does not 'flap'. Otherwise, the protocol proceeds as for connectivity  
20 addition, except that *loss* and *loss confirm* are used instead of *add* and *add confirm*, and the MSSs attached  
21 to the failed LAN are left disabled. The final state of the link components is the initial state assumed in  
22 Figure 23-4—both attached Bridges have seen *MAC\_Operational* transition to indicate that the connectivity  
23 has changed, and the TPMRs in each of the two chains can be reached and managed (if their individual  
24 configuration permits) through the attached Bridge Ports.

Figure 23-5—Losing connectivity

1 In the examples above, if an *add*, or *loss* is lost then the TPMR Port that transmitted or relayed that MSPDU  
2 will revert to using MAC status notification, as will a TPMR that fails to receive the *ack* from the next (or a  
3 subsequent) TPMR in the chain. If the MSPDU is lost on a LAN removed from the TPMR that initiated the  
4 link status notification, then that notification will be retried on expiry of the *linkNotifyWhen* timer, which  
5 also serves to protect against the loss of an *add confirm* or *loss confirm*.

6 Loss of a frame due to physical corruption is rare in LAN technologies, and frame losses due to buffer  
7 overrun are not expected when connectivity is being added (as the link is not usable prior to the addition) nor  
8 when a loss of connectivity is being signaled (as that connectivity loss will have prevented other frames  
9 from being added to the link). The loss of an MSPDU is most likely to be due to failure of one of the LANs,  
10 or to interruption of a TPMR's relay functionality by another MSS whose MSPE is also waiting for  
11 confirmation that a connectivity change that it has detected has been propagated to the end of the link. MSP  
12 does not, and cannot, ensure that information about each and every connectivity change reaches both ends of  
13 the link. Unless link status notification or MAC status notification is disabled or the individual LANs fail to  
14 report MAC\_Operational correctly, MSP does ensure that any change in connectivity is accompanied by one  
15 or more notifications at each end of the link, and that a continuous period during which MAC\_Operational is  
16 reported TRUE at both ends of the link provides unchanged connectivity from 1 second after the start of the  
17 period to 1 second before the end. This guarantee meets the requirements implicit in the initial transmission  
18 and retransmission strategies of well designed protocols. Protocol clients of the MAC Service should not use  
19 the difference between *loss* and *add* MSPDUs to take different actions on receipt, though the distinction can  
20 be useful to a network administrator when investigating connectivity changes.

21 Figure 23-6 provides a common example of simultaneous change. TPMR 2 is powered on and initializes  
22 both its ports. When the LAN MAC becomes operational, each Port attempts to send a notification through  
23 the other, but cannot as they are both waiting for the connectivity addition to be confirmed. However, in this  
24 eventuality, each Port can provide the other with the confirmation required, because the peer system for each  
25 of the individual LANs will also have seen the initial MAC\_Operational transition and will have initiated a  
26 notification toward its end of the link.

27 NOTE—The SNM state machine transition direct from SNM:LINK\_NOTIFICATION to SNM:MAC\_NOTIFYING  
28 supports this behavior (see Figure 23-11).

Figure 23-6—TPMR recovery

1 If the individual LAN that recovers (or loses) connectivity is at the end of the link, MSP ensures that the  
2 other end of the link is also aware of the status change as illustrated in Figure 23-7. This figure also shows  
3 the effect on MSP of including two nonstandard relays in the chain. Provided they (and their attached LANs)  
4 never fail, MSP can continue to operate as intended.

Figure 23-7—Notification from one end of the link to the other

5 If TPMR 4 is configured to use MAC status notification immediately, it does not return an *ack* as the *add*  
6 *confirm* can be sent almost immediately (see Figure 23-8).

Figure 23-8—Immediate MAC status notification at the end of a link

## 23.3 MSP state machines

The operation of the MSPE is represented by an instance of each of the following for each Port of the TPMR:

- a) A Status Transition state machine (STM, 23.8)
- b) A Status Notification state machine (SNM, 23.9)
- c) A Receive Process (23.10)
- d) A Transmit Process (23.11)

Figure 23-9 shows the state machine variables that are used to communicate between these machines and processes, and that support management control over their operation. Variables prefixed with ‘r.’ are those of the corresponding state machines of the other Port of the TPMR.

The notational conventions used in Figure 23-9 and in the specification of the state machine are identical to those used in the specification of MSTP (Clause 13) and RSTP and are defined in Annex E.

Figure 23-9—MSPE state machine overview

Port 1's STM monitors MAC\_Operational transitions for its own LAN, and tells Port 2's Transmit process to send *add* or *loss* link notifications and Port 2's SNM to monitor the progress of status notification, using MAC status notification if necessary. Port 2's SNM receives the *ack* that indicates that it should wait for link status notification to complete, and the *add confirm* or *loss confirm* that indicates that completion. Whether

1 link status or MAC status notification is used, Port 2's SNM tells Port 1's STM when the notification has  
2 been confirmed, so the latter does not have to retry the notification. Port 1's SNM provides the same service  
3 to Port 2's STM.

4 A *loss* or *add* notification that is received from Port 1's own LAN is handled by its STM, which propagates  
5 the notification to Port 2's SNM (in the same way as a local MAC\_Operational transition) while transmitting  
6 an *ack* on Port 1's LAN. Similarly Port 2's STM transmits an *ack* for a link status notification received on its  
7 own LAN, and propagates the notification to Port 1's SNM.

## 8 **23.4 State machine timers**

9 Timers are implemented by variables that are decremented on each timer tick, with timer expiry occurring  
10 when they reach zero.

### 11 **23.4.1 linkNotifyWhen**

12 Causes a link status notification to be sent on each expiry until the original status transition is confirmed.

### 13 **23.4.2 linkNotifyWhile**

14 Started when a change is first propagated through the Port, on expiry allows MAC status notification.

### 15 **23.4.3 macNotifyWhile**

16 Sets the time for which the MAC is disabled for MAC status propagation.

### 17 **23.4.4 macRecoverWhile**

18 Sets the time for which the MAC is permitted to be nonoperational, after being disabled, before the link is  
19 reported as lost.

## 20 **23.5 MSP performance parameters**

21 These parameters are not modified by the operation of MSP but are treated as constants by the state  
22 machines. They can be managed independently for each TPMR Port—default values and permissible ranges  
23 are specified in Table 23-2.

**Table 23-2—MSP performance parameters**

| Parameter       | Recommended or default value | Permitted range |
|-----------------|------------------------------|-----------------|
| LinkNotify      | TRUE                         | TRUE or FALSE   |
| LinkNotifyWait  | 0.4 s                        | 0.2–1.0 s       |
| LinkNotifyRetry | 1.0 s                        | 0.1–1.0 s       |
| MACNotify       | TRUE                         | TRUE or FALSE   |
| MACNotifyTime   | 0.2 s                        | 0.01–0.5 s      |
| MACRecoverTime  | 0.1 s                        | 0.02–0.5 s      |

### 1 **23.5.1 LinkNotify**

2 TRUE if the Port uses link status notification to propagate MAC status, and will wait to allow link status  
3 notification to succeed before using MAC status notification.

4 NOTE—If LinkNotify is FALSE, the TPMR still forwards *loss* and *add* notifications transmitted by other TPMRs prior  
5 to using MAC status notification, but the TPMR will not originate link status notifications.

### 6 **23.5.2 LinkNotifyWait**

7 The initial value of the linkNotifyWhile timer.

### 8 **23.5.3 LinkNotifyRetry**

9 The initial value of the linkNotifyWhen timer of the other TPMR Port.

### 10 **23.5.4 MACNotify**

11 TRUE if the Port uses MAC status notification.

### 12 **23.5.5 MACNotifyTime**

13 The initial value of the macNotifyWhile timer.

### 14 **23.5.6 MACRecoverTime**

15 The initial value of the macRecoverWhile timer.

## 16 **23.6 State machine variables**

### 17 **23.6.1 BEGIN**

18 This is a Boolean variable controlled by the system initialization process. A value of TRUE causes all  
19 TPMR state machines to continuously execute their initial state. A value of FALSE allows all state machines  
20 to perform transitions out of their initial state, in accordance with the relevant state machine definitions.

### 21 **23.6.2 addConfirmed**

22 Set by the other Port's SNM to tell STM that the addition has been confirmed. Cleared by STM.

### 23 **23.6.3 disableMAC**

24 Set by SNM to instruct the individual LAN MAC (via an LMI) to disable itself in a way that will cause  
25 MAC\_Operational to be FALSE for the peer user of the MAC Service provided by that LAN.

26 NOTE—The state machines do not assume that a client of the MAC can tell whether the MAC is not operational because  
27 that client has disabled it, or whether some other client has disabled it.

### 28 **23.6.4 disabledMAC**

29 Set by the SNM when it has set disableMAC and for MACRecoverTime after disableMAC has been reset,  
30 so that the STM does not conclude that a loss notification should be sent through the other TPMR Port.

### 31 **23.6.5 disableMSS**

32 Set (or reset) by the STM to instruct the MSS (via an LMI) to set its MAC\_Enabled status parameter to  
33 FALSE (correspondingly, TRUE).

### 34 **23.6.6 lossConfirmed**

35 Similar to addConfirmed but confirms a loss.

1 **23.6.7 macOperational**

2 The value of MAC\_Operational for the individual LAN MAC.

3 **23.6.8 mssOperational**

4 The value of MAC\_Operational provided by the MSS to the TPMR Port's Bridge transmit and receive  
5 function.

6 **23.6.9 prop**

7 Set by the other Port's STM to Add or Loss to notify SNM that a change is being propagated through the  
8 Port. Reset by SNM to None.

9 **23.6.10 rxAck**

10 Set by the Receive process to tell SNM that an acknowledgment has been received. Cleared by SNM.

11 **23.6.11 rxAdd**

12 Set by the Receive process to tell STM that an *add* notification is being propagated through the TPMR.  
13 Cleared by STM.

14 **23.6.12 rxAddConfirm**

15 Set by the Receive process to tell SNM that an *add confirm* has been received. Cleared by SNM.

16 **23.6.13 rxLoss**

17 Similar to rxAdd, but for a *loss*.

18 **23.6.14 rxLossConfirm**

19 Similar to rxAddConfirm, but for a *loss confirm*.

20 **23.6.15 txAck**

21 Set by the STM to instruct the Transmit process to send an acknowledgment. Cleared by the Transmit  
22 process.

23 **23.6.16 txAdd**

24 Set by the other Port's STM to cause transmission of an *add* notification. Cleared by the Transmit process.

25 **23.6.17 txAddConfirm**

26 Set by the other Port's SNM to cause transmission of an *add confirm* (through this Port) confirming that a  
27 received *add* message has been acted upon. Cleared by the Transmit process.

28 **23.6.18 txLoss**

29 Similar to a txAdd but causes a *loss* message to be transmitted.

30 **23.6.19 txLossConfirm**

31 Similar to a txAddConfirm but causes a *loss confirm* message to be transmitted.

## 23.7 State machine procedures

No procedures are defined beyond those represented in the state machines.

## 23.8 Status Transition state machine (STM)

The STM shall implement the function specified by the state diagram in Figure 23-10 and the attendant definitions contained in 23.4 through 23.7.

Figure 23-10—Status Transition state machine (STM)

## 23.9 Status Notification state machine (SNM)

The SNM shall implement the function specified by the state diagram in Figure 23-11 and the attendant definitions contained in 23.4 through 23.7.

## 23.10 Receive Process

The Receive Process shall receive and validate MSPDUs as specified in 23.16.

## 23.11 Transmit Process

The Transmit Process shall transmit and encode MSPDUs as specified in 23.13 through 23.15. If the Transmit Process is instructed to transmit an MSPDU before it has had the opportunity to transmit a prior MSPDU, that prior MSPDU shall be discarded and not transmitted. If the MAC\_Operational status provided by the MSS for the Port is FALSE, the MSPDU shall be discarded and not transmitted.

Figure 23-11—Status Notification state machine (SNM)

## 23.12 Management of MSP

2 An implementation of MSP in a TPMR:

- 3 a) May allow the performance parameters (23.5) to be read by management.
- 4 b) May allow the performance parameters (23.5) to be modified by management.
- 5 c) May maintain each of the following counts for one or both ports of the TPMR:
  - 6 1) acksTransmitted: The number of *acks* transmitted (23.6.15) by the Port's Transmit Process as a consequence of *txAck* being set.
  - 7 2) addNotificationsTransmitted: The number of *adds* transmitted (23.6.16) by the Port's Transmit Process as a consequence of *txAdd* being set.
  - 8 3) addConfirmationsTransmitted: The number of *add confirms* transmitted (23.6.17) by the Port's Transmit Process as a consequence of *txAddConfirm* being set.
  - 9 4) lossNotificationsTransmitted: The number of *losses* transmitted (23.6.18) by the Port's Transmit Process as a consequence of *txLoss* being set.
  - 10 5) lossConfirmationsTransmitted: The number of *loss confirms* transmitted (23.6.19) by the Port's Transmit Process as a consequence of *txLossConfirm* being set.
  - 11 6) acksReceived: The number of *acks* received (23.6.10) by the Port's Transmit Process.
  - 12 7) addNotificationsReceived: The number of *adds* received (23.6.11) by the Port's Receive Process.
  - 13 8) addConfirmationsReceived: The number of *add confirms* received (23.6.12) by the Port's Receive Process.
  - 14 9) lossNotificationsReceived: The number of *losses* received (23.6.13) by the Port's Receive Process.
  - 15 10) lossConfirmationsReceived: The number of *loss confirms* received (23.6.14) by the Port's Receive Process.
  - 16 11) addEvents: The number of transitions to STM:ADD directly from STM:DOWN or STM:LOSS (23.8).

- 1 12) lossEvents: The number of transitions to STM:LOSS directly from STM:UP or STM:ADD  
2 (23.8).  
3 13) macStatusNotifications: The number of transitions to SNM:MAC\_NOTIFICATION (23.9).

#### 4 **23.13 MSPDU transmission, addressing, and protocol identification**

5 MSPDUs are transmitted and received using the service provided by an LLC entity that uses, in turn, a  
6 single instance of the MAC Service provided at an MSAP. In a TPMR the MSPE transmits and receives the  
7 MSPDUs, and the MSAP is provided by the TPMR Port connectivity function as illustrated in Figure 23-3.  
8 Each MSPDU is transmitted as a single MAC Service request, and received as a single MAC Service  
9 indication, with the following parameters:

- 10 a) destination address (23.13.1)  
11 b) source address (23.13.2)  
12 c) MSDU  
13 d) priority (23.13.3)

14 The MSDU of each request and indication comprises an number of octets that provide EtherType protocol  
15 identification (23.13.4) followed by the MSPDU proper (23.15).

16 NOTE 1—For the purposes of this standard, the term “LLC entity” includes entities that support protocol discrimination  
17 using the EtherType field as specified in IEEE Std 802.

18 NOTE 2—The complete format of an MSP frame “on the wire” or “through the air” depends not only on the MSPDU  
19 format, as specified in this clause, but also on the media access method-dependent procedures used to support the MAC  
20 Service.

##### 21 **23.13.1 Destination MAC Address**

22 The destination address for each MAC Service request used to transmit an MSPDU shall be the group  
23 address identified in Table 8-1 and Table 8-2 as “Nearest non-TPMR Bridge group address”<sup>40</sup>.

##### 24 **23.13.2 Source MAC Address**

25 The source address for each MAC Service request used to transmit an MSPDU shall be an individual  
26 address associated with the MSAP at which the request is made.

##### 27 **23.13.3 Priority**

28 The priority associated with each MAC Service request should be the default associated with the MSAP.  
29 Transmitted MSPDUs are not VLAN tagged or priority tagged.

##### 30 **23.13.4 EtherType use and encoding**

31 All MSPDUs are identified by the EtherType specified in Table 23-3.

**Table 23-3—MSP EtherType assignment**

| Assignment                    | Value |
|-------------------------------|-------|
| MAC Status Protocol EtherType | 22-E2 |

<sup>40</sup> This address was originally assigned by IEEE Std 802.1X-2001 and was identified as an S-VLAN component Reserved Address (Table 8-2) by the IEEE Std 802.1ad amendment to IEEE Std 802.1Q-2005. This standard identifies it as the “nearest non-TPMR Bridge group address,” to be filtered by all relay functions above the sublayer specified for TPMRs (see Table 8-1 and Table 8-2).

## 23.14 Representation and encoding of octets

All MSPDUs consist of an integral number of octets, numbered starting from 1 and increasing in the order that they are put into a MAC frame. The bits in each octet are numbered from 1 to 8, where 1 is the low-order bit. When consecutive octets are used to encode a binary number, the lower numbered octet contains the more significant bits of the binary number.

When the encoding of (an element of) an MSPDU is represented using a diagram in this clause, the following representations are used:

- a) Octet 1 is shown toward the top of the page, higher numbered octets being toward the bottom.
- b) Where more than one octet appears on a given line, octets are shown with the lowest numbered octet to the left, higher numbered octets being to the right.
- c) Within an octet, bits are shown with bit 8 to the left and bit 1 to the right.

## 23.15 MSPDU structure

The MSPDU comprises the octets following the MSP EtherType. All MSPDUs comprise a Protocol Version (23.15.1) and a Packet Type (23.15.2). See Figure 23-12.

|                            | Octet |
|----------------------------|-------|
| Protocol Version (23.15.1) | 1     |
| Packet Type (23.15.2)      | 2     |

**Figure 23-13—MSPDU structure**

### 23.15.1 Protocol Version

The MSP Protocol Version is encoded in all MSPDUs as a single octet, representing an unsigned binary number. Its value identifies the version of MSP supported by originator of the MSPDU. An implementation conforming to this specification shall encode the value 0000 0000 in this field. All other values are reserved.

NOTE—TPMRs that relay an MSPDU do not change its Protocol Version.

### 23.15.2 Packet Type

The MSP Packet Type is encoded as a single octet, representing an unsigned binary number. Table 23-4 lists the Packet Types specified by this standard, and the state machine variables set to indicate reception and transmission of MSPDUs of that type. All other possible values of the Packet Type field are reserved and shall not be used.

**Table 23-4—MSP Packet Types**

| Packet Type        | Value | Transmission            | Reception               |
|--------------------|-------|-------------------------|-------------------------|
| MSP-Add            | 0     | txAdd (23.6.16)         | rxAdd (23.6.11)         |
| MSP-Loss           | 1     | txLoss (23.6.18)        | rxLoss (23.6.13)        |
| MSP-Add Confirmed  | 2     | txAddConfirm (23.6.17)  | rxAddConfirm (23.6.12)  |
| MSP-Loss Confirmed | 3     | txLossConfirm (23.6.19) | rxLossConfirm (23.6.14) |
| MSP-Ack            | 4     | txAck (23.6.15)         | rxAck (23.6.10)         |

## 1 23.16 Validation of received MSPDUs

2 To ensure that backward compatibility is maintained for future versions of this protocol, the validation and  
3 protocol version handling for all MSPDUs, follows general rules developed for this and other protocols. A  
4 received MSPDU shall be processed as specified by Table 23-4 if and only if:

- 5 a) The destination MAC address is the group address specified (23.13.1); and
- 6 b) The MSPDU is identified by the MSP EtherType encoded as specified in 23.13.4; and
- 7 c) The received MSPDU contains at least two octets, i.e., at least the Protocol Version and Packet  
8 Type; and
- 9 d) The Packet Type is one of the values specified in Table 23-4.

10 Otherwise, the received MSPDU shall be discarded. No other checks shall be applied to received MSPDUs,  
11 in particular the value of the Protocol Version is not checked and MSPDUs of length greater than the  
12 minimum of two octets are accepted as valid.

## 13 23.17 Other MSP participants

14 An end station or non-TPMR Bridge attached to the end of a TPMR link can participate in link status  
15 notification, avoiding the need for the last TPMR in the chain to use MAC status notification and thus  
16 speeding the transition of the link to an operational state. Such a participant receives MSPDUs, but acts only  
17 on a received *loss* or *add*, notifying its protocol clients of the change in connectivity, and responding  
18 immediately by transmitting an *add confirm* or *loss confirm* as appropriate. There is no need for such a  
19 participant to transmit an *add*, *loss*, or *ack*, or act upon a received *ack*, *add confirm* or *loss confirm*, or to  
20 initiate MAC status notification.

## 24. Bridge performance

This clause specifies a set of parameters that represent the performance of a Bridge. These parameters have been selected to allow a basic level of confidence to be established in a Bridge, for use in an initial determination of its suitability for a given application. They cannot be considered to provide an exhaustive description of the performance of a Bridge. It is recommended that further performance information be provided and sought concerning the applicability of a Bridge implementation.

The following set of performance parameters is defined:

- a) Guaranteed Port Filtering Rate, and a related time interval  $T_F$ , that together characterize the traffic for which filtering is guaranteed.
- b) Guaranteed Bridge Relaying Rate, and a related time interval  $T_R$ .

### 24.1 Guaranteed Port Filtering Rate

For a specific Bridge Port, a valid Guaranteed Port Filtering Rate, in frames per second, is a value that, given any set of frames from the specific Bridge Port to be filtered during any  $T_F$  interval, the Forwarding Process shall filter all of the set as long as all of the following are true:

- a) The number of frames in the set does not exceed the specific Bridge Port's Guaranteed Port Filtering Rate multiplied by  $T_F$ .
- b) The Guaranteed Port Filtering Rate of each of the other Bridge Port(s) is not exceeded.
- c) The Guaranteed Bridge Relaying Rate is not exceeded.
- d) Relayed frames are not discarded due to output congestion (8.6.7).
- e) The information upon which the filtering decisions are based has been configured in the FDB prior to the start of time interval  $T_F$ .

### 24.2 Guaranteed Bridge Relaying Rate

For a Bridge, a valid Guaranteed Bridge Relaying Rate, in frames per second, is a value that given any set of frames from the specific Bridge Port to be relayed during any  $T_R$  interval, the Forwarding Process shall relay all of the set as long as all of the following are true:

- a) The number of frames in the set does not exceed the Bridge's Guaranteed Bridge Relaying Rate multiplied by  $T_R$ .
- b) The Guaranteed Port Filtering Rate of each Bridge Port is not exceeded.
- c) Relayed frames are not discarded due to output congestion (8.6.7).
- d) The information upon which the forwarding decisions are based has been configured in the FDB prior to the start of time interval  $T_R$ .

## 24.3 RSTP performance requirements

This subclause places requirements on the performance of the Spanning Tree Protocol Entities of Bridges in a Bridged Network to ensure that RSTP operates correctly.

The delay between the occurrence of an external event and the action or actions mandated by the RSTP specification as a consequence of the event shall not exceed the Maximum RSTP processing delay specified in Table 24-1.

**Table 24-1—Transmission and reception delays**

| Parameter                       | Absolute maximum value (s) |
|---------------------------------|----------------------------|
| Maximum RSTP processing delay   | 1.0                        |
| Maximum BPDU transmission delay | 0.2                        |

External events subject to this provision of this specification shall include the following:

- a) Transmission of a BPDU by another Bridge on a LAN to which the Bridge is attached.

Specified actions subject to this provision shall include the following:

- b) Transmissions of BPDUs on all Ports mandated by the RSTP specification, with the exception of transmissions delayed by the Port Transmit state machine (13.34) to enforce transmit rate limits.
- c) Ceasing to learn or forward frames.

The delay between internal timer related events and the transmission of all BPDUs on Ports mandated by the RSTP specification as a consequence shall not exceed the Maximum BPDU transmission delay specified in Table 24-1. Timer events subject to this provision of this specification shall include the following:

- d) Decrementing of txCount by the Port Transmit machine, thus allowing a BPDU transmission if transmit rate limits were being enforced.
- e) Expiry of the helloWhen timer (13.25.3).

## 25. Support of the MAC Service by PBBNs

A PBBN comprises a set of BEBs interconnected by some or all of the S-VLANs supported by a PBN (see Clause 16). Each BEB provides interfaces that encapsulate (or verify the encapsulation of) customer frames, thus allowing Customer MAC (C-MAC) addresses and VIDs to be independent of the Backbone MAC (B-MAC) addresses and VIDs administered by the PBBN operator and used to relay those frames across the backbone. The S-VLANs used to encapsulate customer frames are known as Backbone VLANs (B-VLANs), and the resources that support those VLANs are usually considered to be part of the PBBN.

NOTE 1—The term Customer used in the context of PBBs may refer to a first Provider who is purchasing service from a second Provider. The first Provider deploys a PBN or a PBBN within its domain. The second Provider deploys a PBBN within its domain. In this case, the first Provider is identified as a Customer with respect to the second Provider. The term Customer used here may alternatively refer to each of a pair of Providers communicating as peers.

Figure 25-1 shows peer BEBs within the MAC sublayer and their relationship to customer and backbone bridging functions. The right-most BEB shown is modeled as comprising two types of VLAN Bridge components, an I-component and a B-component, connected together. The two BEBs on the left of the figure each comprise a single VLAN Bridge component of different types. The left-most BEB has a single I-component, while the BEB just to the right of the left-most BEB has a B-component. A T-component may also be used in place of an I-component.

Figure 25-1—Internal organization of the MAC sublayer in a PBBN

Each I-component or T-component is responsible for encapsulating frames received from customers and assigning each frame to a backbone service instance. The backbone service instance consists of a set of BEBs that support a given customer's S-VLANs, and is uniquely identified within the PBBN by an I-SID. The customer frame is encapsulated by an I-TAG, which includes the I-SID, and a set of source and destination B-MAC addresses. The B-MAC addresses identify the BEBs of the backbone service instance where the customer frame will enter and exit the PBBN. If the I-component or T-component does not know which of the other BEBs provides connectivity to a given customer address, it uses a default encapsulating B-MAC address that reaches all the other BEBs in the backbone service instance. Each I-component learns the association between customer source addresses received (encapsulated) from the backbone and the backbone source address, so subsequent frames to that address can be transmitted to the correct BEB.

A PBBN or a series of PBBNs providing the MAC Service to attached end stations is typically modeled as a symmetric sequence of relay functions, as illustrated in Figure 25-1. The outermost peer relay functions are identified as I-components. The next peer relay functions in the sequence are identified as B-components.

1 Between the peer B-components are one or more S-VLAN relay functions. A B-component relay forms the  
2 service layer to an I-component relay. A B-component relay forwards frames taking into account the identity  
3 of a B-VLAN (B-VID), while an I-component relay forwards frames taking into account the identity of an  
4 S-VLAN (S-VID).

5 A single B-component is responsible for relaying encapsulated customer frames to and from I-components  
6 and T-components, either within the same BEB or externally connected, checking that ingress/egress is  
7 permitted for frames with that I-SID, translating the I-SID (if necessary) and using it to assign the supporting  
8 connection parameters (backbone addresses if necessary and VIDs) for the PBBN, and relaying the frame to  
9 and from the PNP(s) that provide connectivity to the other Bridges within and attached to the backbone. A  
10 B-component performs the same functions when relaying frames to and from another B-component when  
11 two PBBNs interconnect (26.6.2).

12 The number of I-components (zero or more), T-components (zero or more), and B-components (zero or  
13 one) within a given BEB is a direct consequence of the type and number of external interfaces supported by  
14 that BEB. The I-components, T-components, and B-component may be in the same BEB or may be in  
15 different BEBs. The types of BEBs may be classified as I-BEB, B-BEB, T-BEB, and ITB-BEB as depicted  
16 in Figure 25-2, where ITB-BEB covers all valid combinations of multi-component BEBs, e.g., IB-BEB.

**Figure 25-2—PBB terminology**

17 This clause discusses the following aspects of PBBN service:

- 18 a) Service transparency (25.1)
- 19 b) Customer service interfaces (25.2, 25.3, 25.4, 25.5)
- 20 c) Service instance segregation (25.6)
- 21 d) Service instance and backbone service instance selection and identification (25.7)
- 22 e) Service priority and drop eligibility selection (25.8)
- 23 f) Service access protection (25.9)

24 NOTE 2—This standard makes use of the term *service* as defined by the OSI Reference Model (ISO/IEC 7498-1). In this  
25 sense, a service comprises a set of primitives and associated parameters, provided by one protocol layer in the  
26 architectural model to the protocol layer above, and the causal relationships between the primitives invoked by an upper  
27 layer protocol entity in one system with those resulting indications to a peer entity in another system. The term *service*  
28 used by backbone providers, while including layering concepts, goes far beyond this formal definition, and commonly  
29 specifies some or all of the following: interfacing considerations across multiple protocol layers (including physical  
30 connectors, for example); selection of interface points; interfacing equipment; QoS guarantees and measurement  
31 methods; charging methods and responsibilities; connectivity verification and other management tools; and regulatory  
32 issues.

## 25.1 Service transparency

The operation of PBBNs is, by design, largely transparent to Provider Bridges and PBNs as illustrated by Figure 25-1. The service provided by BEBs is transparent to the use of the MAC Service by end stations attached to the CBNs through PBNs and transparent to the operation of media access method-independent functions by Customer Bridges.

The service is not transparent to the operation of media access method-dependent convergence functions or to the operation of the media access method-specific functions specified by standards for each media access method. Media access method-dependent and -specific functions operate between Bridges—whether Customer Bridges, Provider Bridges, or PBBs—attached to the same LAN.

## 25.2 Customer service interface

A backbone provider can offer to customers one or more types of service interfaces, each providing different capabilities for service selection, priority selection, and service access protection (25.7, 25.8, 25.9). In some cases it is assumed the customer provides an S-VLAN component of a Provider Bridge while in other cases, more generic customer systems are also allowed. There are four basic types of customer service interfaces—Port-based, S-tagged, I-tagged, and transparent service interface. The customer service interface types are summarized by Figure 25-3.

**Figure 25-3—Customer service interface types**

In all cases, segregation of different service instances is achieved at an interface wholly under the control of the backbone provider, and by verification of customer provided parameters that provide service instance selection. Stronger authentication and authorization of the attached customer systems can be achieved by use of IEEE Std 802.1X.

NOTE—The term service access protection describes provision of service access over multiple access LANs and (or) nodes with redundancy and rapid failover in case of failure of an access LAN or attached equipment.

Access to a given backbone service instance can be provided through different types of customer interfaces.

## 1 25.3 Port-based service interface

9 The Port-based service interface requires specific constraints on the configuration of the I-component. Each  
10 I-component CNP providing a Port-based interface is associated with one and only one VIP with exactly the  
11 same parameters for their tagging functions support. More specifically both CNP and VIP

<sup>17</sup> Figure 25-4 illustrates a customer system attached to a PBBN over a Port-based service interface.

**Figure 25-4—Port-based service interface**

Figure 25-5—Port-based interface equipment

## 25.4 S-tagged service interface

The S-tagged service interface maps a service instance from a PBN, identified by an S-VID, to a backbone service instance on the PBBN, identified by an I-SID. There are two types of S-tagged service interfaces—one performing a one-to-one mapping of S-VIDs to I-SIDs and the other bundling S-VIDs to I-SIDs. Frames that are mapped to the I-SID are carried over the PBBN while frames that are not mapped to an I-SID are not carried over the PBBN.

NOTE 1—The restriction that each PBN S-VLAN map to a single backbone service instance on the PBBN allows the PBN equipment receiving frames to correctly identify the service instance used to deliver that frame and prevents the configuration of the I-component to create a multipoint service from point-to-point service instances, which could result in accidental creation of data loops. The backbone provider can offer a multipoint service through appropriate configuration of the B-VLAN component.

A PBBN may provide an S-tagged service interface for attachment to customer PBNs (15.5). An S-tagged service interface is provided by a BEB over a CNP as illustrated by Figure 25-7 and Figure 25-8. The attached Provider Bridges can in turn provide Port-based, C-tagged, or S-tagged service interfaces to their customers as described in 15.2, 15.3, 15.4, and 15.5.

The S-tagged service interface has the variations shown in Figure 25-3 under the S-tagged branch. The first variation, called a one-to-one S-tagged interface, uses a one-to-one mapping between S-VIDs and I-SIDs. This interface variation maps each S-VID to a single I-SID for use over the PBBN. The one-to-one mapped interface does not carry the S-TAG over the PBBN. The DEI and PCP bits may be regenerated on ingress and are then carried in the I-DEI and I-PCP bits in the I-TAG across the PBBN. On egress from the one-to-one S-tagged interface, the S-TAG can be deduced from the I-TAG received from the PBBN (the I-SID is mapped to an S-VID, the I-DEI and I-PCP bits may be regenerated and are then carried in the DEI and PCP bits).

The second S-tagged service interface variation is the bundling S-tagged service interface. This interface variation maps multiple S-VIDs to a single I-SID for delivery over the PBBN. To allow the remote end to reconstruct the S-VID, this interface variation will carry an S-TAG over the PBBN. On a bundled S-tagged interface, the DEI and PCP bits of the S-TAG may be regenerated and are then carried in both the DEI and PCP bits of the S-TAG and the I-DEI and I-PCP bits of the I-TAG over the PBBN.

A special case of the bundling S-tagged service interface is where all S-VIDs are mapped to a single I-SID. This special case is called an all-to-one bundling S-tagged service interface. The I-component used for an all-to-one bundled S-tagged service interface is constrained to supporting a single S-tagged service interface.

1 Figure 25-6 illustrates the information passed over each of the ISS interfaces of a BEB.

Figure 25-6—Encapsulated service frames at ISS

2 Figure 25-7 illustrates a customer network attached to a PBBN using an S-tagged service interface. The  
3 customer network uses Provider Bridges with S-VLAN components for connecting to the PBBN. The  
4 PBBN in turn is composed of BEBs interfacing to the customer Provider Bridges and BCBs used to forward  
5 frames between the BEBs.

Figure 25-7—S-tagged service interface

1 Figure 25-8 shows an example of equipment used to implement an unprotected S-tagged service interface.  
2 For details on redundant connections and equipment, see 25.9. In this diagram, a BEB is formed by  
3 connecting two I-components and a B-component. These connections may be over a backplane or over a  
4 LAN. An I-component may support one or more S-tagged service interfaces. When an I-component supports  
5 an all-to-one bundled S-tagged service interface, the entire I-component must be dedicated to a single S-  
6 tagged service interface. Each CNP may be associated with one S-tagged service interface. A CNP is  
7 connected to a customer system (or network) using a LAN.

**Figure 25-8—S-tagged service interface equipment**

8 NOTE 2—It is always possible to build equipment that includes both BEB and Provider Edge Bridge components. In  
9 particular, it is possible for a BEB to support a C-tagged service interface (15.4) for attachment to a CBN by including a  
10 C-VLAN component with PEPs that connect to the CNPs of an I-component. A BEB can also support an RCSI (15.6) by  
11 including a C-VLAN component and a Port-mapping S-VLAN component.

## 12 25.5 I-tagged service interface

13 A PBBN may provide a native I-tagged service interface for attachment to another PBBN or for attachment  
14 to a customer's PIP. An I-tagged service interface can provide access to all the backbone service instances  
15 within a PBBN. Access to backbone service instances is controlled by the configuration of the CBP service  
16 instance tables (6.11). Each I-SID delivered over the I-tagged service interface by a customer identifies  
17 a service instance that will be carried over the PBBN. Service instances are carried over the PBBN inside a  
18 B-VLAN selected by the CBP. The customer must provide the B-DA for frames delivered to an I-tagged  
19 service interface.

20 Figure 25-9 illustrates a customer network attached to a PBBN using an I-tagged service interface. The  
21 customer network uses a BEB with an I-component (26.6.1) or a B-component (26.6.2) connecting to the  
22 PBBN. The PBBN in turn is composed of BEBs interfacing to the customer and BCBs in the core of the  
23 PBBN used to forward frames between the BEBs.

24 An I-tagged service interface may be provided at a CBP of a BEB as illustrated by Figure 25-9 and  
25 Figure 25-10. In this service interface, the I-SID provided over the service interface within the I-TAG is  
26 mapped 1-1 to an I-SID within the PBBN. As illustrated, a customer (or peer) may attach to the I-tagged  
27 service interface through a CBP. In this configuration, each PBBN is attached at a CBP.

28 Figure 25-10 shows an example of equipment used to implement an unprotected I-tagged service interface.  
29 For details on redundant connections and equipment, see 25.9. A B-component may support one or more  
30 I-tagged service interfaces. Each CBP may be associated with one I-tagged service interface. These CBP are  
31 connected to a customer system (or network) using an Ethernet LAN.

1

Figure 25-9—S-tagged service interface equipment

Figure 25-10—I-tagged service interface equipment

2 NOTE—A protected I-tagged service interface will have more than one PIP and can have a single backbone service  
3 instance, identified by an I-SID, enabled on more than one of those ports. This creates the potential for transit traffic on  
4 that backbone service instance to pass through the I-BEB without being delivered to a CNP. If this behavior is not  
5 desired, then the protected I-tagged service interface should be configured such that any single service instance is only  
6 enabled on a single PIP at any given time, or that only a single PIP is forwarding at any given time.

## 1 25.6 Service instance segregation

2 Segregation of data frames associated with different instances of MAC Service is achieved by supporting  
3 each service instance with a backbone service instance identified by an I-SID and ensuring that:

- 4 a) No service frames are transmitted through a CBP without an I-TAG.
- 5 b) No frames are accepted, i.e., received and relayed, from any customer system without first being  
6 subject to service instance selection.
- 7 c) No frames are delivered to any customer system without explicit service instance identification.
- 8 d) Prior to transmission through a PNP of a BEB, service frames are received either through an  
9 I-component's CNP or through a CBP. When the customer is attached to a CNP, the port is under the  
10 control of the backbone provider and is exclusively accessed by a single customer. In this case, the  
11 I-component used to support the CNP is under the control of the Backbone provider and is attached  
12 to a CBP through a PIP that is also under the control of the backbone provider and that may be  
13 shared with multiple customers. When the customer is attached to a CBP, the port is under the  
14 control of the provider and is exclusively accessed by a single customer. All frames received through  
15 the CNP or CBP (depending on how the customer is attached) must correspond to a service instance  
16 or instances that the customer is permitted to access. (The method used to ensure the port is attached  
17 to the specified customer and therefore secure is beyond the scope of this standard. See  
18 IEEE Std 802.1X.)
- 19 e) The BCBs and the B-component of each BEB within the PBBN can only be controlled by the  
20 provider.

21 A single backbone service instance may support many customer service instances. Each customer service  
22 instance is supported by a single backbone service instance.

## 23 25.7 Service instance selection and identification

24 Service instance selection is provided to the attached customer system by the Port-based, S-tagged, or  
25 I-tagged service interfaces (25.3, 25.4, 25.5). In the Port-based interface, only one backbone service instance  
26 is offered to the attached customer and the CNP of the I-component is configured to accept only untagged or  
27 priority tagged frames. In all S-tagged service interfaces, the CNP of the I-component is configured with  
28 Enable Ingress Filtering (8.6.2) and the Port is only included in the Member Set for S-VLANs corresponding  
29 to service instances that the customer is permitted to use. The service instance for each frame received by the  
30 attached customer system is identified in the same way as frames transmitted using the same interface, but  
31 not necessarily in the same way that the service instance is selected or identified at other interfaces. In the I-  
32 tagged service interface, the CBP of the B-component is configured (12.16.5, 6.11) with the acceptable  
33 backbone service instances and I-SID values for use by the customer. A single backbone service instance  
34 can support any combination of Port-based, S-tagged, or I-tagged service interfaces.

35 NOTE—The means used by a backbone provider and a customer to determine the S-VIDs and I-SIDs used by the  
36 customer to select and identify a given service instance are outside the scope of this standard.

## 37 25.8 Service priority and drop eligibility selection

38 For all service interface types, the service priority is selected using the received priority for each frame. For  
39 S-tagged and Port-based service interfaces, the priority and drop eligibility may be regenerated using the  
40 Priority Regeneration Table (6.9.4). For I-tagged service interfaces, the priority and drop eligibility may be  
41 regenerated using procedures of 6.11.

42 The mechanism for determining the received priority varies with the type of service interface. Service  
43 priority selection is provided for Port-based service interfaces using the received priority signaled from the  
44 media access method of the port. If the media access method used to attach to the interface does not directly

support priority, this will result in the selection of a single value for all frames. An attached system may also signal priority to a Port-based service interface on a per-frame basis by priority-tagging frames with an S-TAG that has a null VID (6.13).

Service priority selection is provided by S-tagged service interfaces using the PCP and DEI parameters conveyed in the S-TAG of each frame. An S-tagged service interface can provide a single backbone service instance for all S-VIDs received, and in this way functions like a Port-based service interface with the addition of the capability of delivering S-tagged service frames (whose S-TAG has a non-null VID).

Service priority selection is provided by I-tagged interfaces using the received priority decoded from the I-PCP and I-DEI fields in the I-TAG.

## 25.9 Service access protection

A customer system (or systems) that is part of a single PBN or that contains a customer operated I-component or B-component can attach to a PBBN using a protected service interface providing multiple LANs and (or) nodes, thus providing fault tolerance through redundancy of the service interface components. Three classes of service access protection may be supported (see Figure 25-11 and Figure 25-12), which provide for unprotected service interface, for link-level redundancy at the access link or link and node redundancy at the access point. An access service interface may be a Class I, II, III access service interface.

Figure 25-11—S-tagged and Port-based service interface access classifications

1 Protected Port-based, S-tagged, and I-tagged service interfaces are depicted in Figure 25-11 and  
2 Figure 25-12, respectively.

**Figure 25-12—I-tagged service interface access protection classifications**

3 Class I service interfaces depicted in these figures are unprotected service interfaces providing a single LAN  
4 and node. Class I service interface equipment is depicted in Figure 25-5, Figure 25-8, and Figure 25-10.  
5 These provide no redundancy and therefore will fail if any LAN or component fails.

6 Class II service interfaces are link protected service interfaces that provide multiple LANs; however, they do  
7 not provide any node redundancy. Class II service interfaces are tolerant of single or multiple LAN failures.  
8 These provide no node redundancy and therefore will fail if any node fails.

9 Class III service interfaces are link and node protected service interfaces providing multiple LANs and  
10 multiple nodes. Class III service interfaces are tolerant of single or multiple LAN failures and/or single or  
11 multiple node failures. The operation of a Class III service interface switches between access nodes within  
12 both the customer and provider networks; therefore, protection switching over a Class III service interface  
13 always results in state changes spreading over the customer and provider networks.

14 To attach a PBN to a PBBN, the following rules must be maintained to ensure loop-free operation over the  
15 extended network:

- 16 a) Each PBN and PBBN prevents forwarding loops by running an independent spanning tree.
- 17 b) Each PBN connects to other PBNs only through a PBBN.

c) Each PBN ensures that no data frame passes through more than one BEB attachment point into or out of the PBBN. An attachment point is a single LAN connection to a PBBN. This connection may be part of a protected or unprotected Port-based (see Figure 25-4), S-tagged (see Figure 25-7), or I-tagged service interface (see Figure 25-9). A PBN may use L2GP (13.40) to ensure only a single link is active when using a backup link to the PBBN.

d) Each PBN ensures that it attaches any given S-VLAN to no more than one PBBN.

NOTE—When an attached PBN uses the L2GP (13.40) to enforce criterion c), then the PBBN may implement a Class I, II, or III protection interface. If the PBBN is configured for Class I or II protection, then it will provide multipoint services with the services delivered to two or more Class I or II interfaces for attachment to the PBN. In this case, the PBN is responsible for selecting one of the two attachments using the L2GP to ensure criterion c). If the PBBN is configured for Class III protection, then the PBN must support MVRP over the access links to inform the PBBN which S-VIDs are active on which LAN connections.

### 25.9.1 Class II redundant LANs access protection

A Class II redundant interface is implemented using IEEE Std 802.1AX (Link Aggregation). Using Link Aggregation, a single CNP and associated PNP of a Provider Bridge, or CBP and associated PIP, may be implemented using multiple LANs. A failure on any of the LANs implementing the link will cause all traffic to migrate to the remaining LAN. CFM may run both on the aggregate and on each individual link as shown in Figure 22-8.

It is desirable for the distribution algorithm used on a Class II interface to divide traffic between the multiple links based on the service instance. One distribution algorithm that always retains a service on a single LAN is to place all the traffic on one of N links. In the event of a failure, all traffic is shifted to the highest priority remaining link. This distribution algorithm has the advantage that it provides for full reserved bandwidth on the backup link.

Another distribution algorithm that divides traffic by service and also allows traffic on all redundant links is to divide the traffic by either the S-VID or the I-SID. Distributing traffic based on the S-VID would be used for traffic over multiple LANs comprising an S-tagged interface, while distributing traffic based on the I-SID would be used for traffic over multiple LANs comprising an I-tagged interface. With either of these distribution schemes, services are allocated to one of the LANs used to implement the provider CNP or CBP and the customer PNP, PIP, or CBP. In the event of a failure, the services are moved to the remaining LANs.

### 25.9.2 Class III simple redundant LANs and nodes access protection

A Class III interface uses redundant LANs to connect a primary and one or more secondary customer nodes to a primary and one or more secondary BEBs. The operation protects the interface against failures on any of the interconnecting LANs or nodes used on each side of the interface. It is possible to use Class II protected interfaces for each link of the Class III interface. In this case, the Class II protection procedures must happen first and complete before a Class III protection switch begins.

For a Class III interface, each customer node is connected to a BEB using a single LAN. The interface is provisioned with a priority for each LAN that is part of the interface. Each of the LANs is constantly monitored using either PHY management, CFM, or both. In operation, a Class III interface uses only the highest priority operating LAN for traffic. The other LANs are protection paths. In a Class III interface, any switch in the LAN used for traffic will also switch both the customer node and the PBBN BEB since the connections of a Class III interface are sets composed of a customer node, a LAN, and a BEB.

When providing a Class III protected S-tagged interface, multiple CNPs, each on a different BEB, are used to create a single S-tagged interface. Each LAN of the S-tagged interface executes CFM at the port level to detect failures over the interface LANs. Information from CFM is used by the customer to determine which LANs of the S-tagged interface are operating and which are inactive. Each customer network runs MSTP to determine which S-VLANs are active on which LANs of the Class III interface. To avoid loops through the

1 Class III interface, either the I-components participate in the customer network spanning tree (13.42), or the  
2 ports on the customer equipment that connects to the I-components are configured as Layer 2 Gateway Ports  
3 (13.40). Upon an active link failure between customer node and its corresponding BEB or upon the customer  
4 node failure, the customer network switches to one (or more) of the backup links and informs the PBBN  
5 which S-VLANs are active on which links using MVRP (11.2) on the access LANs. The BEB(s), upon  
6 receiving the MVRP message(s) from the customer network, generate the corresponding MRP-based  
7 message(s) for the affected I-SIDs and send these messages over the associated B-VLANs. The far-end  
8 BEBs, upon receiving these messages, will flush their C-MAC entries in their FDB corresponding to the  
9 affected I-SIDs.

10 When providing a Class III protected I-tagged interface, multiple CBPs, each on a different B-BEB, are used  
11 to create the single I-tagged interface. In this scenario, each B-BEB is connected via a single link to the  
12 customer I-BEB where the link can be Class II protected. The customer I-BEB is in turn connected via  
13 multiple CNPs to the customer network. Each customer network runs MSTP to determine which S-VLANs  
14 are active on which LANs of the Class III interface. To avoid loops through the Class III interface, either the  
15 I-components participate in the customer network spanning tree (13.42), or the ports on the customer  
16 equipment that connects to the I-components are configured as Layer 2 Gateway Ports (13.40).  
17 PHY management or port-level CFM is used to detect failures over the interface LANs between the  
18 customer I-BEBs and the customer network. When a failure is detected, the customer network informs the  
19 customer I-BEBs which S-VLANs are active on which links using MVRP (11.2). The customer I-BEBs in  
20 turn notify the provider B-BEBs using MRP-based messages corresponding to the effected I-SIDs. The  
21 provider B-BEBs relay this message to the other BEBs in the PBBN over the associated B-VLANs. The far-  
22 end BEBs, upon receiving these messages, will flush their C-MAC entries in their FDB corresponding to the  
23 effected I-SIDs. Each LAN of the I-tagged interface also executes PHY management or CFM at the port  
24 level to detect failures over the I-tagged interface. In case of a complete I-tagged interface failure between  
25 the customer I-BEB and the provider B-BEB, the I-BEB uses this info to deactivate all its CNP ports toward  
26 the customer network.

## 27 **25.10 Support of the MAC Service by a PBB-TE Region**

28 A PBB-TE Region comprises a continuous set of IB-BEBs and BCBs, capable of providing TESIs, that have  
29 allocated a common subset of B-VIDs to the control of an external agent (8.9) responsible for setting up  
30 Ethernet Switched Paths (ESPs). Each IB-BEB that belongs to a PBB-TE Region can provide interfaces that  
31 encapsulate customer frames in ESPs, thus allowing the PBBN operator to offer TESIs.

32 A PBB-TE Region providing the MAC Service to attached stations is modeled as a sequence of relay  
33 functions, as illustrated in Figure 25-13. The MST Configuration Table associated with each BCB or B-  
34 component of an IB-BEB specifies a set of VIDs, each of which may be exclusively used throughout the  
35 PBB-TE Region to form part of an ESP identifier. Such a VID is called an ESP-VID and is associated with a  
36 special value of the MSTID in the MST Configuration Table, the TE-MSTID (8.9), indicating that the VID  
37 is not under the control of a spanning tree protocol.

38 The I-components of IB-BEBs supporting PBB-TE are responsible for encapsulating frames received from  
39 customers and allocating each frame to a backbone service instance and for decapsulating frames received  
40 from the network via backbone service instances. The allocation of customer frames to backbone service  
41 instances that will be transported by TESIs is done at the PIP as described in 6.10. At the PIP the customer  
42 frame is encapsulated by an I-TAG, which includes the I-SID, and a set of source and destination B-MAC  
43 addresses. The source B-MAC address is the PIP MAC address that is configured to take the same value as  
44 the CBP MAC address of the internally connected CBP on the B-component. As a result, the B-MAC  
45 addresses of frames associated with TESIs, the ESP MAC addresses, are always equal to the CBP MAC  
46 addresses.

**Figure 25-13—Internal organization of the MAC sublayer in a PBB-TE Region**

1 CBPs on B-components in IB-BEBs supporting PBB-TE use the I-SID to map the encapsulated customer  
2 frames to TESIs or B-VLANs (6.11). Figure 25-13 depicts a TESI providing the MAC Service at two CBPs.  
3 For an I-SID mapped to a TESI, the Backbone Service Instance table contains the terminating CBP's MAC  
4 address, the ESP-DA, and the ESP-VID of the associated ESP. I-SIDs mapped to a B-VLAN must not use a  
5 B-VID from the ESP-VID space. The B-Component MAC relay forwards frames belonging to an ESP  
6 between the CBP and PNPs or between PNPs using the ESP-DA and ESP-VID as described in 8.6.

### 7 25.10.1 Provisioning TESIs

8 ESPs are provisioned in a PBB-TE Region by an external agent. This replaces the spanning tree protocols  
9 and populates the filtering tables of the corresponding B-components and BCBs by creating static filtering  
10 table entries for the ESP MAC addresses and ESP-VIDs (Figure 25-14).

11 The ability of a PBB-TE Region to utilize an external management or control plane is facilitated by PBB  
12 because the PIP MACs and correspondingly the ESP MAC addresses can be managed by the Provider and  
13 therefore can all be identified in the Provider's topology by the external management or control plane.

14 The external PBB-TE management/control plane is responsible for maintaining and controlling all the active  
15 topology information to support point-to-point or point-to-multipoint ESPs over the PBB-TE Region. The  
16 PBB-TE active topology can co-exist with active topologies associated with spanning tree protocols and the  
17 allocation to a specific active topology is governed by the B-VID value. The PBB-TE external agent takes  
18 control of the ESP-VID range on the Bridges in a PBB-TE Region.

19 Similar to the forwarding connectivity created by the operation of spanning tree and learning, the PBB-TE  
20 management/control plane can form an active topology of CBP rooted trees, from each CBP belonging to a  
21 PBB-TE Region to a specific subset of any other CBPs in this region. These traffic engineered trees define  
22 the path(s) taken by the frames that belong to ESPs within the PBB-TE Region. Furthermore each such tree  
23 is further qualified by the PBB-TE reserved ESP-VID, thus enabling the construction of independent trees  
24 per ESP-VID. As a result each such CBP rooted tree can be identified by a CBP MAC address associated  
25 with the root of the tree, the CBP MACs associated with the leaves of the tree and the ESP-VID. The PBB-  
26 TE management/control plane routes the ESPs along these trees by explicitly populating the FDBs in the  
27 Bridges along each tree with the Static Filtering Entries containing the CBP MAC DA and ESP-VIDs. The  
28 mechanism by which the PBB-TE management/control plane selects the path for a routing tree is not within

1 the scope of this standard. The PBB-TE management/control plane also manages the bandwidth of all ESPs  
2 along each routing tree. For each destination CBP, which is part of a routing tree maintained by the PBB-TE  
3 management/control plane, PBB-TE will maintain tree(s) which provide symmetric paths from the CBP  
4 MAC DA to the CBP MAC SA. The ESP-VID(s) used in this reverse ESP(s) need not have the same ESP-  
5 VID used for the forward ESP. Accordingly each of the ESPs can be identified by a 3-tuple:

6 <ESP-DA, ESP-SA, ESP-VID>,

7 where the three component fields are described as follows:

- 8 a) The ESP-SA is the address of the PIP encapsulating the customer service instance that by  
9 configuration is the same as the address of the internally connected source CBP.
- 10 b) The ESP-DA identifies the CBP destination address(es).
- 11 c) The ESP-VID is a VID value distinguishing among ESPs having the same <destination, origin> pair.  
12 It can only take values that are allocated to the PBB-TE Region identified by the TE-MSTID (8.9).

13 An ESP is point-to-point or point-to-multipoint:

- 14 — A point-to-point ESP is an ESP where the ESP-DA and the ESP-SA in its 3-tuple identifier are  
15 individual MAC addresses.
- 16 — A point-to-multipoint ESP is an ESP between one root CBP to  $n$  leaf CBPs, identified by a 3-tuple  
17 where the ESP-DA is a group MAC address identifying the  $n$  leaves CBPs, and the ESP-SA is the  
18 individual MAC address of the root.

19 A TESI, is an instance of the MAC Service supported by a set of ESPs, collectively identified by a single  
20 TE-SID, forming a bidirectional service. The following two types of TESIs are described:

- 21 — A point-to-point TESI that is supported by two point-to-point ESPs where the ESPs' endpoints have  
22 the same CBP MAC addresses.
- 23 — A point-to-multipoint TESI that is supported by a set of ESPs that constitute one point-to-multipoint  
24 ESP from a root to each of  $n$  leaves plus a point-to-point ESP from each of the  $n$  leaves to the root.

25 NOTE—For reasons relating to TESI monitoring diagnostics, operational simplicity, etc., this standard assumes the  
26 point-to-point ESPs associated with a point-to-point TESI are symmetric and that the point-to-point ESPs associated  
27 with a point-to-multipoint TESI are routed from each of the  $n$  leaves to the root along the branches of the point-to-  
28 multipoint ESP. Support for a TESI that comprises ESPs not routed in this way is problematic, and is not defined in this  
29 standard.

30 Although an ESP is identified by the 3-tuple <ESP-DA, ESP-SA, ESP-VID> it is only the ESP-DA, ESP-  
31 VID pair that are used for forwarding decisions. The combination (ESP-DA, ESP-VID) is treated as though  
32 it was a single 60-bit address, where 12 bits are the ESP-VID and 48 bits are the ESP-DA. This ESP-VID  
33 field is used as a path selector to the destination CBP rather than a B-VID, allowing up to  $2^{12}$  unique routing  
34 trees to any single CBP. In Figure 25-14, two paths are configured to reach S2. These two paths are  
35 separated by using a different ESP-VID in combination with the ESP-DA for a second path.

36 If the ESP-VID range delegated is the 4094 possible values, then each CBP termination can sink  $(2^{12} - 2)$   
37 routing trees, and the theoretical network maximum is about  $2^{60}$  ESPs. The number of ESPs supported by  
38 PBB-TE is constrained by issues related to coordinated management, independent management of groups of  
39 nodes or independent routing choices through parts of the path, limit through intermediate nodes, etc. In the  
40 cases where B-VLAN services are also offered by the same network, it is expected that most B-VIDs will be  
41 allocated to those B-VLANs since the use of the MAC addresses as part of the ESP identifiers allows at least  
42  $2^{48}$  ESPs and the ESP-VIDs can be used mainly to provide path diversity.

**Figure 25-14—PBB-TE Region**

## 1 25.10.2 ESP forwarding behavior

2 Forwarding of frames belonging to an ESP-VID differs from forwarding of frames belonging to B-VLANs  
3 in the following ways:

- 4 a) Frames associated with the ESP-VID are discarded when a Static Filtering Entry corresponding to  
5 the (ESP-DA, ESP-VID) is not found in the FDB [item b) in 5.4.5]. Proper operation of PBB-TE  
6 requires the provisioning of an FDB entry in each Bridge through which an ESP passes in order to  
7 specify the forwarding of traffic associated with that ESP. Such an entry may be absent due to a  
8 provisioning error. In the event of such an error, it is important that frames associated with the  
9 improperly configured ESP not be flooded, as PBB-TE would be violated if traffic intended for a  
10 particular ESP is sent on one or more other ESPs. Further, flooding based on the ESP-VID may  
11 result in unbounded looping and replication as the ESP-VID is not associated with a spanning tree.  
12 For this reason, frames associated with the ESP-VID are discarded when a Static Filtering Entry  
13 corresponding to the (ESP-DA, ESP-VID) is not found in the FDB. Such an ESP MAC address may  
14 represent an individual address, for which no more specific Static Filtering Entry exists or a group  
15 address, for which no more specific Static Filtering Entry exists (8.8.1).
- 16 b) MAC learning is not performed on receipt of a frame carrying an ESP-VID [item a) in 5.4.5]. Where  
17 ESPs have been correctly provisioned, learning would not interfere with the proper operation of  
18 Bridges, but in the presence of provisioning errors, learning may result in undesired behavior.
- 19 c) The active topology for the ESP-VIDs allocated to PBB-TE is no longer controlled by spanning tree  
20 protocols but by an external agent that is responsible for setting up the ESPs [item b) in 5.4.5].

21 NOTE 1—In a network supporting both VLAN (i.e., PBB) and ESP (PBB-TE) traffic, the establishment of an ESP and  
22 the policing of traffic at the ingress of the ESP are necessary but not sufficient conditions to ensure that traffic associated  
23 with an ESP receives the QoS intended by the network operator. The operator should ensure that the QoS requirements  
24 of an ESP are satisfied and that sufficient network capacity is available to accommodate broadcast-unknown traffic,  
25 spanning tree control traffic, and other traffic associated with VLAN usage.

26 Key properties of an ESP are as follows:

- 27 — The ESP is identified at all points along its path by a single identifier  
28 <ESP-DA, ESP-SA, ESP-VID>.
- 29 — The information referenced for forwarding <ESP-DA, ESP-VID> is contained within the ESP  
30 Identifier.
- 31 — The information referenced for forwarding <ESP-DA, ESP-VID> does not change along the length  
32 of the ESP.

33 NOTE 2—The static and provisioned nature of an ESP provides support for traffic engineering. These properties of the  
34 ESP, together with policing and queuing functions supported by a Bridge (8.6) can provide per ESP QoS.

## 25.11 Transparent service interface

A PBBN may provide a transparent service interface for customer attachment. A transparent service interface is delivered on a CNP provided by a BEB as illustrated in Figure 25-15 and Figure 25-16. A transparent service interface may attach to a Provider Bridge, C-VLAN Bridge (5.9), MAC Bridge, router, or end-station. The service provided by this interface forwards all frames over the backbone on a single backbone service instance.

A transparent service interface does not recognize, add, remove, or modify either S-tags or C-tags on customer frames. It does not learn customer addresses, nor does it filter frames based on any MAC addresses except the TPMR component Reserved addresses listed in Table 8-3 and the management address of the TPMR component.

Figure 25-15 illustrates a customer network attached to a PBBN using a transparent service interface. The customer network uses End Stations, Customer Bridges, or Provider Bridges for connecting to the PBBN.

Figure 25-15—Transparent service interface

Figure 25-16 shows an example of equipment used to implement a transparent service interface. In this diagram a BEB is formed by connecting two T-components and a B-component. These connections may be over a backplane or over a LAN. A T-component supports a single transparent service interface associated with a CNP. A CNP is connected to a customer system (or network) using a LAN.

**Figure 25-16—Transparent service interface equipment**

## 26. Principles of Provider Backbone Bridged Network (PBBN) operation

This clause establishes the principles and a model of PBBN operation. It provides the context necessary to understand how the:

- a) Operation of individual Backbone Edge Bridges (BEBs) and Backbone Core Bridges (BCBs) (Clause 8, Clause 25);
- b) Configuration and management of individual BEBs and BCBs (Clause 12); and
- c) Management of spanning tree and VLAN topologies within a PBBN (Clause 7, Clause 11, and Clause 13)

support, preserve, and maintain the quality of each of the instances of the MAC Service offered to the customers of the PBBN (Clause 6, Clause 25) including the following:

- d) Independence of each service instance supported by a PBBN from other service instances (25.6).
- e) Identification of service instances and backbone service instance within the PBBN (25.7, 8.8).
- f) Maintenance of service availability in the event of the failure, restoration, removal, or insertion of LAN components connecting a customer network to a PBBN (Clause 6, Clause 11, Clause 13, 25.9).

A PBBN is a Virtual Bridged Network that comprises BEBs at the edge of the PBBN and BCBs at the core of the PBBN and attached LANs, under the administrative control of a single backbone provider. The principal elements of PBBN operation are those specified in Clause 16, as amended by this clause.

NOTE 1—The term PBBN is used exclusively to refer to networks configured and managed as specified by this clause and comprising only (a) BCBs and BEBs and (b) communications media and equipment providing the ISS (IEEE Std 802.1AC). While the requirements of Clause 25 are generally applicable to similar services, a generalized framework for all the network designs that could support these requirements, while useful in the context of other equipment and services, is outside the scope of this standard. This clause describes specific best practice for PBBNs to ensure that the requirements for Bridge functionality are clear. Conformance of a BEB implementation to this standard does not require that the implementation be used as specified in this clause; merely, that it is capable of being so used.

NOTE 2—Within a PBBN, an instance or instances of the MAC Service are reserved for the backbone provider's own use to configure and manage the network. All frames associated with such service instances, and that are not confined to an individual LAN, are subject to service instance selection, segregation, and identification as specified in 26.1.

### 26.1 PBBN overview

The principal elements of PBBN operation comprise the following:

- a) Encapsulation/de-encapsulation of service frames in B-MAC Frames (6.10).
- b) Service instance segregation within a PBBN for service frames (25.6).
- c) Service instance selection on ingress, and service instance identification on egress, for each customer frame (25.7).
- d) Service access protection (25.9).
- e) Resource allocation and configuration to provide service instance connectivity (26.3).

The following may also be included:

- f) Management of customer end station address learning (26.4)
- g) Prevention of connectivity loops formed through attached networks (26.5)
- h) Scaling of PBBNs (26.6)
- i) Provisioning of PBBN services (26.7)
- j) Management of PBBN service connectivity (26.8)

## 26.2 PBBN example

An example PBBN is illustrated by the Figure 26-1. The example network is divided into three major areas: the customer equipment area, which is owned by the customer and is interfaced to the PBBN; the PBBN area, which is owned by the backbone provider and interconnects to the customer equipment and to other PBBNs; and the other PBBN area, which is owned by the same or other backbone providers and interconnects to multiple PBBNs allowing the network to scale indefinitely.

Figure 26-1—PBBN example

The interface between a BEB and a Provider Bridge is a CNP of an I-Component as specified in 6.10. The interfaces between BEBs and BCBs and between BCBs and BCBs are PNPs. In Figure 26-1, these interfaces are over LANs labeled S and B. The interfaces between B-BEB and I-BEBs, or between B-BEBs in different PBBNs, are over LANs labeled I. All exterior interfaces from a PBBN are over S, I, or C LANs; whereas, all interior interfaces within a PBBN are over B LANs. The S, I, and C LANs (exterior interfaces) are at the boundary between the PBBN and the attached customer networks.

1 The B LANs (interior interface) are backbone LANs, which interconnect all the PBBs within a PBBN.

2 Within the network example, BEBs, BCBs, and B LANs are secured so that only the backbone provider  
3 operating the PBBN can manage the reception, transmission, and relay of frames between BEBs and BCBs.  
4 The arbitrary physical network topology of the PBBN and the connectivity that it provides to support  
5 segregated instances of the MAC Service is designed and managed by the backbone provider to meet  
6 bandwidth and service availability requirements at the CBPs and PIPs. Application of the service instance  
7 ingress and egress rules at these Ports in support of service instance selection and identification ensures that  
8 frames cannot be transmitted or received on any backbone service instance by any customer's equipment  
9 without prior agreement with the provider.

10 The active MSTP topology of the PBBN area is separated from the active topology of the customer  
11 equipment area. This is accomplished by isolating the MST BPDUs for each customer network from the  
12 PBBN at the BEBs that surround the perimeter of the PBBN. The BEBs also stop the propagation of MST  
13 BPDUs, used to support the active topology of the PBBN, into the Provider Bridged area. In Figure 26-1,  
14 Provider Bridge MST BPDUs are propagated over the A, P, C, and S LANs but not over the I or B LANs,  
15 while PBB MST BPDUs are propagated over the B LANs but not over the I, C, A, P, or S LANs.

16 For Port-based service interfaces, the entire C LAN is treated as a single instance of the MAC Service. The  
17 BEBs extend the C LAN over the backbone by mapping all service frames on a single backbone service  
18 instance identified by an I-SID. The I-SID used is provisioned by the provider operating the PBBN. The  
19 provider sets the I-SID on each BEB port attached to a C LAN that is part of the port based service. The  
20 BEBs encapsulate the service frames with an I-TAG, B-TAG, B-SA, and B-DA. During the encapsulation,  
21 any C-TAG delivered to the CNP is retained in the encapsulated frame as part of the SDU. The BEBs then  
22 map the frames onto a B-VLAN with its B-VID contained in the B-TAG and which interconnects the BEBs  
23 provisioned for the service. These new frames are transmitted over the B LANs by the BEBs and by the  
24 BCBs that carry the B-VLAN. Since the initial octets of the data conveyed in each backbone frame comprise  
25 an S-TAG, the frames may be forwarded by BCBs of the PBBN until they reach the next BEB where they  
26 might be de-encapsulated. During de-encapsulation, the B-DA, B-SA, B-TAG, and I-TAG are stripped. The  
27 C-DA and C-SA from the I-TAG will become the DA and SA transmitted to the receiving C LAN. If the  
28 encapsulated SDU contains a C-TAG, it becomes the outside tag as the frame is transmitted to the receiving  
29 C LAN.

30 For S-tagged service interfaces, each instance of MAC Service is carried over the S LANs on one or more  
31 S-VLANs. The BEBs preserve the S-VLAN over the backbone by mapping them onto an I-SID and in the  
32 case of S-VLAN bundling carrying the S-TAG. This operation is performed by the backbone provider  
33 operating the PBBN by configuring the VIP-ISID on each BEB attached to an S LAN. The BEB maps the  
34 S-VID to I-SID and encapsulates the original service frame with a new I-TAG, B-SA, and B-DA. The BEB  
35 then maps the frame onto a B-VLAN, which interconnects BEBs. This new frame is transmitted over the B  
36 LANs by the BEBs and by the BCBs. Since the initial octets of the data conveyed in each backbone frame  
37 comprise an S-TAG, the frames may be forwarded by BCBs of the PBBN until they reach the next BEB  
38 where they might be de-encapsulated.

39 For I-tagged service interfaces, each instance of MAC Service is identified by an I-SID value carried over  
40 the I LAN in an I-TAG. The BEB maps the frame onto a B-VLAN, which interconnects BEBs. This new  
41 frame is transmitted over the B LANs by the BEBs and by the BCBs. Since the initial octets of the data  
42 conveyed in each backbone frame comprise an S-TAG, the frames may be forwarded by BCBs of the PBBN  
43 until they reach the next BEB where they might be de-encapsulated.

44 B-MAC addresses are used to identify the destination BEB's PIP. These B-MAC addresses are learned by  
45 each PBB as frames are exchanged over B-VLANs. To perform the encapsulation and de-encapsulation of  
46 service frames, BEBs use the connection identifier stored in the FDB (see 8.8) to correlate C-MAC  
47 addresses to B-MAC addresses. At startup, the BEBs have not learned the B-MAC or C-MAC addresses yet.  
48 When the B-MAC address is unknown, the BEB encapsulates the service frames using the Default

1 Backbone Destination address. The same holds true for the service frames having a group or broadcast  
2 destination address. An individual B-DA is used for forwarding unknown or group frames when the service  
3 is point-to-point and where the far end individual address is known. Both the B-MAC and C-MAC addresses  
4 are learned by the provider BEB (see Clause 8).

5 Frames containing encapsulated service data are carried within the B-VLANs created over the PBBN. It is  
6 also possible to carry unencapsulated S-VLAN traffic in the PBBN core by allocating some of the PBBN  
7 VID space to S-VLANs. The B-VLAN determines the route that the frames will take and limits broadcasting  
8 within the backbone. The B-TAG is added to the frame at the CBP. The selection of B-VLAN used to form  
9 the B-TAG is determined by the configuration of the CBP Backbone Service Instance table. This table maps  
10 I-SIDs to B-VIDs and is created as part of service provisioning.

11 If a BEB's PIP receives a B-MAC Frame whose B-SA is the same as the B-MAC address of the PIP, then a  
12 loop exists through the BEBs. Optionally, the BEB may use this condition for loop detection.

### 13 **26.3 B-VLAN connectivity**

14 The B-VLAN topology of each B-VLAN is established by the mechanisms introduced in 7.1 and  
15 Figure 7-1. The backbone provider can use and configure MSTP to provide a number of independent  
16 spanning tree active topologies and can assign each B-VLAN to one of these active topologies to best use  
17 the resources in the network. MVRP running in the context of each spanning tree active topology configures  
18 the extent of each B-VLAN to the subset of that active topology necessary to support connectivity between  
19 the customer points of attachment to the instance of MAC Service provided, and can reconfigure that  
20 connectivity as required if the spanning tree active topology changes.

21 The operation of MSTP within a Backbone Provider's network is independent of the operation of any  
22 spanning tree protocol within attached provider or customer networks. This is achieved by removing all  
23 MST BPDUs received or to be transmitted at the service access interfaces.

24 The operation of MVRP within a PBBN is independent of the operation of any configuration protocol within  
25 attached customer networks. The Provider Bridge MVRP address (Table 8-1) is used as the destination  
26 address of all MRPDUs transmitted in support of the MVRP Application. Frames received by CBPs and  
27 addressed to the Customer Bridge MVRP address (Table 10-1) are subject to service instance selection and  
28 relay in the same way as service frames. The MVRP Administrative Control for each B-VLAN is either  
29 Registration Fixed (New Ignored) or Registration Forbidden on all CBPs, so no information is received from  
30 any BEB MVRPDU that has been erroneously transmitted by a customer system.

### 31 **26.4 Backbone addressing**

32 When customer frames enter a PBBN they are encapsulated by the addition of B-MAC addresses and the  
33 creation of an I-TAG. The encapsulation is the result of the actions of a PIP as specified in 6.10. The PIPs  
34 represent the endpoints of a backbone service instance, and the B-MAC addresses identify these endpoints.  
35 (More specifically the VIPs of the PIP represent the endpoints of a backbone service instance, and the  
36 combination of the B-MAC addresses and the I-SID identify these endpoints. Since the I-SID identifies  
37 which VIP of a PIP is the Backbone Service Instance endpoint, the B-MAC address need only identify  
38 the PIP. Therefore, all VIPs of a PIP can share the same MAC address.) This encapsulation ensures that only  
39 I-components learn C-MAC addresses, while B-components and Bridges in the PBBN core learn only  
40 B-MAC addresses.

41 The B-SA of an encapsulated frame identifies the PIP that performed the encapsulation and is referred to as  
42 the PIP MAC address. For a PIP that connects to an external LAN, this is the address of the PIP itself. For a  
43 PIP that has an internal connection to a CBP in the same BEB, this can be any address that results in

1 delivering received I-tagged frames to the I-component, such as the Bridge address of that I-component.  
2 When the PIP MAC address is also used by CFM MPs instantiated on the PIP, there are additional  
3 constraints on the uniqueness of that address (26.4.3).

4 The B-DA of an encapsulated frame identifies the PIP(s) to which the frame should be delivered. The  
5 default value for the B-DA is the Backbone Service Instance Group address constructed by concatenating  
6 the three octet OUI shown in Table 26-1 with the three octet I-SID, and asserting the I/G bit in the first octet  
7 of the resultant value to signify a group MAC address. In a Backbone Service Instance Group address  
8 formed in this way, the OUI value is encoded in the first three octets of the address, with the most significant  
9 octet of the OUI encoded in the first octet, with the I/G bit (the LSB) set, and the least significant octet of the  
10 OUI encoded in the third octet; the most significant octet of the I-SID is encoded in the fourth octet of the  
11 address and the least significant octet of the I-SID in the sixth octet.

**Table 26-1—Backbone Service Instance Group address OUI**

| Name                                                    | Value    |
|---------------------------------------------------------|----------|
| IEEE 802.1Q Backbone Service Instance Group address OUI | 00-1E-83 |

12 NOTE—Table 26-1 uses the Hexadecimal Representation specified in IEEE Std 802.

13 When the B-DA of a frame is the Backbone Service Instance Group address, the nominal behavior of the  
14 PBBN is to deliver the frame to all CBPs reachable within the B-VLAN to which the backbone service  
15 instance is mapped. Filtering based on I-SID by the egress CBP ensures that frames are not transmitted by  
16 CBPs that are not part of the backbone service instance. Flooding frames throughout the B-VLAN and  
17 filtering at egress provides the correct connectivity for the backbone service instance, but may result in  
18 inefficient use of PBBN resources. More efficient frame delivery can be achieved by configuring Static  
19 Filtering Entries in the backbone Bridges, or using MMRP to create MAC Address Registration Entries, that  
20 restrict the delivery to just the endpoints of the backbone service instance. More efficient delivery can also  
21 be achieved by learning individual B-MAC addresses at a PIP, and in some cases by configuring the CBPs to  
22 translate the Backbone Service Instance Group address.

#### 23 **26.4.1 Learning individual backbone addresses at a PIP**

24 Individual backbone addresses are learned by means of the connection\_identifier parameter generated by the  
25 PIP and stored in the FDB. For each received frame, the PIP includes in the EM\_UNITDATA.indication a  
26 connection\_identifier parameter that identifies the backbone source address of the frame. When the  
27 I-component Learning Process creates or updates a Dynamic Filtering Entry for a Customer Source MAC  
28 address (C-SA) of a frame received through a PIP, it stores the connection\_identifier parameter of the  
29 EM\_UNITDATA.indication for that frame. The connection\_identifier parameter is included in the  
30 EM\_UNITDATA.request for subsequent frames destined to that customer address. Within the PIP, the  
31 connection\_identifier determines the individual backbone address associated with the customer address.  
32 This individual address is then used as the B-DA in place of the Backbone Service Instance Group address.

33 When a backbone service instance includes only two VIPs, it is possible to use a learned individual  
34 backbone address as the default B-DA instead of the Backbone Service Instance Group address. This is  
35 accomplished by configuring the AdminPointToPointMAC parameter for the VIP to ForceTrue, which  
36 results in the operPointToPointMAC parameter having a value of TRUE. In this case, the PIP copies the  
37 B-SA of frames received for that VIP (i.e., the individual MAC address of the peer PIP) to the Default  
38 Backbone Destination parameter of the VIP. Subsequent frames transmitted by the PIP on that backbone  
39 service instance will then use the individual MAC address of the peer PIP as the B-DA even if the C-DA is  
40 unknown or broadcast. Enabling the enhanced filtering criteria (8.7.2) on a VIP will prevent the

1 I-component from creating Dynamic Filtering Entries for C-MAC addresses unnecessarily when the  
2 backbone service instance is point-to-point and the S-VLAN that maps to the backbone service instance has  
3 only the VIP and one CNP in its member set.

4 When the enableConnectionIdentifier of a VIP is set to FALSE, the connection\_identifier is kept to a NULL  
5 value and correspondingly the B-DA used by frames associated with this VIP is always the Backbone  
6 Service Instance Group address.

#### 7 **26.4.2 Translating backbone destination addresses at a CBP**

8 In some cases, when the B-DA is the Backbone Service Instance Group address it may be advantageous that  
9 the CBP translate this to a different address. Examples where such translation may be useful include the  
10 following:

- 11 a) When a backbone service instance has only two endpoints within a PBBN, the Backbone Service  
12 Instance Group address may be translated at the ingress CBP to the individual address of the egress  
13 CBP.
- 14 b) When multiple backbone service instances connect the same set of CBPs, the ingress CBP may  
15 translate the Backbone Service Instance Group address to a single group address chosen for the set  
16 of backbone service instances.

17 These translations can be accomplished by configuring the Default Backbone Destination parameter in the  
18 service instance table of the CBP (6.11). Whenever an ingress CBP is configured to translate the B-DA, the  
19 egress CBP must be configured to translate the B-DA back to the Backbone Service Instance Group address.  
20 This allows multiple PBBNs connected through Peer E-NNIs to use addresses local to each PBBN.

21 The CBP is also capable of translating the I-SID on frames entering and exiting the PBBN. This allows the  
22 values of the I-SID to be local to a PBBN. If the B-DA of the frame is the Backbone Service Instance Group  
23 address and the CBP translates the I-SID, the CBP will also reconstruct the Backbone Service Instance  
24 Group address using the new value of the I-SID.

#### 25 **26.4.3 Backbone addressing considerations for CFM MPs**

26 Possible placement of CFM shims in a PIP and a CBP are shown in Figure 26-2. In the PIP, these include  
27 MPs to monitor backbone service instances (identified by I-SIDs) in the PBBN, as well as MPs to monitor  
28 service instances (identified by VID of S-VLANs) in the attached PBNs. In the CBP, these include MPs to  
29 monitor backbone service instance (identified by I-SIDs) in the PBBN, as well as MPs to monitor B-VLANs  
30 in the PBBN. All of these MPs are assigned individual addresses subject to the constraints specified in 19.4;  
31 however, there are additional considerations for the addresses used by MPs in PIPs and CBPs.

32 In a PIP, the individual address assigned to the backbone service instance-level MPs must be unique within  
33 the PBBN. The individual address assigned to the S-VLAN-level MPs must be unique within the set of  
34 PBNs interconnected by any backbone service instance supported by the PIP. Therefore, these two groups of  
35 MPs may use a common address that is globally unique; however, they may need distinct addresses if local  
36 addressing is used in the PBBN.

37 In the CBP, both the backbone service instance-level MPs and the B-VLAN-level MPs require an individual  
38 address that is unique within the PBBN. Therefore, these two groups may use a common address whether it  
39 is a global or local address.

## 1 26.5 Detection of connectivity loops through attached networks

2 The transmission and reception of MST BPDUs through CNPs will detect accidental direct connection of  
3 those ports. A backbone provider cannot rely on any customer network relaying such frames, and should  
4 develop a policy and mechanisms to deal with potential data loops that can arise if the attached customer  
5 systems do not operate their own instance or instances of a spanning tree protocol.

6 A bridged network can be redundantly attached to a PBBN by the means of several Layer Two Gateway  
7 Ports (13.40). By way of communication within their region and without any influence from the PBBN,  
8 those ports will provide connectivity to the PBBN through a single Layer Two Gateway Port, thus avoiding  
9 any bridging loop between the PBBN and the network.

10 NOTE 1—Use of the restrictedRole parameter at ingress ports ensures that receipt of BPDUs addressed to the Provider  
11 Bridge Group address cannot disrupt internal connectivity within the PBBN.

12 NOTE 2—Specification of PBBN policies, mechanisms, and heuristics used to detect or minimize the impact of data  
13 loops created by customer systems is not addressed by this standard. They can include, but are not limited to, bandwidth  
14 limitation, charging policies, detection of the repetitive movement of the apparent location of customer stations, and  
15 customer agreement to allow the use of PBBN loop detection protocols by not filtering the associated frames.

16 NOTE 3—A data loop is not the only possible cause of excess bandwidth consumption by a given customer of a PBBN,  
17 and the PBBN is usually required to meet service guarantees to other customers irrespective of the cause of the excess  
18 bandwidth demand. Data loops are not a unique threat to satisfactory overall network performance. Their distinct  
19 characteristic is consumption of discretionary bandwidth without benefiting any customer. The customer that creates the  
20 loop can suffer particularly serious network degradation or excess cost as the PBBN limits the total bandwidth consumed  
21 by that customer. It is therefore in the interests of each individual customer and the PBBN to raise service satisfaction by  
22 preventing and detecting loops.

## 23 26.6 Scaling of PBBNs

24 For PBBN deployments, it is important to be able to interconnect PBBNs operated by different  
25 organizations. The interfaces between PBBNs are examples of the MEF Forum External Network to  
26 Network Interface (E-NNI) referred to in the MEF reference model (section 7.2 and Figure 3  
27 of MEF 4 [B53]). E-NNIs for interconnection of PBBNs can be further classified into two types:  
28 hierarchal interconnect and peer interconnect. Examples of hierarchal and peer interconnects are depicted in  
29 Figure 26-1 at the interfaces marked 4 and 5.

### 30 26.6.1 Hierarchal PBBNs

31 The hierarchal interconnect connects the PBBNs in a leveled hierarchy. In this interconnect model one  
32 PBBN acts as a second-level ( $n + 1$ ) PBBN to a first-level ( $n$ ) PBBN. This model allows scaling the number  
33 of services by additional hierarchal level. Each level of a hierarchal interconnect adds an additional  
34 encapsulation layer.

35 In the hierarchical model, the ( $n + 1$ )-level PBBN carries the  $n$ -level PBBN B-VLANs as services in the
